Land Management

Alaska Outer
Continental Shelf
Office

Lower Cook Inlet
Petroleum Development Scenarios
Local Socioeconomic Systems Analysis

The United States Department of the Interior was designated by the Outer Continental Shelf (OCS) Lands Act of 1953 to carry out the majority of the Act's provisions for administering the mineral leasing and development of offshore areas of the United States under federal jurisdiction. Within the Department, the Bureau of Land Management (BLM) has the responsibility to meet requirements of the National Environmental Policy Act of 1969 (NEPA) as well as other legislation and regulations dealing with the effects of offshore development. In Alaska, unique cultural differences and climatic conditions create a need for developing additional socioeconomic and environmental information to improve OCS decision making at all governmental levels. In fulfillment of its federal responsibilities and with an awareness of these additional information needs, the BLM has initiated several investigative programs, one of which is the Alaska OCS Socioeconomic Studies Program (SESP).

The Alaska OCS Socioeconomic Studies Program is a multi-year research effort which attempts to predict and evaluate the effects of Alaska OCS Petroleum Development upon the physical, social, and economic environments within the state. The overall methodology is divided into three broad research components. The first component identifies an alternative set of assumptions regarding the location, the nature, and the timing of future petroleum events and related activities. In this component, the program takes into account the particular needs of the petroleum industry and projects the human, technological, economic, and environmental offshore and onshore development requirements of the regional petroleum industry.

The second component focuses on data gathering that identifies those quantifiable and qualifiable facts by which OCS-induced changes can be assessed. The critical community and regional components are identified and evaluated. Current endogenous and exogenous sources of change and functional organization among different sectors of community and regional life are analyzed. Susceptible community relationships, values, activities, and processes also are included.

The third research component focuses on an evaluation of the changes that could occur due to the potential oil and gas development. Impact evaluation concentrates on an analysis of the impacts at the statewide, regional, and local level.

In general, program products are sequentially arranged in accordance with BLM's proposed OCS lease sale schedule, so that information is timely to decisionmaking. Reports are available through the National Technical Information Service, and the BLM has a limited number of copies available through the Alaska OCS Office. Inquiries for information should be directed to: Program Coordinator (COAR), Socioeconomic Studies Program, Alaska OCS Office, P. O. Box 1159, Anchorage, Alaska 99510.

LIST OF TABLES

	Page
1. Major Onshore Facilities and Activities by Scenario and Phase, Lower Cook Inlet Sale #60, Kenai Area, Homer Area and Afognak Island	6
2. Forecast of Non-OCS Employment and Population, Kenai-Cook Inlet Census Division, Lower Cook Inlet, 1980 - 2000	25
3. Forecast of Non-OCS Employment and Population, Kenai-Soldotna Area, Lower Cook Inlet, 1980 - 2000	26
4. Forecast of Non-OCS Employment and Population, Homer Area, Lower Cook Inlet, 1980 - 2000	27
5. Average Annual Full-Time Employment, Kenai-Cook Inlet Labor Area, 1979	29
6. Average Annual Full-Time Employment, Kenai-Soldotna Labor Area, 1979	30
7. Average Annual Full-Time Employment, Homer Labor Area, 1979	31
8. Estimated Population, Kenai-Cook Inlet Census Division and Selected Areas, 1979	34
9. Distribution of Population, Kenai-Soldotna and Homer Areas, 1978	35
10* Percentage Allocation of Estimated Non-OCS Population, Selected Kenai-Cook Inlet Census Division Areas, 1980 - 2000	36
11. Yearly Onshore Onsite Manpower Requirements by Task, Medium Find Scenario, Lower Cook Inlet (Sale CI), 1979 - 1998	42
12. Yearly Offshore Onsite Manpower Requirements by Task, Medium Find Scenario, Lower Cook Inlet (Sale CI), 1979 - 1998	43
13. Assumptions for the Distribution of Employment Among the Coastal Areas of Kenai and Homer, Medium Find Scenario, Lower Cook Inlet - Sale CI	46
14. Estimated Direct Onshore Onsite Employment by Task, Medium Find Scenario, Lower Cook Inlet (Sale CI) - Kenai Area, 1979 - 1998	50
15. Estimated Offshore Onsite Employment by Task, Medium Find Scenario, Lower Cook Inlet (Sale CI) - Kenai Area, 1979 - 1998	51
16. Estimated Direct Onshore Onsite Employment by Task, Medium Fi nd Scenario, Lower Cook Inlet (Sale CI) - Homer Area, 1979 - 1998	52
17. Estimated Offshore Onsite Employment by Task, Medium Find Scenario, Lower Cook Inlet (Sale CI) - Homer Area, 1979 - 1998	53
18. Employment Multiplier Values for the Kenai-Cook Inlet Coastal Area	54

	Page
19. Estimated Employment and Population from OCS Onshore Development, Medium Find Scenario, Lower Cook Inlet (Sale CI) - Central Peninsula Area (Kenai), 1980 - 1998	56
20. Estimated Employment and Population from OCS Onshore Development, Medium Find Scenario, Lower Cook Inlet (Sale CI) - Southern Peninsula Area (Homer), 1980 - 1998	57
21. Estimated Employment and Population from OCS Offshore Development, Medium Find Scenario, Lower Cook Inlet (Sale CI) - Central Peninsula Area (Kenai), 1980 - 1998	58
22. Estimated Employment and Population from OCS Offshore Development, Medium Find Scenario, Lower Cook Inlet (Sale CI) - Southern Peninsula Area (Homer), 1980 - 1998	59*
23. Percentage Allocation of Estimated OCS Related Population, Selected Kenai-Cook Inlet Census Division Areas, 1980 - 2000	61
24. Allocation of Estimated Population from OCS Onshore Development, Medium Find Scenario, Lower Cook Inlet (Sale CI) - Central Peninsula Area (Kenai), 1980 - 1998	62
25. Allocation of Estimated Population from OCS Offshore Development, Medium Find Scenario, Lower Cook Inlet (Sale CI) - Central Peninsula Area (Kenai), 1980 - 1998	63
26. Allocation of Estimated Population from OCS Onshore Development, Medium Find Scenario, Lower Cook Inlet (Sale CI) - Southern Peninsula Area (Homer), 1980 - 1998	64*
27. Allocation of Estimated Population from OCS Offshore Development, Medium Find Scenario, Lower Cook Inlet (Sale CI) - Southern Peninsula Area (Homer), 1980 - 1998	65
28. Estimated Direct Onshore Onsite Employment by Task, North Kenai LNG Plant Construction and Operations, Kenai Area, 1980 - 2000	67
29. Estimated Employment and Population, North Kenai LNG Plant Construction and Operations, Central Peninsula Area (Kenai), 1980-2000	70
30. Allocation of Estimated Population, North Kenai LNG Plant Construction and Operations, Central Peninsula Area (Kenai), 1980-2000	72*
31. Forecast of Employment and Population, Base Case, Lower Cook Inlet - Kenai-Soldotna Area, 1980 - 2000	77
32. Forecast of Employment and Population, Base Case, Lower Cook Inlet - Homer Area, 1980 - 2000	78
33. Forecast of Population, Base Case, Lower Cook Inlet - Kenai-Cook Inlet Census Division, 1980 - 2000	81
34. Forecast of Population, Base Case, Lower Cook Inlet - City of Kenai, 1980 - 2000	82
35. Forecast of Population, Base Case, Lower Cook Inlet - City of Soldotna , 1980 - 2000	83
36. Forecast of Population, Base Case, Lower Cook Inlet - City of Homer, 1980 - 2000	84

	Page
37. Forecast of Net Change in Housing Demand, Base Case, City of Kenai, 1982 - 2000	99
38. Estimated Demand for Residential Land, Base Case, City of Kenai, 1982 - 2000	100
39. Projected Capacity Requirements, Water Supply System, Base Case, City of Kenai, 1982 - 2000	101
40. Estimated Capacity Requirements, Domestic Sewage Treatment, Base Case, City of Kenai, 1982 - 2000	102
41. Estimated Electric Power Capacity Requirements, Base Case, Kenai Area, 1982 - 2000	103
42. Estimated Disposable Solid Wastes, Base Case, City of Kenai, 1982 - 2000	104
43. Estimated Capacity Requirements, Telephone System, Base Case, City of Kenai, 1982 - 2000	105
44. School Enrollment Forecast, Base Case, City of Kenai, 1982 - 2000	106
45. General Fund, Revenue Forecast, Base Case, City of Kenai, 1982 - 2000	107
46. Forecast of Revenues and Operating Expenditures, Base Case, City of Kenai, 1982 - 2000	108
47. Forecast of Net Change in Housing Demand, Base Case, City of Soldotna, 1982 - 2000	124
48. Estimated Demand for Residential Land, Base Case, City of Soldotna, 1982 - 2000	125
49. Projected Capacity Requirements, Water Supply System, Base Case, City of Soldotna, 1982-2000	126
50. Estimated Capacity Requirements, Domestic Sewage Treatment, Base Case, City of Soldotna, 1982 - 2000	127
51. Estimated Electric Power Capacity Requirements, Base Case, Soldotna Area, 1982 - 2000	128
52. Estimated Disposable Solid Wastes, Base Case, City of Soldotna, 1982 - 2000	129
53. Estimated Capacity Requirements, Telephone System, Base Case, City of Soldotna, 1982 - 2000	130
54. School Enrollment Forecast, Base Case, City of Soldotna, 1982 - 2000	131
55. General Fund, Revenue Forecast, Base Case, City of Soldotna, 1982 - 2000	132
56. Forecast of Revenues and Operating Expenditures, Base Case, City of Soldotna, 1982 - 2000	133
57. Forecast of Net Change in Housing Demand, Base Case, City of Homer, 1982 - 2000	149
58. Estimated Demand for Residential Land, Base Case, City of Homer, 1982 - 2000	150
59. Projected Capacity Requirements, Water Supply System, Base Case, City of Homer, 1982 - 2000	151
60. Estimated Capacity Requirements, Domestic Sewage Treatment, Base Case, City of Homer, 1982-2000	152

	Page
61. Estimated Electric Power Capacity Requirements, Base Case, Homer Area, 1982 - 2000	153
62. Estimated Disposable Solid Wastes, Base Case, City of Homer, 1982 - 2000	154
63. Estimated Capacity Requirements, Telephone System, Base Case, City of Homer, 1982 - 2000	155
64. School Enrollment Forecast, Base Case, City of Homer, 1982 - 2000	156
65. General Fund Revenue Forecast, Base Case, City of Homer, 1982 - 2000	157
66. Forecast of Revenues and Operating Expenditures, Base Case, City of Homer, 1982 - 2000	158
67. Assumptions for the Distribution of Employment Among the Coastal Areas of Kenai, Homer and Afognak Island, Exploration Only Scenario, Lower Cook Inlet	161
68. Forecast of Total Employment from Exploration Only Scenario, Lower Cook Inlet - Kenai-Cook Inlet Census Division, 1982 - 2000	163
69. Forecast of Total Population from Exploration Only Scenario, Lower Cook Inlet - Kenai-Cook Inlet Census Division, 1982 - 2000	164
70. Forecast of Population, Exploration Only Scenario, Lower Cook Inlet - Kenai-Cook Inlet Census Division, 1982 - 2000	165
71. Estimated Offshore Onsite Employment by Task, Exploration Only Scenario, Lower Cook Inlet - Kenai Area, 1982 - 2000	166
72. Estimated Employment and Population from OCS Offshore Development, Exploration Only Scenario, Lower Cook Inlet - Central Peninsula Area (Kenai), 1982 - 2000	167
73. Estimated Direct Onshore Onsite Employment by Task, Exploration Only Scenario, Lower Cook Inlet - Kenai Area, 1982 - 2000	168
74. Estimated Employment and Population from OCS Onshore Development, Exploration Only Scenario, Lower Cook Inlet - Central Peninsula Area (Kenai), 1982 - 2000	169
75. Estimated Offshore Onsite Employment by Task, Exploration Only Scenario, Lower Cook Inlet - Homer Area, 1982 - 2000	170
76. Estimated Employment and Population from OCS Offshore Development, Exploration Only Scenario, Lower Cook Inlet - Southern Peninsula Area (Homer), 1982 - 2000	171
77. Estimated Direct Onshore Onsite Employment by Task, Exploration Only Scenario, Lower Cook Inlet - Homer Area, 1982 - 2000	172
78. Estimated Employment and Population from OCS Onshore Development, Exploration Only Scenario, Lower Cook Inlet - Southern Peninsula Area (Homer), 1982 - 2000	173

INTRODUCTION

Volume One of the "Final Technical Report, Lower Cook Inlet Socioeconomic Systems Impact Analysis" presented detailed baseline data about existing community conditions at Kenai, Soldotna and Homer. The objective of this Volume Two is to analyze how the growth and **community** infrastructure of these settlements might be affected as a consequence of the proposed Lower Cook Inlet OCS Lease Sale #60. This is a second-generation federal OCS lease sale in Cook Inlet, following upon OCS Sale **CI** held in October, 1977. Figure 1 illustrates the general location of the petroleum basins containing the tracts being considered for Sale #60.

In order to assess the range of possible community impacts of the proposed lease sale over two decades, the scenario method was used to construct and compare four different growth cases, a base case without the Lower Cook Inlet Lease Sale #60 and three distinct petroleum development cases.

To identify the significant **community** impacts of the different petroleum scenarios, this logical sequence of analyses was followed, proceeding from the baseline data published in Volume One:

- First, using techniques of economic base analysis and employment and population multipliers, local forecasts of future annual employment by economic sector and of future population were prepared for the base case and for each of three OCS petroleum

FIGURE 1
LOCATION OF THE STUDY AREA

development scenarios. These scenarios were prescribed by Dames and Moore, based on oil and gas reserves estimates supplied by the U.S. Geological Survey. The specific forecasts of OCS-related employment used in the present study, from which indirect employment and future population estimates were derived, were adopted directly from Dames and Moore's petroleum scenarios.

- Second, a set of uniform standards and assumptions was developed for forecasting. For a given population, future public service and facility requirements and local governmental revenues and expenditures to facilitate comparisons among the different communities and alternative scenarios were developed.
- Finally, the standards and assumptions were used to quantify population-related community impacts of the various scenarios for purposes of comparative analysis.

As background for the analysis of the different scenarios, a brief explanation of the role of scenarios and the forecast methodology is provided below. A fuller explanation of the forecast methodology is given in the Appendices to this report.

Petroleum Development Scenarios

The outcome of the search for oil and gas is by nature highly speculative and it is thus impossible to advance any definitive **single** forecast about the community development impacts of a particular OCS lease sale. At the time of the lease sale and, indeed, for some years after, resource estimates and corporate decisions about development schedules and production facilities must be considered tentative, pending decisive exploration results and economic analyses.

Still, even preliminary and **pre-lease** resource data can be used statistically to calculate the likelihood of various recoverable reserve estimates. These different estimates, coupled with insight into the critical factors governing petroleum development decisions and operations, can be used to hypothesize forecasts or scenarios of how petroleum development might unfold in accord with one or another of the reserve estimates. Finally, the petroleum development scenarios provide a basis for constructing coherent, plausible accounts of potential socioeconomic impacts upon nearby communities of the proposed **OCS** lease sale to match the different assumptions about ultimate reserves and development decisions

This report characterizes the socioeconomic impacts on **Kenai, Soldotna** and Homer of a base case and of three different **OCS** petroleum development scenarios:

- Base Case. This is a forecast of how the settlements would most likely evolve were there no second Lower Cook Inlet OCS lease sale. It is the basis for comparison with the OCS scenarios.
- 95 Percent Probability Resource Level Scenario. This is the low or exploration only scenario, corresponding to that volume of "recoverable resources low enough to have a 95 percent probability of being realized. Under reasonable economic assumptions, the 95 percent resource level is not commercially profitable and is thus not produced.
- 5 Percent Probability Resource Level Scenario. This is the high scenario, corresponding to that volume of recoverable resources high enough to have only a 5 percent probability of being realized.
- Mean Probability Resource Level Scenario. This is a statistical mean scenario which is a mean of the high and low scenarios.

Detailed petroleum development scenarios for the Lower Cook Inlet Lease Sale were prepared for the Alaska OCS Office by Dames and Moore, based on oil and gas reserve estimates supplied by the U.S. Geological Survey. Table 1 lists the chief **OCS-related** industrial facilities and activities and associated employment assigned by Dames and Moore to onshore sites under each of these three petroleum scenarios. Local community impacts

3. Production	Service base operation, extended use of existing Nikiski oil facilities	Not Applicable	Service base operation, oil terminal operation (192,000 bpd, 32 jobs)
<u>5 Percent Scenario</u>			
1. Exploration	Service base operation	Air support, service base operation	Service base construction
2. Development	Expanded service base, operation, pipe-coating	Air support, expanded service base operation, onshore pipeline construction	Service base operation, oil terminal construction
3. Production	Service base operation, extended use of existing Nikiski oil facilities	Not Applicable	Service base operation, oil terminal operation (384,000 bpd, 84 jobs)

Source: Alaska Consultants, Inc. Derived from facility and OCS employment scenarios prepared by Dames and Moore.

for the most part stem from the construction, operation and staffing of these facilities. Thus, the validity of the socioeconomic scenarios necessarily depends on the realism of the petroleum scenarios. Most critical in this respect are the Dames and Moore **workforce** figures for construction camp and oil terminal operations, since they involve the largest share of employment.

The base or non-sale case describes the likely course of community growth, assuming a continuation of current economic trends, that is, without any further **OCS-related** economic activities. For the base case, a full analysis of **community** growth needs was prepared, focusing on the critical elements of community infrastructure: housing and residential land supply; public utilities (water supply; sewage systems; electric power; solid waste disposal; telephone); public safety; health and social services; education and recreation. Emphasis was given to those services and facility needs customarily provided by local government. A forecast was also prepared for the fiscal impact of growth on local governmental revenues and expenditures.

The base case forecasts and analyses were then used as the benchmark for assessing the incremental significance of the impact forecasts prepared for each of the three OCS cases. The analyses of the petroleum scenarios stress the noteworthy departures from base case conditions.

Methods of Forecasting

EMPLOYMENT AND POPULATION

The method employed to forecast future employment and population was the economic base method, outlined in detail in the Appendices to this report. Briefly explained, this method divides all local economic activities into two categories: exporting or basic industries which bring money into the locality by exporting locally produced goods and services; and non-exporting or service industries which produce goods and services for local consumption. Then, current employment is tabulated by economic sector and grouped as basic or service employment. Next, the recent trends and future prospects for each basic economic sector are analyzed and future levels of basic employment are forecast for each year. Finally, suitable ratios or multipliers relating basic employment to service or indirect employment are applied to basic employment projections to yield overall employment forecasts by sector. The suitable ratios vary from locality to locality, depending upon specific features of the local economy.

The employment forecasts are then used to project future population by applying an appropriate ratio of local employment to local population. The ratio proper to a given locality can be derived empirically, with adjustments as needed to account for any future factors that might alter it. This employment/population ratio will vary with the social composition of the local population, particularly with its age structure and labor force participation rate, and with the vitality of the local economy.

The local employment forecasts for the base case were derived in a straightforward way from existing economic data. However, the calculation of total local employment forecasts for the OCS scenarios was more complicated.

The petroleum development scenarios prepared by Dames and Moore summarize at a regional level the basic employment for a whole array of offshore industries. However, this regional **summary** was not immediately usable for community level forecasts. A number of intermediate steps was required to obtain community employment forecasts:

- First, regional **OCS** employment was disaggregated and jobs were assigned to Kenai, **Soldotna** or Homer.
- Second, certain unusual traits of the workforce in the offshore industries were examined in order to interpret the numerical data in terms meaningful for economic base analysis. For example, among other factors, account was taken of personnel rotation policies, shift lengths, **seasonality**, round-the-clock operations, worker turnover and transiency, resident hire, and **community/construction** camp residency patterns as these factors affect different job categories, before an assessment was made of the quantitative impact of regional **OCS-related** employment on a given locale's overall employment, population and community infrastructure. The special assumptions and methods adopted herein to disaggregate and allocate **OCS-related** employment and

the step-by-step results are recounted in the Appendices to this report.

- Third, to calculate indirect employment a series of assumptions was made assigning appropriate employment multipliers to different basic job categories.
- Fourth, the total indirect employment was distributed to various economic sectors in a proportion selected as descriptive of the economic structure toward which the relatively immature economies of Alaska's smaller coastal communities would tend under the economic stimulus of OCS industries.

The end product of these operations was a series of annual employment forecasts by economic sector for each locality for each OCS scenario, and a parallel population forecast.

COMMUNITY INFRASTRUCTURE AND FINANCES

A set of uniform standards was developed for forecasting local public facility and service demands and local revenues and expenditures, usually on a per capita basis. Quantitative standards were developed for the following items of community infrastructure: housing demand by type of unit; residential **land** use; water system capacity; domestic sewage treatment capacity; electric generating capacity; disposable solid wastes; telephone system capacity; **police officers; jail** facilities;

fire stations; hospitals; school enrollment and classroom needs; and recreational facilities.

The utility requirements of specific OCS industrial facilities such as service bases, pipe coating yards, construction camps and oil and LNG terminals, were estimated separately from community needs. Depending on the scenario and locality, various of these facilities may be wholly isolated from the settlement, or connected by road or in close proximity to the settled area. As a **rule**, it was presumed that large industrial enterprises would develop their own primary or backup utility **systems**, because they would find it more timely, economical and reliable to do so whenever existing excess local capacity was not readily available for their use. In those scenarios where industrial **uti**ilities may be a pertinent community development issue, their impact on community utility systems is evaluated.

These standards were then applied to the population forecasts to generate for each community its forecast of public service and facility needs for the base case and the OCS scenarios.

This use of uniform standards uniformly applied has the advantages of simplicity, of minimizing local biases and of yielding easily compared forecasts of impacts upon individual communities under the different scenarios. Conversely, the methodology has the disadvantage of slighting local features which may importantly influence the shape that impacts take. As a result, the methodology may occasionally generate unrealistic

impact forecasts. Whenever(the uniform standards produced a forecast at odds with **common** sense or known local constraints, this was noted and an alternative forecast and the reasons for it were **presented**.

The revenue and expenditure forecasts require some **special** qualifications for their proper use and understanding. The fiscal forecasts simply carry forward into the future the local revenue patterns and expenditure practices which prevailed before the forecast period, adjusted for population growth (as determined by the economic base analysis) and for inflation at an annual rate of 6 percent. In terms of purchasing power, local property tax revenues were **kept** at a constant per capita level by ignoring inflation, except for the addition of revenue from new **OCS-** related industrial property **which is** taxed at the prevailing local rate, subject to the **limits of** State law.

The general fund and school district expenditure forecasts assume that each local governing unit will maintain its present level, variety and quality of services at its present per capita costs. On the **whole, this** is a debatable assumption, though it is not easy to pinpoint when and where exceptions to it may occur. Finally, the forecast of funds surplus to operating expenditures and available for capital improvements, debt' service or other purposes is obtained by subtracting expenditures from revenues.

The fiscal forecasts also do not take into account the possible changes in local tax policies (i.e., adoption of a use tax) or in local

governmental operations (i.e., assumption of additional functions by the Kenai Peninsula Borough) or State tax policies (i.e., revision of the statutes governing local taxation of oil and gas property) or many other factors which could radically upset the fiscal balance. While it is granted that factors of this sort may well alter fiscal relationships, they are not for that reason alone germane to the fiscal analysis of growth impacts stemming from the OCS lease sale.

Again, it should be emphasized that this methodology has limited validity for predicting the services and facilities which will actually be provided in the future or for predicting actual expenditure and revenue patterns. For example, since the methodology imposes common standards for public service levels and assumes a continuation of current local fiscal practices, it cannot allow for local decisions to alter the assumed pattern of services or the pattern of taxation and expenditures. Nevertheless, the methodology does provide comparisons, within the framework of the assumptions, suggestive of the trend of growth impacts on the settlements under study and that is the point of these OCS scenarios.

Finally, a major but necessary omission from the forecasts of local government revenues and expenditures is a projection of a long term capital requirements to finance major capital improvements. In order to present such information, a complete needs assessment of the **range** of **community** facilities and services for each community would be required, a local assessment of the relative priority for improvement or replacement of various projects would then be made, and cost estimates and the means

for financing such projects would be developed. Such Information is not available for **Kenai, Soldotna** or Homer and its development is well beyond the scope of this study. Nevertheless, it is needed to present a complete picture of the probable financial demands on communities under conditions of a non-OCS and several OCS scenarios and its absence from this report and the reasons for it are hereby noted.

PROJECTIONS OF GROWTH - BASE CASE

Kenai-Cook Inlet Census Division

BASE CASE - EMPLOYMENT AND POPULATION

Non-OCS Employment

The base case forecast of employment and population growth for the cities of Kenai, **Soldotna** and Homer was derived from an overall analysis of the **economy** of the **Kenai-Cook** Inlet Census Division, which comprises the western half of the **Kenai** Peninsula Borough.

For the forecast period, anticipated trends in the region's economic base were assessed and, upon this assessment, sector-by-sector growth rates were projected for future employment in the **Kenai-Cook** Inlet Labor Area and the Homer Labor Area.

Two events were segregated and treated as separate incremental contributors to the region's economic growth, apart from the economic base analysis: the first-generation OCS Sale **CI** and construction and operation of the proposed Pacific-Alaska LNG plant at North Kenai. The employment attributable to these two projects was individually estimated and then incorporated into the employment forecasts for the **Kenai-Cook** Inlet and Homer Labor Areas. Next, by use of a population/employment ratio, population estimates were calculated for the **Kenai-Cook** Inlet and Homer

Labor Areas. Finally, each labor area's population estimate was subdivided among the cities and their respective hinterlands.

Thus, this base case forecast is not a non-OCS forecast. It does include a level of OCS activity corresponding to a medium level of exploration success in Sale **CI** as well as a strong base level of oil and gas-related industrial facilities developed for earlier leases in the Cook Inlet Province. This aspect of the base case assumes significance in the impact assessment of the petroleum scenarios since it presents a situation in which many Sale 60 activities can draw upon industrial facilities with excess capacity due to the decline of earlier producing fields.

The sector-by-sector analysis of regional economic trends follows.

Oil and Gas. An inelastic demand for petroleum will exist throughout the planning period from 1980 through 2000 for Cook Inlet petroleum resources.

Although petroleum production from existing Upper Cook Inlet oil and gas **fields** will be declining throughout the planning period, strong demand for domestic oil and gas production will result in tertiary recovery from these fields through the year 2000. In addition, new petroleum production is assumed from State leases in the Cook Inlet area (and from offshore leases in OCS Lease Sale **CI**).

It is also assumed that the existing and forecast natural gas reserves are sufficient to maintain current levels of production throughout the forecast. However, substantial additions to processing capacity are not seen to occur during this period.

Any shortfall in crude oil production from Cook Inlet fields supplying Cook Inlet refineries is assumed to be offset by crude oil importation from other areas of Alaska or elsewhere. Thus, these facilities are assumed to operate at or above current levels throughout the planning period. However, substantial additions to processing capacity are not seen to occur during the period of forecast.

Possible declines in petroleum mining related employment due to production from Upper Cook Inlet platforms ceasing is assumed to be more than compensated for by increases in oil service industry employment resulting from servicing oil developments in other areas of the State.

Fishing and Seafood Processing. Growth in fishing and seafood

processing employment is assumed to result from increased-yields in the traditional fisheries of the **Kenai-Cook** Inlet area and successful entry and exploitation of deep sea fishing resources.

The harvesting and processing of deep sea fishery resources (**or so called groundfish or bottomfish**) is assumed to take place in the southern Kenai Peninsula area, particularly Homer. Also, some supply of **bottomfish** to offshore processing vessels by fishing boats based in this area is foreseen.

Although involvement in deep sea fisheries is forecast to result in substantial employment increases, the sum of the increase in employment in the fishing and fish processing sector is assumed to be even greater since the base which is vested in the traditional fisheries is forecast to increase also.

Traditional fishing and fish processing are forecast to increase modestly throughout the planning period. These increases are based in part upon increased knowledge and experience by the State of Alaska in the management of traditional species such as salmon, king crab, tanner crab and other species taken in this area. This more capable management will enable the regulatory authorities to stabilize the production of these fisheries and permit catches approaching optimum yields.

It is also assumed that further diversification of fisheries products **with** the addition of **bottomfish** as an example and the fisheries product mix in Cook Inlet plants, especially the southern **Kenai** Peninsula plants, will result in a substantial year-round operation with a more stable, resident labor force in the fishing and fish processing sector.

Improved management and greater yields in Alaska's fisheries districts will continue to result in part from the 200 miles offshore limit imposed by the United States and the recently agreed upon **U.S./Japan** treaty which limits Japanese salmon catches beyond the 200 mile limit.

Overall, it is assumed that the improved management of Alaska fishery resources gained through law, treaty, knowledge and experience will result in a more dependable and larger harvest of fisheries resources during the period of this forecast.

Tourism and Recreation. The tourism and recreation industry is forecast to become a more significant factor in the economic growth of the Kenai-Cook Inlet area. General population growth, as forecast for the Southcentral region by the Institute of Social and Economic Research for a "moderate base case", together with increased visitor traffic to the **Kenai** Peninsula Borough originating outside the State, are expected to intensify use of the area's tourism and recreational assets.

The tourism and recreation sector within the **Kenai-Cook** Inlet area is seen responding to this increased potential by providing the facilities and services necessary to support increased tourism and recreation.

The **Kenai-Cook** Inlet area is assumed to attract a more than proportionate share of the total visitor traffic venturing beyond the Anchorage area. Especially important in attracting and accommodating visitor traffic will be the Homer area although all areas within the **Kenai-Cook** Inlet area will realize visitation increases:

Logging and Wood Products. Although the **Kenai-Cook** Inlet area contains substantial timber resources with major wood processing plants located at **Jakolof** Bay and Tyonek, conflicts with the fishing and fish

processing industry and the tourist and recreation industry **are** seen as inhibiting factors to further growth.

Logging and wood processing currently occupy a small position in the economy and basic employment of the Kenai-Cook Inlet area and, despite the potential of this industry to expand, **it** is assumed to remain at current levels throughout the forecast **period**, for reasons noted **in** the preceding paragraph. ,

Government. A modest rate of growth is assumed to take place in basic government employment during the forecast period. Increases in resident population and visitors, especially those engaged in tourism and **recreation**, are assumed to result in the need **for** more intensive management in areas of fish and wildlife. Additional basic Federal employees are seen to be needed to protect and manage the fish and wildlife within the Kenai Moose **Range**. Also, additional basic State employees will be required to protect the productive fish streams, rivers and beaches of this area as well as to manage State Parks and recreational facilities provided to accommodate visitors.

Increased offshore activities in petroleum development and deep sea fishing as well as increased recreational boating will necessitate increases in U.S. Coast Guard employment. And in the air, the increases in fixed wing and helicopter traffic resulting from offshore development and general economic and population growth will result in increased basic Federal and State employment.

It is also assumed at the State and local level that the substantial intergovernmental transfers, principally in the form of grant funds, resulting in basic employment within the **Kenai-Cook** Inlet area will be maintained roughly in proportion to increases in population within the area.

In summary, increases in basic employment during the period of the forecast are assumed to result from the same natural resource-based industries now supporting basic employment in the area. However, these industries are forecast to range further from the **Kenai-Cook** Inlet area in providing the products supporting basic employment. The fishing industry is forecast to range further into the ocean for **bottomfish**. The petroleum industry will move further out on the continental shelf to produce oil and gas and utilize more extensive methods to realize tertiary recovery from existing fields. And greater numbers of visitors will **travel** to the area from greater distances to enjoy tourist and recreation opportunities on the lands and waters of the **Kenai-Cook** Inlet area.

In the principal sectors, basic employment in Agriculture, Forestry and Fisheries is forecast to increase in the **Kenai-Cook** Inlet Census Division at 4 percent per year from 1979 to 1990 and 2.5 percent per year from 1991 to 2000. This increase is based solely upon growth in the fisheries with **bottomfishing** being a major factor. Since a large portion of the growth is forecast to take place through **bottomfishing** and through greater yields in the total mix of fish catches, the southern **Kenai** Peninsula area is forecast to experience greater growth. Homer area

basic employment in Agriculture, Forestry and Fisheries is forecast to increase at a rate of 5 percent per year from 1979 to 1990 and 3 percent per year from 1991 to 2000. On the other hand, basic employment in this sector in the **Kenai-Soldotna** area, where salmon fishing dominates, is forecast to increase steadily at 1.5 percent per year throughout the planning period.

Basic employment in manufacturing which is vested primarily in petroleum processing and seafood processing is forecast to increase at a modest 2 percent per year in the **non-OCS** forecast for the **Kenai-Cook Inlet** Census Division. (The inclusion of the OCS Sale **CI** in the base case does not alter this growth since the same facilities and **employment** are used to process the petroleum production of Sale CI. However, it results in maintaining a share of petroleum employment at current levels).

Of course, basic employment growth varies for the area under study within the Kenai-Cook Inlet Census Division. The Homer Area whose basic manufacturing employment is vested in seafood processing is forecast to increase at 5 percent per year from 1979 to 1990 and 3 percent per year from 1991 to 2000. In the **Kenai-Soldotna** area, where petroleum processing employment dominates, basic employment is expected to increase at 2 percent per year throughout the forecast period.

Basic **non-OCS** employment in mining in the **Kenai-Cook Inlet** Census Division is **located** almost exclusively in the **Kenai-Soldotna** area and is almost **exclusively** petroleum industry related employment. This basic employment

sector is forecast to increase by 1.0 percent per year in the **Kenai-Soldotna** area, whereas no employment is recorded in this sector in the Homer area.

The distributive industry sectors of Transportation, Communications and Public Utilities, Trade and Services support basic **non-OCS** employment in the **Kenai-Cook** Inlet Census Division through provision of goods and services primarily to basic industries, visitors, transient fishing vessels and offshore petroleum operations.

Basic employment in Transportation, Communications and Public Utilities is forecast to increase at 3.5 percent per year throughout the planning period in the **Kenai-Cook** Inlet Census Division. The **Kenai-Soldotna** area where this sector, especially in transportation, is extensively developed is forecast to increase at 3 percent per year from 1979 to 2000. Some economies of scale are seen in this sector. The Homer area with a less developed basic economy in this sector is forecast to increase at 4 percent per year throughout the forecast period.

Activities in the trade sector and service sector are forecast to result in a basic employment growth of 3.75 percent per year in the **Kenai-Cook** Inlet Census Division. Primarily because of tourism and recreation, basic employment in the Homer area is forecast to increase at 4 percent per year while lesser involvement in the **Kenai-Soldotna** area will result in an annual growth of 3.5 percent for the length of the forecast.

Basic employment in the sectors of Contract Construction and Finance, Insurance and Real Estate facilitate the development of basic economic activities such as petroleum development. The basic employment in the **Kenai-Cook** Inlet Census Division is forecast to increase at 3.5 percent per year. Basic employment in the Homer area is somewhat higher at 4 percent per year in each of these sectors while in the **Kenai-Soldotna** area both sectors are forecast to increase by 3 percent per year throughout the forecast period.

The forecast for basic employment in the Government sector in the **Kenai-Cook Inlet** Census Division Area as a **whole** and the **Kenai-Soldotna** and Homer areas is forecast at 3 percent per year throughout the period of the forecast.

The overall growth rate in basic employment for all industry sectors in the **Kenai-Cook** Inlet Census Division is estimated at approximately 2.8 percent per year (Table 2), with the Homer area increasing at about 3.8 percent per year (Table 4) and the **Kenai-Soldotna** area increasing roughly at 2.4 percent per year (Table 3).

Secondary Employment. Since the existence of service employment is dependent upon expenditures of the basic sector, service employment can be derived roughly from basic employment through the use of a multiplier to elicit **total** employment. Total employment minus basic employment equals service employment.

Source: Alaska Consultants, Inc.

The 1979 employment estimate by Alaska Consultants, Inc. derived from Alaska Department of Labor, Employment Security Division statistics for the **Kenai-Cook** Inlet Labor Area totaled 7,795. Estimates of basic and service employment were 4,451 and 3,344 respectively (see Table 5). Thus, the multiplier derived is 1.75. The multiplier appears reasonably representative of an area in which there is a mixture of stable, year-round industrial employment with high wage rates and seasonal activities with large transient work forces.

The sum of the basic employment in the industrial sectors for each of the years forecast multiplied by the multiplier of 1.75 produces the estimate of **total employment** for each year. Of course, there are many factors **which could result** in the multiplier changing. However, rather than speculating upon these changes, the multiplier is assumed to be constant throughout the forecast period.

The estimate of total employment for the **Kenai-Soldotna** area made by Alaska Consultants, Inc. from Employment Security Division data is 5,075 in 1979. The estimate of basic employment is 2,893 with secondary employment estimated to be 2,182 (see Table 6). Thus, the multiplier derived is 1.75 which is the same as that estimated for the **Kenai-Cook** Inlet Labor Area. However, it is not at all surprising that these multipliers are similar considering the dominance of the **Kenai-Soldotna** area with approximately 65 percent of the Labor Area's employment.

a/ Includes self-employed and military personnel.

b/ The Homer Labor Area is defined as the Homer Precinct, Anchor Point, Fritz Creek, Diamond Ridge and Kachemak.

c/ Number of fishermen employed on an average annual year-round basis estimated by using yearly registration data, length of fishing season and normal "crew" sizes for various types of fishing vessels.

d/ Minor employment in sand and gravel considered with contract construction and transportation.

Source: Alaska Consultants, Inc.

The Homer area in which Alaska Consultants, Inc. conducted its own employment count during 1979 totaled **1,621** employees; however, this figure included self-employed persons and military personnel. The estimate of basic **employment** is 883, with secondary employment estimated to be 738 (see Table 7). The multiplier derived is 1.84.

This is a high multiplier for a rural area. However, this employment count includes a large number of self-employed persons engaged in marginal retailing and service enterprises. These enterprises are heavily weighted toward providing goods and services to the resident population and are therefore classed as secondary.

Total Employment. Since the multiplier of basic to secondary employment is assumed to remain constant during the forecast period, the rate of increase in basic employment is equal to the rate of increase in total employment. Therefore, the **Kenai-Cook** Inlet Labor Area in which total employment is forecast to increase from an estimated 7,795 employees in the 1979 base year (Table 5) to 15,794 employees estimated in the year 2000 (Table 2) is forecast to increase by approximately 2.8 percent per year.

The **Kenai-Soldotna** area is projected to increase from an estimated 5,075 employees in 1979 (Table **6**) to 8,246 in 2000 (Table 3) or by about 2.4 percent per year. And the Homer area is projected to increase by approximately 3.8 percent annually or from 1,621 employees in 1979 (Table 7) to 3,619 employees in 2000 (Table 4).

Non-OCS Population

Given the population composition and the propensity for people desiring a semi-rural lifestyle in an attractive, natural setting to migrate to the **Kenai-Cook** Inlet Census Division, the ratio of population to employment in this area is assumed to remain constant at approximately 3.0.

(Population in Table 8 divided by employment in Table 5). This ratio coupled with the growth in employment results in a population growth forecast to be approximately 3 percent per year. The **non-OCS** population of the **Kenai-Cook** Inlet Census Division is forecast to increase from 23,552 (Table 8) in the base year of 1979 to 41,382 (Table 2) in the year 2000, or by a total of **71** percent.

In the **Kenai-Soldotna** area, where a large portion of the basic employment is outside these two incorporated cities and where the growth rates among industries are forecast to change, the distribution of population among the City of **Kenai**, City of **Soldotna** and the remaining area (Table 9) is assumed to change (Table 10) during the period of the forecast. The ratio of population to employment in this area is 2.8 (population in Table 8 divided by employment in Table 6) and is forecast to remain constant. As a result, the population of the City of Kenai is forecast to increase from 4,631 in 1979 to 6,932 (Table 3) in 2000. Although this is an increase of 46 percent, the growth rate is slightly less than 2 percent per year. The City of **Soldotna's** population, conversely, is forecast to increase at a rate slightly over 3 percent per year from 2,486 in 1979 to 4,622 (Table 3) in 2000, or by approximately 80 percent overall.

Bottomfish processing and tourism and recreation are forecast to be principal factors in the City of Homer's population growth which is forecast to increase at slightly over 5 percent per year. The City of Homer's population is projected to increase by 153 percent during the period of the forecast or from 2,171 in 1979 to 5,429 (**Table 4**) in 2000. Population increases during the next decade are forecast to result in an increasing proportion of the Homer area's population living within the City of Homer (see Tables 9 and 10).

OCS Sale CI

Employment. The Sale **CI** portion of the Base Case employment and population is derived from a petroleum scenario which is assumed to be representative of a medium find scenario for the current OCS Lease Sale cr. In deriving the Sale **CI** Medium Find Scenario, the following assumptions were made:

A Sale **CI** Medium Find Scenario is assumed as part of the base case of employment and population forecasts for the Kenai-Cook Inlet coastal area (**Kenai-Cook** Inlet Census Division).

The USGS resource estimates for the Lower Cook Inlet OCS area are allocated two-thirds for Sale **CI** and one-third for Sale 60.

The estimates for the Sale **CI** medium find scenario are 400 million barrels of oil and 402 billion cubic feet of unassociated natural gas.

Field development in Sale 60 considers costs, especially pipeline, to be shared with Sale CI.

- The Sale 60 high find scenario assumes an offshore and onshore gas pipeline to be in place as a result of field development from Sale **CI**. A subsea gas pipeline is assumed to have been constructed from a field(s) between Cape Douglas and the Barren Islands to Anchor Point for a distance of 97 kilometers (60 miles). Onshore, a 129 kilometer (80 mile) pipeline is assumed to have been constructed which would carry the gas from Anchor Point to existing LNG facilities in **the** Niki ski area.
- The Sale 60 medium find scenario assumes an offshore and onshore oil pipeline in the same vicinity. A subsea oil pipeline is assumed to have been constructed as a result of Sale **CI** development from a field(s) off Point Bede to Anchor Point for a distance of 129 kilometers (40 miles). The onshore portion of this pipeline is assumed to have been constructed from Anchor Point for a distance of 97 kilometers (80 miles) to existing oil **terminal** facilities in **Nikiski**.

No precise scenario had been developed for the Sale **CI** medium find scenario. However, a medium find oil production schedule was forecast by Dames and **Moore** based upon the USGS resource estimates.

- Approximate production was 400 million barrels of **oil**.
- Production would begin during **1986** and terminate during 1998 or production would last 13 years.

The Sale 60 high find scenario for the Lower Cook **Inlet** (excluding the **Shelikof** Strait area) is assumed to be representative of the Sale **CI** medium find scenario with specific modifications.

- This scenario results in the production of 400 million barrels of oil and 363 billion cubic feet of natural gas.

The modifications assumed for the Sale 60 high find scenario for Lower Cook Inlet are as follows:

- The production schedule and, therefore, the sequence of activities in all phases resulting in oil production is shifted to 1986 for oil and 1987 for gas.
- Oil production is assumed to terminate in 1998 or after 13 years of production.
- o Gas production which begins in 1987 is assumed to terminate after 10 years or during 1996 rather than after 8 years. This is assumed to **allow** the recovery of **400 billion** cubic feet of gas rather than 363 billion cubic feet.

- e Previous offshore pipeline employment in the model is discounted as well as its effects on service base, helicopter and supply boat employment.
- Offshore pipelaying employment to construct 129 kilometers (40 miles) of subsea oil pipeline during 1986 and 97 kilometers (60 miles) of subsea gas pipeline during 1987 is substituted along with the employment effects on the other groups of tasks.
 - Onshore pipelaying employment to ~~construct~~ 129 kilometers (80 miles) of oil pipeline and 129 kilometers (80 miles) of gas pipeline during 1985-86 is substituted for the previous onshore pipelaying in the Sale 60 high find scenario for the Lower Cook Inlet portion only.

Since Sale **CI** concludes within the period of the Base Case forecast, the annual additions of Sale **CI** employment and population to the non-OCS forecast result in higher annual averages and intermediate changes in the rates of growth but do not alter the long-term growth rates from the 1979 base year to the end of the forecast period in 2000. However, Sale **CI** is foreseen to assure the utilization of existing Cook Inlet petroleum facilities at or near capacity. And, although no tertiary recovery is assumed in this scenario, should the level of production in the forecast result there is a distinct probability of tertiary recovery under the assumption for the **non-OCS** forecast.

The basic or direct employment exhibited by the Medium Find Scenario for Sale **CI** is reasonably typical of **OCS** petroleum development. Onshore employment is reasonably **small** during the first 5 years (1979-83) of exploration. Service bases located on the waterfront provide materials to the offshore rigs while at the airport, helicopters transport employees and small volume, light weight freight to the rigs (see Table 11). This is followed by 4 years (1984-87) of intensive development where offshore platform installation, development drilling and subsea pipelaying and burying are supported from onshore. In this scenario it is onshore pipelaying and pipe coating which result in the onshore employment peak of 283 **onshore-on-site** employees. However, the largest onshore employment impact is generally created by oil terminal and LNG plant construction. This scenario assumes that the existing Cook **Inlet** plants and employees will accommodate the oil and gas production from this scenario.

The onshore production phase (1988-98) provides stable employment until platforms are taken off line beginning in 1997. Again, a higher level of employment is usually encountered where oil terminal and LNG plant employment is provided in this scenario.

Offshore employment (Table 12) is much greater than onshore employment except where platform construction and other major facilities construction takes place onshore during the development phase. This is not the case here. It is important to note that onsite employment is used in Table 12 to convey what is actually taking place at a given period of time offshore. Actually, much of the intensive employment offshore such as

Source: Dames and Moore/Alaska Consultants, Inc.

work on rigs and platforms is performed by crews who work two weeks on and two weeks off. Therefore, there is an equal number of employees on leave ashore.

As with onshore employment, reasonably consistent yearly employment is assured during the exploration phase. This is followed by a peak in employment of almost three times this number during the development phase when platforms are being installed, subsea pipeline is being laid and buried and development drilling is taking place. This is followed by a stable yearly production phase employment which is in the range of 40 percent below the development phase.

Only basic employment onshore and offshore by task is depicted in this scenario (Tables 11 and 12) for the entire Sale CI work force. This provides a graphic indication of the OCS petroleum development taking place, but it does not necessarily indicate employment-related impacts upon the local communities. In this scenario, it is necessary to make assumptions regarding the area of location of onshore employees and the secondary employment generated by the onshore activity. With offshore employment, assumptions must be made as to the numbers assumed to be resident in the local area as well as the secondary employment generated. The sum of the onshore and offshore basic employment resident in the **Kenai-Cook** Inlet Census Division and the secondary employment generated by this offshore and onshore employment is the total employment resident in the area under study.

The principal assumptions for OCS operations necessary to disaggregate onshore employment in the general Kenai and Homer areas involve the location of facilities (see Table 13). Service bases are assumed for both the Kenai area and the Homer area. The Homer service base is assumed to be a forward service base which will **accommodate** all survey vessel activity and one-third of the rig service activities during the exploration phase. During the development phase, it will provide **one-third** of the support for platform construction, subsea pipelaying and burying and development drilling from platform. In addition, a construction camp for one-half of all onshore pipeline construction will be located in this area. However, all of these activities are assumed to cease upon entry into the production phase. Only the helicopter service operating from Homer Airport is forecast throughout the petroleum scenario.

An existing permanent service base in the Kenai area is assumed to support two-thirds of the rig activity during the exploration phase, two-thirds of all offshore activities during the development phase and all offshore activities during the production phase. In addition, a pipeline construction camp will be located in the Kenai area to complete one-half of all onshore pipeline construction.

Thus, the basic OCS employment onshore and offshore is distributed by function and task (Table 18) between the Central Peninsula area of the **Kenai-Cook Inlet Census Division-Kenai** area (Tables 14 and 15) and the Southern Peninsula area of the **Kenai-Cook Inlet Census Division-Homer** area (Tables 16 and 17).

a/ The coastal area is assumed to **be** the **Kenai-Cook** Inlet Labor Area. This area does not include any portion of the Lower Cook Inlet OCS lease sale area (Sale **CI**) which is in federal waters.

b/ The employment multiplier values are applied to the direct **onshore-on-site** employment in the coastal area.

c/ The employment multiplier values are applied only to the estimated portion of total **offshore employment** resident in the **Kenai-Cook** Inlet coastal area.

Source: Alaska Consultants, Inc.

All basic **onshore-onsite** employment is assumed **to** be resident employment of the local area of employment activity. However, the secondary **employment** supported by the onshore activities is assumed to vary considerably based upon the onshore activities in the respective areas. Thus, different multipliers are applied to the various groups **of** tasks (Table 18) to derive total employment (Tables 19 and 20). Total employment minus basic employment provides secondary employment.

OCS employees are technically not employees in the area under study. In fact, they are not even employees in the State since they are outside the State in federal waters. However, for purposes of analyzing impacts upon the study area, their place of residence is assumed as the location of basic employment. Therefore, percentages of offshore employment by task are assumed to reside within the **Kenai-Cook** Inlet Census Division. The percentages vary according to the function and phase of petroleum development (Table 18). A small percentage is assumed to be resident locally during the exploration phase. However, a larger part of the work force is assumed to be resident during the production phase. A common multiplier value of **1.50** (Table 18) is assumed for total offshore employment resident in the **Kenai-Cook** Inlet Census Division. Table 21 shows the forecast of total offshore OCS employment in the **Kenai** area while Table 22 exhibits the Homer area.

Population. Given the **non-OCS** forecast of population for the **Kenai-Cook** Inlet Census Division (Table 2), the OCS population as derived from the employment scenarios (Tables 19 and 20) indicates a modest

increase in population from 1980 through 1998. For example, the OCS population of 234 added in the typical exploration year of **1981** represents an addition of approximately **1** percent to the **non-OCS** population of 24,690 forecast for that year. As OCS development peaks in 1988, a total of 2,124 persons are added to the **non-OCS** population of 30,018, or about 7 percent. And, during a typical year of the production phase (1994), 1,320 **OCS-related** people are added, or less than a 4 percent addition to the **non-OCS** population which is forecast to be 35,292.

However, as the population is allocated to the communities of study within the **Kenai-Cook** Inlet Census Division (Table 23), the population of 30 persons added at **Kenai** in the typical exploration year of 1981 (Tables 24 and 25) results in less than a 1 percent addition to the forecast **non-OCS** population of **4,819** (Table 3). In 1988, during the height of the development phase, 289 persons or an addition of approximately 5.5 percent is made to the **non-OCS** population forecast of 5,035 persons. During the typical production year of 1994, 186 persons or 3 percent, are added to the **non-OCS** forecast of 6,005 persons.

The OCS forecast results in a somewhat greater population impact on the City of **Soldotna** where 26 persons or 1 percent (Tables 24 and 25) are added to the **non-OCS** population forecast of 2,595 (Table 3) during the typical exploration year of 1981. The peak OCS population addition during the development phase year of 1988 is 273 people or 8 percent added to the non-OCS population base of 3,390 persons. The typical production phase year of 1994 would see the addition of **170** persons or 4 percent to the **non-OCS** base of 4,003 persons.

The City of Homer, with a smaller population base and a greater individual share of the forecast OCS population assumed to reside there, is forecast to experience added OCS population in the typical exploration year of 1981 of 61 persons (Tables 26 and 27) or somewhat less than 3 percent of the non-OCS population projected to be 2,229 persons (Table 4). During the peak year of 1988, 509 persons would be added as a result of OCS activities or 14 percent over the non-OCS population of 3,527. And, production phase employment during 1994 would average 306 persons or 7 percent of the forecast non-OCS population of 4,467.

Proposed Pacific Alaska LNG Plant

Employment. In order to portray the proposed Pacific Alaska LNG facility as an element in the Base Case of employment and population, a scenario involving only the construction and operations employment was developed. The facility as currently proposed by the Pacific Alaska LNG Company is assumed to have a capacity of 400 million cubic feet per day. The timing and direct employment required in the construction and operation of this facility were obtained from the Institute of Social and Economic Research, University of Alaska. These were used by ISER in the Lower Cook Inlet, State-wide and Regional Population and Economic Projections. Construction is forecast to take place beginning in 1980 and concluding with a finished plant during 1983. Production is assumed to begin in 1984 and to extend at full production beyond the year 2000 (Table 28).

The basis for the construction of this plant is not vested with OCS gas production. It is assumed to utilize gas reserves from existing fields which are shut in and from future onshore and offshore fields brought into production by a more intensive development in upper Cook Inlet. However, as with Sale **CI**, it **is an** integral part of the foundation upon which the Lower Cook Inlet petroleum scenarios are constructed. The North **Kenai LNG** facility capacity is assumed as a portion of the total capacity available for the processing of natural gas critical to the high find scenario.

Since the supply of natural gas to this facility is not dependent upon a major find of Pacific Alaska LNG Company's making, the offshore and onshore employment involved in developing the gas reserves or transporting them to the plant are not included in this scenario. This employment is accounted for as part of the **non-OCS** employment where onshore and offshore reserves of upper Cook Inlet are utilized or OCS employment in the case of Sale **CI**.

The basic or direct employment forecast to be required to construct the Pacific Alaska LNG Company plant peaks in construction year 3 (1982) with an annual average full-time employment of 1,323 persons. The construction employment requirements forecast are typical for these large complex facilities. Year **1** (1980) is foreseen as a year of site preparation with foundation work being undertaken. Year 2 (1981) is seen as the year **the** liquefaction trains which cool and condense natural gas into liquid form are placed upon completed foundations. Year 3

(1982) is seen to involve the major part of plumbing the facility and year 4 is forecast as the year in which construction is completed and the plant tested.

Production, which is forecast to begin during 1984, will require a relatively small work force of 60 employees. This operations employment is forecast to remain constant throughout the period of the forecast. Therefore, 60 employees are forecast to be employed from 1984 through 2000 in LNG plant operations.

The only employment tallied in this LNG plant scenario is onshore employment. Onshore employment by task is shown in Table 28 is direct employment. This provides a graphic indication of the scale of the facility and its operations, but it does not necessarily indicate employment related impacts upon the communities.

In this case, it is assumed that the impacts in this scenario will fall upon the **Kenai area communities** only. During the construction phase, it is assumed that the construction **workforce** will be composed almost exclusively of transient workers who are rotated through the Kenai-Cook Inlet area to their permanent residences outside. Furthermore, these employees are assumed to reside in construction camps on the site of the facility construction. These camps are seen to contain a wide range of amenities for comfortable living. Thus, excellent camps coupled with limited leisure time and scheduled rotation for employees are assumed to minimize impacts in the Kenai area. This is the basis for the assumption of a low multiplier of 1.10.

On the other hand, all of the LNG plant operations employees are assumed to be permanent employees whose permanent residence is seen to be relatively close to the plant. Therefore, all LNG plant operations employees are forecast to live within the **Kenai** area. Since these employees are provided long-term, stable employment, the multiplier is assumed to be 1.50.

The multiplier for LNG plant construction and operations when applied to the direct employment for these tasks (Table 29) provide total employment. **Total** employment minus basic employment provides secondary employment.

Population. Given the direct construction employment, assumed to be transient, and permanent employment (direct and indirect), total population is derived. It is assumed that the dependency ratio for this largely immigrant petroleum-related employment will be more representative of national norms or somewhat lower than the **Kenai-Cook** Inlet area. Therefore, instead of a dependency ratio of 3 as currently exists, a ratio of 2.5 persons per employee is assumed. This ratio is applied to all permanent employment. Where direct construction employment is involved, this is added into the population without application of the dependency ratio. This is based upon the direct construction employees living without families in camps. Thus, despite employment peaking at 1,323 during 1982, the population peak is a modest 1,653 (Table 29).

The population resulting from the LNG facility is allocated within the **Kenai-Soldotna** area on an historical basis (Table 23) with the City of

a/ Construction camp population located outside the cities of Kenai and **Soldotna**.

Source: Alaska Consultants, Inc.

Kenai receiving 30 percent, the City of Soldotna 20 percent and the remaining area outside these two incorporated cities 50 percent. However, where a construction camp is located on a specific site, the population is assigned to that area and the remainder distributed according to the above percentages (Table 30). Therefore, the population impact during construction is biased toward the outside area where the camps are located. However, the fact that these enclaves are used serves to abate the effects of population impacts in the areas of the construction employment.

Upon the conclusion of the construction phase, the stable employment during the operations phase is not particularly large. Of the total of 225 persons, it is estimated that 68 **will** reside within the City of Kenai, 45 within the City of **Soldotna** and 112 in the remaining area.

Base Case Total Employment Forecast

For purposes of forecasting future employment levels, an overall projection was first developed for the regional economy, that is, for the **Kenai-Cook Inlet** Census Division. Then, on the basis of past and anticipated economic trends, a share of the regional projection was assigned to the **Kenai-Soldotna** and Homer Labor Areas. Individual employment forecasts were not developed for each city in view of the high work force mobility within the economic sub-areas and in view of the fact that resident population, not employment, was the critical variable for estimating community impacts. Separate population forecasts were developed for

each city by distributing the population growth generated by the new employment in each area to their respective cities (**Kenai** and **Soldotna** or Homer) and their unincorporated hinterlands. The base case population forecasts **provide** the basis for the individual city's base case impact analysis.

Kenai-Soldotna Labor Area. Base Case employment in the **Kenai-Soldotna** area is projected to increase from 5,386 jobs in 1980 to 8,336 jobs by 2000 (see Table 31). The pace of expansion is generally expected to be steady, with the exception of a strong surge in construction employment during the building of the proposed Pacific Alaska **LNG** plant scheduled for 1981-84. At peak, this project creates up to 1,323 direct jobs. Many of these short-term construction jobs are assumed to be filled by a temporary work force residing in camp facilities at the project site. Other noteworthy sectors of basic growth include continuing oil and gas development related to Sale **CI** and to other State leases and the transportation industry.

Homer Labor Area. The employment forecast for the Homer Area anticipates rapid, steady growth over the next two decades. Particularly strong advances are projected for the fishing and fish processing industry, partly as a result of exploitation of groundfish resources. The trade and services sector of the economy is expected to exhibit strong growth, due to expansion in Homer's tourism industry and diversification of the local service economy. Sale **CI** is potentially also a major growth factor: the medium find scenario assumed for that sale is estimated to

generate as many as 407 jobs in the Homer area, about 14 percent of total local employment.

Overall, Homer area employment is forecast to more than double from 1,742 jobs in 1980 to 3,619 by 2000 (see Table 32).

Base Case Total Population Forecast

The sum of the **non-OCS** population forecast and the forecast for **OCS** Lease Sale **CI** and the North **Kenai LNG** facility for each year forecasted is **equal** to the Base Case forecast.

The Base Case forecast estimates population in the **Kenai-Cook** Inlet Census Division to be 41,607 persons in the year 2000 (Table 33). This is an increase of approximately 2.8 percent per year over the **life** of the forecast. Although this is a moderate growth rate, the Census Division increases **by** 77 percent from the 1979 population estimate of 23,552 (Table 8).

Within the Census Division study area, the City of Kenai is forecast to experience the slowest growth. It is expected to increase from the **1979** estimate of 4,604 people to 7,000 by 2000 (Table 34) or by approximately 2.0 percent per year. Although this is a reasonably low growth rate in **Southcentral** Alaska, it is forecast as a 52 percent increase in population by the year 2000.

The City of Soldotna's population growth is expected to be higher with an increase of approximately 3 percent per year forecasted. Soldotna is projected to increase from 2,479 persons in 1979 to 4,667 in 2000 (Table 34) for a total increase of 88 percent.

The City of Homer is expected to experience the greatest rate of growth as forecast in the Base Case. Homer is expected to increase to approximately 5,429 people (Table 36) by the year 2000. This is an overall growth in excess of 150 percent since 1979. The population growth rate for the City of Homer is forecast to be 4.8 percent per year.

Kenai

COMMUNITY FORECASTS - BASE CASE

Future Population

Over the period of the base case forecast, the City of **Kenai's** population is estimated to grow at a steady pace from about 4,755 in 1980 to about 7,000 by 2000, an increase of 47 percent (see Table 31). This is equivalent to an annual average growth rate of about 2 percent. By far the bulk of this population growth is attributed to economic events unrelated to Sale CI or the proposed Pacific Alaska **LNG** plant. At the beginning and close of the forecast, these two projects are very minor elements in **Kenai's** growth. In the middle years of the base case, when Sale **CI** activities peak and the new LNG plant begins operation, these projects momentarily inflate population by about 6 percent. Essentially, these noteworthy projects amount to a continuation of the growth trend that has characterized the City of **Kenai** for the recent decade or more rather than a departure from that trend.

IMPACT ASSESSMENT

Social Impacts

The economic and population growth forecast for the City of Kenai under the base case does not seem to portend any radical change in the social

character of the community. Essentially, under this scenario, **Kenai** confirms its role as the center of Cook Inlet oil and gas development. The construction of the proposed LNG **plant** can be expected to foster a short-term economic boom, but even that event **will** echo **the** boom-bust pattern that has become familiar at **Kenai** in the course of its emergence as the primary scene **of** Alaska's oil and gas processing industries.

Impacts on Community Infrastructure

Housing and Residential Land. The general pattern of housing demand in **Kenai** under the base case scenario anticipates a steady demand for new housing units. Housing demand peaks from 1985 to 1988 coincident with the development phase for the **CI sale** and the onset of production at the North **Kenai** LNG facility and again from 1992 to 1996 during the height of **CI Sale** onshore and offshore production (see Table 37).

The housing forecast for the base case estimates that there will be a net increase in demand of 663 housing units in the City **of Kenai** by 2000 for additional residents (see Table 37). Assuming the continuation of historic patterns, slightly more than half of the increase will be accounted for by single family units, while multi family units will account for about one-third of the total. Trailers will comprise about 15 percent of the housing unit demand.

According to the growth forecast, an estimated 51 hectares (**126** acres) of undeveloped land will be required to accommodate residential expansion

(see Table 38). A recent planning study (R.W. Thorpe and Associates, 1979) indicates that there are about 5,666 hectares (more than 14,000 acres) of undeveloped land in the City of Kenai. While some of this is in public hands or is undesirable because of poor soil conditions or flood hazards, there is more than adequate land, particularly in the outlying areas of the City, to absorb residential expansion with an ample reserve for commercial and other uses.

Utilities

- Water. In 1978, domestic water use accounted for roughly 75 percent of the total water consumed in the City of Kenai, while commercial use accounted for the remainder. For purposes of forecasting, it is assumed that this ratio will remain constant and that major industrial users will as at present continue to provide their own water. Water demand is estimated to increase approximately 40 percent during the forecast period (see Table 39). While existing pumping capacity and the distribution system, if extended, will be adequate to meet this demand, recent fluctuations in groundwater levels in the Kenai-North Kenai-Soldotna area are the cause of some concern. Extended and severe changes in groundwater levels combined with substantial growth in water consumption in the Central Peninsula area may necessitate development of an alternative to the current **groundwater** sources.

- Sewer. The City of **Kenai's** sewer system was thoroughly studied and a program of improvements recommended in the 1978 Wastewater Facilities Plan prepared by CH2M Hill. The City adopted the plan and is now implementing it. Apart from incremental extensions of the system to service new development, the plan recommends three basic improvements to the distribution system prior to 1985. These include central and west **Kenai** interceptors and several lift stations.

The sewage treatment plant has several reported defects. Although the plant's design capacity of 169 kiloliters (44,600 gallons) per hour peak flow is well above the City's current peak output of 126 kiloliters (33,300 gallons) per hour, there are occasions when infiltration and inflow overload the system. This is caused primarily by inefficient operation of the plant and poorly designed equipment, problems which are being addressed by the City.

The Wastewater Facilities Plan recommends a number of expansions and improvements to the treatment plant through the year 2000 to **accommodate** a peak flow in that year of 7,570 kiloliters (two million gallons) per day (315 kiloliters or 83,000 gallons **an** hour). Capacity requirements estimated for the base case will exceed this standard in 1986 (see **Table** 40). Thus, to **meet** base case requirements at the end of the forecast, additional capacity may be demanded.

- Electric Power. The Homer Electric Association, an REA consumer cooperative, provides electric power for the Kenai area, as well as most of the rest of the **Kenai** Peninsula. Power is purchased from **Chugach** Electric Association's gas turbine facilities at **Beluga** and Bernice Lake and from its hydro-electric facility at Cooper Landing. If the Corps of Engineers builds a hydro facility at Bradley Lake as planned, an additional 322 million kilowatt hours of electricity will be available to the area by 1987. Thus, it appears that as long as natural gas supplies last, HEA will have adequate power available to meet base case forecasts (see Table 41).
- Solid Waste Disposal. Commercial and residential garbage in Kenai is collected by a private contractor and hauled to one of two **12** hectare (30 acre) landfills in the area operated by the Kenai Peninsula Borough. Both dump sites are nearly filled to capacity and the Borough **will** have to **locate** new landfills in the next five years. Borough public works personnel have determined that about 0.4 hectare (one acre) is required to dispose of 8,028 cubic meters (10,500 cubic yards) of solid waste. In the base case, the estimated 579,387 cubic meters (757,765 cubic yards) of disposable solid waste to be generated from the City of **Kenai** during the forecast will consume roughly 29 hectares (72 acres) of landfill by the year 2000 (see Table 42). Landfill requirements for the remaining Central Peninsula area under the base case total approximately 65 hectares or **161** acres.

- Communications. The base case anticipates an increase in the number of telephone hook-ups at Kenai of about 53 percent, from 2,039 telephones in 1982 to about 3,111 hook-ups in the year 2000 (see Table 43). It does not appear that Glacier State Telephone Company, which provides telephone service to the Kenai area, should have any problem in maintaining adequate service, although historically the company has been behind in adding new stations and delays were often encountered in phone installations.

Public Safety

- Police. The City of Kenai police department provides police services within the City, while law enforcement outside the City is the responsibility of the Alaska State Troopers. To maintain an adequate level of police service during the base case forecast, the City can expect to require at least five new police officers and five additional jail cells. Furthermore, if Kenai continues to provide jail facilities for both Soldotna and the Alaska State Troopers, an additional 30 cells will be demanded to accommodate growth in areas under the police jurisdiction of these two entities.
- Fire Protection. Provision of fire protection and emergency medical services in the City of Kenai is the responsibility of the Kenai fire department. Kenai's fire insurance rating

varies from 6 to 9 depending on the availability of fire hydrants and distance from the fire station. Areas on the hydrant system and within 8 kilometers (5 miles) of the station have a rating of 6, while those areas more than 8 kilometers (5 miles) distant have a rating of 8 where hydrants are available and 9 where they are not. The City anticipates that the rating of the downtown area will be lowered to 5 when the new 11,355 kiloliter (3 million gallon) storage tank at the airport becomes operational. The new storage capacity will serve to meet fire flow requirements in newly developing areas.

With continuing growth in the northern and eastern sectors of town, the ability of the single centrally located fire station to maintain a satisfactory response time is declining. The planned construction of a substation at mile 5 on the Spur Highway will improve response time to the eastern reaches of the City, and a proposed substation near **Wildwood** will **similarly** reduce response time in outlying areas to the north.

The construction of the two new substations, the acquisition of required fire personnel and equipment, and the provision of additional water storage to meet fire flow requirements should ensure that **Kenai's** fire protection is adequate for the foreseeable future.

Health and Social Services. The **Kenai-Soldotna** area is large enough to require and support a diverse mix of medical facilities and professional services. Health facilities include the Borough-owned Central Peninsula General Hospital in **Soldotna** which serves the hospital needs of **Kenai, North Kenai, Kasilof, Sterling, Cooper Landing and Soldotna**; the **Kenai** Health Center operated by the State Department of Health and Social Services; and the Medical Center at Wildwood run by the **Kenai** Native Association for the area's Alaska Natives.

Based on the standard of three acute care beds for 1,000 population, the 30-bed Central Peninsula General Hospital is already short 14 beds for existing needs and, by the end of the forecast period, about 40 additional beds are likely to be demanded. However, recent hospital occupancy rates of about 30 percent suggest that this standard is too high, probably because area residents are seeking some hospital services outside the community. If this trend continues, the Central Peninsula General Hospital may require few, if any, new hospital beds during the base case forecast period.

Although hospital beds are adequate to accommodate a substantially larger population, both space and equipment for outpatient and emergency services **are** inadequate for existing needs. A proposal to expand these **will** go before service area voters in the **fall** of 1979 and, if approved, outpatient and emergency services should be adequate for the base case forecast period.

In 1979, there were ten doctors affiliated with the Central Peninsula General Hospital and practicing in the **Kenai-Soldotna** area. In addition, medical specialists visit regularly or are on call for assistance from Anchorage. Applying the standard of two physicians for a community of 3,000 **plus** another physician for each additional increment of 1,500 population, three to four more physicians are likely to be needed in the **Kenai-Soldotna** area by the year 2000. During the base case forecast period, no demand for new dentists is anticipated.

In general, by the standards adopted by the State of Alaska, the facilities and services available to the **Kenai-Soldotna** area, with the possible exception of the need for an alcohol and drug detoxification center, meet or exceed recommended levels and should be able to be expanded to meet new service loads anticipated under the base case.

Education. The City of **Kenai** is not directly responsible for financing and administering a local school district as the Kenai Peninsula Borough provides educational services on an areawide basis for the entire Borough. The school system is funded mainly through State contributions, supplemented by Borough revenues raised on an areawide basis. The Borough operates two elementary schools, a junior high school and senior high school in **Kenai**. The two elementary schools serve students from **Kenai** and **Kalifonsky**, while the junior high school serves North **Kenai** as well as **Kenai** and **Kalifonsky**. The service area for the senior high school currently includes the City of **Kenai** and the communities of North **Kenai**, **Soldotna**, **Kalifonsky**, **Kasilof**, **Sterling** and

Cooper Landing, but with the completion of the new **Soldotna** high school in 1980, students from **Soldotna, Kalifonsky, Sterling** and Cooper Landing **will attend that facility**, leaving the Kenai high school with a considerably smaller service area. However, it should be noted that the future enrollment trends used in this forecast are for the City of **Kenai's** students only and do not include students from other communities who may attend **Kenai** junior and senior high schools in the future.

For the purpose of the base case, it is assumed that students account for approximately 20 percent of the total population, with elementary students comprising 60 percent of the total and high school students (grades 7 through 12) accounting for the remaining 40 percent throughout the forecast period. Forecasts of capacity requirements are based on a ratio of 25 elementary students and 20 high school students per classrooms.

The school enrollment forecast for the base case envisions a relatively **slow** and steady growth throughout the period (see Table 44). Net growth in enrollment is about 30 percent, to about 840 elementary students and 560 high school students in the year 2000. A review of the present capacity and condition of the school facilities at **Kenai** indicates that **Kenai** is **well** equipped to accommodate such expansion. The two elementary schools have a total capacity of 41 classrooms, about 6 more classrooms than will be forecasted to be demanded under the base case. **Kenai** Junior High School and **Kenai** Central High together contain about 60 classrooms, more than double the number projected to be needed to meet base case secondary school enrollment forecasts. **Kenai** schools have

been maintained in good condition and should remain in use throughout the forecast period.

Recreation. Kenai possesses a variety of major recreational facilities such as a swimming pool, gymnasiums, tennis courts, a hockey rink and ball fields that compare favorably with standards for a town its size. As in many Alaska communities, many of these are provided by the Borough school district even though the City retains the parks and recreation power. The major deficiency in **Kenai's** outdoor recreation facilities is the lack of neighborhood parks and play equipment for young children. By the end of the base case forecast, **Kenai** is expected to experience a demand for a total of 8 hectares (21 acres) to meet outdoor recreational needs. Indoor facilities that may be needed to meet base case recreational demands are an additional swimming pool and a community center.

Local Government Finances. In fiscal year 1978, the City of Kenai obtained most of its revenue from local sources. Property taxes (42 percent), sales taxes (26 percent) and a variety of service charges and miscellaneous other sources (8 percent) provided over three-fourths of the City's general fund income. Intergovernmental transfers, mainly from federal and State revenue sharing, accounted for the remaining 24 percent.

For the future, it is assumed that the City's revenues will grow at the same rate as its population grows. By this standard, the City's 1982

general revenue fund income estimate of \$3,560,000 annually is forecast to climb to about \$5,000,000 by 2000 (see Table 45).

As for operating expenditures, under the base case, it is assumed that the City of Kenai **will** continue to maintain about the same **level** of services at about the same level of per capita cost as it does at present (see Table 46). Only about one-third of the projected growth in the Central Peninsula area under the base case is allotted to Kenai so the brunt of the fiscal impact of growth on the City will be somewhat mitigated. Fiscal impact will be further tempered by the fact that the Borough government administers and funds the local share of educational services as well as certain other areawide services such as garbage disposal and hospital services. In addition, certain utility services in Kenai, such as power and telephone are financed through independent public and private utilities.

At present, the City's general financial position in terms of its per capita debt, ratio of debt to valuation, property valuation per capita, property tax rates and other **indexes** of fiscal soundness are about equal to or poorer than the average of other Alaskan municipalities. This suggests that **Kenai** may have some difficulty financing future capital improvements within its existing fiscal framework and may, instead, have to rely on State and federal grants to finance new facilities or develop new revenue sources.

λ

CAUSE/EFFECT OF IMPACTS

Under the base case, growth impacts at **Kenai** are expected to stem from consolidation of its position in the economic functions that now support the community. Continuing economic growth is forecast, but with no noteworthy sudden departures from recent economic trends. The Kenai area will maintain its oil and gas and petrochemical base, drawing upon existing and yet-to-be proven hydrocarbon reserves anticipated from new State Leases and Sale **CI**. An additional LNG plant will be constructed as scheduled. Expanded commercial fisheries and fish processing and tourism industries are expected to support some growth.

The pace of population growth, estimated to average about 2 percent annually, is even slower than during the post-1970 period and is quite different from the explosive growth pattern of the 1960-70 decade. In sum, the base case projection envisions a diminished rate of economic and population growth for the City of Kenai.

PROBLEMS/ISSUES AFFECTING THE COMMUNITY INFRASTRUCTURE

The projected base case growth is not expected to generate any exceptional growth-related burdens on Kenai's municipal facilities and services. The relatively easy pace of town growth since 1970 has enabled Kenai to catch up with the backlog of municipal needs that accumulated during the hectic expansion of the 1960's. Now, **Kenai** is generally better positioned to absorb without disruption such growth impacts as may occur in

conjunction with another LNG plant project, Sale CI and other anticipated developments. On the whole, the forecast gradual growth is expected to generate demand for such routine improvements as expanded water supply, minor improvements and corrections to the sanitary waste system, a new landfill site and additional fire station and recreational facilities.

SUMMARY OF IMPACTS

In contrast to its status in the boom years during the initial phase of Cook Inlet oil and gas development, Kenai has now matured into a relatively broad-based community with a developed infrastructure in relation to the growth demands likely to be placed upon it in the next two decades under the base case. Therefore, it is not expected that Kenai will be facing growth impacts of stressing proportions.

Soldotna

COMMUNITY FORECASTS - BASE CASE

Future Population

Considering all sources of growth, the base case population of the City of **Soldotna** is estimated to increase from about 2,572 in **1980** to about 4,667 by 2000, an increase of 81 percent (see Table 31). Except for minor flutters caused by Sale **CI** and the LNG project, **Soldotna** is expected to maintain a steady upward trend, averaging an annual growth rate of about 3 percent over the two decades of the forecast. Thus, **Soldotna** is projected to grow at a somewhat faster rate than **Kenai**.

Soldotna attracts new residents from Sale **CI** and the new LNG plant in absolute numbers about equal to Kenai but, because of its lesser population base, these projects assume a somewhat larger role in **Soldotna's** growth pattern. This is especially so **in** the middle years of the forecast, when the employment bulge associated with these projects causes a **short-term** bulge in **Soldotna's** population trend. Nevertheless, over the full term of the forecast, the impact of Sale **CI** and the LNG project are far outweighed by other growth factors in **Soldotna's** future.

IMPACT ASSESSMENT

Social Impacts

The social impact of the base case scenario upon **Soldotna** appears likely to be neutral. This scenario does not portend any significant change in **Soldotna's** economic structure, but a continuation of its role as a governmental and commercial center and as a bedroom community for its more industrialized vicinity. Foreseeable is a gradual transition in scale to a more urban type of settlement due to the cumulative effect of population growth.

Impacts on Community Infrastructure

Housing and Residential Land. In **Soldotna**, the base case forecast estimates that 608 additional dwellings will be demanded by 2000 to house population growth. The need for new housing is heaviest during the mid-1980's during a period when the basic growth trend is augmented by onshore and offshore **CI Sale** development and the start-up of production at the LNG facility in North **Kenai**. Mild interruptions to the increase in **housing** demand occur in 1989 following the completion of the **CI Sale** development phase and in 1999 when **CI Sale** production is scheduled to phase out (see Table 47).

Assuming that the future demand for housing types resembles today's pattern, about 56 percent of the demand (344 units) will be single

family units, about 16 percent (99 units) will be multi family and the remaining 28 percent (168 units) will be trailers.

It is estimated that about 48 hectares (119 acres) of undeveloped land will be demanded to accommodate new residential development in **Soldotna** (see Table 48). With only about one-third of the land inside the City's corporate limits in use in 1979 (Ted **Forsi** and Associates, 1979), there appears to be sufficient land available for future expansion.

Utilities

- Water. **Soldotna's** municipal water system was first constructed in 1972 and has been expanded yearly since that time. Total pumping capacity at the City's three wells amounts to 7,570 kiloliters (about 2 million gallons) per day, well in excess of current and anticipated base case demands of 3,354 kiloliters (886,000 gallons) per day for the year 2,000 (see Table 49).

Since water is not metered and records of wellhouse production have not been maintained consistently in **Soldotna** until recently, City water officials have no accurate measure of actual water consumption. In the past, groundwater supply has been adequate to meet demand and the recent addition of a new well should insure that water supply is adequate for at least the near term. The sufficiency of **Soldotna's** groundwater supply, as

opposed to pumping capacity, over the long term is the subject of some concern with Borough planning officials as groundwater levels in the Central Peninsula area have experienced fluctuations in recent years. Extended and severe fluctuations in **groundwater** levels combined with substantial growth in the Central Peninsula Area may necessitate the development of additional or alternative water sources.

- Sewer. **Soldotna's** sewer system was thoroughly studied and a program of improvements recommended in the 1977 Wastewater Facilities Plan and its 1979 amendment. The City adopted the plan and is now implementing it. Aside from incremental extensions of the system to service new development, only minor improvements to the collection system are anticipated to meet base case demands. These include expansion of the existing 25.4 centimeter (10-inch) line connecting to the treatment plant and the addition of lift stations to prevent build-up of sludge in the distribution system.

Both" daily average and peak flows through **Soldotna's** treatment facility are well above the plant's design standard. The **Wastewater** Facilities Plan and amendment **recommended modification** and expansion of the plant in two phases to meet projected capacity requirements through 1998. Phase I, scheduled for completion in 1981, is designed to serve a population of 6,200 in 1988 and process a peak daily flow of

3,785 kiloliters (one million gallons). Phase II expansion will double the plant's 1988 capacity to 7,570 kiloliters (two million gallons) per day and serve a projected 1998 population of 16,000.

Daily capacity requirements for the base case for the year 2000 are 3,354 kiloliters (886,000 gallons), slightly less than the capacity planned for the treatment plant at the end of Phase I expansion. Consequently, it appears that even without the Phase II project, **Soldotna** will have excess treatment capacity throughout the base case forecast period (see Table 50).

- Electric Power. The Homer Electric Association, an REA consumer cooperative, provides electric power for the **Soldotna** area, as well as for most of the rest of the Kenai Peninsula. Power is purchased from **Chugach** Electric's gas turbine facilities at **Beluga** and **Bernice** Lake and from its **hydro-electric** facility at Cooper Landing. A Corps of Engineers **hydro-electric** facility proposed for construction at Bradley Lake will provide an additional 322 million kilowatt hours of **electricity** to the area by 1987. Thus, it appears that as long as natural gas supplies last, there will be adequate electric power generation capacity to meet base case demands in **Soldotna** (see Table 51).

- Solid Waste Disposal. Commercial and residential garbage in the City of **Soldotna** is collected by a private contractor and hauled to one of two 12-hectare (30 acre) landfills in the area operated by the Kenai Peninsula Borough. These same dump sites are also used to dispose of **solid** waste from other Central Peninsula communities. Both landfills are nearly filled and the Borough will have to locate new landfills in the next five years. Public works personnel have determined that about 0.4 hectares (one acre) are needed to dispose of 8,028 cubic meters (10,500 cubic yards) of disposable solid waste. In the base case, the estimated 363,296 cubic meters (475,145 cubic yards) of disposable solid waste to be generated by **Soldotna** during the forecast period will require roughly 18 hectares (45 acres) of **landfill 1** (see Table 52).

- o Communications. During the base case forecast, the number of telephone hook-ups in **Soldotna** is estimated to increase about 80 percent, from about 1,103 hook-ups in 1982 to 1,981 in the year 2000 (see Table 53). It does not appear that Glacier State Telephone Company, which provides telephone service to the Central Peninsula area, should have any problem maintaining adequate service for this level of growth.

Public Safety

- Police. The **Soldotna** police department provides police protection inside the **Soldotna** City limits and outside the City to mile 90 on the Sterling Highway, to mile 20 on the **Kalifonsky** Beach Road and to mile 2 on the **Kenai** Spur Road. Unincorporated areas outside this perimeter are served by Alaska State Troopers stationed in **Soldotna**. The police department is currently staffed by a chief and seven commissioned officers. To maintain an adequate level of police protection, four to five new police officers will be called for under the base case forecast.

The **Soldotna** police station includes two temporary holding cells appropriate for only short term incarceration. Consequently, prisoners requiring detention of any duration are accommodated in the Kenai jail. Assuming this practice is continued throughout the base case forecast, a demand for an additional four to five cells is foreseen at the Kenai facility to meet **Soldotna's** needs during the base case.

- Fire Protection. Fire protection and emergency medical services in **Soldotna** are provided by the **Soldotna** volunteer fire department. The department is staffed by four salaried firemen and about 15 volunteers. Service is provided throughout the City and, under contract, to State land within a 6.5

kilometer (four mile) radius of the City. Soldotna's ISO rating of 6 depends on the presence of fire hydrants. Residential areas outside the hydrant system have a rating of 7, while commercial properties outside the system are rated on the merits of the property.

Soldotna's fire protection service has several deficiencies. One is the excessively long run to outlying areas of the City often not equipped with fire hydrants. With continuing growth in the outlying reaches of town, particularly along the Sterling Highway to the north and in the vicinity of the airport across the river, the ability of the single fire station to maintain good response time is declining.

The distribution of fire hydrants is also inadequate, particularly in the commercial sections of town. In the spring of 1979, a bond issue was proposed to expand and upgrade the hydrant system, but this proposal was turned down by local voters.

The fire department's pumping capacity is adequate for a city of Soldotna's size. However, because of limited water storage, peak capacity cannot be sustained over an extended period.

The City has obtained a Coastal Energy Impact Program grant to design a second 1,892 kiloliter (500,000 gallon) reservoir. Construction is expected within the next five years.

In sum, to meet fire protection needs during the base forecast, the City may have to construct two new substations, obtain the additional personnel and equipment to operate them, upgrade the water and hydrant system and expand water storage capacity to meet fire flow requirements.

Health and Social Services. **Soldotna** residents are fortunate to have available within their area a broad mix of medical facilities and professional services. Health facilities include the Borough-owned Central Peninsula General Hospital which serves the hospital needs of **Kenai, North Kenai, Kasilof, Sterling and Cooper Landing as well as Soldotna;** the **Kenai** Health Center in **Kenai** operated by the State Department of Health and Social Services; and the Medical Center at Wildwood run by the **Kenai** Native Association for the area's Alaska Natives.

Based on the standard of three acute care beds for each 1,000 population, the 30-bed Central Peninsula General Hospital today has 14 fewer beds than needed to meet existing service area demands and, by the end of the base case forecast period, is projected to require about 30 additional beds. However, recent hospital occupancy rates of about 30 percent suggest that this standard is too high, probably because area residents are seeking at least some hospital services outside the community. If this trend continues, it is expected that the Central Peninsula General Hospital will need few, if any, new hospital beds during the base case forecast.

a

Although hospital bed capacity is adequate to accommodate a substantially larger population, both space and equipment for outpatient and emergency services are inadequate for existing needs. A proposal to expand outpatient and emergency service facilities will go before service area voters in the fall of 1979. If the proposed improvements are made, outpatient and emergency services should be adequately equipped for the base case forecast period.

In 1979, there were ten doctors affiliated with the Central Peninsula General Hospital and practicing in the **Soldotna** area. In addition, medical specialists visit regularly or are on call for assistance from Anchorage. An estimated three to four additional physicians may be needed in the **Soldotna** area to maintain a standard level of medical care during the base case. The seven dentists currently practicing in the area should be sufficient for base case needs.

Education. Because the **Kenai** Peninsula Borough provides educational services on an areawide basis for the entire Borough, the City of **Soldotna** is not responsible for financing and administering a local school district. The Borough school system is funded primarily through State contributions, but the Borough contributes some funds raised on an areawide basis. The Borough operates two elementary schools and a junior high school in **Soldotna**. The elementary schools house students from **Soldotna** only, while the junior high school serves students in grades 7 through 9 from **Soldotna** and **Kasilof**. Until 1980 when the new high school is completed, **Soldotna** students in grades 10 through 12 will attend school in **Kenai**.

The new high school will house grades 9 through 12 from **Soldotna**, Sterling, **Kasilof** and Funny River and the junior high will be reorganized to accommodate grades 7 and 8 only.

While it is anticipated that **Soldotna** junior and senior high schools will continue to accept students from outside the community, the base case enrollment estimates and capacity requirements used in this forecast only take into account students resident in the City of **Soldotna**.

Soldotna school enrollments for the base case are projected to grow steadily throughout the forecast period (see Table 54). Net growth in enrollment is about 65 percent, to 560 elementary and 373 high school students in the year 2000. A review of the present capacity and condition of the school facilities at **Soldotna** indicates that **Soldotna** is well equipped to accommodate such expansion. The two elementary schools have a total of 48 classrooms, about double the number expected to be needed to house enrollments forecast for the base case. The **Soldotna** junior and senior high schools together contain about 64 classrooms, more than three times the number expected to be needed to meet secondary enrollments. **Soldotna** school plants are new and well maintained and, thus, should be useful throughout the forecast period.

Recreation. Although the **Soldotna** area possesses an abundance of outdoor recreation resources used by residents and visitors alike, outdoor facilities provided by the City are limited and are designed primarily for use by visitors rather than local residents. The only

neighborhood park in the City is the Jack Farnsworth Memorial Park on Birch Lane. Portions of Centennial Park given over to ballfields and the City Fairgrounds are heavily used by Soldotna residents. The City does not provide any indoor recreation facilities or activities.

As in many Alaska communities, the public schools in Soldotna provide a focal point for both outdoor and indoor recreational activities. The three multipurpose rooms in Soldotna's elementary and junior high schools are available during non-school hours for community athletic programs. Facilities to be included in the new high school will substantially enlarge the recreation opportunities for local residents. The new high school will house a swimming pool, an 800-seat auditorium, a gym and a multi-use room, all of which will be available for public use. With the completion of the new school, Soldotna will have more than adequate indoor recreation capacity for base case needs. Although provision of a community center is normally demanded for a town this size, the new auditorium and excess capacity in the school plants may accommodate some of the functions usually incorporated in a community center and thereby postpone the necessity for the City to provide a community center.

Local Government Finances. As of 1978, nearly five-sixths of Soldotna's general fund revenues were raised locally from property taxes (29 percent), local sales tax (30 percent) and miscellaneous other local revenue sources (24 percent). Only about 17 percent of general fund revenues were derived from intergovernmental transfers. Since 1974, the City's mill rate has fallen considerably from 20.20 to 16.10 mills, a

trend which is probably related to a period of rapid expansion in the City's residential and commercial property tax base.

For the base case forecast, it is assumed that the City's revenues will increase at a rate proportionate to population growth. By this assumption, the City's 1982 estimated general fund revenues of about **\$1,913,000** will climb to about \$3,165,000 by the year 2000, an overall increase of 65 percent (see Table 55).

Under the base case, it is also assumed that the City will maintain its customary mix and quality of municipal services and facilities and that its general fund expenditures **will** have to be maintained at about the same per capita level as prevailed at the outset of the forecast period. Thus, general fund operating expenditures are estimated to grow by 65 percent from about \$1,618,000 in 1982 to \$2,677,000 by 2000 (see Table 56). Operating expenditures are projected to consume about 85 percent of general fund receipts, with the remainder available for capital improvements and debt service.

At present, the City's overall financial situation seems improved over recent years. The City's per capita valuation is now typical **of** middle-sized Alaska cities, thanks to recent town development. However, it should be noted that **Soldotna's** role as a residential community and governmental and commercial center for the Central Peninsula area may help perpetuate an imbalance and relatively disadvantageous property tax base structure for **Soldotna**. The City must **rely** heavily on residential

and commercial development for revenues, since it does not have tax access to the highly valued industrial plants in the North Kenai-Niki ski industrial complex which employs so many of the area's residents.

The City of **Soldotna** now experiences a relatively high indebtedness ratio when the City's own debt **is** combined with the City's share of borough indebtedness. This situation, in conjunction with the **above-**noted imbalance in its property tax base, may place financial strain upon the City's debt capacity, if **major** capital improvements are needed during the forecast period.

CAUSE/EFFECT OF IMPACTS

Soldotna is estimated to grow at an annual average rate of about 3 percent under the base case forecast. This growth rate is slower than in the previous decade and much slower than the decade before that.

Soldotna's growth is linked to its role as a residential community and commercial and service center for the Central Peninsula area upon whose overall economic vitality its own prosperity depends. It is not anticipated that any major new industrial employers will locate within **Soldotna**, although the City is expected to capture a part of the region's resident offshore work force for Sale Cl.

PROBLEMS/ISSUES AFFECTING THE COMMUNITY INFRASTRUCTURE

As **Soldotna's** population is estimated to increase by about 65 percent over the forecast period, the City should experience a trend toward a more urbanized community. The major growth impact issues at **Soldotna** will likely be related to relatively routine matters such as the town's perennial water supply problem, the already scheduled waste treatment plant improvements, development of a new **sanitary landfill site** and construction of additional fire stations to service new development. In comparison to **Soldotna's** recent history, the forecast imposes only moderate physical growth management demands upon the city.

SUMMARY OF IMPACTS

The base case forecast for **Soldotna** is for gradual growth, about 3 percent annually, along with the ordinary demands for additional public services and facilities implied by such growth. The forecast does not anticipate any transforming events such as the oil and gas boom which radically affected the communities of the Central Peninsula area in the 1960's.

Homer

COMMUNITY FORECASTS - BASE CASE

Future Population

The City of Homer is currently the smallest of the three **Kenai** Peninsula communities under study. It is also forecast to be the fastest growing during the next two decades. Strong advances in the fishing and seafood processing industries and the local service sector are expected to promote Homer's growth. Also, Homer is expected to be the most affected of the three communities by the scenario for Sale CI, mainly as a result of its nearness and attractiveness as a place of residence for offshore OCS workers.

Homer is forecast to grow from about 2,148 residents in 1980 to 5,429 by 2000 (see Table 32). This is an overall increase of 153 percent or an average rate of better than 4.5 percent a year. Growth is swiftest during the latter part of the 1980's, corresponding with the onset of Sale CI production. At a peak, Sale CI supports almost 13 percent of the City's population, mainly through its role as home base for offshore field workers rather than as itself a site for much Sale CI activity. Homer is also prone to be proportionately more impacted by Sale CI than **Kenai** or **Soldotna** due to its smaller size and because previous to Sale CI it has had little oil and gas related employment.

IMPACT ASSESSMENT

Social Impact

Of the three **Kenai** communities, Homer appears most vulnerable to social change **under** the base case scenario. Homer is forecast to experience the most **rapid** economic and population growth. Furthermore, a substantial portion of its expansion accrues from its function as a residential community serving the Sale **CI** offshore work force. This rapid growth trend may tend to erode the semi-rural atmosphere which has been the source of Homer's appeal to many of its residents. The Sale **CI** scenario poses few direct burdens upon Homer, so there is little likelihood of direct physical conflict at Homer between fishing operations and offshore marine support activities. Nevertheless, there is potential for conflict between the fishing and oil industries based on fishermen's fears that offshore operations may adversely affect fishery resources or operations. If so, then the perceived incompatibility of the fishing and oil and gas industries may become a continuing divisive issue in the community.

Impacts on Community Infrastructure

Housing and Residential Land. The housing forecast for Homer under the base case scenario estimates that a net increase of 951 units will be demanded by 2000 to house new residents (see Table 57). The strongest demand will occur during the first half of the forecast period when Homer experiences the combined economic stimulation of an expanding deep

sea fishery and OCS Lease Sale CI. If the future-housing demand resembles the current pattern of housing types, then about 60 percent (572 units) of the **housing** units **will** be conventional single family dwellings, about 32 percent (303 units) will be trailers, and only 8 percent (76 units) will be in multi family dwellings.

For future residential development, natural hazards, poor soil conditions and drainage patterns, competition for other uses and public ownership of large parcels of land virtually rule out Homer Spit as a potential site. Similar **physical** factors affect the pattern of development on the Homer mainland. **Still**, there appears to be an ample supply of undeveloped land for future residential and commercial expansion. There are many vacant lots on the main streets in town and many undeveloped tracts near the commercial center of town which currently have no road access. It is estimated that about 77 hectares (190 acres) of undeveloped land will be demanded to accommodate housing construction to meet needs generated by the base case scenario (see **Table 58**) and that sufficient land for the purpose can be made available through installation of needed public access and utilities.

Utilities

- Water. Homer derives its water from the Bridge Creek Reservoir which has a storage capacity of 548,825 kiloliters (145 million gallons). A reservoir at the water treatment plant and a second reservoir provide approximately 2,839 kiloliters (750,000

gallons) of storage. Water service is provided within the City limits, including the Homer Spit.

During periods of peak demand, industrial consumption currently accounts for as much as 90 percent of Homer's total water demand and, on an annual basis, for about 56 percent of the total. For the base case forecast, industrial demand is assumed to account for an even higher annual average of about 65 percent. This increase is related to the water consumption requirements of the fish processing industry and the marine service base serving offshore rigs during Sale CI exploration, development and production. Both of these industries are intensive water users and will be supplied by the City system.

Over the base case forecast period, water demand in Homer is forecast to increase about 114 percent, from 3,471 kiloliters (917,000 gallons) in 1982 to just under 7,570 kiloliters (2 million gallons) in the year 2000 (see **Table 59**). Water supply from present sources is adequate to **accommodate** this increase. However, treatment capacity is restricted. As designed, the treatment facility is meant to serve a population of 2,350 only if industrial demand remains relatively constant. As the base case population is forecast to reach this level by 1981 and a steep rise in industrial demand is forecast, it appears that existing treatment capacity will soon be outrun, and that capacity may need to be expanded two to threefold over the forecast period.

- Sewer. The City of Homer sewer system serves the central **commercial** district and residential areas to the north and east of town. Not served by the system are outlying subdivisions within the City limits and the Homer Spit where sewage is treated by individual septic tanks with soil absorption systems. Wastewaters from the seafood processing plants are treated and discharged separately through **outfalls** into Kachemak Bay.

The 1977 Comprehensive Sewer Plan adopted by the City determined that if housing density remained constant, Homer's sewer system was adequate to serve a population of about 2,700. The City's sewage treatment plant can process 1,048 kiloliters (277,000 gallons) per day.

Under the base case, treatment plant capacity requirements are estimated to climb to 1,166 kiloliters (308,000 gallons) per day by 1982 and to 2,570 kiloliters (679,000 gallons) per day by 2000 (see **Table 60**). If these forecasts hold true, then the present capacity of the treatment plant will be exceeded in a couple of years and major expansion will be in order to meet long-term needs. The sewage collection system will also require **significant** improvements and expansion to serve new residential development and may need to be extended to the Spit to serve the development expected to be located there.

- Electric Power. The Homer Electric Association (HEA), an REA cooperative serves the Homer area with power purchased from Chugach Electric Association's natural gas-powered generating plant at Beluga across Cook Inlet. The proposed Corps of Engineers hydro-electric project at Bradley Lake north of Homer could provide an additional source of power to the area in 1987. It appears that as long as local natural gas supplies are adequate to fuel the Beluga plant, HEA will be able to purchase sufficient power to meet base case requirements in Homer through the forecast period (see Table 61).

- Solid Waste Disposal. Commercial and residential garbage in the Homer area is collected by a private contractor and hauled to a new 4 hectare (10 acre) landfill on the Sterling Highway north of the City operated by the Kenai Peninsula Borough. The Borough estimates the landfill to have a useful life of about five years, although optimum maintenance could extend this somewhat longer.

Borough public works personnel have determined that about 0.4 hectare (one acre) is required to dispose of 8,028 cubic meters (10,500 cubic yards) of solid waste. In the base case scenario, the estimated 395,737 cubic meters (517,574 cubic yards) of disposable solid waste to be generated by the City of Homer will consume roughly 20 hectares (50 acres) of landfill by the year 2000 (see Table 62). Disposable solid waste

generated by people residing outside the City but within the Homer area will consume an additional 20 hectares (50 acres) of landfill.

- **Communications.** During the base case, the number of telephone hook-ups in Homer is estimated to increase about 140 percent, from 957 hook-ups in 1982 to 2,303 hook-ups in the year 2000 (see Table 63). Although expanding the system to accommodate growth is reportedly a routine matter, Glacier Telephone Company, which provides service to the Homer area, is currently way behind demand in adding new stations and installing new telephones in Homer. Similar service delays may occur in the future **during** periods of rapid population growth.

Public Safety

- **Police.** The Homer Department of Public Safety provides police protection within the City of Homer, while areas outside the City are served by the Alaska State Troopers. The Department of Public Safety is currently staffed by six police officers, including a chief. Beyond existing facilities and staff, the Homer police department may need to acquire an additional six new officers along with support facilities and an additional 10 to 11 jail cells in order to maintain standards of service in pace with population growth.

- Fire Protection. The Homer volunteer fire department provides fire protection services throughout the City and, when possible, to road connected areas outside the City limits. Fire protection at the State airport is provided by the City under contract to the State. The fire department also provides emergency medical services in the City. The Coast Guard vessel has its own firefighting capability although Coast Guard firefighting personnel and equipment have been used by the City in emergencies.

● Even without the growth forecast in the base case, Homer's fire protection service has a number of deficiencies which need attention. These include the lack of a full-time staff, inadequate pumping and water storage capacity, poorly distributed fire hydrants and outmoded equipment.

● Homer's major fire protection problem area is Homer Spit where the crowded small boat harbor and heavy concentration of valuable commercial and industrial property increase the potential for serious fire. The long equipment run from the central fire station and the single 25.4 centimeter (10-inch) water main serving the Spit adversely affect the ability of the Department to respond adequately to fires in this locale. Expansion of the small boat harbor, the planned acquisition of a new 63 liter per second (1,000 gallon per minute) pumper to be stationed on the Spit and the construction of water storage capacity here will do much to alleviate the problem. Regardless,

with the increased concentration of high value property on the Spit envisioned in the base case, the City may need to construct a substation on the Spit. Also, with increasingly heavy residential development in the East Hill area, the need for additional water storage capacity to meet fire flow requirements will become more apparent.

Health and Social Services. For a community of its size, Homer has available a good mix of medical facilities and professional services. Health facilities include the Borough-owned South Peninsula Hospital which serves Homer and its environs to just north of **Ninilchik**.

Based on the standard of three acute beds for each 1,000 population, the 17-bed South Peninsula Hospital today has an excess capacity of several beds, but by the end of the base case forecast will probably need to double its capacity. Recent occupancy rates of less than 40 percent, however, suggest that the standard of three beds per 1,000 population may be too high for communities such as Homer which have reasonably good access to a wide variety of superior medical facilities and services in Anchorage. If the rate of use of local hospital facilities remains well below the standard throughout the forecast period, Homer is likely to require few, if any, additional hospital beds.

While hospital occupancy rates have declined in recent years, use of outpatient and emergency room facilities has undergone a dramatic increase. This has placed a tremendous strain on both space and equipment used for

these purposes. If Homer area residents continue to rely heavily on the Hospital's outpatient clinic and emergency room for the provision of medical services, these facilities will probably have to be significantly expanded to meet area population growth during the base case forecast.

In 1979, there were six doctors practicing in the Homer area. In addition, about 35 specialists visit Homer periodically and provide on-call assistance. Applying the standard of two physicians for a community of 3,000 plus another physician for each additional increment of 1,500 population, one or two additional physicians will be demanded in the Homer area by the year 2000. There are presently two dentists available to area residents. During the base case forecast, at least one additional dentist will be demanded.

Education. Because the Kenai Peninsula Borough provided educational services on an areawide basis for the entire Borough, the City of Homer is not required to finance and administer a local school district. The Borough school system is funded primarily through State contributions, but the Borough contributes some funds raised on an areawide basis. The Borough operates an elementary school and a junior/senior high school in Homer. The elementary school houses students in grades K through 5 from Homer and the road-connected area up to, but not including, Anchor Point. The junior/senior high school serves students in grades 6 through 8 as far north as, but not including, Anchor Point, while the service area for grades 9 through 12 includes the communities of Anchor Point and Nikolaevsk, although few students from the latter village go beyond grade 8.

Although it is anticipated that Homer schools **will** continue to accommodate students from outside the community during the base case forecast, enrollment estimates and capacity requirements used in this forecast are for Homer students only. However, assuming the school system service area is equivalent to the Homer area, it can be assumed that classroom demands for the area will be roughly double those of the City as the population of the area is about double that of the City. Base case enrollment figures also assume the traditional organization of grades K to 6 in elementary school and grades 7 through 12 in high school rather than the organization which now exists in Homer of grades K to 5 in elementary school and grades 6 to 12 in high school.

Homer school enrollments for the base case are projected to grow steadily throughout the forecast period (see Table 64). Net growth in enrollment is about 120 percent, to 652 elementary students and 434 high school students in the year 2000.

A review of the present capacity and condition of Homer's school facilities indicates that the community is not equipped with facilities to handle such long-term enrollment expansion. The 652 elementary school students projected for the year 2000 should need from 26 to 27 classrooms, nearly double the number of existing elementary classrooms. The Borough is currently considering two expansion proposals, a six-classroom addition to East Homer Elementary School and a new **10-room** facility. However, neither would suffice to accommodate projected enrollments through the year 2000. Assuming the construction a new 10-room elementary school,

an additional four to five classrooms would be demanded sometime before 1995.

The recent addition of nine classrooms to the Homer Junior/Senior High School brings that facility's total classroom capacity to 19, about three fewer than demanded at the end of the base case forecast. However, the Borough does intend to construct an addition to the existing facility to house a theater, cafeteria, domestic science classrooms and offices. It is conceivable that some of this space could be modified into general classrooms. Otherwise, several high school classrooms will probably have to be added near the end of the forecast.

Recreation. With the possible exception of a new **community** center, Homer's indoor recreation facilities are adequate for the base case forecast. Public outdoor facilities, particularly neighborhood parks and recreation areas, appear to be deficient and several are likely to be demanded throughout the City. Homer's small boat harbor is an important recreational asset for local residents as well as an economic asset for its tourism and recreational industry. The boat harbor is severely overcrowded now and needs expansion to satisfy current and future demand.

Local Government Finances. As of fiscal year 1978, the most recent year for which data is available, local property taxes were the main source of general fund revenues for the City of Homer, providing about 55 percent of the City's general fund income. Various other local revenues account for another 9 percent of general funds while intergovernmental

transfers account for the remaining 36 percent, better than one-third of all general funds.

As a general **rule**, it is expected that the City's revenues will increase in proportion to its population growth. By this standard, it is estimated that the City's general fund income of approximately \$910,000 as of fiscal year 1978 will reach about \$2,400,000 by the close of the forecast period, or an increase of about 164 percent (see Table 65).

In the base case forecast, it is also assumed that the City will maintain essentially the variety and level of public services at about the same relative **level** of per capita cost as it does at present. Thus, operating expenditures are projected to grow at about the same rate as general fund income. If this relationship between growth in revenues and expenditures persists, then the City should receive income in excess of operating needs to apply to capital expenditures and debt service (see Table 66). Also, if the City maintains its 3 percent sales tax, which is at present earmarked for debt service, those additional revenues may also be applied to capital improvement needs.

The City of Homer's present financial status appears to be representative of medium-sized Alaska municipalities in regard to its per capita assessed valuation and better than average in its ratio of bonded debt to valuation. This last factor is important, since it appears that the City may be called upon **to** sponsor public improvements for water supply and waste treatment in the near future to serve a rapidly growing population.

CAUSE/EFFECT OF IMPACTS

The economic base analysis indicates that the City of Homer's growth will be stimulated **by** a continuing dynamic economy during the forecast. Strong growth in a number of different sectors is expected to contribute. Development of a groundfish industry in Lower Cook Inlet waters will likely be based at Homer's port, which will also benefit from improved economic conditions in the traditional fisheries. Homer is also advantageously located to serve as the home **community** for a substantial share of the permanent offshore work force operating the fields developed in Sale **CI** lease areas. Finally, Homer's continuing appeal as a tourism and recreation center can support further expansion in the trade and services sectors of its economy.

The net result of these factors is that Homer, the smallest in population of the three study cities, is projected to grow at the fastest rate, about 4.5 percent annually, for a cumulative increase of 153 percent over the forecast period. For a **community of** Homer's size, this is a high rate of sustained growth.

PROBLEMS/ISSUES AFFECTING THE COMMUNITY INFRASTRUCTURE

Homer's projected rapid growth, especially in comparison to its present size, can be expected to place some heavy demands upon the City for maintenance of community infrastructure and services. Particular issues of potential concern are residential land development, including

the extension of utility services; additional water treatment capacity (the basic water supply appears adequate for the base forecast); major expansion of the sanitary waste treatment facility; development of a new sanitary landfill site; and expanded police and fire protection services, including additional jail facilities and fire stations. Also, growth in the fishing fleet and local fish processing industry is likely to necessitate further port development.

SUMMARY OF IMPACTS

Homer is projected to attain a relatively high rate of growth, amounting to a cumulative increase of 153 percent over the forecast period largely accruing from expansion in its fisheries and OCS employment base. As a result, Homer may be called upon to make significant improvements to a wide range of its public facilities and services.

PROJECTIONS OF GROWTH - EXPLORATION ONLY SCENARIO

Introduction

The exploration only and other two OCS petroleum scenarios or cases which form the basis of the socioeconomic impact assessment for **Kenai**, **Soldotna** and Homer in this study **were** selected by the U.S. Bureau of Land Management's Alaska OCS Office and developed by Dames and Moore from U.S. Geological Survey resource estimates. Although reasonably precise locations, quantities, methods of operation and time frames are necessary to the development of plausible scenarios, such scenarios and their impacts should not be interpreted as forecasts of what is actually going to happen. There is far too much uncertainty in oil and gas exploration and development for this degree of precision. However, an indication is given of the type and scale of activities which could impact Lower Cook Inlet communities and the extent **to which** individual communities would logically be impacted.

The exploration only scenario assumes that the proposed Lower Cook Inlet and **Shelikof** Strait OCS Lease Sale #60 **will** take place as scheduled in September 1981. Exploration begins in the year following the lease sale, activity peaks in the second year and terminates in the third year after the lease sale with no commercial finds. A total of 19 exploratory wells are drilled, 11 in **Shelikof** Strait and 8 in Lower Cook Inlet. Exploration support for this scenario is provided from existing facilities at **Nikiski** and, to a lesser extent, from **Homer**. Following the conclusion

of exploration at the end of 1984, there is no further OCS activity in the **region** as a consequence of this lease sale.

During the three years of active exploration, effects on the economy and population of **Kenai, Soldotna** and Homer are minimal and are mainly related to support services supplied from the **Nikiski-North Kenai** area and logistic air support based at Homer (see **Table 67**). Offshore crews are employed on a rotation schedule and most are assumed to live outside the **Kenai-Cook Inlet Census Division**. Consequently, most employees travel between work stations and permanent residences with only passing visits to Kenai Peninsula communities. Overall, the exploration only scenario stimulates no new industrial or port development and imposes no lasting burden on the infrastructure of any of the three communities under study.

At the peak of exploration, the direct and indirect economic stimulus of Sale #60 supports at most about 187 jobs and about 467 residents in the entire **Kenai-Cook Inlet Census Division**, spread among the cities of Kenai, **Soldotna** and Homer and surrounding rural areas (see **Tables 68 and 69**). Following early shutdown of the exploration phase, community conditions revert to the patterns forecast under the base case.

Kenai

COMMUNITY FORECASTS - EXPLORATION ONLY SCENARIO

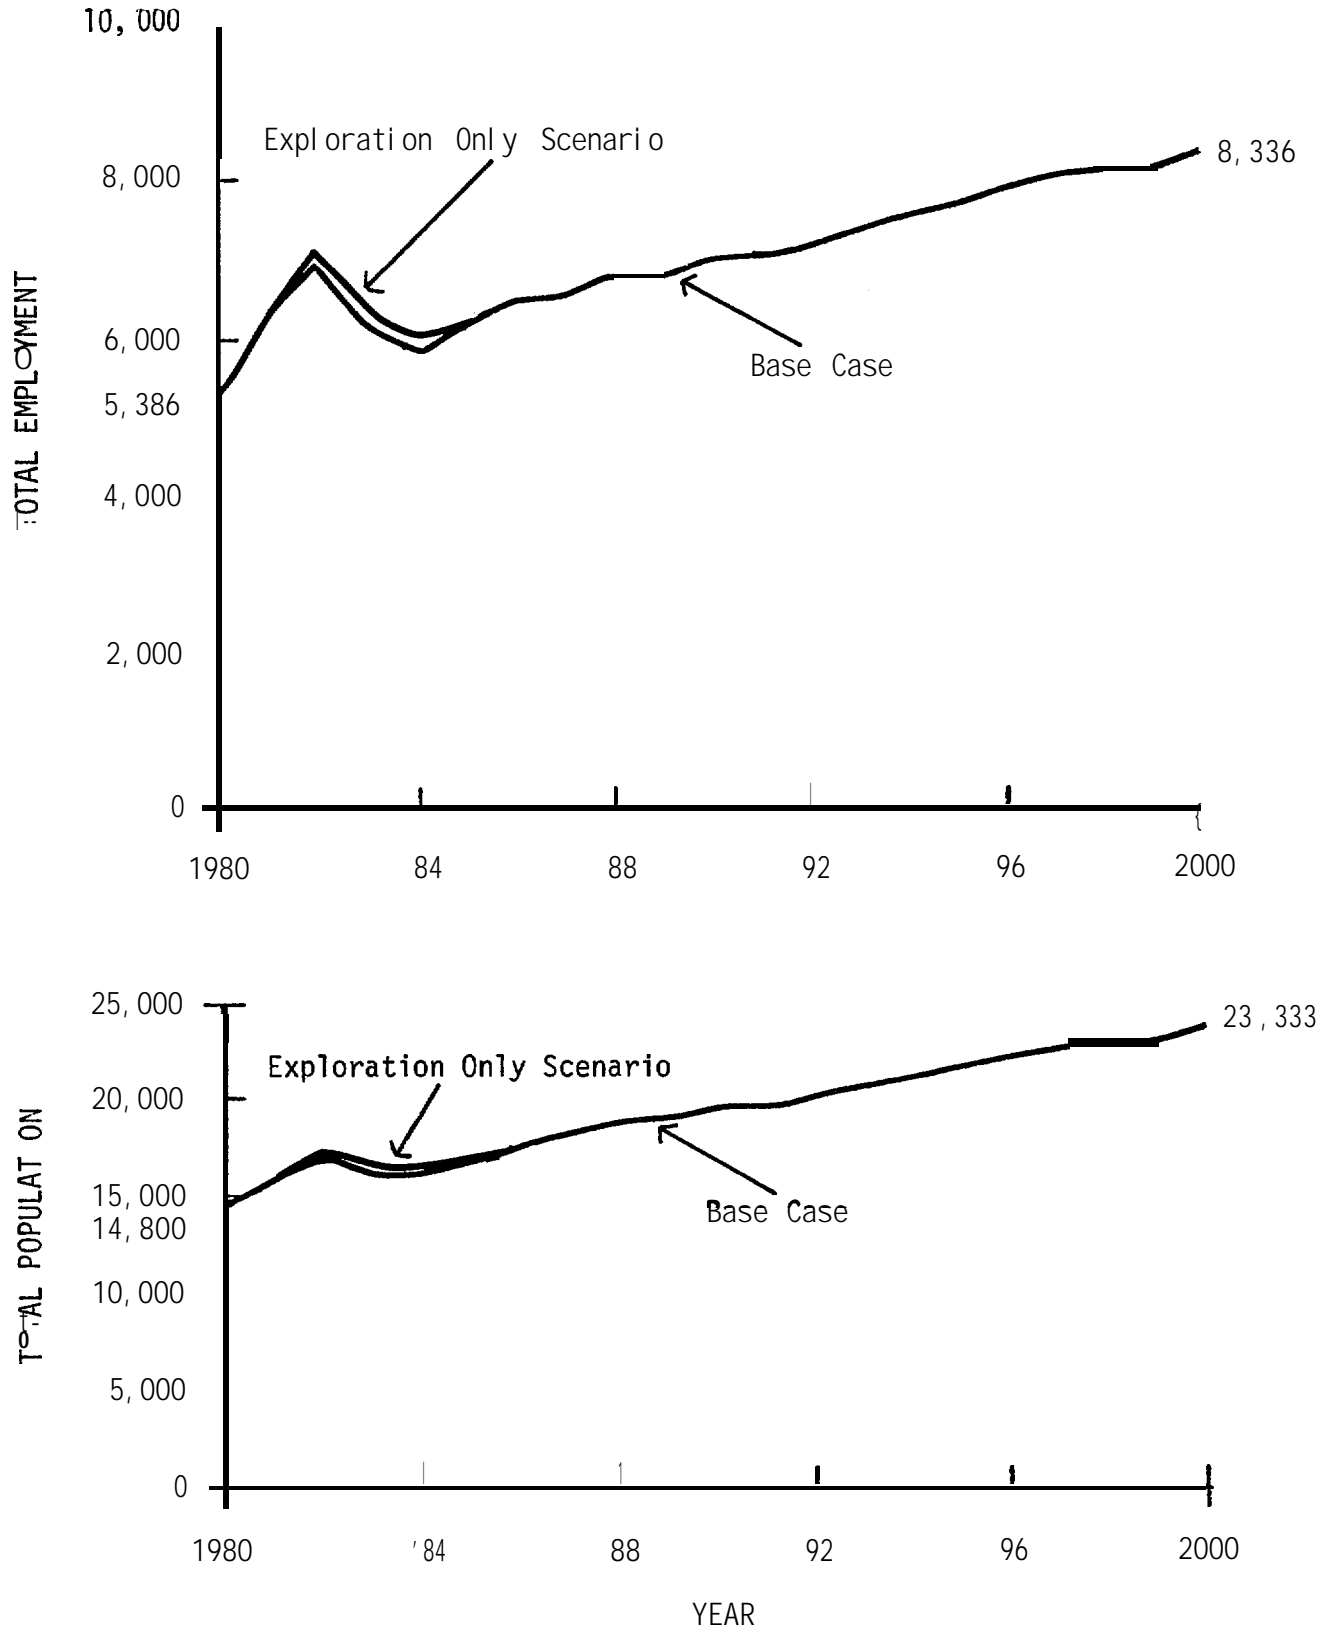

Significant Factors Affecting Growth

This scenario's growth impacts on Kenai are minor and brief (see Table 79 and Figure 4). The **Nikiski-North Kenai** area is already the support center for ongoing operations offshore and onshore in Upper Cook Inlet as well as the assumed support base for Sale **CI** in Lower Cook Inlet. The area is, therefore, well located and able to support exploration for the Lower Cook Inlet portion of Sale #60. Lower Cook Inlet operations add an estimated maximum of 58 direct and 30 indirect jobs in the second year of exploration for the entire Central Peninsula area, supporting an estimated temporary population increase of 59 persons in the City of Kenai (see Table 79). Another estimated 110 persons are drawn to the unincorporated **Nikiski-North Kenai** area, outside the City of Kenai proper. By 1985, exploration activities in Lower Cook Inlet and **Shelikof Strait** are shut down with the related employees and their dependents either departing the area or being absorbed by other areas of the local economy.

Overall, compared to growth accruing from general economic expansion, the 1977 Lower Cook Inlet **lease** sale, and development of the North Kenai LNG **facility**, Sale #60 contributes only marginally to the demand for new public services and facilities in Kenai and then only for the **period** 1982-84 (see Tables 80 to 89).

Soldotna

COMMUNITY FORECASTS - EXPLORATION ONLY SCENARIO

Significant Factors Affecting Growth

Under the exploration only scenario, growth impacts on **Soldotna** are minimal (see Table 90). An existing base at **Nikiski** supports exploration for the Lower Cook Inlet portion of Sale #60. Exploration activities generate an estimated maximum of 58 in direct employment and an additional 30 indirect jobs for the entire Central Peninsula area, mostly in the **Nikiski-North Kenai** area and the City of **Kenai**. This economic activity results in a temporary population increase in **Soldotna** of 51 at the peak of this scenario (see Table 90). By 1985, exploration activity in Lower Cook Inlet ceases and the related employees and their dependents either depart the area or are absorbed into other areas of the local economy.

In general, compared to growth accruing under the base case, the exploration only scenario contributes only little to the demand for new public services and facilities, and then only during the three year exploration period (see Table 91 to 100).

Homer

COMMUNITY FORECASTS - EXPLORATION ONLY SCENARIO

Significant Factors Affecting Growth

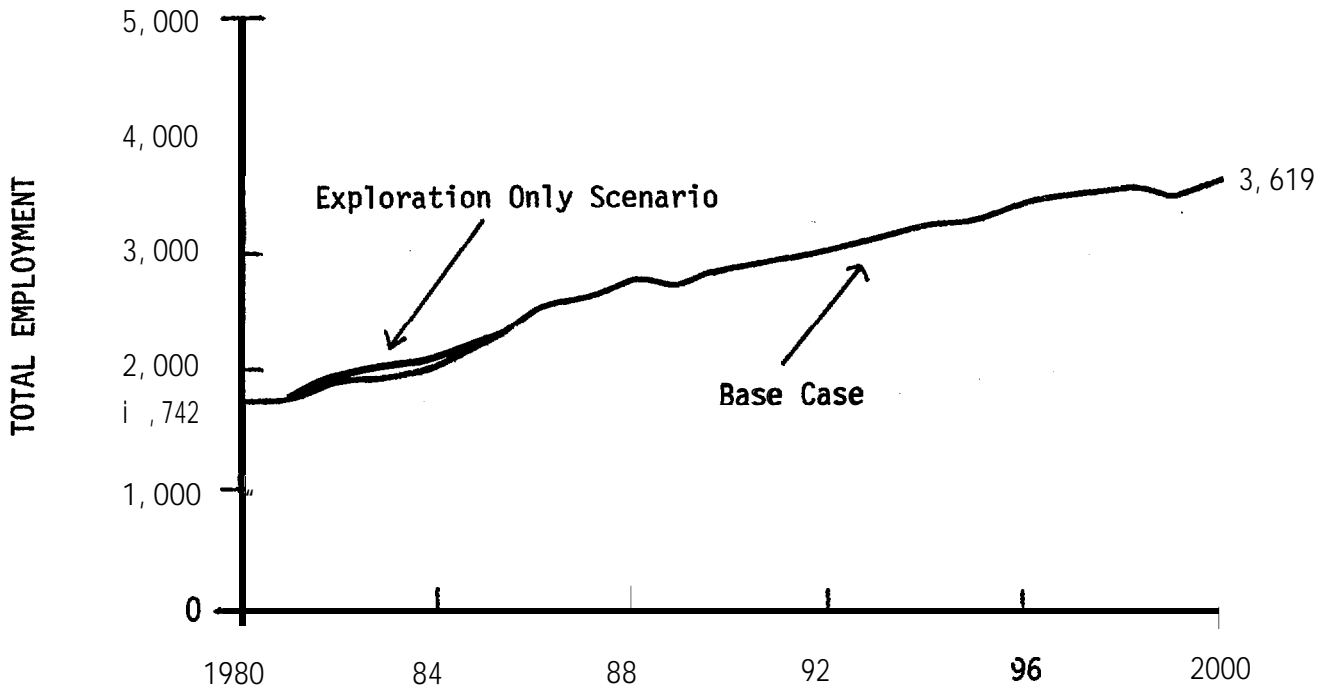

Under this scenario, Homer Airport serves as the base for **transport** of offshore personnel and some light supplies, while the Port of Homer functions to provide minor marine support. Growth **impacts on** the community are minor and limited to the three year exploratory period (see Table 101). Homer is already the center of helicopter support services for Sale **CI** activity in Lower Cook Inlet and is, therefore, an obvious choice to support exploration activity for Sale #60. **Shelikof** Strait and Lower Cook Inlet operations at their peak add an estimated 99 jobs to the Homer area which support a temporary maximum population increase of 247 during the exploration only scenario (see Table 69). This **OCS-** related population is about evenly divided geographically between the City of Homer and other smaller settlements in the Homer area.

By 1985, however, exploration activities are terminated and there is no further activity at Homer in connection with this scenario. **All** related employees and their dependents either depart the area or are absorbed by other areas of the economy.

Compared to growth resulting from general economy expansion and the economic stimulus provided by Sale CI, this scenario stimulates **very**

PROJECTIONS OF GROWTH - MEAN SCENARIO

Introduction

The mean and the other two OCS petroleum scenarios or cases which form the basis of the **socioeconomic** impact assessment for **Kenai, Soldotna** and Homer in this study were selected by the U.S. Bureau of Land Management's Alaska OCS Office and developed by Dames and Moore from U.S. Geological Survey resource estimates. Although reasonably precise locations, quantities, methods of operation and time frames are necessary to the development of plausible scenarios, such scenarios and their impacts should not be interpreted as forecasts of what is actually going to happen. There is far too much uncertainty in oil and gas exploration and development for this degree of precision. However, an indication is given of the type and scale of activities which could impact Lower Cook Inlet communities and the extent to which individual communities would logically be impacted.

Following the September 1981 lease sale, exploration begins in 1982, peaks in 1984 and terminates in 1985 with a total of **40 wells** drilled: 16 exploratory wells and 2 delineation wells in Lower Cook Inlet and 20 exploratory wells and 2 delineation wells in **Shelikof** Strait. Exploration activities in both **Shelikof** Strait and Lower Cook Inlet are supported by the existing **marine** base at Nikiski and forward base at Homer. Ultimately, two commercial fields are found, one of 500 million barrels in **Shelikof** Strait and a second, smaller find of **198** million barrels in Lower Cook

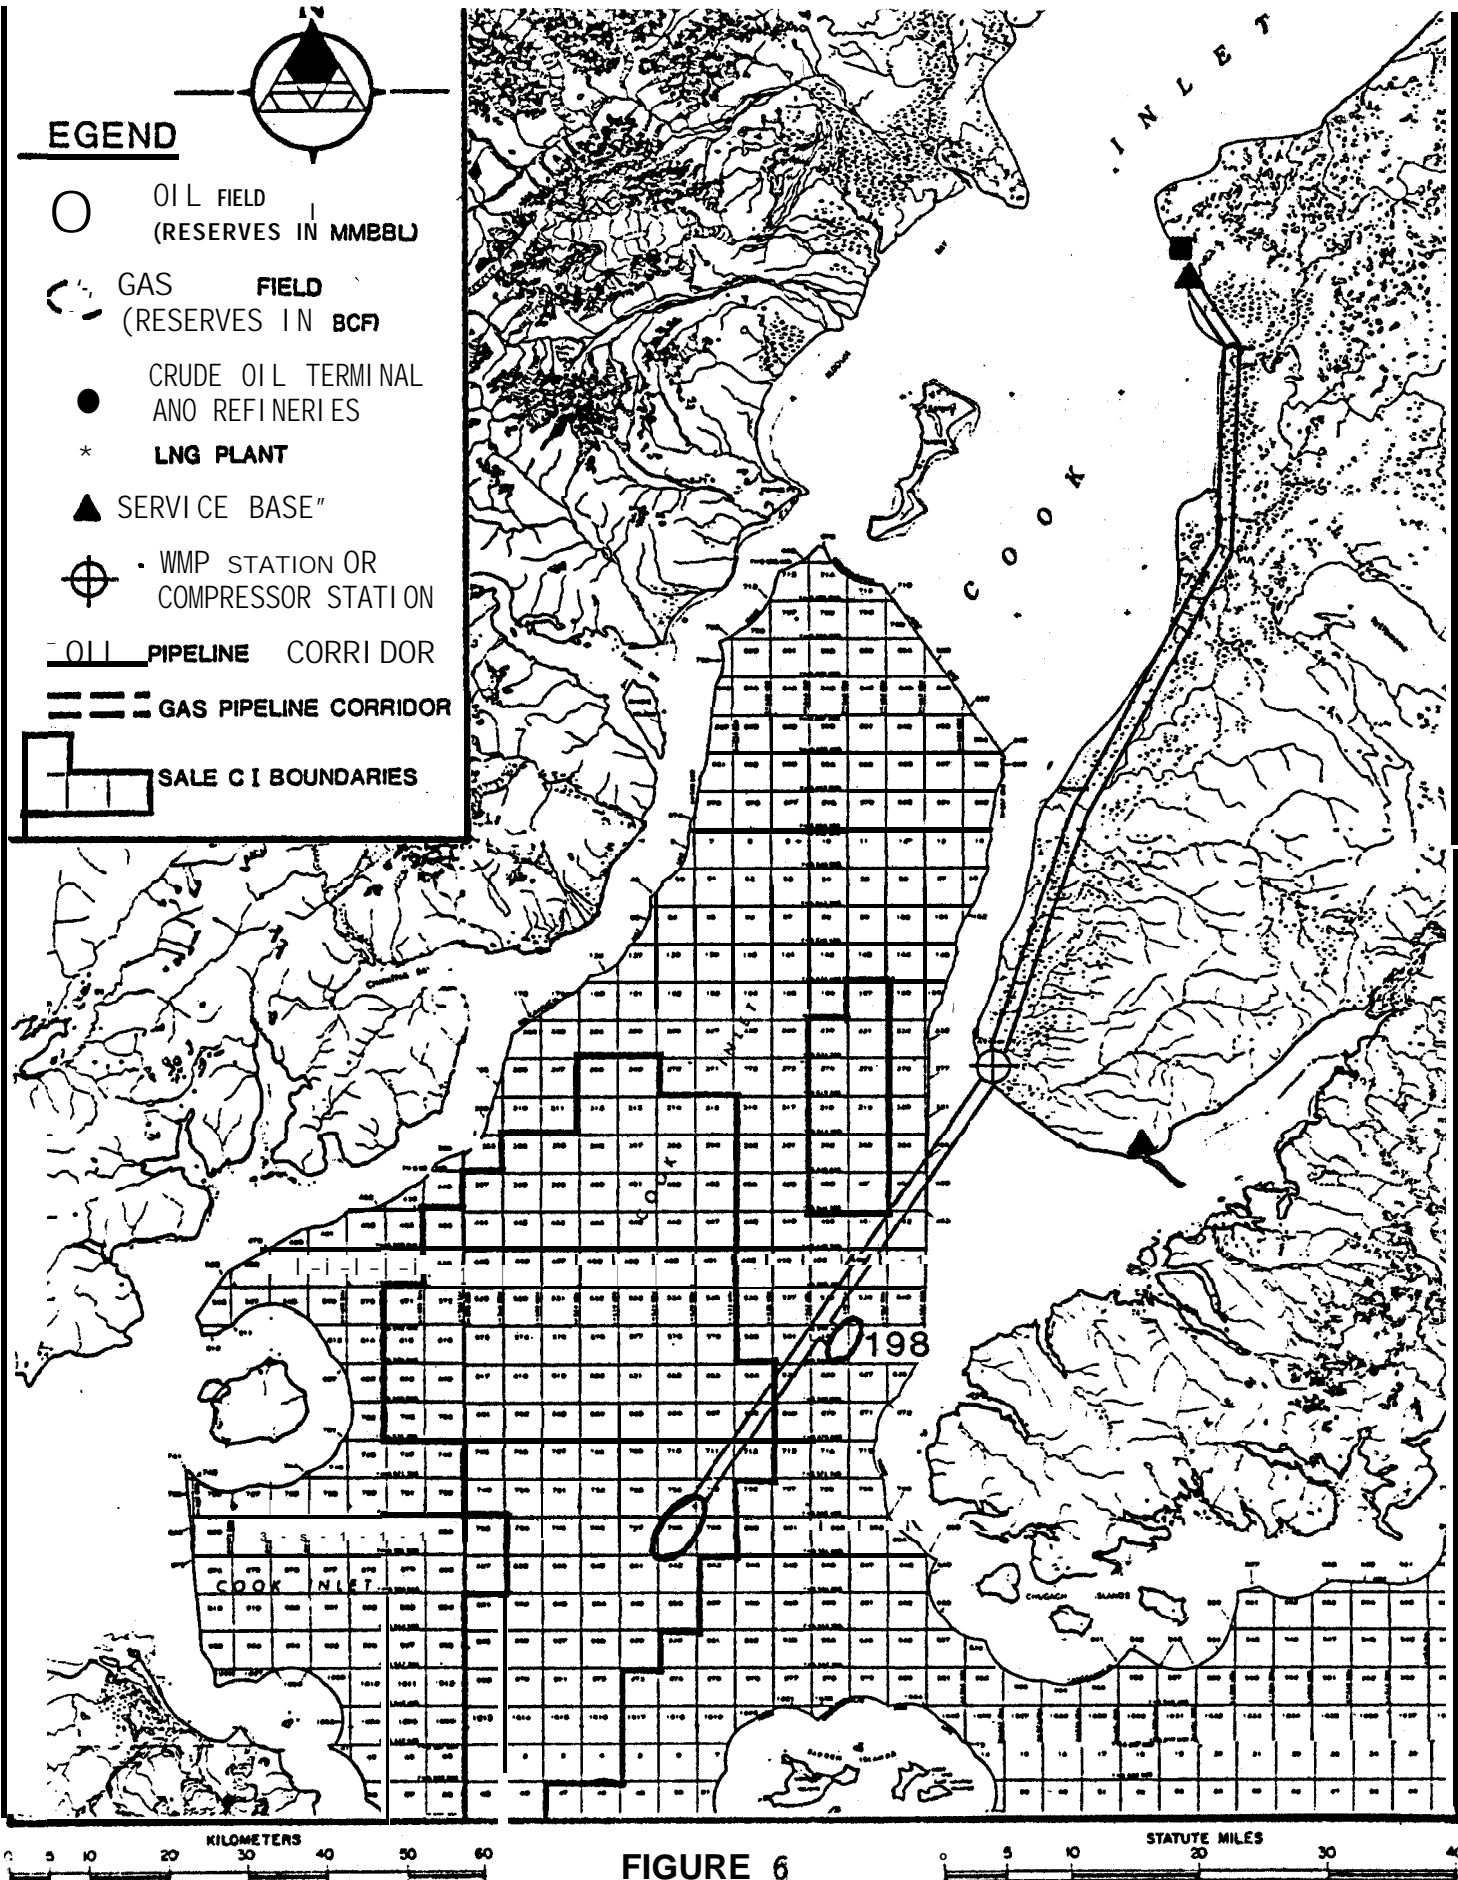

Inlet. **No natural** gas discoveries of commercial value are made (see Figures 6 and 7 and Table 112).

Field development begins in 1985 and production platforms are installed in both fields in 1987. Production **in the** Cook Inlet field begins in 1989 **but** does not reach peak capacity of 28 million barrels per year **until** 1991 when the full complement of 40 production **wells is** completed. The productive life of the Cook **Inlet field is** 14 years. In 2002, two years beyond the forecast period, production in the **field** ceases.

Production in the larger **Shelikof** field also **begins** in 1989, peaks at 70 million barrels annually in 1991-1992 and continues with declining volumes through 2006.

Because of its great distance from existing Cook **Inlet facilities**, most development and production support for the giant **Shelikof** field is provided from the west coast of Afognak Island, although some additional construction support is provided by **Nikiski** and Seward. Due to the circumstances of this scenario, the greater part of the oil reserves discovered **as** a result of Lower Cook Inlet **OCS** Sale #60 are produced with little impact on **Kenai** Peninsula communities.

Construction support for the smaller Cook Inlet field is provided from **Nikiski** and the existing forward support base at Homer which is used to ferry workers back and forth and to transport light supplies. Oil from the Lower Cook **Inlet** field is transported by an existing pipeline to processing facilities at **Nikiski**.

COMMUNITY FORECASTS - MEAN SCENARIO

Significant Factors Affecting Growth

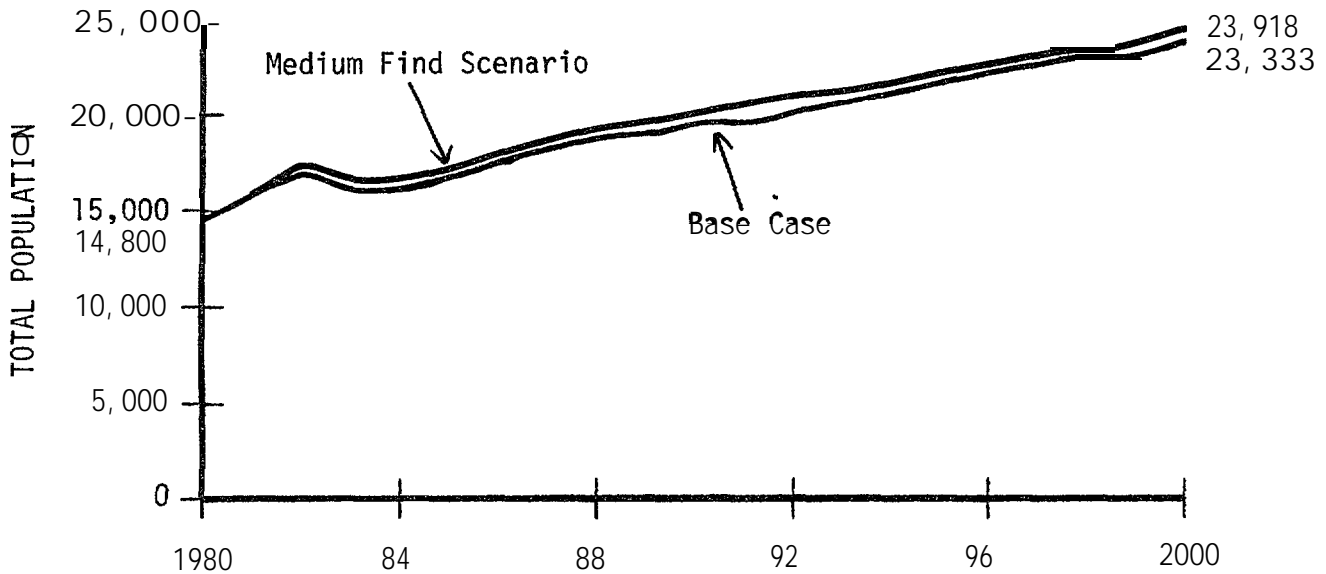

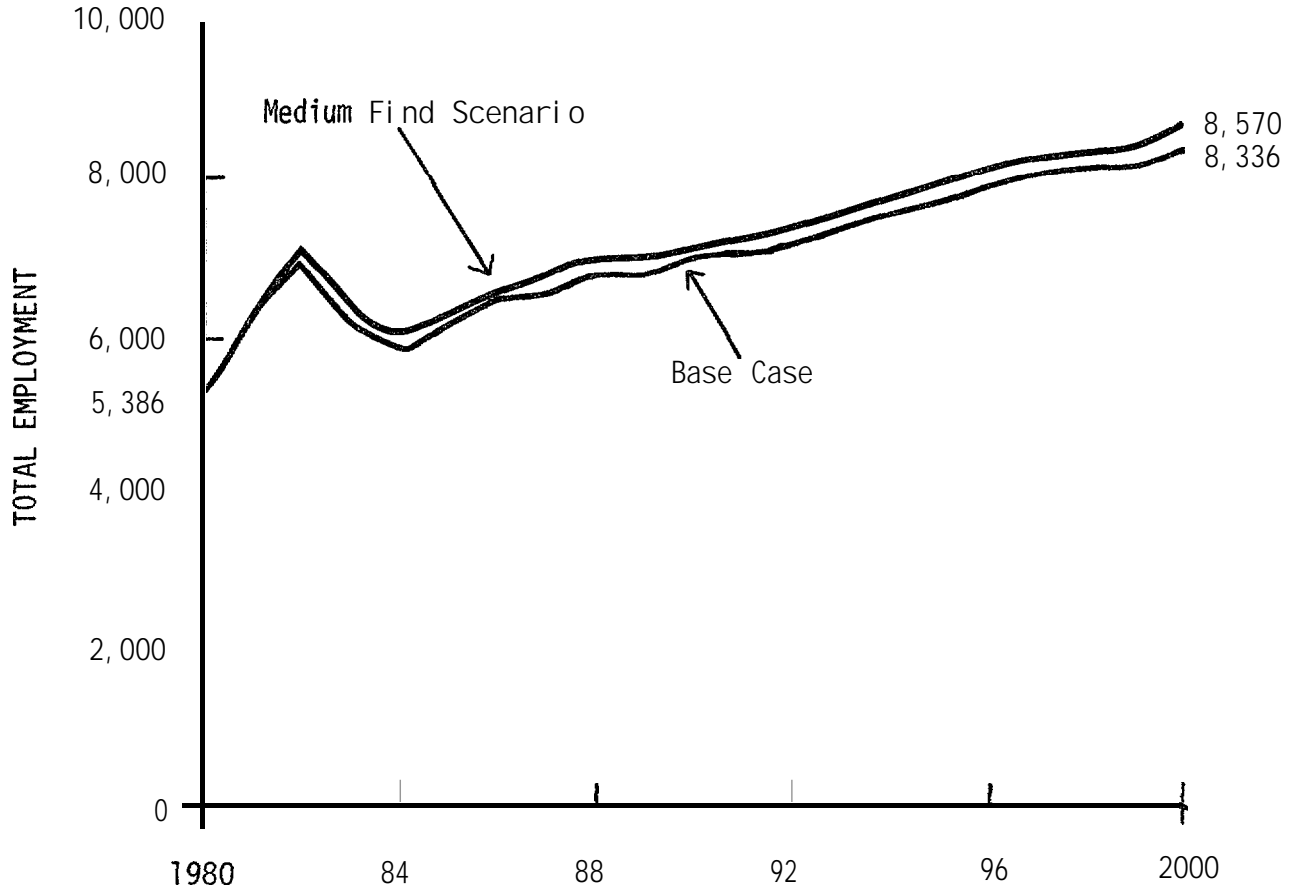

Under the mean scenario for Sale #60, the existing marine support facilities at **Nikiski** and a forward 'base at Homer provide **all** support for both the Lower Cook Inlet and **Shelikof** Strait fields through the exploration phase. Then support for the development and production of the **Shelikof** Strait field shifts to Afognak Island, where a new service base and oil terminal are constructed to service the **Shelikof** Strait oil field. For the smaller and more accessible Lower Cook Inlet field, however, existing service facilities at **Nikiski** are used to provide primary marine support through the development and production phases. The crude oil produced from the Lower Cook Inlet field is transported to **Nikiski** for the most part by existing pipeline systems to be processed there in facilities originally built to handle older Cook Inlet fields.

Overall, this scenario anticipates very moderate impacts at Kenai for two reasons.

First, the bulk (nearly two-thirds) of the jobs nominally attributed to the Central Peninsula or Kenai area derive from jobs actually located offshore **in** the Lower Cook Inlet and **Shelikof** Strait fields or on Afognak Island. These are jobs held by residents in the Central Peninsula area.

2000	7,000	134	15	7,149

Source: Alaska Consultants, Inc.

Most of the employment **truly** occurring **in** the **Kenai** area involves indirect jobs generated as a result of new basic offshore employment. As for timing, areawide employment grows little during exploration, climbs during field development to peak at about **314** jobs in 1990-1991 and then falls off to a level of 234 for the rest of the forecast period.

Second, the **total** population growth associated with this new employment in the Central Peninsula area has been approximately allocated among the City of **Kenai** (25 percent), the City of **Soldotna** (25 percent) and the remaining Central Peninsula area (50 percent), mainly the unincorporated North **Kenai** area.

Thus, the physics^c impacts of the job and population growth **accru**ing in the City of **Kenai** under this scenario are effectively diminished on a regional scale since the impacts are spread throughout the **whole** Central Peninsula area. According to the forecast, the mean scenario adds at peak some 200 residents (or about 3.5 percent) to the City of **Kenai's** population base and **substanti**ally **less** than that during the rest of the forecast period.

The single most important effect on community infrastructure from the mean scenario comes in the demand for additional housing units which is particularly heavy at the beginning of exploration and again from 1987 to 1990. However, the overall impact on **public** facilities and services is not appreciable, especially when compared to the growth stimulated by economic expansion assumed to occur during the base case (see Tables 125 to 134).

Soldotna

COMMUNITY FORECASTS - MEAN SCENARIO

Significant Factors Affecting Growth

The consequences of the mean scenario for Sale #60 upon the City of **Soldotna** are forecast to **be** very similar in scale and timing to Sale #60's effects upon the City of Kenai, for the two cities share a common role as a place of residence for offshore employees and for onshore **OCS-**related workers concentrated in the North **Kenai-Nikiski** area. This scenario stimulates a moderate degree of town growth, in two phases. The first phase (1982-1983) responds to the stimulus of exploration activity following Sale #60 and temporarily adds about 52 persons to the population base. The second growth phase occurs during 1988-1990 as field development and production get underway. This scenario is estimated to add about 193 residents at **Soldotna** in the peak year and about 144 residents during the ongoing production phase.

At the anticipated level of growth for this scenario, the public facilities and services developed to accommodate base case growth appear to be sufficient to absorb scenario growth as well (see Tables 136 to 145).

Homer

COMMUNITY FORECASTS - MEAN SCENARIO

Significant Factors Affecting Growth

Homer experiences some direct onshore growth impacts under the mean scenario due to its role as a forward base for air and marine logistic support for exploration and offshore operations in Lower Cook Inlet and **Shelikof** Strait. However, direct onshore employment is minor, peaking at 33 jobs during exploration.

Homer is far more affected by the offshore **workforce**, part of which is assumed to settle in the Homer area, especially during the production phase. Thus, the major impacts at Homer are delayed until the start-up of production. For purposes of calculating indirect employment and total local population impact, a portion of these offshore jobs is assigned **to** the general Homer area and the derived population is split equally between the City of Homer and its vicinity.

Between 1989 and the close of the forecast period, State #60 is estimated to generate from 187 to 303 jobs in the Homer area, about two-thirds of which are in offshore operations. This employment, in turn, supports population growth in the City of Homer ranging from 234 to 379 residents. During the peak year, **OCS-related** residents account for under 9 percent of Homer's total population and for about 5 percent during most of the

production phase. Compared to other sources of growth, Sale #60 is responsible for less than 10 percent of the permanent growth forecast to occur in the Homer area during the next two decades. Thus, the overall impact of the mean scenario upon community facilities and services is to add slightly to the substantial growth otherwise anticipated for Homer (see Tables 147 to 156).

PROJECTIONS OF GROWTH - 5 PERCENT SCENARIO

Introduction

The 5 percent and the other two **OCS** petroleum scenarios or cases which form the basis of the socioeconomic impact assessment for **Kenai, Soldotna** and Homer in this study were selected by the U.S. Bureau of Land Management's Alaska **OCS** Office and developed by Dames and Moore from U.S. Geological Survey resource estimates. Although reasonably precise locations, quantities, methods of operation and time frames are necessary to the development of plausible scenarios, such scenarios and their impacts should not be interpreted as forecasts of what is actually going to happen. There is far too much uncertainty in oil and gas exploration and development for this degree of precision. However, an indication is given of the type and scale of activities which could impact Lower Cook Inlet communities and the extent to which individual **communities** would logically be impacted.

The high or 5 percent scenario represents a highly successful outcome to Sale #60, corresponding with a level of recoverable oil and gas reserves that has one chance in twenty of being realized according to U.S. Geological Survey estimates. Also, the features of field location and reservoir characteristics are economically very favorable for efficient production. Under this scenario's assumptions, 1.4 billion barrels of crude oil and 1.363 trillion cubic feet of natural gas are discovered and produced from fields in Lower Cook Inlet and **Shelikof** Strait.

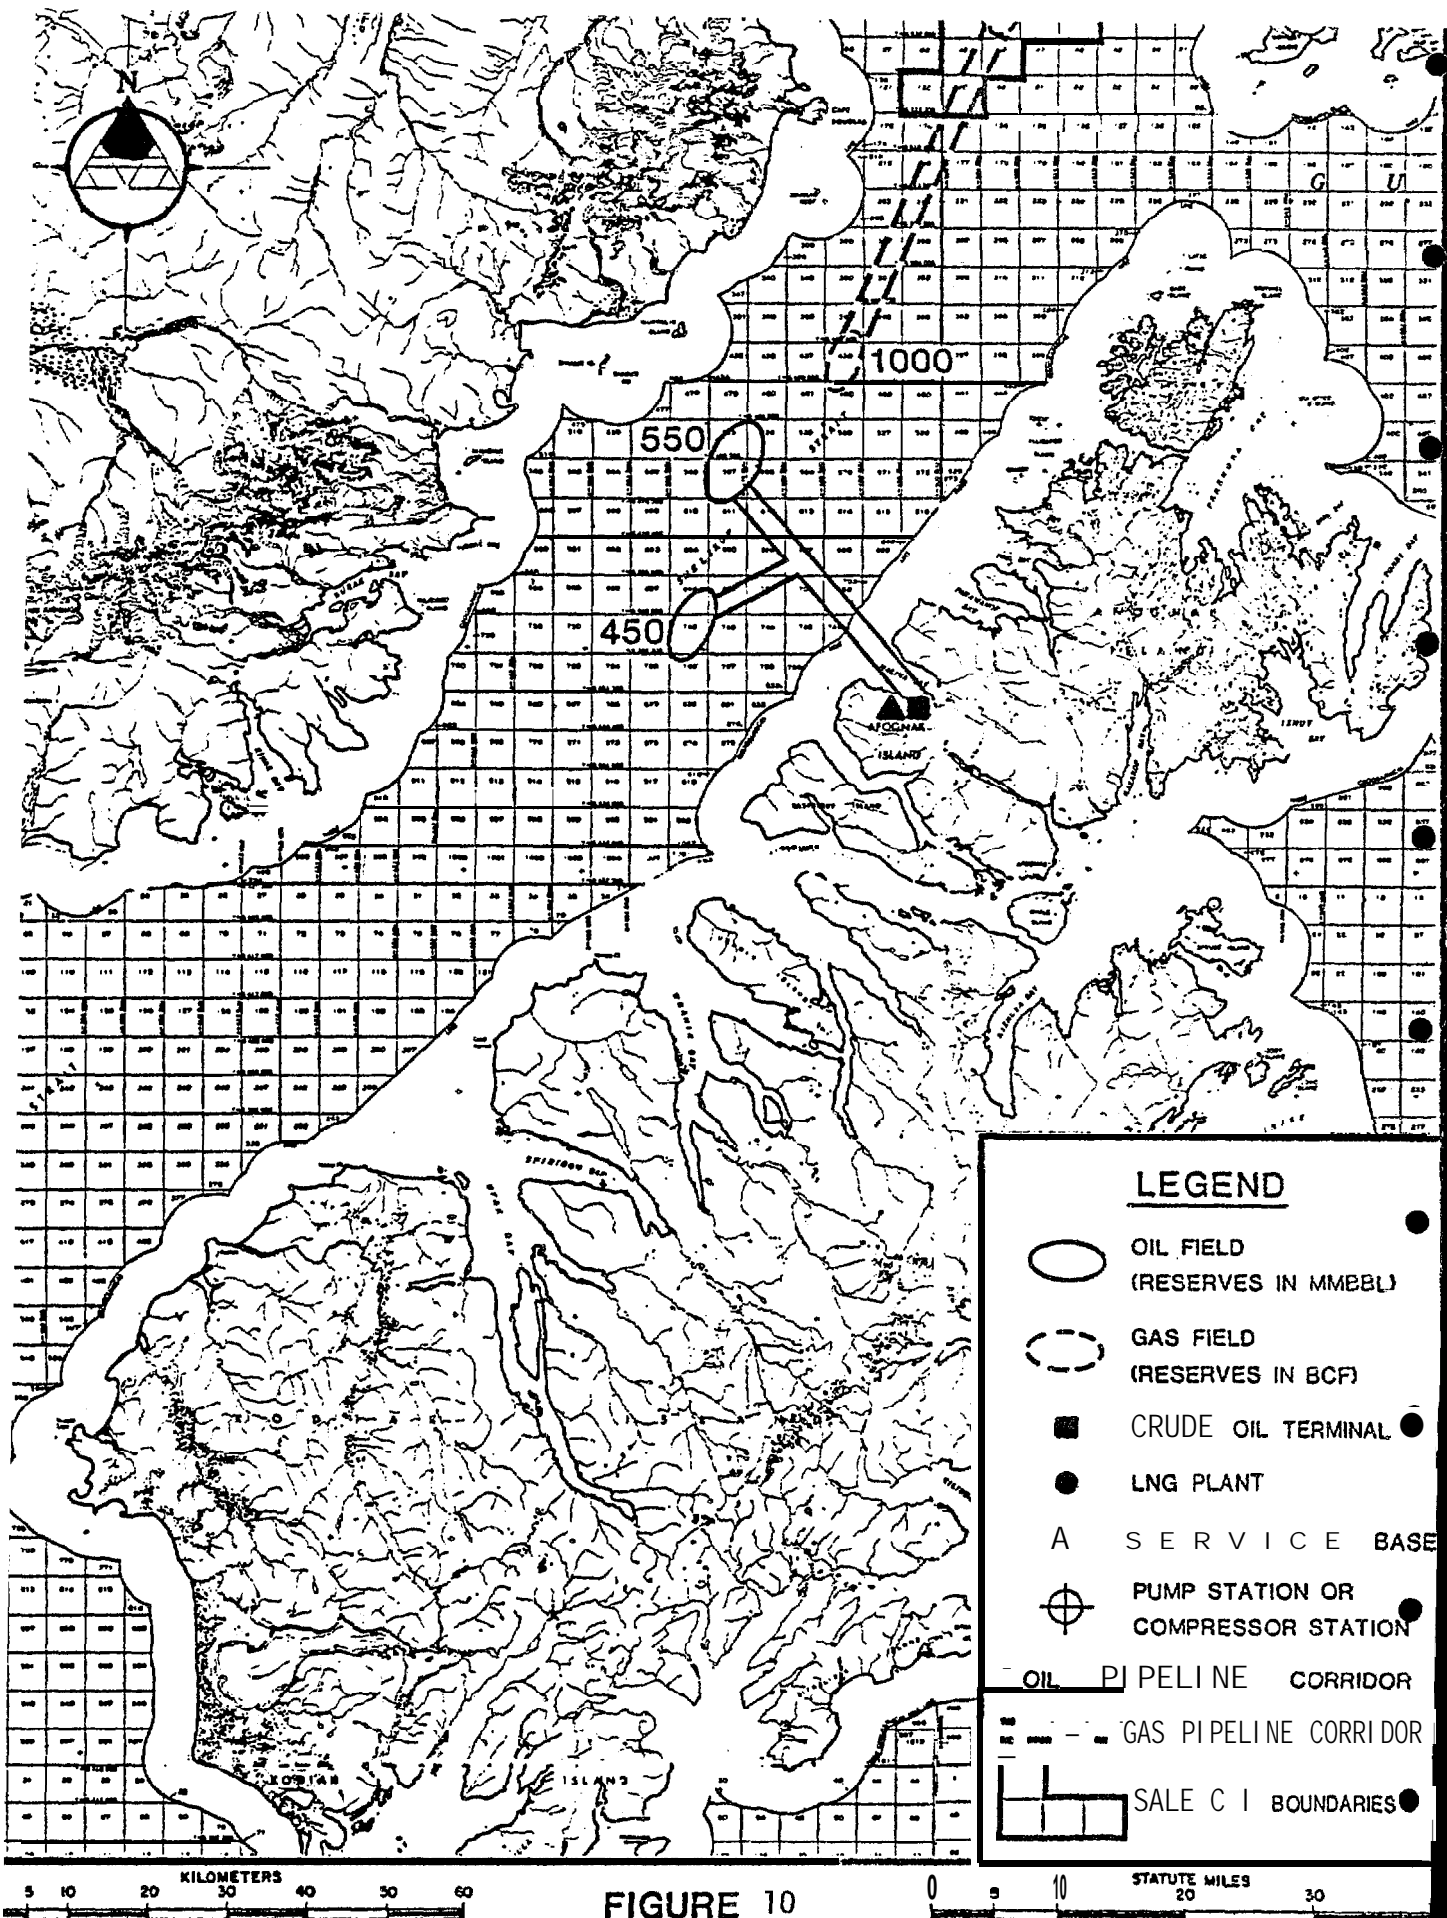

Offshore exploration, development and production of the oil and gas reserves discovered under this scenario is a major industrial undertaking, stretching over decades, involving a great commitment of capital, labor and material resources. However, the same scenario features that permit efficient, economical development and production also structure the enterprise in a way that results in little new industrial development onshore and, generally, in relatively limited onshore impacts upon Kenai Peninsula communities for the assumed level of oil and gas production.

Sale #60 is scheduled to take place a few years after Sale **CI** and near an established oil and gas region experiencing declining production and excess capacity. As a result, the offshore industry is largely able to use existing onshore support and product handling facilities developed previously for older oil and gas fields and for OCS Sale **CI**.

Under the 5 percent scenario, exploration and development interest concentrates on two offshore areas, Lower Cook **Inlet** and **Shelikof** Strait. Exploration activities begin in the year following the sale and extend over a five year period. Exploration support is supplied through existing marine facilities at **Nikiski** and an advance base established at Homer, with air service support also being provided via Homer. Over the exploration period, a total of 57 exploration and delineation wells are drilled, with effort about evenly divided between the Lower Cook Inlet and **Shelikof** Strait fields.

e The first discovery is made in the initial year of exploration and favorable findings continue in succeeding years. Eventually, six producible fields are found, including two giant oil fields (550 and 450 million barrels respectively) and one gas field (1 billion cubic feet) in the **Shelikof** Strait province and two major oil fields (200 million barrels each) and one gas field (363 billion cubic feet) in Lower Cook Inlet. Total recoverable reserves are estimated at 1.4 billion barrels of oil and 1.363 trillion cubic feet of natural gas, with about **three-**quarters of the reserves situated in **Shelikof** Strait.

The development phase begins in the third year after the sale. The process of platform installation and facility construction continues over a six year period. Field characteristics are such that a single platform suffices for each field and six steel platforms, fabricated at West Coast sites, are installed. Associated onshore facility development includes an oil terminal at **Afognak Island** to handle **Shelikof** Strait oil production, a service base on **Afognak** Island to support oil and gas field development and production in the **Shelikof** Strait province and expanded marine support facilities at Homer and **Nikiski** to service offshore activities in Lower Cook Inlet. As oil production in Lower Cook Inlet is transported by submarine and overland pipeline to the existing terminal at Drift River on the west shore of Cook Inlet, new onshore construction for that purpose is limited to pipeline construction and, possibly, some oil treatment facilities.

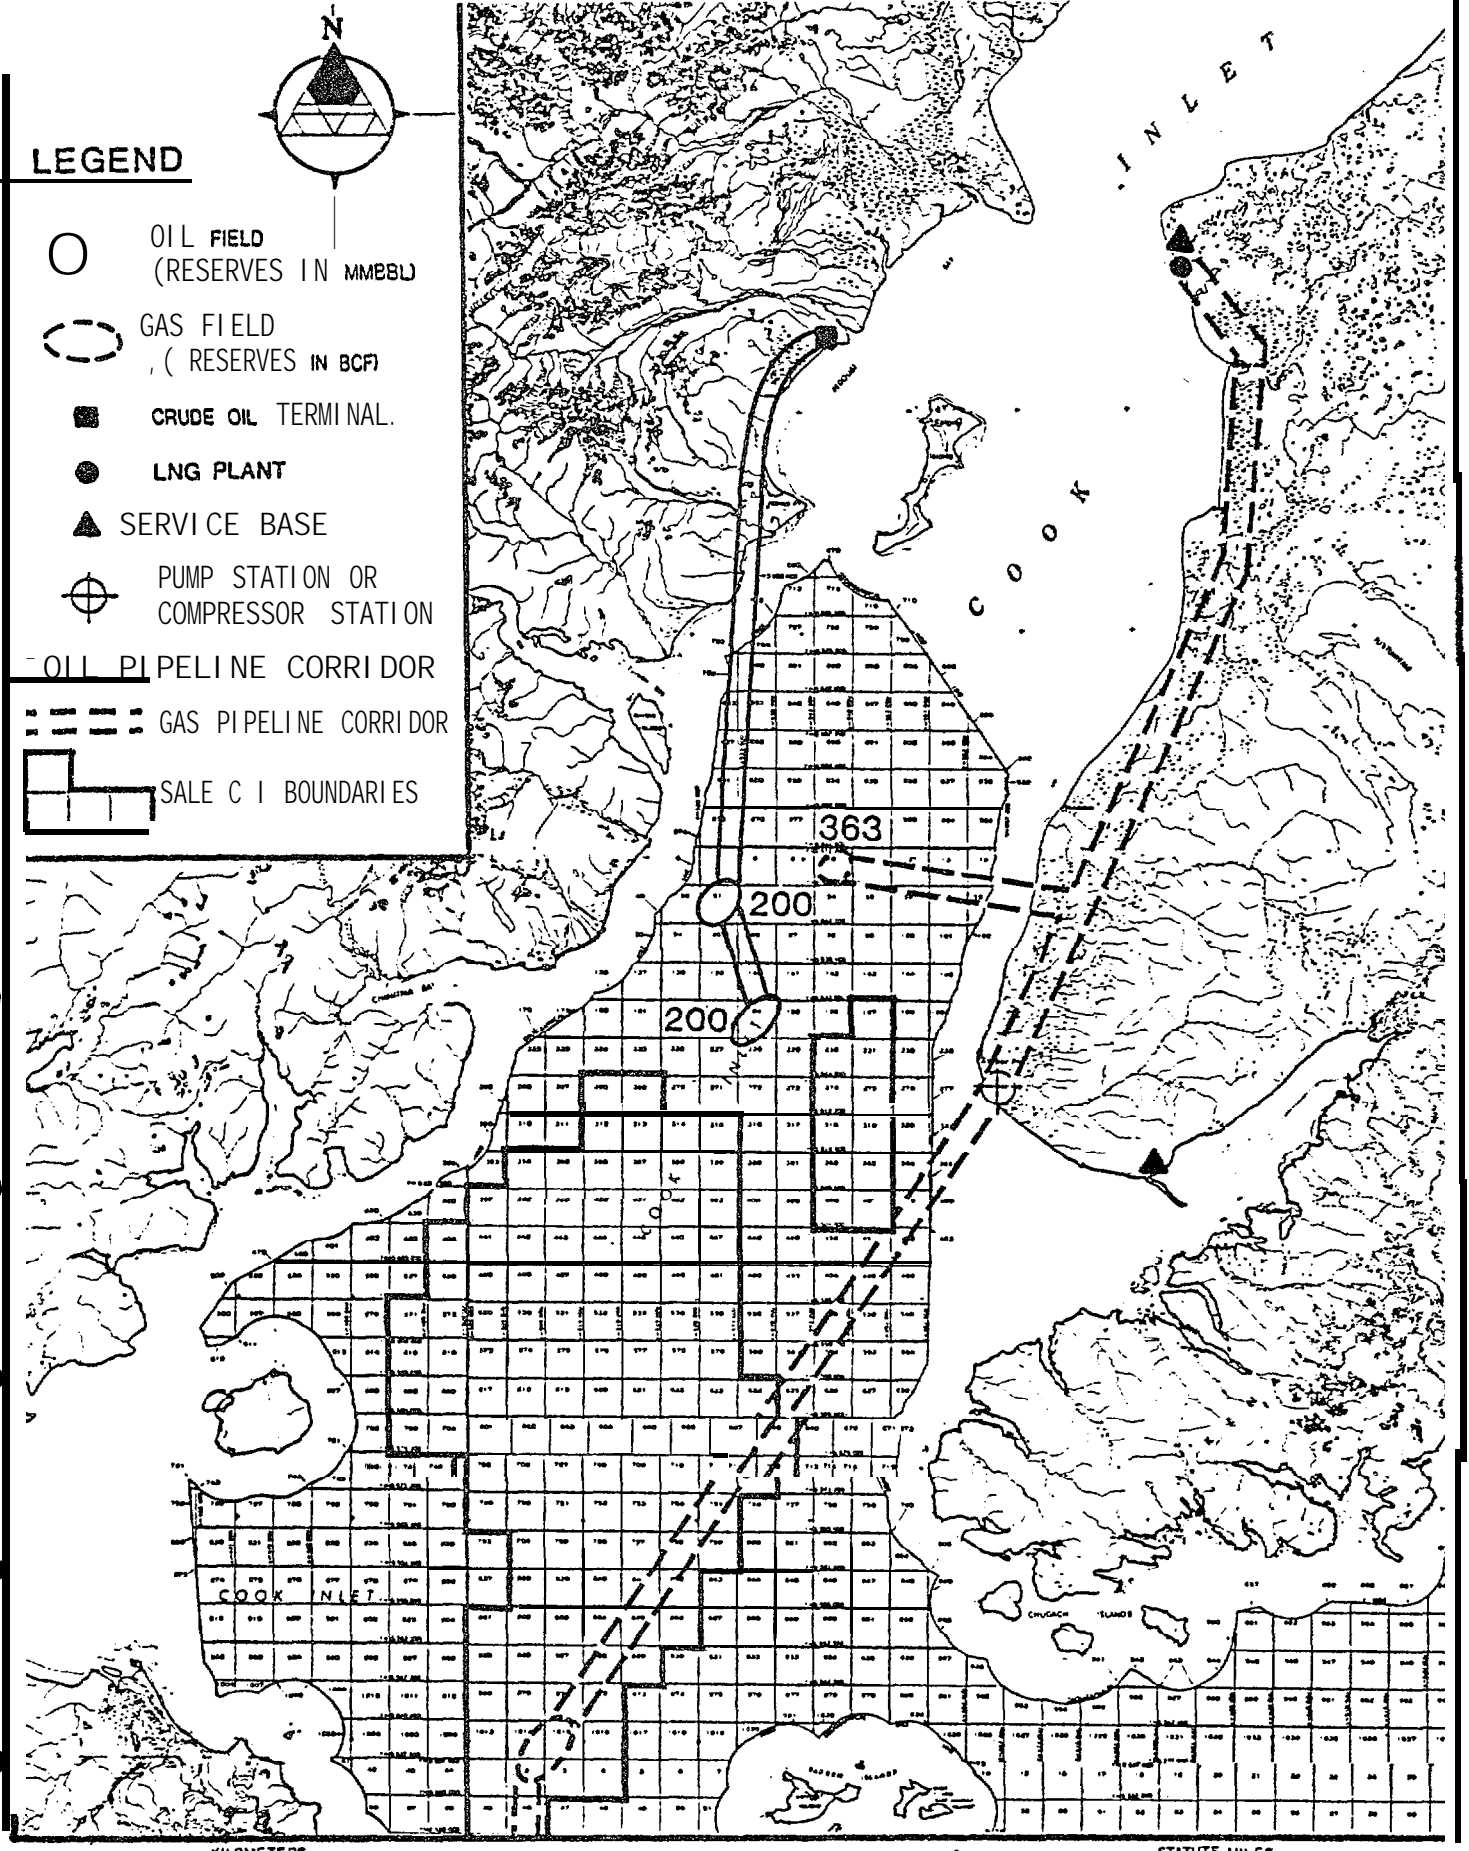

FIGURE 11

**LOWER COOK INLET
HIGH FIND SCENARIO**

SOURCE: DAMES & MOORE

The gas fields in **Shelikof** Strait and Lower Cook Inlet are similarly located close to producing fields previously leased. This circumstance makes it economically feasible to deliver new gas production to established submarine and overland trunk pipelines and gas processing facilities, once the connecting submarine pipeline links are installed.

While field development activities persist through 1994, oil production is assumed **to** begin as early as 1989 and gas production by 1990. Oil and gas production peaks within two to five years after startup and then begins to decline. Gas production from both the **Shelikof** and Cook Inlet fields concludes before the end of the forecast period, but oil production lasts through the first few years beyond the end of the scenario.

REGIONAL ECONOMIC FORECASTS - 5 PERCENT SCENARIO

Significant Factors Affecting Growth

Because of the 5 percent scenario's assumed geographic distribution of development activities, particularly the diversion of most oil production to a remote terminal on **Afognak** Island, Sale #60's high scenario has relatively minor direct onshore impact upon the **Kenai** Peninsula communities, despite the high **level** of oil and gas production assumed.

This **scenario** assumes major OCS oil and gas discoveries and production. As has been the case with previous Cook Inlet oil and gas operations, this **scenario** also assumes that the Kenai-Soldotna-Ni kiski communities

Dames and Moore.

will be the local settlements most directly involved in provision of various support services to the oil industry. Nevertheless, because of the geography of new resource finds and the timing of development activities, the scenario forecast projects relatively modest direct onshore impacts upon the Central Peninsula area in relation to the anticipated scale of production.

The major oil and gas finds are located in **Shelikof** Strait near Afognak Island and, as a result, related field development and operations support are diverted to new remote facilities built on Afognak. Also, all oil production from the **Shelikof** fields is routed to a new oil terminal on **Afognak**. Those Sale #60 activities which rely upon the Central Peninsula area for industrial support mostly take up slack in existing industrial facilities that would otherwise be phased out or underused. No major new onshore facilities or construction employment result from Sale #60.

Thus, few new onshore jobs are created in petroleum-related enterprises and what growth occurs is layered on top of a solid base of existing petroleum development. Numerically more significant is the impact of the offshore workers in the Lower Cook Inlet and **Shelikof** Strait fields who already live in or opt to resettle in the Central and Southern Peninsula areas. On the average in this scenario, there are ten local residents employed at offshore jobs for every resident employed at an onshore job in **OCS-related** endeavors. The forecast assumes that a substantial share of the offshore platform work force and the **Afognak** terminal work force will choose to **live in** the study area once production

begins. Thus, while the total number of Kenai-Cook Inlet area employees including resident offshore workers attributable to this scenario is relatively **low** (about 140 to 240 jobs) through exploration and **field** development, employment climbs to over 1,500 during the peak production years and then stabilizes at about **1,200** thereafter.

Future Employment

It is a peculiarity of this scenario that the level of offshore and remote employment is a more significant factor in the local economies than direct onshore jobs in **OCS-related** industries. The offshore work force in the **Shelikof** Strait and Lower Cook Inlet provinces together with the onshore work force at the remote terminal and **service** base on **Afognak** Island exceeds many times over the onshore OCS industrial employment. The scenario assumes that a share of these offshore and remote workers **will** come from or choose to take up residence within the study area. For purposes of forecasting population impacts, these workers have been tallied in the study area's employment forecast and assigned either to the **Kenai-Soldotna** or Homer Labor Areas.

Kenai-Soldotna Labor Area. The direct onshore employment generated in the **Kenai-Soldotna** area by Sale #60 is low, confined mainly to support operations based in the North **Kenai-Nikiski** area. There is a **single-**year employment high of 103 direct onshore jobs during the peak of development activity, but otherwise an average of about 40 new **OCS-**related jobs in the **Kenai** area.

As previously noted, under this scenario, the offshore workforce in the Shelikof Strait and Lower Cook Inlet provinces, together with the onshore work force at the remote terminal and service base on Afognak Island, exceeds the onshore work force many times over. It is largely the pattern of off-work residency adopted by this offshore work force that influences the local employment and population flows ensuing from the OCS scenario. The Kenai-Soldotna area's share of permanent offshore employment is estimated to stabilize in the approximate range of 350 to 450 workers throughout the production phase of Sale #60 development. When direct onshore OCS employment and indirect employment are considered as well, the total number of jobs assigned to the Kenai-Soldotna area as a result of Sale #60 is maintained at roughly about 100 during the first half-dozen post sale years, then rises abruptly to the range of 550 to 750 jobs with the onset of production. The employment peak is reached about 10 years after the sale, and then gradually declines over the rest of the forecast period.

Homer Labor Area. The period of exploration and field development adds few employees to the Homer area's workforce. A variety of marine and air support activities add perhaps 30 onshore jobs to Homer's employment base. Resident offshore workers and employees in secondary economic sectors outweigh direct local OCS employment. Counting all sources of employment, Sale #60 supports somewhat more than 100 jobs in the Homer area over the first half-dozen years of the scenario.

There is **little** change anticipated in the number of OCS-related onshore jobs over the forecast period. A very different pattern is expected in the case of locally-resident offshore workers. Their numbers are forecast to rise sharply with the onset of production to an estimated peak of 480 workers around 1990 and to decline slowly over the rest of the production period.

Thus, after a slow start, the high scenario is estimated to support up to 759 direct and indirect employees in the Homer area and an average of about 600 employees over the decade after 1990. It should be noted that less than 40 percent of these employees actually work onshore in the Homer area, while more than 60 percent are residents employed offshore.

Kenai

COMMUNITY FORECASTS - HIGH SCENARIO

Future Population

Under the base case, **Kenai** is forecast to grow steadily, increasing at a rate of about 2 percent annually from 4,755 in 1980 to about 7,000 by 2000. The high scenario contributes a relatively **small** increment -- less than a hundred new residents -- to **Kenai's** population through the exploration years. As the level of offshore employment rises during field development and production, **Kenai** draws a significant share of the region's **OCS-related** population growth. By **1991**, this scenario adds an estimated 498 residents to **Kenai's** population base. In the following decade, the OCS dependent population is expected to decline slowly, falling to about 346 **by the** close of the forecast period. Over this decade of impact, the Sale #60 high scenario increases the City of **Kenai's** total population by a factor of 8.5 percent at peak to about 5 percent at the close of the scenario.

IMPACT ASSESSMENT

Social Impacts

With the exception of the brief period of accelerated growth in conjunction with development work and production start-up, this scenario does not

appear to portend any notable social impacts for Kenai. Overall, growth under this scenario is at a lesser rate than the City has experienced in recent years. The City's infrastructure has generally attained a threshold of development that should enable it, with relatively easy adjustments, to absorb the scenario's added **population**. Furthermore, the type of economic growth projected under the base case, together with the scenario's increment, appears likely to fit well into the area's existing pattern of industry. In sum, there do not seem to be any noteworthy long-term social impacts upon **Kenai** that can be attributed to this scenario.

Impacts on Community Infrastructure

Housing and Residential Land. Under the high scenario, the City of **Kenai** may need about 103 additional dwelling units or about one-sixth more than estimated to be needed to satisfy base case demand (see Table 170). Almost all this demand is expected to be felt prior to 1992 although there is a small increase in demand from 1994 to 1996. In the last three years of the forecast period there is excess housing capacity. An estimated 8 hectares (20 acres) will be demanded for residential development under the high scenario (see Table 171). According to a recent land inventory study, the supply of land at Kenai is adequate for this level of development.

Utilities

- Water. Aside from incremental extensions to meet the requirements of new residential and commercial development, **Kenai's** water distribution system should be adequate for the growth anticipated under the high scenario. The 4 percent growth in water consumption envisioned for Kenai should not in itself burden the existing water supply. However, the groundwater which supplies Kenai also serves the entire Central Peninsula area and there is some question as to its ability to sustain major growth in the region. Development of an alternative water source for the Kenai-North **Kenai-Soldotna** area is under study. The most likely alternative, the Kenai River in the vicinity of **Soldotna**, would require construction of a pipeline to transport water to Kenai (see Table 172).
- Sewer. The high scenario forecast is not significantly different from the base case forecast (see Table 173).
- Electric Power. Assuming that natural gas remains available for the production of electric power in the Central Peninsula area and that the Bradley Lake **hydro-electric** facility is constructed as planned in the mid-1980's, the Homer Electric Association **will** have sufficient electric power available to accommodate growth anticipated in the high scenario (see Table 174).

- Solid Waste Disposal. Disposable solid wastes estimated to be produced by Kenai under the high scenario will consume about 2 hectares (5 acres) more landfill than solid wastes generated in the base case (see Table 175). There is sufficient Borough land in the area to meet this demand.
- Communications. The high scenario forecast is not appreciably different from the base case forecast (see Table 176).

Public Safety

- Police. Kenai is not expected to need any additional police officers or jail cells beyond those called for in the base case to maintain standard levels of police service. However, if the Kenai jail continues to also serve the jail needs of both the City of Soldotna and the Alaska State Troopers, an additional three cells will be demanded to accommodate population growth in the Kenai-North Kenai-Soldotna area forecast under the high scenario.
- Fire Protection. The improvements in firefighting facilities and services estimated to be needed to serve base case growth should be adequate to cover the added fire protection requirements of the high scenario.

Health and Social Services. The health and social service facilities to be provided for the base case should suffice for growth anticipated during the high scenario.

Education. The high scenario's enrollment growth adds a demand for two elementary and two secondary classrooms in **Kenai** (see Table 177). Existing school facilities can absorb this level of growth.

Recreation. The scale of growth stemming from the high scenario would not add to the demand for recreational facilities in **Kenai**.

Local Government Finances. In general, the method used to forecast local government revenues and expenditures assumes that localities will maintain about the same level of public services and the same revenue structure as prevailed on a per capita ratio in the baseline year (see Tables 178 and 179). In specific cases where major taxable onshore OCS facilities are programmed, the local real property tax base and revenue forecast may be adjusted to take account of the major increases in revenue which these capital-intensive properties may yield at prevailing mill rates.

However, in the Sale #60 scenarios, no new major onshore industrial facilities are anticipated in the Central Peninsula area. Such existing facilities as are used are mostly located in the unincorporated North **Kenai-Nikiski** area. As a result, as **Kenai's** population grows, the City may become relatively more dependent upon its already strained residential and commercial property tax base to support additional services.

Even under the base case conditions, it was noted that the City of **Kenai** might be pressed to finance future capital improvements. In view of the tax base and service area population trends noted above for **OCS-related** development at **Kenai**, it is impossible that the City's fiscal situation may worsen under the high scenario.

CAUSE/EFFECT OF IMPACTS

Under the high scenario, the petroleum industry is not expected to make its presence felt in **Kenai** in the form of local jobs or physical plants. Nevertheless, the industry adds a boost to **Kenai's** steady upward growth trend in the early and middle period of the scenario. The community impacts accrue largely from **Kenai's** function as the home community for a share of the permanent offshore work force. The addition of these workers and their families and payrolls stimulate, in turn, secondary economic and population growth.

Thus, the thrust of this scenario tends to promote growth in local income, population and residential settlement without a corresponding increase in local jobs and basic economic development or employment facilities.

PROBLEMS/ISSUES AFFECTING THE COMMUNITY INFRASTRUCTURE

The high scenario is estimated to add up to 498 new residents to **Kenai's** population at the time of peak impact. This growth accumulates over a

number of years and it is estimated that no more than 141 new residents are added due to Sale #60 in any single year. As a result, in comparison to the existing population base and growth trend, the high scenario does not materially alter the type and scale of community facilities and services that would otherwise be in demand. Those elements of the community infrastructure most likely to be at all affected are utility and service systems closely related to new residential development such as water supply and waste treatment, fire protection and neighborhood recreational facilities.

SUMMARY OF IMPACTS

The high scenario speeds the pace of population growth in **Kenai** over a few years, adding at most a total of nearly 500 new residents. The physical impact of the scenario on Kenai is minimized by the fact that no **OCS-related** industrial facilities are located in Kenai. In view of the City of **Kenai's** history of growth in recent decades, its current economic structure, and the decelerating economic and population growth forecast under the base case, the impact of the high scenario seems compatible with past and future trends and contributes only modestly to the town's public facility and services requirements.

Soldotna

COMMUNITY FORECASTS - HIGH SCENARIO

Future Population

In terms of absolute numbers of people, this high scenario engenders virtually the same population growth at **Soldotna** as at **Kenai**. This is because nearly all of the Central Peninsula region's Sale #60-related growth is tied to the offshore work force rather than local worksites. **Soldotna** and Kenai were assigned an equal share of offshore workers from Sale #60, although Kenai, because of its closeness to industrial employment sites in North **Kenai-Nikiski**, attracts as residents a few more onshore workers.

Through 1987, the projection is that **Soldotna** will accumulate less than 80 additional residents from the high scenario as a result of new offshore exploration activity. However, once the recoverable reserves assumed under the high scenario are confirmed and field development commences, the base population is augmented by about 450 additional residents during the peak years, and only slightly less during the **following** years. In the peak period, 1990 to 1992, the scenario accounts for about 12 percent of **Soldotna's** total population (see Table 180).

IMPACT ASSESSMENT

Social Impacts

The City of Soldotna is projected to grow at a rate of 3 percent annually under the base case. The high scenario tends to accelerate this rate during the first post-sale decade during the build-up of offshore employment, then slackens the growth rate once OCS-related employment starts to decline. Compared to Kenai, Soldotna enters the forecast period with a smaller population base and a higher growth rate projection. Thus, Soldotna is likely to be more affected than Kenai by a population increase comparable to Kenai's. Nevertheless, in the perspective of Soldotna's base population forecast and the growth management problems implied by it, the scenario makes a relatively minor incremental addition to growth ensuing from other sources. Also, for comparison's sake, the scenario population forecast implies a far slower growth rate than Soldotna has undergone in the previous two decades covering the earlier history of Cook Inlet petroleum development. In short, the social impacts of this scenario upon Soldotna appear to be a matter of minor degree, involving growth on a scale that can be assimilated into the existing community without major social disruptions or change.

Impacts on Community Infrastructure

Housing and Residential Land. Population growth generated by the high scenario will call for about 98 new housing units, or about 13

percent more than estimated to be needed to fulfill base case demand (see Table 181). Almost all demand for new housing occurs in the first ten years of the forecast, while in the last four years of the period, there may be a housing surplus in **Soldotna**. An estimated additional 7.6 hectares (19 acres) will be demanded to accommodate new residential development under the high scenario (see Table 182). According to a recent planning study, the supply of land at **Soldotna** is more than adequate for this level of development.

Utilities

- e Water. Apart from the need to extend the system to meet new development, **Soldotna's** water distribution system is adequate for capacity requirements projected under the base case (see Table 183). While the City's three wells have the pumping capacity to meet projected high scenario requirements, there have been indications in recent years that the groundwater which supplies the entire Central Peninsula area is being overdrawn and is not sufficient to meet long range demand. If such is the case, the City may have to develop an alternative water source at some time during the forecast period.
- Sewer. The high scenario forecast is not significantly different from the base case forecast (see Table 184).

- Electric Power. Under the high scenario electric power capacity requirements are projected **to** be about 7 percent more than estimated for the base case. Assuming the continuing availability of natural gas for the generation of power and the construction as planned of the Bradley Lake hydro-electric facility, Homer Electric Association should have adequate electric power to meet capacity requirements for its entire service area during the forecast period (see Table 185).
- Solid Waste Disposal. Disposable solid wastes estimated to be produced by **Soldotna** under the high scenario will demand about 1.3 hectares (3.3 acres) of additional landfill above that called for in the base case (see Table 186). There is sufficient Borough land in the area to meet this demand.
- Communications. The high scenario forecast is not appreciably different from the base case forecast (see Table 187).

Public Safety

- Police. **Soldotna** will not need any additional police officers or jail cells beyond those assumed for the base case to maintain adequate police service.
- Fire Protection. The improvements in firefighting facilities and services called for to serve base case growth will be

adequate to cover the added fire protection requirements of the high scenario in **Soldotna**.

Health and Social Services. The health and **social** services **provided** under the base case should be sufficient to meet the **level** of growth forecast for the high scenario.

Education. Existing and planned public school facilities in **Soldotna** are more than adequate to meet the enrollment growth forecast for the high scenario.

Recreation. The scale of growth generated by the high scenario would not add to the demand for recreational facilities in **Soldotna**.

Local Government Finances. Assuming a continuation of **Soldotna's** recent expenditure and revenue patterns, the fiscal forecasts for **Soldotna** do not indicate any major change in the City's financial status (see Tables 189 and **190**). However, there is reason to suspect that the impact of the high scenario upon **Soldotna's** public finances may be adverse, if only marginally so. The basis for this supposition is the nature of **Soldotna's** economic participation in the scenario. In relation to the petroleum industry, **Soldotna** functions primarily as a local governmental center and as a commercial center and residential community catering to oil industry employees and their service needs. **Soldotna's** local real property tax base is relatively **undiversif**'ied, with few valuable industrial properties, numerous untaxed public facilities

requiring local services and a heavy reliance upon residential and commercial rate payers. Since the high scenario appears likely to accentuate this imbalance property tax structure, it may adversely affect the City's ability to maintain services without imposing higher tax burdens. Also of importance in this regard is the fact that at present, Soldotna already exhibits a relatively high ratio of bonded indebtedness to property tax valuation, a situation reflective of the structure of its property tax base and a situation which could be worsened by the high scenario.

CAUSE/EFFECT OF IMPACTS

The effects of the high scenario upon Soldotna are indirect, for Soldotna is geographically removed from any shore-based support operations in connection with Sale #60. Nevertheless, Soldotna's role as a residential community and provider of secondary services results in some cumulative population growth over the first decade of the scenario, up to as many as 450 additional residents or about 12 percent of Soldotna's total population at that time. The incremental impact of Sale #60 diminishes over the second decade of the scenario. Thus, the impact of Sale #60 on Soldotna can be defined essentially in terms of the need to accommodate some additional population growth, but without local industrial development.

PROBLEMS/ISSUES AFFECTING THE COMMUNITY INFRASTRUCTURE

In past years and somewhat more slowly under the base case forecast, Soldotna is seen to be in **trans**ition toward a more developed and urbanized settlement. The high scenario, which accounts for a small share of the total growth forecast for **Soldotna**, lends some impetus to this trend and to the level of demand for public facilities and services. However, **Soldotna** appears to be adequately supplied with developable land and the basic utility and facility capacities projected under the base case forecast also seem adequate to accommodate scenario growth. In the perspective of **Soldotna's** twenty-year growth projection, a review of specific facility and service demands indicate that the high scenario will not of itself pose major growth management problems to the City.

SUMMARY OF IMPACTS

The Sale #60 high scenario will indirectly promote some population growth in **Soldotna**, but much less than will accrue from base case growth. Overall, the estimated growth rate will be less than **Soldotna** has experienced during the opening period of Cook Inlet oil development. In view of the public improvements that **Soldotna** has now installed, it is expected that **Soldotna** will be able to expand to absorb the scenario's population without overtaxing the community infrastructure.

Homer

COMMUNITY FORECASTS - HIGH SCENARIO

Future Population

The trend of future population growth in the Homer area attributable to the high scenario parallels the pattern of employment growth. That is, sale-related population growth is slow and small-scale during the first half-dozen years following the sale, then climbs rapidly during the early production years and falls off **slowly** but steadily thereafter.

The population forecast uses a multiplier of 2.5 added persons for each added job in the area's employment base. Applying this multiplier to the employment forecast yields an estimated peak population impact in the Homer area of **1,989** persons. The average **OCS-dependent** population over the production years is about 1,550 persons. It is anticipated that **half** of this areawide population growth will occur within the City of Homer's boundaries and half in the unincorporated area surrounding Homer. Thus, the population impact upon the City of Homer during the production years averages about 775 persons (see Table 191).

Under base case assumptions, the City of Homer is anticipated to grow in population by more than 150 percent from an estimated 2,148 persons in 1980 to 5,429 by the close of the forecast period in 2000. In comparison, Sale #60 is expected to account for about 20 percent of the City's total

*

population growth under the high scenario by 2000 at which time an estimated 10 percent of the City's residents may be directly or indirectly supported by OCS Sale #60.

IMPACT ASSESSMENT

Social Impacts

Even under the base case, Homer is projected to attain a rapid growth rate of 4 to 5 percent annually and will, therefore, confront a full agenda of growth management issues. It is expected that offshore oil and gas activities unrelated to Sale #60 will assume a significant and perhaps controversial position in the town's changing economic base and community life, particularly with reference to the town's traditional fisheries and tourism economy and rural life style.

Sale #60 is forecast to accelerate the pace and to magnify the scale of population growth as Homer continues in its transition toward a more diversified and urban settlement. Of special importance from the point of view of social impact on the community is the circumstance that the large increment of population resulting from Sale #60 will be economically dependent on and oriented to the offshore petroleum industry.

Consequently, there is latent potential for economic and social polarization within the community based on the divergent attitudes toward development of the energy industry and Homer's traditional and familiar fisheries and tourism and recreation industries.

Impacts on Community Infrastructure

Housing and Residential Land. Compared to the base case, the high scenario accelerates substantially the estimated rate of growth in housing demand during the middle years of the forecast period. As Homer's role as a forward support base diminishes when the gas and oil production peak in 1992, demand for new housing decreases and in the last years of the forecast, there is a housing surplus in Homer under the high scenario. Overall, the incremental effect above the base case upon demand levels at the close of the forecast period is about 200 dwelling units and about 16 hectares (40 acres) of land newly converted to residential use (see Tables 192 and 193). This is more than one-fifth of the total increase in housing and residential land estimated to be needed under the base case.

Utilities

- Water. Even with the additional industrial water consumption associated with the support base supplying offshore activities, the water demand estimated for the high scenario can be supplied by the City through the end of the forecast (see Table 194).
- Sewer. Apart from improvements to the distribution system and treatment plant designed to accommodate base case growth, an additional 806 kiloliters (213,000 gallons) per day in treatment plant capacity will be called for to process sewage generated during the high scenario forecast (see Table 195).

- Electric Power. Assuming the continuing availability of natural gas for power generation and the construction of the Bradley Lake **hydro-electric** facility, Homer Electric Association **will** be able to maintain adequate electric power for the high scenario (see Table 196).
- Solid Waste Disposal. Disposable solid wastes produced in the Homer area during the high **scenario will** consume an **additional** 6 hectares (15 acres) of landfill above that **called** for by the base case (see Table 197).
- Communications. The high scenario is not materially different from the base case (see Table **198**).

Public Safety

- Police. To maintain a standard level of police service under the high scenario, it is estimated that the City of Homer may need one additional police officer and jail cell beyond those demanded by the base case. Some expansion in staffing of the Alaska State Troopers may also be warranted since that agency provides police protection outside the City of Homer.
- Fire Protection. The improvements in firefighting facilities and services needed to serve base case growth should be adequate to cover the added fire protection requirements of

e the **high** scenario in the City of Homer. However, residential development north of the City may necessitate establishment of a new fire service area.

Health and Social Services. The level of growth forecast for the Homer area under the high scenario is likely to merit the addition of three to four hospital beds and one physician.

Education. Under the base case forecast, the **Kenai** Peninsula Borough was seen to construct a new elementary school with 13 to 14 classrooms and an addition to the secondary school of about three classrooms. Enrollment growth forecast for the high scenario **will** probably warrant the construction of at least three more elementary and two secondary school classrooms (see Table 199).

Recreation. The high scenario places no additional demand on Homer for recreation facilities beyond those expected to be developed for the base case.

Local Government Finances. The imposition of Sale #60's growth on top of Homer's generally rapid growth will likely generate significant additional fiscal burdens upon the City. Even under the base case, major public improvements programs will be called for, to the point where heavy demands upon Homer's debt service capacity are expected. Currently, Homer has a better than average ratio of debt to assessed valuation in comparison to most middle-sized Alaska municipalities, but

also a relatively small share of revenues available to support capital projects (see **Table 201**). Since the Sale #60 scenario does not augment Homer's property tax base with new OCS industrial facilities to offset its allied expenditure burdens, it appears that the scenario considered apart may adversely affect the already pinched balance of revenues and expenditures for the City of Homer.

CAUSE/EFFECT OF IMPACTS

Even under the base case, Homer is propelled into a role in offshore oil and gas development by virtue of the convenient location of its port and airport in relation to the Sale **CI** tracts. The high scenario of Sale **#60** magnifies Homer's direct involvement in OCS activities. In fact, it is expected that Homer will host more Sale #60 onshore employees than either **Kenai** or **Soldotna**. Even more significant is that Homer also attracts a larger share of offshore employees as permanent residents. Thus, Homer is, in numerical terms of population growth, more powerfully impacted than **Kenai** or **Soldotna**. Because it is a smaller community to start with, it is also relatively more affected. Finally, because the expected impact of Sale #60 comes on top of a rapidly growing base population -- over a 150 percent increase during the forecast period -- the high scenario compounds growth impacts which would in any case be formidable.

PROBLEMS/ISSUES AFFECTING THE COMMUNITY INFRASTRUCTURE

At the outset of the scenario, Homer is, of the three study area communities, least equipped with basic public utilities and most hampered by physical constraints on its development. The high scenario may be expected to aggravate the infrastructure problems previously noted in the base case forecasts.

These problems include inadequacies in the water treatment and sanitary waste treatment facilities; solid waste disposal and public safety facilities. Projected expansion of Homer's role in the fishing and fish processing industry as well as the offshore support industries may intensify development demands upon Homer Spit and the City's port facilities.

SUMMARY OF IMPACTS

The effect of the high scenario is forecast to be an intensification of growth at Homer, contributing to a near tripling of the City's population by the end of the forecast period. Sale #60 alone accounts for about one-quarter of this growth. Together with the impact of earlier Sale CI, this represents the entrance of a substantial **OCS-related** economic component to Homer's economy and a new dimension in the community's economic base. Because of competing demands for port facilities, potential conflicts between oil and fishing operations and the stresses on overtaxed housing and public services, there is potential for conflict and unrest

in the community. **If** the growth forecasts of this scenario are realized, it is likely that Homer's semi-rural and distinctive life style will be compromised by a swift trend to a more developed and business-like character.

APPENDIX

Methods, Standards and Assumptions

INTRODUCTION

The following assumptions and standards have been developed for **local** government services and revenues for the Lower Cook Inlet communities of Homer, **Kenai** and **Soldotna**. These standards, methods and assumptions were refined and modified during the course **of** this study as additional inputs were made by other subcontractors and as additional data were developed by this subcontractor. Therefore, the methods, standards and assumptions which follow are the basis for the impact analysis.

ECONOMY AND POPULATION

Forecasting economic growth or decline which serves as a basis for the population forecasts in the Lower Cook Inlet Analysis is complicated since a previous OCS lease sale is assumed to be a part of the base case forecast. The first generation Lower Cook Inlet lease sale referred to as "Sale **CI**" was held on October 27, 1977. It is further complicated by an assumed North **Kenai** liquefied natural gas (**LNG**) facility construction and operations. This plant is not directly related to OCS lease sales and is assumed to be operating at capacity prior to the flow of Sale 60 gas. However, it is assumed as a part of the overall processing capacity demanded for OCS gas processing.

The incorporation of Sale **CI** into the base case necessitates a **non-OCS** forecast of economy and population as if no OCS development was taking place or would continue in the future and the development of an OCS scenario representative of Sale **CI**. In addition, a scenario representative of the construction and operations of a North **Kenai** LNG facility must be formulated. The **non-OCS** forecast, the sale **CI** forecast and the North **Kenai** LNG facility forecast added together form the base case. The base case is completed prior to portraying the effects of the forthcoming Lower Cook Inlet (and **Shelikof** Strait) OCS Lease Sale Number 60 scenarios upon the **Kenai-Cook** Inlet Census Division and the cities of **Kenai**, **Seldovia** and Homer.

Non-OCS Forecast

The method of forecasting **non-OCS** growth (or decline) which serves as a basis for the forecasts of population is the economic base method. This method stresses the importance of export activity as a determining factor in regional and community economic growth. Regions or cities within a specialized economy must import goods and services to survive. To pay for these imports, these regions or communities must in turn export to other regions. Therefore, a basic sector of regional or **community** activity will be the production of goods and services for export. Another sector (secondary) of regional or community activity which because of convenience and comparative cost will take place within the region or community.

This method is derived from modern theories of international and interregional trade and it makes use of such economic concepts as the multiplier. The method is clearly restricted since among other reasons difficulties are encountered in allocating activities to basic and secondary sectors, external money flows into a region are not generally accounted for and the handling of indirect effects is necessarily unclear. However, the sensitivity to fluctuations of an export base will be greater, the smaller the area. (In populous areas of the nation, the multiplier approximates that of the nation.) Thus, it provides an adequate explanation of economic development in small **communities** where the flow of goods and services within the community is limited.

Although to varying degrees, economic base studies have used units of measure such as jobs, payroll, value added, value of production and dollar income and expenditure accounts, most studies have involved employment as a sole or primary unit of measure. In this study, employment is used as the primary unit of measure and as the basis for forecasting the magnitude of future economic and population growth or decline.

In this economic base forecast, the activities of certain employers are classified as basic (exogenous). This group is composed of employees working in export industries or performing labor based upon fortunes determined by forces outside the city or region. All other employees are classified as secondary (**endogenous**). The fortunes of the employees of these industries are determined by internal forces which are represented by a multiplier linking the export sector to total regional or community employment.

In a simple economic model, secondary employment is shown as a function of total employment

$$Y_s = f(Y_t)$$

and

$$Y_t = Y_s + E$$

where: Y_t = total community or regional employment
 Y_s = total community or regional secondary employment
 E = total community or regional basic employment. This is the sum of all basic employment as arrayed in the

Standard Industrial Classification Manual by following divisions: Agriculture, Forestry and Fishing; Mining; Contract Construction; Manufacturing; Transportation, **Communications** and Public Utilities; Trade; Finance, Insurance and Real Estate; Service; and Government.

Furthermore, this analysis hypothesizes simple homogeneous relationships expressing secondary employment as a constant proportion, k , of total employment

i.e.: $Y_s = kY_t$

so that: $Y_t = \left(\frac{1}{1-k} \right) E = mE$

and so that m , the multiplier, $\frac{1}{1-k} = \frac{1}{1 - \frac{Y_s}{Y_t}} = \frac{Y_t}{E} = \frac{Y_s + E}{E} = 1 + \frac{Y_s}{E}$.

The multiplier is estimated by observing the historic relationship between the activities of the export sector and **total** regional activities. Then given the estimates of the future magnitude of basic employment as foreseen in each SIC division resulting from export activity, the application of the multiplier yields a forecast of total employment as a reflection of total regional or community economic activity. Furthermore, total regional or **community** employment multiplied by a population dependency ratio gained by observing the historic relationship of total employment to total population produces a forecast of total population.

Present Employment Estimates. As a result of research into economic prospects of the State, region and local economies from published materials, a precise definition of the region and the communities to be studied was determined. The region of study is defined as the Kenai-Cook Inlet Census Division. This conforms by definition to the **Kenai-Cook Inlet Labor Area**. The Homer area was defined by the census area of Homer Precinct, Anchor Point, Fritz Creek, Dimond Ridge and Kachemak. And, because of the interrelationship between the communities of the City of Kenai and adjacent areas and the City of **Seldovia** and adjacent areas, these areas were integrated into one area defined by the census areas of **Kenai** Precinct Numbers 1, 2 and 3, Niki shki Precinct Numbers 1 and 2, **Soldotna**, Ridgeway and **Kalifonsky**.

Within these areas of study, informal interviews of employers and other knowledgeable individuals were conducted. From a review of written materials and the interviews, the basis of the present economic activities and the potential for future growth or decline of the **Kenai-Soldotna** and Homer area are assessed. The process of investigation is carried out for each sector of the regional and local economies.

In the less populous Homer area, informal interviews of all employers are conducted. Among the information obtained is the following:

- The number of full-time and part-time salaried employees.
- The number of months worked by the employees.
- The product(s) or services(s) produced or delivered.

- The quantities of product produced by major manufacturers such as fish processing plants.
- The months during which the product is produced.
- The suppliers to the major manufacturing plants such as the number and type of fishing vessels (to estimate the number of jobs in fishing).
- The percent of the firm's business (revenues) resulting from activities (sales) related to firms and individuals outside the region or the local area.
- The plans of the firms regarding expansion or retrenchment which would result in increased or decreased employment.
- The views of the owners or operators of the firm regarding future prospects of their firm and their industry, estimates and timing of major growth or decline in terms of employment and opinions on future **seasonality**.

In the more populous Kenai-Soldotna area, only selected informal interviews are conducted. This sample interviewing together with published and unpublished employment data provided by the Employment Security Division of the Alaska Department of Labor are relied upon to convey information similar to that obtained by interviewing the universe in the Homer area.

Since the **Kenai-Soldotna** and Homer areas are the main components of the **Kenai-Cook** Inlet Census Division, the information collected for these areas coupled with published and unpublished employment data provided by

the Employment Security Division of the Alaska Department of Labor provide the basis of current employment estimates for the **Kenai-Cook Inlet Census Division**. Since the employment information collected for the Homer area is 1979 data, past trends by sector are calculated to project **the** Employment Security Division data from the **last** reporting period in 1977 to 1979. Thus, the average annual full-time employment for the **Kenai-Cook Inlet Census Division**, the **Kenai-Soldotna** area and the Homer area are 1979 estimates or counts.

The employment in each of these geographic areas is then arrayed by major industrial division in conformance with the Office of Management and Budget's Standard Industrial Classification. The SIC Manual defines industries in accordance with the composition and structure of the economy and covers the entire field of economic activity. The following base year data necessary for the forecasting process is produced:

- The distribution of basic and secondary employment by industrial sector.
- The basic, secondary and total employment.
- The employment multiplier.

The 1979 base year average annual full-time employment is provided in Table 1 as an illustration. The multiplier is as follows:

$$\frac{Y_t}{E} = \frac{1621}{922} = 1.7581 \text{ or } 1.76$$

d/ Minor employment in sand and gravel considered with contract construction and transportation.

Source: Alaska Consultants, Inc.

Forecast of Non-OCS Employment. With the significant factors which would affect future growth or decline in the regional or community industries identified and basic employment by industry sector for the base year estimated, basic employment by industry as translated into SIC industry sectors is forecast by industry sector. For example, the following abbreviated assumptions regarding growth in basic employment in percentage form were made for 1980 in the Homer area.

<u>Industrial Classification</u>	<u>1979 Basic Employment</u>	<u>Forecast Growth %</u>	<u>1980 Basic Employment</u>
Agriculture, Forestry and Fishing	392	5	412
Mining	0	0	0
Contract Construction	6	4	
Manufacturing	143	5	15:
Transportation, Communication, and Public Utilities	64	4	67
Trade	115	4	120
Finance, Insurance and Real Estate	24	4	25
Service	53	4	55
Government	125	3	<u>129</u>
Total	922		964

The sum of the basic employment forecasts by industry sector in any given year equals total basic employment in that year. And, since the multiplier is assumed to remain constant over time, the employment multiplier times total basic employment equals total employment. In the Homer area forecast, for example, the following results for 1980:

$$Y_t = m E = 1.76 \times 964 = 1697.$$

Secondary employment is then derived through the following formula:

$$Y_s = Y_t - E = 1697 - 964 = 733.$$

Present Non-OCS Population Estimates. Population in the base year 1979 is derived from a special census of population for the Kenai Peninsula Borough conducted in 1978. Population was enumerated for the **Kenai-Cook** Inlet Census Division which conforms to the area of the employment tabulation or the **Kenai-Cook** Inlet labor area. Similarly, the areas in which the employment was counted or estimated, the **Kenai-Soldotna** area and the Homer area, conform to the precinct areas in the census. The Homer area includes the Homer Precinct (City of Homer), Anchor Point, Fritz Creek, **Dimond** Ridge and **Kachemak**. The **Kenai-Soldotna** area includes **Kenai** Precinct Numbers 1, 2 and 3 (City of **Kenai**), Niki shki Precinct Numbers 1 and 2, **Soldotna** (City of **Soldotna**), Ridgeway and **Kalifonsky**.

A projection of population based upon the rate of growth for these areas between the 1970 Census and the 1978 Census is made for one year so that the present employment estimates and the present population estimates are for the same base year.

The base year **non-OCS** population is then divided by the base year **non-OCS** employment. The product is a dependency ratio for estimating total **non-OCS** population from total **non-OCS** employment in future years. An example of this ratio in the base year for the **Kenai-Cook** Inlet Census Division is:

$$\frac{\text{Estimated 1979 Population}}{\text{Estimated 1979 Employment}} \cdot \frac{23,552}{7,795} = 3.0 \text{ Dependency Ratio}$$

Forecast of Non-OCS Population. The dependency ratio produced by dividing total non-OCS employment into total non-OCS population is employed to forecast total non-OCS population on an annual basis throughout the planning period from 1980 to 2000. Although dependency ratios are subject to change based upon a number of factors, this forecast utilizes a constant dependency ratio throughout the forecast period. There is an exception, the Homer area, where there is an inordinately high dependency ratio of 3.3 persons per employee in the base year. Because of the nature of the activities forecast in the Homer area, it is assumed that the ratio will be closer to the Kenai-Cook Inlet Census Division of which the Homer area is part. Therefore, 3.0 persons per employee was maintained as a constant throughout the forecast period. An example of the application of this ratio in the Homer area in 1980 is as follows:

$$\begin{array}{r} \text{Total} \\ \text{Non-OCS} \\ \text{Employment} \end{array} \times \begin{array}{r} \text{Dependency} \\ \text{Ratio} \end{array} = 1,697 \times 3 = 5,091 \begin{array}{r} \text{Total} \\ \text{Non-OCS} \\ \text{Population} \end{array}$$

Forecast of OCS Lease Sale CI Employment and Population

In order to portray Sale CI as an element in the base case forecast of employment and population, it is necessary to construct a medium find scenario which would result in the production of approximately 402 million barrels of oil and 402 billion cubic feet of unassociated natural gas. It is also necessary to simulate the construction of basic pipelines upon which major elements of the OCS Lease Sale 60 scenarios depend. Sale CI must be incorporated into the base case along with the North Kenai LNG facility scenario prior to portraying the effects of Lease Sale 60.

The production of the Sale CI Medium Find Scenario is similar to the Sale 60 High Find Scenario for Lower Cook Inlet only (not including Shelikof Strait) with the exception of the timing of production which would take place in 1986 rather than 1989, the termination of production which would be in 13 years rather than 15 years and the pipelines required for transportation.

Because of the close relationship between these scenarios, the forecasts of employment and resulting population from Sale CI were modeled from Sale 60. Employment by groups of tasks (see Table A-2) in the Lower Cook Inlet portion of the High Find Scenario of Sale 60 as described in the Alaska OCS Socioeconomic Studies Program Lower Cook Inlet and Shelikof Strait OCS Lease Sale No. 60 Petroleum Development Scenarios prepared by Dames and Moore was used with modifications.

The schedule was adjusted with production beginning in 1986. The period of oil production was shortened from 15 to 13 years. Conversely, the period of gas production was increased from 8 to 10 years. And the pipeline scenarios were altered to accommodate the Lower Cook Inlet oil production scenario in the Sale 60 Medium Find Scenario and the gas production scenario in the Sale 60 High Find.

This scenario to portray the impact of Sale CI upon the **Kenai-Cook** Inlet Labor Area and the communities of Homer, Kenai and **Soldotna** was reviewed by Dames and Moore and deemed to be representative of the Medium Find Scenario for Sale CI.

As in the Sale 60 OCS forecasts, an understanding of pertinent information in the petroleum scenarios such as the size and location of the offshore fields and a forecast of onshore activities such as the general location of facilities and a measure of the quantities and timing involved is necessary.

In regard to onshore impact on the **Kenai-Cook** Inlet coastal area and the communities of Homer, Kenai and **Soldotna** contained within the coastal area, the following information is required for each community on a yearly or, preferably, monthly basis:

- The OCS oil-related facilities to be located there, such as marine service bases, pipe coating plants, helicopter facilities and oil terminals.
- The operating employment in these facilities during the exploration, development and production phases.
- The employment desired is onsite employment which disregards those workers rotated offsite. Onsite employment is used since workers engaged in onshore activities within the **Kenai-Cook** Inlet coastal area would not be rotated if they were resident in the coastal area. Thus, it can be assumed that all onshore employment rotated in this coastal area will leave the area upon rotation.

In regard to onshore impact on the **Kenai-Cook** Inlet coastal area as a result of employment offshore beyond this coastal area, the following information is required for this scenario in each community on an annual basis: -

- The survey vessel employment operating from specific ports performing geophysical and geological surveys.
- The supply/anchor/tug boat employment operating from specific ports during the exploration, development and production phases.
- The rig employment during the exploration phase.
- The platform installation and offshore pipeline employment during the development phase.
- The platform employment during the development and production phases.
- The **offshore-onsite** and the offshore-offsite employment for the above **activities**.

In order to process the employment data by the onshore and offshore categories mentioned, it is first necessary to aggregate onshore and offshore employment by task. The complete array of tasks developed by Dames and Moore is aggregated in Table A-2.

Since the data aggregated by category provides only employment by lease sale area, it is necessary to disaggregate the computer model by task, duration of employment, crew **size** and the number of shifts worked per day to allocate employment to onshore facilities. Also, assumptions must be made as to the offshore areas and activities serviced from the shore based facilities in communities within the lease sale area.

The jobs associated with offshore oil and gas development do not submit easily to the application of a general regional multiplier. There are

extreme differences in employment sectors relating to petroleum development. For example, most construction employment of the magnitude associated with onshore petroleum development will reside in construction camps, work **long** hours (probably 12 hours per day) and be on the job continuously (7 days per week) **until** rotated for leave. Since most of these employees have a permanent residence outside the coastal community under study, most employees will spend their off duty hours outside this community while on leave. Thus, the impact on the local economy from this activity will be small.

On the other hand, transportation employees working at service bases will have considerably greater impact since these people will be **year-**round residents of the community. Thus, for purposes of estimating total employment in each of the communities for the scenario, a series of multiplier values is developed for each employment category.

A study of each employment category **is** then completed and employment assumptions which are reflected in the multiplier values are applied to each category. The assumptions reflected in the multiplier values for each employment category are listed in Table A-3.

With the direct **OCS-related onshore-onsite** employment calculated for each community for each year of the scenario, **total** employment is derived by applying the multiplier values (see Table A-4) to the direct (basic) employment in the task groups (see Table A-2) and totaling the product of the group. The total OCS onshore employment by location provides the

TABLE A-3

EMPLOYMENT ASSUMPTIONS REFLECTED IN MULTIPLIER VALUES
MEDIUM FIND SCENARIO - SALE CI
KENAI-COOK INLET COASTAL AREA

ONSHORE - WITHIN KENAI-COOK INLET COASTAL AREA

Service Base. With minor **exceptions**, while providing support to offshore platform installation and commissioning and pipelaying and burying, all service base employees working within the **Kenai-Cook** Inlet coastal area will be permanent employees resident **in** the **Kenai-Cook** Inlet coastal area.

Helicopter Service. During the exploration phase a number of the helicopter pilots, mechanics and operations personnel will be permanent residents of the **Kenai-Cook** Inlet coastal area, **Oil** activity in Cook Inlet during the past two decades has resulted in the development of a basic local helicopter service operation and work force. However, it is estimated that a portion of this work force will be rotated between the **Kenai-Cook** Inlet coastal area and employees' permanent residences outside this region. Although long-term employment in helicopter service will be assured with entry into the development phase, it is assumed that a portion of this work force required to meet the peak demands during the development phase will rotate out of the coastal area to their permanent residences. However, during the development phase the helicopter service work force is seen as permanent employees resident in the coastal area. For some employees this could involve an extended rotation pattern enabling the location of employees and their families in the **Kenai-Cook** Inlet coastal area.

Onshore Pipeline Construction. Onshore oil pipeline construction employees are assumed to be temporary employees housed in construction camps. These camps are assumed to contain a wide range of amenities for comfortable living. Thus, the excellent camps coupled with limited leisure time and scheduled rotation for employees are assumed to minimize impacts in the **Kenai-Cook** Inlet coastal area.

Pipe Coating. Employees engaged in the coating of pipe for emplacement offshore are assumed to be temporary employees housed in a construction camp with periodic rotation outside the **Kenai-Cook** Inlet coastal area to their permanent places of residence. These construction employees will be housed in small construction camps offering reasonable amenities. Therefore, although their impact within the **Kenai-Cook** Inlet coastal area will be limited, it is assumed that the per construction employee impact will be greater than a major construction project such as onshore pipeline.

OFFSHORE

Survey. Offshore crews of vessels engaged in geophysical and geological surveying are assumed to be composed of transient workers. These vessels will travel into the **Lower Cook Inlet** Sale CI lease sale area during a portion of the year to carry out their investigations. No offshore survey employees are assumed to be employed or to be resident in the **Kenai-Cook** Inlet coastal area despite their activities on the Outer Continental Shelf beyond the coastal area and occasional visits to service bases. Therefore, the direct and indirect impact of this employment upon the coastal area is assumed to be negligible.

Rigs. Offshore rig crews engaged in exploration **drilling** are assumed to be **compased** for the most part of transient workers who are rotated through the **Kenai-Cook** Inlet coastal area. Only a small percentage (10 percent) of the offshore **rig** employment is assumed to be resident **in** the coastal area. Therefore, the **direct** and indirect **impact** of rig employees upon the **Kenai-Cook Inlet** coastal area is assumed to be reasonably small.

Platforms. Although a large part of offshore employment **during** the development phase is assumed to be composed of transient workers who are rotated through the **Kenai-Cook** Inlet coastal area to their permanent residences outside the coastal area, it is assumed 30 percent of those employees engaged in development drilling **will** elect to reside within the **Kenai-Cook** Inlet coastal area.

During the production phase, it is estimated that approximately 70 percent of those employees engaged in platform operations **will** elect to reside in the coastal area.

Therefore, there will **be** a substantial direct and indirect impact in **the Kenai-Cook Inlet** coastal area based upon those employees electing to reside there. The **impact** of the remaining transient employees is deemed to be negligible.

Supply/Anchor/Tug Boats. **During** the exploration phase offshore boat crews are assumed to be in large part composed of transient workers who are rotated through the **Kenai-Cook** Inlet coastal area to their permanent residences outside the coastal area. It is assumed that only **20** percent of the **total** boat crew employment **will** reside in the coastal area. During the development phase, a greater percentage of the total boat crew employment (30 percent) will be composed of employees resident in the **Kenai-Cook Inlet** coastal area, while during the production phase the great majority (80 percent) are assumed to reside in the **Kenai-Cook Inlet** coastal area. Therefore, there will be a direct and indirect impact in the coastal area based upon the employees electing to reside there. The impact of the remaining transient employees is deemed to be negligible.

Platform Installation and Offshore Pipeline Construction. The offshore crews engaged in platform installation and pipeline construction which takes place during the development phase are assumed to be largely transient workers who are rotated through the **Kenai-Cook** Inlet coastal area to their permanent residences outside the coastal area. A small number of offshore platform installation and pipeline construction employees (10 percent) are assumed to be employed or be resident within the **Kenai-Cook Inlet** coastal area. Therefore, the direct and indirect of these offshore activities upon the coastal area is assumed to be relatively small.

Source: Alaska Consultants, Inc. June 1979.

basis for the onshore **OCS-related** population within the area of location. Onshore employees are assumed to reside within the **Kenai-Soldotna** area or the Homer area depending upon the location of onshore facilities.

On the other hand, the necessity of rotating offshore OCS employees provides these employees with a greater latitude in the location of their permanent residences. Within limits, the principal requirement for the ultimate location of these employees is an airport. During the exploration phase it is assumed that most offshore employment will be provided from outside the **Kenai-Cook** Inlet Census Division or, conversely, the number of employees resident in the area of study will be proportionally low. However, resident employment is assumed to increase during the development phase and during the production phase most offshore OCS employment is assumed to be resident in the **Kenai-Cook** Inlet Census Division (see Table A-4). Within the **Kenai-Cook** Inlet Census Division, it is assumed that half of the offshore OCS employees will elect to reside in the Southern Peninsula Area (Homer area) and half in the Central Peninsula Area (Kenai-Soldotna area).

Thus, total offshore OCS employment derived by multiplying each task group by its rotation factor is multiplied by the percentage assumed to reside within the **Kenai-Cook** Inlet Census Division. The total number of direct offshore OCS employees assumed to reside within the study area is then apportioned with one half assumed to reside in the Homer area and one half assumed to reside in the **Kenai-Soldotna** area. The multiplier (see Table A-4) which is common to all direct offshore OCS employment is

applied to total direct offshore employment assumed to reside in either the Homer area or the Kenai-Soldotna area to derive total offshore OCS-related employment in these areas.

The OCS-related employees in terms of dependent family members and unrelated individuals are assumed to exhibit a dependency ratio closer to national averages rather than the high dependency ratio of the Kenai-Cook Inlet Census Division. Therefore, a dependency ratio of 2.5 persons per employee is assumed for all OCS-related employees. Thus, the dependency ratio is applied to total onshore OCS-related employment by area and total offshore OCS-related employment by area to produce total OCS-related population in the Homer and Kenai-Soldotna areas.

Forecast of an Additional North Kenai LNG Facility Employment and Population

Since the gas processing capacity of an additional North Kenai LNG facility is assumed as part of the total capacity available for the processing of natural gas critical to the OCS high find scenario, a scenario is developed for its inclusion in the base case. Although the construction of this facility is not premised upon Sale 60 OCS finds, it is assumed that by the time Sale 60 OCS gas is produced, enough capacity will exist among the North Kenai plants to process the gas without further major additions in plant capacity. This particular plant proposed by Pacific Alaska LNG Company is assumed to have a capacity of 400 million cubic feet per day.

The plant is seen utilizing gas reserves from existing fields which are shut in and from future onshore and offshore fields brought into production by more intensive exploration and development in the Cook Inlet area as well as possible Sale CI purchases. Since it is assumed that the supply of natural gas to this facility is not dependent upon major finds of the Pacific Alaska LNG Company's making, the offshore and onshore employment which would be included in developing the major reserves or transporting them to the plant are not included in this scenario. The employment forecast to be required in making gas available for this plant is included as a part of the non-OCS employment forecast where onshore and offshore reserves of upper Cook Inlet are utilized or OCS employment in the case of Sale CI.

The timing and direct employment required in the construction and operation of this facility were obtained from the Institute of Social and Economic Research, University of Alaska. These were used by ISER in the Lower Cook Inlet State-wide and Regional Population and Economic Projections.

Construction is forecast to begin during 1980 and conclude with a finished plant during 1983. The following direct onshore construction employment and schedule is assumed:

1980	146
1981	844
1982	1,323
1983	400

Production is assumed to begin in 1984 and continue through the life of the forecast period. This activity is assumed to directly employ an average of 60 persons per year in onshore LNG **plant** operations. No other direct employment is included in this scenario.

The impacts in the North **Kenai** LNG facility scenario are assumed to affect the **Kenai-Soldotna** area only. Thus, population increases are seen **occurring** in the City of Kenai, City of Soldotna, and the remaining areas outside these cities.

The direct construction **workforce** is seen to be composed almost exclusively of transient workers who are rotated through the Kenai-Cook **Inlet** Census Division to their permanent residences outside this area. Furthermore, these employees are assumed to reside in a construction camp on the site of the LNG plant. Such a camp is seen to contain 'a wide range of amenities for comfortable living and this, coupled with limited leisure time and scheduled rotation for employees, is assumed to minimize impacts in the **Kenai-Soldotna** area. Thus, a low multiplier of **1.10** is assumed during the construction of the North Kenai LNG plant.

On the other hand, all of the LNG plant operations employees are assumed to be **permanent** employees whose permanent residences are reasoned to be **close** to the plant. Therefore, **all** LNG **plant** operations employees are forecast to 'live within the **Kenai-Soldotna** area. Since these employees are provided long-term, stable employment, the multiplier is assumed to be 1.50.

The multiplier values are then applied to each employment category to produce total employment for each category. The sum of the total employment for each category equals total employment (basic and secondary employment for all categories). Total employment minus basic employment provides secondary employment.

As in the other cases, total population is derived by the application of a dependency ratio. It is assumed that the dependency ratio for this North **Kenai LNG** plant scenario will be similar to the ratio in the petroleum related OCS Sale CI scenario since the employees are assumed to be largely oil industry related employees who will migrate to the area from outside the **Kenai-Cook Inlet** Census Division. Thus, a ratio of 2.5 persons per employee is assumed rather than the existing **Kenai-Cook Inlet** Census Division ratio of 3.0 persons per employee. This ratio is applied to all permanent employment. Where direct onshore construction employment is involved, this is added to the population without application of the dependency ratio.

The resulting population is forecast to reside only in the **Kenai-Soldotna** area. Population is also assumed to be distributed on an historical basis as the Sale CI distribution with the City of **Kenai** receiving 30 percent, the City of **Soldotna** 20 percent and the remaining area outside these two incorporated cities, 50 percent. However, the population (direct employment) living at the LNG plant construction camp site is assigned to North Kenai or the remaining area outside the cities of **Kenai** and **Soldotna**.

Base Case Population Forecast

The base case population forecast for the **Kenai-Cook Inlet** Census Division is derived by adding the **non-OCS** population estimate in a given year to the **Sale CI offshore OCS-related, Sale CI onshore OCS-related** and LNG facility related populations in the same year. Similarly, the base case population for the **Kenai-Soldotna** area is derived by adding the **non-OCS** population estimates in a given year to the **Sale CI offshore OCS-related, Sale CI onshore OCS-related** and LNG facility related populations in the same year. Since the resident population associated with the North **Kenai** LNG facility is assumed to be located in the **Kenai-Soldotna** area, the base case population for Homer is derived by adding the **non-OCS** population estimates in a given year to the **Sale CI offshore OCS-related** and **Sale CI onshore OCS related** population in the same year. The populations allocated in the **Kenai-Soldotna** area to the City of **Kenai**, City of **Soldotna** and the remaining **Kenai-Soldotna** area and in the Homer area to the City of Homer and the remaining Homer area are derived in a similar manner.

Forecast of OCS Lease Sale 60 Employment and Population

The OCS petroleum scenarios (or cases) which form the basis of the socioeconomic impact assessment were selected by the U.S. Bureau of Land Management and developed by Dames and Moore from U.S. Geological Survey resource estimates. The cases are as follows:

- High Find Scenario
- Medium Find Scenario

- The employment desired is **onsite** employment which disregards those workers rotated offsite. **Onsite** employment is used since workers engaged in onshore activities within the **Kenai-Cook Inlet** coastal area **would** not be rotated if they were resident in the coastal area. Thus, **it** can be assumed that all onshore employment rotated in this coastal area **will** leave the area upon rotation.

In regard to onshore impact on the **Kenai-Cook Inlet** coastal area as a result of onshore employment located outside the **Kenai-Cook Inlet** coastal area, the **following** information is required for each scenario on an annual basis:

- The oil related facilities to be located there, such as marine service bases and oil terminals.
- The employment required to construct these facilities.
- The operating employment in these facilities during the phases operated.
- The employment desired is total employment which includes onsite employment and **offsite** employment. Total employment is used in this case since no workers are assumed to be resident in the Lower Cook Inlet and **Shelikof** Strait lease sale area outside the **Kenai-Cook Inlet** coastal area. Also, all workers are assumed to be initially rotated to a point within the **Kenai-Cook Inlet** coastal area.

In regard to onshore impact on the Kenai-Cook Inlet coastal area as a result of employment offshore beyond this coastal area, the following information is required for each scenario in each community on an annual basis:

- Survey vessel employment operating from specific ports performing geophysical and geological surveys.
- Supply/anchor/tug boat employment operating from specific ports during the exploration, development and production phases.
- Rig employment during the exploration phase.
- Platform installation and offshore pipeline employment during the development phase.
- Platform employment during the development and production phases.
- Offshore-on-site and the offshore-off-site employment for the above activities.

In order to process employment data by the onshore and offshore categories mentioned, it is first necessary to aggregate onshore and offshore employment by task. The complete array of tasks developed by Dames and Moore is aggregated in Table A-2.

Since the data aggregated by category provides only employment by lease sale area for each scenario, it is necessary to disaggregate the computer model by task, duration of employment, crew size and the number of shifts worked per day to allocate employment to onshore facilities. In

the case of construction employment and operating employment in LNG plants and oil terminals, scaling factors developed for the model must be employed. Also, assumptions must be made as to the offshore areas and activities serviced from the shore based facilities in communities within each lease sale area for each scenario.

A simple example from the exploration only scenario developed by Dames and Moore is provided for onsite employment at service bases during year 1 of the scenario or 1982 as follows: (All references to page or table numbers refer to Alaska OCS Socioeconomic Studies Program, Lower Cook Inlet and Shelikof Strait Lease Sale No. 60, Petroleum Development Scenarios, Dames and Moore, March 1979).

- Step 1. Identify onshore manpower requirements.
Refer to Table 4-4, p. 68
- Step 2. Select activity 1 and identify.
Refer to List of Tables, Table 4-4 (Attachment), p. 69.
Activity 1 - Service Bases.
- Step 3. Convert yearly manpower requirements by activity onsite from man months to man years.
Refer to Table 4-4, p. 68. Year 1 (1982), Activity 1 (Service Bases).
Divide man months by 12. $303 \div 12 = 25$ man years.
- Step 4. Investigate assumed locations of service bases.
Refer to p. 65.

Principal service base at **Nikiski (Kenai-Soldotna area)**.

Advance service base at Homer (Homer area).

step 5. **Make** assumptions as to the type of activity and the amount of activity that will take **place** at each facility.

Assumed for Homer: all survey vessel support, one-third rig support.

Assumed for **Nikiski**: two-thirds rig support.

Note: Rig support includes support for supply/anchor vessels attending rigs.

Step 6. Determine **onshore-onsite** employment by task at service bases during exploration.

Refer to Appendix **D-16**, Table 4.

6 **onshore-onsite** employees directly supporting a rig.

2 **onshore-onsite** employees directly supporting an supply/anchor boat.

2 **onshore-onsite** employees directly supporting a survey vessel.

Step 7. Investigate footnote regarding unit of analysis for use in the calculation of employment by task for survey vessels since these must be allocated exclusively to the Homer area.

Refer to footnote 2, Appendix 18.

Indicates scenario specific values are employed. Also, "Additional notes on next page."

Refer to p. 70 not next page. Check Task 2.

Approximately 1 month of geophysical work per well.

2 **onshore-onsite** at service base.

- Step 8. Determine the number of exploration wells.
Refer to Table 4-1, p. 64.
7 wells drilled during year 1 (1982).
- Step 9. Determine the amount of survey vessel work.
Refer to Table 4-1, p. 64.
1 month per well x 7 wells drilled = 7 months survey vessel work.
- Step 10. Calculate employment based upon a 12 month year.
 $7/12 \times 2 = 1.167$ or 1 service vessel support employee at Homer service base.
- Step 11. Allocate remaining service base employees.
 $24 \times 2/3 = 16$ Total service base employment at Nikiski.
 $24 \times 1/3 = 8$ Employment support for rigs and supply/anchor boats at Homer.
- Step 12. Calculate total service base employment.
 $8 + 1 = 9$ Total service base employment at Homer
16 Total service base employment at Nikiski.
25 Total service base employment for exploration only scenario Sale 60 during year 1 (1982).

As in Sale CI, the jobs associated with offshore oil and gas development in Sale 60 do not submit easily to the application of a general regional multiplier. There are extreme differences in employment sectors relating to petroleum development. Thus, for purposes of estimating total employment in the Kenai-Soldotna and Homer area for each of the scenarios, a series of multiplier values is developed for each employment category.

A study of each employment category is then completed and employment assumptions which are reflected in the multiplier values are applied to each category. The assumptions reflected in the multiplier values for these employment categories are listed in Table A-5.

With the direct **OCS-related onshore-onsite** employment within the **Kenai-Cook Inlet** coastal area calculated for the **Kenai-Soldotna** area and the Homer area for each year of the scenario, total employment (basic and secondary) is derived by applying the multiplier values (see Table A-6) to the direct (basic) employment derived in the task groups (see Table A-2) and totaling the product of the group. The total OCS onshore employment by location provides the basis for the onshore **OCS-related** population within the area of onshore facilities location. Onshore employees within the **Kenai-Cook Inlet** coastal area are assumed to reside within the **Kenai-Soldotna** area or the Homer area depending upon the location of onshore facilities.

On the other hand, the necessity of rotating offshore **OCS** employees and onshore OCS employees located outside the **Kenai-Cook Inlet** coastal area such as those on Afognak Island, provides these employees with greater latitude in the location of their permanent residences. Within limits, the principal requirement for the ultimate location of these employees is an airport. For purposes of clarity, the onshore **OCS** employees located outside the **Kenai-Cook Inlet** coastal area are assumed as a part of the offshore OCS employment since the process of deriving and distributing employment is identical.

TABLE A-5

EMPLOYMENT ASSUMPTIONS REFLECTED IN MULTIPLIER VALUES
KENAI-COOK INLET COASTAL AREA
LOWER COOK INLET - SALE 60

ONSHORE - WITHIN KENAI-COOK INLET COASTAL AREA

Service Base. With **minor** exceptions, while providing support to offshore platform installation and commissioning and pipelaying and burying, all service base employees working within the **Kenai-Cook Inlet** coastal area **will** be permanent employees resident in the **Kenai-Cook Inlet** coastal area.

Helicopter Service. During the exploration phase a number of the **helicopter pilots**, mechanics and operations personnel will be permanent residents of the **Kenai-Cook Inlet** coastal area. Oil activity in Cook Inlet during the past two decades **has** resulted in the development of a basic local helicopter service operation and work force. However, it is estimated that a portion of this work force will be rotated between the **Kenai-Cook Inlet** coastal area and employees' permanent residences outside this region. Although long-term employment in helicopter service **will** be assured with entry into the development phase, it is assumed that a portion of this work force required to meet the peak demands during the development phase will rotate out of the coastal area to their permanent residences. However, during the development phase the helicopter service work force is seen as permanent employees resident in the coastal area. For some employees this **could** involve an extended rotation pattern enabling the location of employees and their families in the **Kenai-Cook Inlet** coastal area.

Onshore Pipeline Construction. Onshore oil pipeline construction employees are assumed to **be** temporary employees housed in construction camps. These camps are assumed to contain a wide range of amenities for comfortable living. Thus, the excellent camps coupled with limited leisure time and scheduled rotation for employees are assumed to minimize impacts in the **Kenai-Cook Inlet** coastal area.

Pipe Coating. Employees engaged in the coating of pipe for emplacement offshore are assumed to be temporary employees housed in a construction camp with periodic rotation outside the **Kenai-Cook Inlet** coastal area to their permanent places of residence. These construction employees will be housed in small construction camps offering reasonable amenities. Therefore, although their impact within the **Kenai-Cook Inlet** coastal area **will** be limited, it is assumed that the per construction employee impact will be greater than a major construction project such as onshore pipeline.

ONSHORE - OUTSIDE THE KENAI-COOK INLET COASTAL AREA

Service Base. A large proportion of the service base employees located at the Afognak Island service base will be permanent residents in the Kenai-Cook Inlet coastal area. These employees will be rotated from or through the Kenai-Cook Inlet coastal area to the service base site on Afognak Island.

Service Base Construction. Employees engaged in service base construction on Afognak Island are assumed to be temporary employees housed in a construction camp with periodic rotation mostly through the Kenai-Cook Inlet coastal area to their permanent places of residence. Therefore, the impact upon the Kenai-Cook Inlet coastal area will be limited.

Oil Terminal and Onshore Pipeline Construction. Onshore oil pipeline construction will take place in conjunction with oil terminal construction of Afognak Island. Also, since the onshore oil pipeline which terminates at the oil terminal is accessible from the oil terminal construction camp, pipeline construction employees will be considered with oil terminal construction employment and reside in the oil terminal site construction camp.

The employees engaged in these construction activities on Afognak Island are assumed to be temporary employees who are periodically rotated mostly through the Kenai-Cook Inlet coastal area to their permanent places of residence. Therefore, the impact upon the Kenai-Cook Inlet coastal area will be limited.

Oil Terminal Operations. A large portion of the oil terminal employees located at the Afognak Island oil terminal will be permanent residents of the Kenai-Cook Inlet coastal area. These employees will be rotated from or through the Kenai-Cook Inlet coastal area to the oil terminal site on Afognak Island.

OFFSHORE

Survey. Offshore crews of vessels engaged in geophysical and geological surveying are assumed to be composed of transient workers. These vessels will travel into the Lower Cook Inlet Sale CI lease sale area during a portion of the year to carry out their investigations. No offshore survey employees are assumed to be employed or to be resident in the Kenai-Cook Inlet coastal area despite their activities on the Outer Continental Shelf beyond the coastal area and occasional visits to service bases. Therefore, the direct and indirect impact of this employment upon the coastal area is assumed to be negligible.

Rigs. Offshore rig crews engaged in exploration drilling are assumed to be composed for the most part of transient workers who are rotated through the Kenai-Cook Inlet coastal area. Only a small percentage (10 percent) of the offshore rig employment is

assumed to be resident in the coastal area. Therefore, the direct and indirect impact of rig employees upon the Kenai-Cook Inlet coastal area is assumed to be reasonably small.

Platforms. Although a large part of offshore employment during the development phase is assumed to be composed of transient workers who are rotated through the Kenai-Cook Inlet coastal area to their permanent residences outside the coastal area, it is assumed 30 percent of those employees engaged in development drilling will elect to reside within the Kenai-Cook Inlet coastal area.

During the production phase, it is estimated that approximately 70 percent of those employees engaged in platform operations will elect to reside in the coastal area.

Therefore, there will be a substantial direct and indirect impact in the Kenai-Cook Inlet coastal area based upon those employees electing to reside there. The impact of the remaining transient employees is deemed to be negligible.

Supply/Anchor/Tug Boats. During the exploration phase offshore boat crews are assumed to be in large part composed of transient workers who are rotated through the Kenai-Cook Inlet coastal area to their permanent residences outside the coastal area. It is assumed that only 20 percent of the total boat crew employment will reside in the coastal area. During the development phase, a greater percentage of the total boat crew employment (30 percent) will be composed of employees resident in the Kenai-Cook Inlet coastal area, while during the production phase the great majority (80 percent) are assumed to reside in the Kenai-Cook Inlet coastal area. Therefore, there will be a direct and indirect impact in the coastal area based upon the employees electing to reside there. The impact of the remaining transient employees is deemed to be negligible.

Platform Installation and Offshore Pipeline Construction. The offshore crews engaged in platform installation and pipeline construction which takes place during the development phase are assumed to be largely transient workers who are rotated through the Kenai-Cook Inlet coastal area to their permanent residences outside the coastal area. A small number of offshore platform installation and pipeline construction employees (10 percent) are assumed to be employed or be resident within the Kenai-Cook Inlet coastal area. Therefore, the direct and indirect of these offshore activities upon the coastal area is assumed to be relatively small.

Source: Alaska Consultants, Inc. June 1979.

During the exploration phase, it is assumed that most offshore employment will be provided from outside the **Kenai-Cook** Inlet Census Division or, conversely, the number of employees resident in the area of study will be proportionally low. However, resident employment is assumed to increase during the development phase and, during the production phase, most offshore OCS employment is assumed to be resident in the **Kenai-Cook** Inlet Census Division (see Table A-6). Within the **Kenai-Cook** Inlet Census Division, it is assumed that **half** of the offshore **OCS** employees will elect to reside in the Southern Peninsula Area (Homer area) and half in the Central Peninsula Area (Kenai-Soldotna area).

Thus, total direct offshore OCS employment derived by multiplying each task group by its rotation factor is multiplied by the percentage assumed to reside within the **Kenai-Cook** Inlet Census Division. The **total** number of direct offshore OCS employees assumed to reside within the study area is then apportioned with one half assumed to reside in the Homer area and one half assumed to reside in the **Kenai-Soldotna** area. The multiplier (see Table A-6) which is common to all direct offshore OCS employment is applied **to total** direct offshore employment assumed to reside **in** either the Homer or **Kenai-Soldotna** areas to derive total offshore **OCS-related** employment in these areas.

The **OCS-related** employees in terms of dependent family members and **unrelated individuals** are assumed to exhibit a dependency **ratio closer to** national averages rather than the high dependency ratio of the **Kenai-Cook** Inlet Census Division. Therefore, a dependency ratio of 2.5

- a/ The coastal area is assumed to be the **Kenai-Cook** Inlet Labor Area. This area does not include any portion of the Lower Cook Inlet and **Shelikof** Strait OCS lease sale area (Sale 60) which is in Federal waters.
- b/ The employment multiplier values are applied to the direct **onshore-onsite** employment in the coastal area.
- c/ The employment multiplier values are applied only to the estimated portion of total onshore employment outside the **Kenai-Cook** Inlet coastal area which is resident in the **Kenai-Cook** Inlet coastal area.
- d/ The employment multiplier values are applied only to the estimated portion of total offshore employment resident in the **Kenai-Cook** Inlet coastal area.
-

Source: Alaska Consultants, Inc. June 1979.

persons per employee is assumed for **all OCS-related** employees. The dependency ratio is applied to total employment resulting from offshore OCS activities in the **Kenai-Soldotna** and the Homer areas to obtain population added here as a **result** of offshore OCS activities. The same ratio is applied to all permanent employment resulting from onshore OCS activities within the **Kenai-Soldotna** area and the Homer area. However, where direct onshore construction employment is involved, this population (direct employment) is added without application of **the** dependency ratio.

The allocation of population is closely tied **to historical** distribution patterns. In the **Kenai-Soldotna** area 30 percent is allocated **to** the City of Kenai, 20 percent to the City of **Soldotna** and 50 percent to the remaining area outside these incorporated cities. In the Homer area, 50 percent is allocated to the City of Homer and 50 percent to the remaining **area**. However, the population (direct employment) at construction camp sites is not distributed but rather assigned to the area within which the site is located.

The population for the various **lease Sale 60** scenarios is then added to the base case in the forecast years of 1982 - 2000 to produce forecasts of population which include Sale 60 **OCS** activity during the exploration only scenario, medium find scenario and high find scenario.

The extent of the impact upon the **Kenai-Cook Inlet** Census Division and the cities of Kenai, Homer and **Soldotna** is then elicited by comparing

the base case forecasts of population with the population forecasts which include the OCS Sale 60 cases.

LAND

The major uses of land required in the existing **communities** under study as a **result** of growth are lands in public (principally rights-of-way, parks and recreation areas), industrial and residential **1** uses. The future demand for other public, commercial and semi-public land uses will be comparatively minor.

In the **communities** where land uses have recently been quantified, land availability and suitability will be equated against estimates of future total land use requirements. **In communities where** existing land use has not already been quantified, rough estimates **will** be developed for land capability and the lands required to be added in major public, industrial and residential uses. **Minor** public, commercial and semi-public uses are estimated as a percentage of the lands in residential and industrial use where relevant, based upon land uses in communities of comparable **size** and industrial mix.

In forecasting the use of residential land, the following factors are assumed:

- The new residents forecast **will** desire **to** reside within the cities of Kenai, Homer and **Soldotna** or within the unincorporated areas around these communities.

- The types of housing desired by the new population will approximate current usage in the communities under study.
- Although some **infilling** may occur, most development will occur on virgin land or on land suitable for residential development of size.
- The development or redevelopment of the land **will** adhere roughly to present standards established in zoning ordinances for the respective communities.
- It is assumed that the development of raw land and the redevelopment of land for residential purposes will result in approximately 28 percent of the gross land area being devoted to street rights-of-way (Simpson, Usher, Jones, Inc., June 1977).
- An average right-of-way width will be established based upon current standards in the zoning ordinances applicable to the respective communities.
- The lineal footage of sewer and water lines is roughly equivalent to the lineal footage of the street rights-of-way. (Simpson, Usher, Jones, Inc., June 1977).

To estimate the amount of land required for residential use in the future, a density of development for one and two family units, multi family units and mobile homes must be derived from the zoning ordinances applicable to each **community**.

Using .4 hectares or 1 acre of land as a common measure, 28 percent (1,333.1 square meters or 12,197 square feet) would be in rights-of-way. Thus, the remaining 72 percent (2,913.6 square meters or 31,363 square feet) would be available for residential use.

The method of calculating the amount of land required is as follows:

- o One acre minus **28** percent in street rights-of-way provides the developable land per acre.
- o The developable land per acre divided by the minimum lot size allowable as per the locally applicable zoning ordinance provides the number of lots per acre allowable.
- o The number of lots allowable times the maximum allowable housing units per lot provides the number of housing units which can be accommodated on an acre.
- The number of housing units forecast to be added divided by the maximum allowable housing units per acre provides the number of acres required to accommodate the housing units and street rights-of-way forecast to be added throughout the planning period.
- o The number of acres required multiplied by 72 percent provides a gross forecast of residential land required to accommodate the housing units forecast to be added.
- The number of acres required multiplied by 28 percent provides a gross forecast of lands needed for street rights-of-way.

Once the land requirements **for** one and two family, multi family and mobile homes have been determined, these quantities are aggregated to produce a gross forecast of residential and street rights-of-way land needs.

The remaining uses which place heavy demands upon a community are public lands in park and recreation use and industrial lands. Major industrial land requirements **will** be estimated based upon the Impact Analysis of the Fishing Industry by the University of Alaska's Sea Grant Program and the Petroleum Development Scenarios prepared by Dames and Moore. **The** future requirements for parks and recreation **lands** are specified in the recreation standards elsewhere in this appendix.

The **total** of lands in the major public uses of **parks**, recreation and street rights-of-way plus the land requirements for housing and industrial uses and, to a lesser extent, minor public, commercial and semi-public uses are used to assess the pressures on developable land within the communities under study.

HOUSING

A distinction is made in the forecast of populations to be housed onshore in the future. Total forecast population is divided into households (i.e. a mix of family and unrelated individual households) and those **living** in group quarters (i.e. the number of people living in bunkhouses, construction camps, military compounds and other group

circumstances). The population forecast to be living in households is divided **by** the estimated **family size** (the average number of persons per unit) to produce the total number of housing units forecast to satisfy household demands. A subtraction of units in the base year from units forecast in a succeeding year produces the yearly requirement of new housing units.

The number of structures is of little relevance in group housing. The building of group housing is generally assumed by the employer and is most often modular construction. Therefore, group housing is shown as places for persons which is equivalent to group housing population. A subtraction of the number of persons in group housing in the base year from the number of persons forecast to be living in group housing the **succeeding** year produces the yearly requirement for new places to be **provided** in group housing.

Group housing has resulted in large part from the **seasonality** inherent in the past exploitation of fishery resources. However, recent trends in the fishing and fish processing industry have been toward a **year-round** fishery. The fishing industry which processed essentially only salmon during the summer season has since added king crab, tanner crab and other fisheries products resulting in fishing **and** fish processing being a more yearround enterprise. It is assumed that the addition of **bottomfish** will serve further to abate the **seasonality** in this industry since it is essentially a yearround fishery requiring a permanent **year-round** resident labor force. Thus, it is assumed that with reduced

seasonal variations in the demand for labor, increased group quarters of a permanent nature **will** not be needed or desired in the **non-OCS** case.

In order to obtain an indication of land requirements, the number of housing units forecast are estimated as to one and two family units, multifamily units and mobile homes. It is assumed that the relative proportion as measured in the most recent inventory **or** estimate on types of housing units for a **given** community will be maintained throughout the planning period.

The forecast of housing to accommodate persons added as a result of OCS oil and gas activities will utilize the same methodology employed for the **non-OCS case**. However, an important assumption in the **OCS** cases is that the construction employees engaged in building or fabricating major OCS facilities onshore will be housed onsite in construction camps throughout the period of construction.

COMMUNITY FACILITIES AND SERVICES

A series of assumptions has been made and standards developed for assessing future needs for a range of community facilities and services in the communities under study in both the **non-OCS** and OCS cases. These assumptions and standards and the methodology employed in forecasting are contained in the following pages.

Public Safety

Police. The following basic assumptions have been made for police protection:

- Police protection services will continue to be provided by the cities of Kenai, Homer and **Soldotna** for areas within their corporate limits.
- Law enforcement in the road-connected areas outside these communities will continue to be provided by State troopers.

To arrive at reasonable standards for police protection, commonly used nationwide standards for the number of law enforcement officers and jail **cells** needed to serve a given number of people were obtained. These standards were then reviewed in relation to existing conditions in the **communities** under study and special situations in the communities were noted.

Nationwide, the desired ratio of law enforcement officers to population is one for every 500 people: According to the Alaska Department of Public Safety, when a community reaches a size where it becomes desirable to have an officer on duty 24 hours per day, 7 days per week, a minimum of 6 officers (mathematically, 5.75) must be hired when factors such as annual leave, sick leave and others are taken into account. A similar situation exists with support personnel.

According to the Alaska Department of Public Safety, a commonly used standard for jail cells is one for every 500 people. However, since State law requires that male, female and juvenile offenders be separated during incarceration, a minimum sized jail in Alaska should have at least three cells.

A review of existing jail conditions in the under study indicates that Kenai, Homer and **Soldotna** exceed national standards, while **Soldotna**, which does not maintain its own jail facility, has the use of Kenai's jail, as needed. Kenai, Homer and **Soldotna** have more police officers than would ordinarily be considered necessary. Additional officers are needed to provide police protection services to these communities' large transient populations composed in large part of summer tourists and transient fishing boat crews. Nevertheless, despite the larger than normal complement of police personnel in these communities, the number of jail cells provided is generally consistent with national standards.

On the basis of the foregoing, the following standards were derived for policemen and jail cells in the **non-OCS** case:

- The existing relationships between population and the number of police officers in the cities of **Kenai**, Homer and **Soldotna** is assumed as the base from which forecasts are made with an additional officer to be required for each successive growth of 500 population.
- One jail cell for every 500 people.

In the various OCS" cases, offshore personnel are assumed not to have a significant impact on local law enforcement requirements as it is assumed that these people will be shuttled directly in and out of the region with essentially no layover time. However, all onshore personnel, including construction crews in camps, are assumed to have an impact on local protection capabilities comparable to the **non-OCS** case, i.e. one additional officer and one additional jail **cell** for each successive **growth of** 500 persons.

Fire Protection. Fire protection is a normal responsibility of Alaska cities and one which is exercised by the communities under study. In addition, unincorporated areas may form volunteer fire departments while, if they are within organized boroughs, they may elect to have this service provided by the borough on a service area basis. The cities of **Kenai**, Homer and **Soldotna** have their own fire protection capabilities and the unincorporated North Kenai has established a volunteer fire department.

The **State** has no established qualitative fire protection standards except that an individual fire department must be registered with the Division of Fire Prevention to be eligible to receive State revenue sharing funds for firefighting purposes. However, the Insurance Services Office, on behalf of fire insurance companies and as an aid to the underwriting of fire insurance premiums, publishes comprehensive fire protection guidelines to enable the classification of communities throughout the United States in relation to the adequacy of their fire

defenses and their physical characteristics. Based upon the extent to which local fire departments **meet these** standards, individual communities are graded on a class 1 (best) to a class 10 (worst) scale and local insurance rates are adjusted to reflect these differences in fire protection capability. Present ratings for the **communities** under study range from 6 to 9 within the City of **Kenai**, and from 6 to 7 within **Soldotna**, depending upon whether the local area is served by hydrants. The City of Homer's rating is 7.

According to the Insurance Services Office, the minimum criteria for a recognized fire department are as follows:

- Organization: The department shall be organized on a sound, permanent basis under applicable state and/or local laws. The organization shall include one person (usually with the title of Chief) responsible for the operation of the department.
- Membership: The department shall have an active membership which provides a response of at least 4 members to alarms.
- Training: Training shall be conducted for all active members.
- Apparatus: Response to any alarm or fire shall be with at least one piece of apparatus suitably designed and equipped for fire service. Provisions shall be made for the housing and maintenance of apparatus.
- Alarm Notification: Means shall be provided for 24-hour receipt of alarms and immediate notification of members.

In, addition to minimum criteria for fire departments, the Insurance Services Office also establishes minimum criteria for water supplies for firefighting purposes, quoted as follows:

"A **minimum** recognized water supply usually contemplates a network of mains and hydrants capable of delivering at least [15.77 liters per second] 250 gallons per minute (over and above normal consumption) for a period of at least two hours. Where there are numerous commercial buildings, this minimum might be converted to at least [~~31.54 liters per second~~] 500 gpm for one hour (the same total quantity of water but available at a greater flow rate for a shorter period of time).

. . . the small settlement of a few hundred people and comprised of the usual number of small mercantile structures in a central **commercial** district would require [31.54 liters per second] 500 gpm in residential sections (well spaced or scattered small single family dwellings). In the commercial **district**, water in the range of [63.08 to ~~189.24~~ liters per second] **1,000** to 3,000 gpm would be required. A school complex serving the settlement and the surrounding territory probably would need something on the order of [189.24 to 315.4 liters per second] 3,000 to 5,000 gpm if there is a large building such as a gymnasium."

A great deal of flexibility is built into guidelines developed by the Insurance Services Office. This is necessary since firefighting requirements for individual **communities** vary greatly depending on population densities, land use patterns and the natural terrain, all of which affect running distances and response times for **firefighting** equipment. In addition, water requirements vary according to the character and scale of an area to be served. For example, the flow of water required to service low density residential areas is **much less** than that needed in a typical waterfront industrial area.

Recognizing that precise standards for fire protection are not generally applicable, the following standards are nevertheless offered.

- All communities to have at least one fire station with at least two fire trucks. The capacity of the fire trucks and the need for additional equipment will be determined primarily by fire flow requirements.
- Additional fire stations (each with at least two fire trucks) to be required where areas of concentrated development are beyond a 3.2 to 6.4 kilometer (2 to **4 mile**) radius of existing fire stations. (The actual distance to vary according to possible response time).
- Established fire flow requirements for various areas of each community are assumed to remain approximately the same except in developing residential areas where a water flow minimum of 1,892.5 liters (500 gallons) per minute is assumed.

Each of the fire departments under consideration (**Kenai, Soldotna, Homer, North Kenai**) falls short of these standards in some respect, most often in regard to response time or availability of water for firefighting purposes, with detrimental effect on their insurance ratings.

In both the non-OCS and **OCS** cases, future demands for land will be estimated and additional **firefighting** capabilities needed to service population growth will be determined. In the **OCS** cases, it is assumed that major onshore oil and gas-related facilities such as an **LNG** plant or an oil terminal would provide their own fire protection capabilities, as is currently the case in **Nikiski**. However, facilities with relatively low inherent fire risks, such as service bases, would depend on municipal fire protection services.

Health

Of the communities under study, **Kenai, Soldotna** and North **Kenai** are served by the Central Peninsula General Hospital and Homer and its surrounding area are served by South Peninsula Hospital. The standards used to determine existing and future needs **for** medical facilities and services in the communities under study are those developed by South Central Health Planning and Development, Inc. These standards have been adopted and are used by the State of Alaska and are summarized on the following two pages.

The most critical element involved in health care is the presence of a physician. On average, it is assumed that one physician requires a practice of a minimum of 1,500 people. However, physicians are reluctant to work alone since there are occasions when back-up assistance is required and time is also needed away from the practice for vacations, conferences, education and other purposes. Therefore, physicians in isolated Alaska communities commonly practice in pairs. To support these two physicians, a population base of 3,500 people is generally required.

In some areas, the practice need not be confined to permanent residents nor need it be precisely 3,500. It may be economically feasible to have a practice for two physicians with a population base of closer to 3,000 people or less. A portion of the patient load in Homer, for example, is made up of fishermen, cannery workers and other visitors who are not permanent residents but are a part of the physician's load.

Source: South Central Health Planning and Development, Inc.

It is assumed that each addition of an increment of 1,500 people above a population of 3,000 would require another physician in the communities under study.

In regard to hospital beds (used as a measure of hospital facility needs) acute care beds are used as an index. Acute care beds are general hospital beds as distinguished from long-term care or nursery beds. South Central Health Planning and Development, Inc. estimate the maximum capable of being adequately funded to be 3 to 3.5 acute care beds per 1,000 people in communities of at least 3,000 persons where the services of a physician are available.

In the non-OCS case and the OCS cases, 3.5 acute care beds per 1,000 people will be used as a standard for projection for communities with a population of more than 3,000. Given the high incidence of injury inherent in large scale construction projects and the more hazardous offshore operations such as loading and unloading supply boats and driving, the upper range of the standard for hospital beds is deemed to be warranted. In addition, the threat of fire or explosion is present with any activity involving **fuels,** and toxic materials are often intentionally or unintentionally handled.

Education

It is assumed that education facilities in the communities under study will continue to be provided by existing authorities, i.e. the **Kenai Peninsula Borough for Kenai, Soldotna** and Homer.

TABLE A-8

INDICATORS OF AVAILABILITY

<u>Level One</u>	<u>Level Two</u>	<u>Level Three</u>	<u>Level Four</u>
1 itinerant public health nurse <u>a/</u>	1 mid-level practitioner	1 primary care M.D. per 3,500 people (no less than 2)	1.3 physicians per 1000 (less than half specialists) people
1 health aide and 1 alternate <u>b/</u>	1 public health nurse	3 acute care beds per 1000 people	3 acute inpatient beds per 100 people
1 clinic space	1 EMT <u>ii c/</u>	community mental health center and psychologist	paramedics and advanced life support <u>c/ d/</u>
1 " trained person	1 dentist extender	1 dentist per 4000 people	inpatient psychiatric beds
1 equal itinerant dental visits	diagnostic x-ray capability	x-ray technician	long term alcoholism treatment beds <u>c/</u>
1 monthly itinerant behavioral health worker visits	1 behavioral health counselor or social worker	detox capability <u>c/</u>	neonatal beds/ live births <u>d/</u>
1 communications system	medical laboratory capability (microscope and refrigerator)	Class 4 emergency room (AMA) <u>c/</u>	therapeutic radiation capability <u>d/</u>
1 equal itinerant home care	home health aide or long term care alternative	mobile e.m.s. capacity with EMT trained attendants	surgical capacity <u>d/</u>
1 representative health decision-making group		medical technologist	1 CAT Scanner per 250,000 residents <u>d/</u>
		1 optometrist	pathology and autopsy capability
		short term shelter care	blood bank
		itinerant M.D. specialist visits	specialists/population (see Table VC)

● Definition to include **audiologic** testing, immunization.
 Range of services provided by health aide as described in Guidelines for Primary Health Care

● SCHPD will emphasize, during the first AIP, the development of additional and specific manpower, facilities and equipment standards -- particularly in the areas of behavioral health and emergency medical services (as relate to our highest health problem areas)

● Federal guidelines have been issued related to these areas of medical care services. At the time of this publication, the Board of Directors has not made specific recommendations regarding them.

n-cc: South Central Health Planning and Development, Inc.

Generally, students make up a reasonably consistent proportion of a community's population, although recently a declining one due to the nationwide drop in birth rates. A comparison of school enrollment as a proportion of total population for five boroughs in Southeast and **Southcentral** Alaska (**Ketchikan** Gateway Borough, City and Borough of Sitka, **Kenai** Peninsula Borough, Kodiak Island Borough and **Matanuska-Susitna** Borough) indicated that students accounted for an average of 27.2 percent of the total population of these areas in 1970. By 1977, this had declined to 23.2 percent and would have declined even more significantly had it not been for the inclusion of the Kodiak Island Borough (where the closure of the Naval Station during this period resulted in an increase in the proportion of students to total population). Some further decline in the student to total population ratio is anticipated. For example, students accounted for only 18.3 percent of Anchorage's population and for 19.8 percent of that of the Ketchikan Gateway Borough in 1977. However, continued declines should be much less dramatic and student to population ratios are then expected to stabilize.

For purposes of forecasting school enrollment in the **non-OCS** case, the following assumptions have been made:

- The current average ratio for selected Southeast and **Southcentral** Alaska boroughs of approximately 23 percent of the population being enrolled in school is assumed to apply to Kenai, **Soldotna** and Homer. This ratio is then assumed to

decrease by 1 percent per year until students account for 20 percent of total forecasted population, with that ratio to remain constant thereafter.

In the various OCS cases, assuming that most offshore population plus construction camp personnel are discounted, no significant changes in ratios of students to total population are anticipated.

Once total school enrollment has been forecasted, allocation of students between elementary and high school grades is necessary since standards for the number of students per classroom normally differentiate between the two levels. Approximately 60 percent of school students in Alaska are usually enrolled in the elementary grades. This proportion has been slightly lower recently as the "peak" student years are not in high school. However, the normal 60/40 ratio should again hold true in the near future.

According to the National Education Association, there are no established national or State standards for the number of students per classroom. Nevertheless, a standard used by many Alaska school districts is 25 students per classroom for the elementary (K-6) grades and 20 students per classroom for the high school grades.

To determine future classroom needs in the **non-OCS** case, the following assumptions have been made:

- Student enrollment will be divided on a 60 percent elementary (K-6) and 40 percent high school (7-12) basis throughout the forecast period.
- Standards of 25 students per classroom for elementary grades and 20 students per classroom for high school grades will apply throughout the forecast period.

For the various OCS cases, if new offshore population plus construction camp personnel are discounted, no significant changes in the assumptions made for the **non-OCS** case are anticipated in forecasting future school requirements.

Recreation

Recreation is a power which has been retained by the cities of Kenai, **Soldotna** and Homer (i.e. not transferred to the Kenai Peninsula Borough). However, as elsewhere in Alaska, much of the recreation **function** in these communities is **assoc**'ated with the schools. Thus, recreation facilities and services in Kenai, **Soldotna** and Homer are also provided by the **Kenai** Peninsula Borough School District.

The following standards suggested by the National Recreation and Park Association are basic standards which are slightly modified to apply to the communities of Kenai, **Soldotna** and Homer.

- Neighborhood Parks: 1.01 hectares (2.5 acres) per 1,000 people serving a population of 500 to 10,000 people.

- - Play Lots and Other Neighborhood Recreation Areas: 0.2 hectares (0.5 acres) per 1,000 people serving a population of 250 to 2,500 people.

● Therefore, a total of 1.2 hectares (3 acres) per 1,000 people is assumed to be required in outdoor neighborhood park and recreation areas. These outdoor areas are assumed to accommodate all outdoor basketball courts, baseball or softball diamonds, tennis courts, jungle gyms, etc.

● However, while national standards provide adequate guidelines for local parks and recreation, the combination of isolation, geography, climate and local desires for parks and recreation facilities in Alaska must also be taken into account.

● Most isolated Alaska communities feel deprived without a reasonably full range of common parks and recreation facilities. For example, the national standard for 50 meter **swimming** pools is one per 20,000 people. However, almost every coastal Alaska coastal community of 2,000 people has a **swimming** pool as well as every major high school in the urban areas of the State. Perhaps a more extreme deviation from national standard! occurs with indoor basketball courts where most **communities** of any size have an indoor facility of some description.

● Thus, in addition to outdoor recreation facilities, indoor basketball courts and swimming pools are needed and desired recreation facilities in the communities under study. These facilities provide recreational alternatives, especially during the long inclement Alaska winters.

Also, swimming pools permit the local populations to learn to swim and to develop swimming skills. In areas where a large proportion of the people work on boats or on the waterfront, these skills may be necessary for survival and they cannot be easily learned in the frigid ocean waters, streams or lakes of Alaska.

Therefore, the following minimum standards are assumed to apply to the communities under study:

- Indoor Basketball Courts: One for every 2,000 people.
- Swimming Pools: One for every 5,000 people.

There must also be some indoor recreation provision for those not desiring strenuous indoor recreation. In most Alaska communities, this form of recreation is provided through a community center or, as they are often called, a community hall. Thus:

- Community Center: One for every 25,000 people.

These standards will be applied to both **the non-OCS** and the OCS cases. However, it is assumed that the onshore **OCS** construction **workforces** located in camps **will** have recreation facilities provided at the camps, as was the case with the **Alyeska** pipeline project camps.

- Utilities

Water. **Kenai, Soldotna** and Homer have public water systems, while the unincorporated area of **Nikiski-North Kenai** is served mainly by

private wells. Water usage in the coastal municipalities under study is separated into two basic classes of service. These are industrial, which is the major consumer, and domestic. However, since water is not metered in these coastal communities, it is difficult to accurately estimate the consumption of each user class.

Present rates of water usage in coastal communities such as those under study are estimated by the U.S. Public Health Service to be approximately 454 liters (120 gallons) per person per day in domestic use. Local utilities estimate usage at approximately 473 liters (125 gallons) per person per day. This higher figure is believed to be warranted as the communities under study receive significant numbers of visitors for purposes of recreation, fishing and other activities. Thus, in the **non-OCS** case, the estimate of future water consumption for domestic purposes is calculated by multiplying the estimated annual average population by 473 liters (125 gallons) per person per day by the **number of** days in the year to arrive at estimated total annual domestic water use.

Industrial water use, estimated to be total water usage minus water used for domestic purposes, is forecast to maintain its current proportion of water estimated to be required in the **non-OCS** case for each community.

Thus, it is assumed in the **non-OCS** case that added industrial activity, such as expansion in fishing and fish processing, results in water usage proportionate to the water usage resulting from the added population derived from the expanded industrial activity.

Forecast increases in population in the non-OCS case are based upon growth in existing economic sectors, and the distribution of employment (and therefore population) among these economic sectors was not significantly altered in forecasting future employment (and population). Therefore, it is assumed that the increase in domestic water consumption in the future provides **an** indication of potential industrial water consumption.

In the OCS cases, however, due to extreme fluctuations in demand during the exploration and development phases and the diversity of demands possible in the manufacturing and transportation processes **during** the production phases, forecasts of water requirements call for estimates based upon assessments of water usage of individual **industrial** activities as well as resulting domestic demands.

In the OCS cases, it is assumed that the per capita usage of water for domestic purposes will remain at 473 liters (125 gallons) per person per day. It is also assumed that normal water usage in all of the onshore OCS facilities will be 473 liters (125 gallons) 'per day per onsite employee. Offshore requirements on a'11 boats, barges, rigs and platforms for general use are assumed to be 378.5 liters (100 gallons) per day per onsite employee. On the **other** hand, the water requirements for exploration wells drilled from rigs and development wells drilled from platforms were derived from the estimates provided by the Alaska State Department of Community and Regional Affairs based **upon** exploration drilling during Lease Sale No. 39 in the Northern Gulf of Alaska.

Approximately 40,000 gallons per day per offshore rig operation including supply boats was estimated by ARCO to be the offshore consumption. Of this amount 30,000 gallons is estimated to be **drill** water. **Workover** well drilling was assumed to require only 12.5 percent of normal platform consumption on average during the workover periods established by Dames and Moore.

The supply of water to offshore activities and to onshore service bases during construction and operations is assumed to be provided by the City of Homer or by the service base operator at **Nikiski**. Also, given the remote location of the Afognak Island facilities, their water requirements are not included in the water demands for the **community** systems.

Sewer. According to the U.S. Public Health Service, the quantities of domestic wastewater can be assumed to equal domestic water use and, since industrial wastes are not run through the sewage collection system and treatment plants in the communities under study, domestic wastewater can be assumed to equal total wastewater. Therefore, given a per capita consumption of 473 liters (125 gallons) per day of water usage and a peak flow being an estimated three times the average flow, a treatment plant would be required to have the capacity to process approximately 59.16 **liters** (15.63 gallons) per person per hour or:

- $473 \text{ liters (125 gallons)}/\text{day} - 24 \text{ hours}/\text{day} = 19.72 \text{ liters (5.21 gallons) /hour} \times 3 = 59.16 \text{ liter (15.63 gallon) capacity to accommodate peak loads.}$

Therefore, it is assumed that sewage treatment plants must have the capacity to accommodate 59.16 liters (15.63 gallons) of wastewater per person.

In the non-OCS case, it is also assumed that industrial wastes will continue to be processed by the industries generating the industrial waste.

In the OCS cases, the service base at Homer is assumed to be on the community sewer system. However, it is assumed that all sewage from the **Nikiski** service base and industrial facilities will be collected and treated by the industry at the respective plants. It is further assumed that all wastewater from offshore rigs, boats, barges and platforms will be treated onboard.

Electric Power. Electric power is distributed to **all** the communities under study by the Homer Electric Association, Inc. which purchases bulk power from **Chugach** Electric Association. Present firm demand amounts to about 3.75 KW per person of installed capacity for **all uses**. These uses with rare exceptions do not include heating nor do they include basic service to several **Nikiski** industrial **plants** which maintain their own generators but rely upon Homer Electric Association for stand-by power.

In calculating future demands for the **non-OCS** case, it is assumed that an installed capacity of 3.75 KW per person of installed capacity. This assumption is based upon servicing the same basic household functions

currently being serviced and an industrial mix within each community that is similar to the present industrial distribution.

In the OCS cases, 3.75 KW per person of installed capacity is demanded for each new resident. It is also assumed that construction site and construction camp activities will require 3 KW per person. However, it is assumed that only the construction sites and camps related to service bases on the **Kenai** Peninsula and the resulting operating facilities will be newly served by the existing power system. Service bases are assumed to have demand for electric power exceeding the overall 3 KW per person standard. Approximately 650 KW is required to drive **the** pumps for loading water, fuel, and powdered mud and cement onboard the supply vessels. This block of power is sufficient to accommodate two berths. Additional increments of two berths **will** require 650 KW to power like equipment. The service base, **oil** terminal and other facilities assigned to **Afognak** Island are presumed to meet their own power supply needs.

Communications. Telephone service in the communities under study is currently provided by Glacier State Telephone Company, a subsidiary of Continental Telephone System. The Alaska Public Utilities Commission, the Municipality of Anchorage's Telephone Utility and the Southeastern Telephone Company were contacted in an attempt to derive standards for future levels of telephone service which are likely to be demanded in these communities.

According to the Anchorage Telephone Utility, in order **to** determine future levels of demand, the number of lines (i.e. excluding extensions) is estimated by using past trends and applying them to forecasts of **populat**ion growth. The consulting engineers for the Southeast Telephone Company employ a linear trend equation based upon past lines installed.

Both means of forecasting are short range and depend upon yearly installation figures. A relationship, however, was found between telephone lines in use and housing units. In the **three communities** under study, the number of lines per housing unit was between 1.1 and 1.2. Using Anchorage as a comparison, Anchorage has approximately 2 telephone lines per housing unit. On the other hand, in 1970 Anchorage had only 0.57 telephone lines per housing unit (or with the military housing units totally discounted 0.89). This represents a growth rate of over 15 percent per year. However, Anchorage's unique function as the hub of Alaska's communications and transportation and its Statewide appeal as a retail and services area must be taken into account.

In both the **non-OCS** and the **OCS** cases, it is assumed that 1.25 lines will be required initially for each housing unit added increasing yearly by .01 **until** there are 1.40 lines per housing unit. However, housing units do not include group housing such as construction camps or cannery barracks as a basis for calculating future requirements. It is also assumed that telephone equipment and services will be provided by the existing telephone utility companies.

pounds per cubic yard since it is composed in large part of steel items such as used drill bits. Upon completion of development, one-fourth the amount generated by maximum platform activity is assumed to return from the platforms during the production phase.

In terms of tonnage and density, there is a limited amount of toxic solid waste returning to shore for disposal. Generally, this is in the form of used oil or oiled materials. Onshore, some used oil plus sediment materials, sludge, scum and other wastes from the manufacture of LNG and the treatment of crude oil are toxic. The quantities are small and can be disposed of by the community in an environmentally sound manner on a small especially prepared site.

LOCAL GOVERNMENT REVENUES

Where possible, the following standards, methods and assumptions will be employed to forecast community revenues and expenditures. The resulting surplus or deficit calculated provides an indication of the community's ability to fund capital improvements or upgrade services employing current rates and measures to capture revenues.

The following assumptions are made:

- Forecasts of revenues are made using current rates and measures as a basis for projection. A 5-year average or an average appropriate to reflect recent circumstances will be utilized.

Solid Waste Disposal. The standards for solid waste disposal are based upon disposal records of the Municipality of Anchorage and trends of solid waste generation in Anchorage. According to the Solid Waste Division of the Public Works Department, the average Anchorage resident during 1977 generated 5.35 pounds of solid waste per day. This has been projected to increase at an average rate of 2 percent per year through 1985 then at an average rate of 1 percent through 1990. Thereafter, it is assumed that no increase in the per person rate of solid waste generation **will** take place.

In terms of sanitary landfills, the Municipality records an average density of 330 pounds per cubic yard delivered and 800 pounds per cubic yard in place. These standards are assumed for the forecast of the **non-OCS** cases in the communities under study.

In the OCS cases, the same standards as the **non-OCS** case are assumed. In addition, it is assumed that all onshore facilities with the exception of the helicopter operations will generate 6.5 pounds per day per employee of additional non-toxic solid waste.

Offshore, all combustible materials are assumed to be incinerated and only noncombustible materials are returned to shore for disposal. **This** is estimated to be one ton per week per semi submersible rig, platform rig or barge operation including any refuse from supporting boats **during** the exploration and development phases. Furthermore, the average density of this **solid** waste is estimated to be **approximately 4,000**

- The existing level of service is used as the basis for projection. Despite a level of service which may be less than desired, expenditures for services are maintained at current levels.
- Current State statutory limitations on taxation of certain oil and gas properties by local governments will continue to be in force. Although local governmental units theoretically have the power to levy property taxes of up to 30 mills, in reality their taxing ability may fall far short of this because of limitations on the taxation of certain oil and gas properties as defined in Title 43.56 of the Alaska Statutes. These limitations are set forth in Section 29.53.045 of the Alaska Statutes, which is quoted in part:

“ (a) A municipality may levy and collect taxes on taxable property taxable under AS 43.56 only by using one of the methods set out in (b) or (c) of this section.

“ (b) A municipality may levy and collect a tax on the full and true value of taxable property taxable under AS 43.56 as valued by the Department of Revenue at a rate not to exceed that which produces an amount of revenue from the total municipal property tax equivalent to \$1,500 a year for each person residing within its boundaries.

“ (c) A municipality may levy and collect a tax on the full and true value of that portion of taxable property taxable under AS 43.56 as assessed by the Department of Revenue which value, when combined with the value of property otherwise taxable by the municipality, does not exceed the product of 225 percent of the average per capita assessed full and true value of property in the State multiplied by the number of residents of the taxing municipality.”

Title 29.53.055 of the Alaska Statutes states that there is no limitation on taxes levied or pledged to pay or secure the payment of the principal and interest on bonds. In this

regard, Chapter 94 SLA 1977 stressed that the per capita limitation did not include debt service. AS 29.53.055 is quoted as follows:

NO LIMITATION ON TAXES TO PAY BONDS. The limitations provided for in Sec. 45 or 50 of this chapter do not apply to taxes levied or pledged to pay or secure the payment of the principal and interest on bonds. Taxes to pay or secure the payment of principal and interest on bonds may be levied without limitation as to rate or amount, regardless of whether the bonds are in default or in danger of default.

Therefore, at the extreme, AS 43.56 serves only to limit municipal operating budgets.

- The limitation imposed in AS 29.53.045(b) is used in this study as the upper limit of municipal property tax revenues. Therefore, total property tax equivalent to \$1,500 a year for each person residing within the municipal boundary is assumed as the upper limit of property tax revenues.
- It is also assumed that the excise tax limitation imposed in AS 43.56.030 cited below will remain in effect throughout the planning period.

AS 43.56.030(2): . . .all other taxes imposed by a municipality on or with respect to the property subject to tax under this chapter or exempted from taxation by Section 20 of this chapter, including, but not limited to,

- (A) taxes on the retail sale or use of the property except for the retail sales tax on the first \$1,000 of each sale;
- (C) taxes on the sale or use of services used in or associated with the property or in its maintenance or operation except for the sales tax on the first \$1,000 of each sale;
- (E) any license, excise, fee, charge or other tax on or pertaining to the property or services.

AS a result of this limitation, significant revenues are not forthcoming from oil and gas activities. Therefore, a projection of current sales tax revenues on a per capita basis is assumed to be representative of the future receipts from this revenue **source.**

- It is assumed that current federal law prohibiting State or local government taxation of properties beyond the three mile limit or revenue sharing from oil and gas development on the Outer Continental Shelf will remain in effect throughout the planning period.

Revenues

Revenues are grouped and forecast under the headings of property taxes, sales taxes, intergovernmental revenue and other revenue. School District revenues are forecast as to funds forthcoming from local, State and federal sources.

Property Tax Revenues. The non-OCS property tax revenue estimates are based upon per capita additions to assessed valuation. Thus, each new resident is assumed to add to the assessed value of the community an amount equal to the total assessed value in the base year divided by the total population. The total assessed value is then multiplied by the current **millage** rate to obtain the forecast of uninflated property tax revenue for each year.

In the OCS cases, property tax revenue estimates are based upon per capita additions to assessed valuation as the estimates are in the base case. However, the increase in assessed value due to major capital investment in onshore oil and gas facilities is factored in, based upon the investment costs and schedules provided by Dames and Moore in the **petroleum** development scenarios. **It** is recognized that improvements in a given year will not appear as increases in assessed value until the tax **rolls** are compiled the following year. Thus, there is a lag in the receipt of revenue.

An exception to the per capita calculation is construction employment living in construction camps. Outside of the assessed valuation of the construction camp which is included in the cost of the construction of major onshore oil and gas facilities, these workers' contribution to the assessed valuation of the community is small. Therefore, the estimated per capita additions do not include workers on major construction projects living in construction camps.

Also, the limitation of total property tax equivalents to **\$1,500** a Year for each person residing within the municipal boundary in AS 29.53.045(b) is employed as a indicator of the limitation under State law. However, this should not be construed as the maximum estimate of property tax revenues since the formula developed with the State Department of Revenue under AS 29.53.045(c) may prove more remunerative. The limitation under the formula cannot be derived for this study since the formula requires the determination of assessed value by the State.

Sales Tax Revenues. Sales tax revenues in the non-OCS case are based upon the current per capita additions to sales tax receipts. Thus, each new resident is assumed to add to the total sales tax receipts of the community an amount equal to the total sales tax receipts in the base year divided by the total population.

In the OCS cases, sales tax revenue estimates are based upon per capita additions to sales tax receipts as the estimates are in the base case. However, in the OCS cases where major construction activities take place onshore, it is assumed that the construction workers will live in camps with accommodations of excellence. It is assumed that, on average, an employee residing in a camp will spend only 1/10 as much as an employee with a permanent residence outside the construction camp. Therefore, in the calculation of sales tax revenues only 10 percent of the workers resident in construction camps will be counted.

Intergovernmental Revenues. In the **non-OCS** case and the OCS cases, intergovernmental revenues estimates are based upon per capita additions to intergovernmental revenues. Thus, each new resident is assumed to add to the intergovernmental revenues transferred to the community an amount equal to the total value of intergovernmental revenues in the base year divided by the population.

Other Revenues. In the **non-OCS** case, other revenues estimates are based upon per capita additions to the total of other revenues such as license fee, permits, interest earnings, rentals, etc. Thus, each new

resident is assumed to add to other revenues of the community an amount equal to the total value other revenues in the base year divided by the total population.

In the OCS cases, other revenues estimates are based upon per capita receipts as are the estimates in the base case. However, in the OCS case where major construction activities take place onshore, it is assumed that the construction workers will live in construction camps of excellence with a wide range of recreation facilities and services. Thus, it is assumed that on average an employee residing within a camp will contribute little to the generation of these revenues. Therefore, in the calculation of other revenues on a per capital basis only 10 percent of the workers resident in construction camps will be counted.

School District Revenues. School District revenues are forecast on a per student basis for local, State and Federal revenues. It is assumed that approximately the same proportion of revenues from these three governmental divisions will continue throughout the planning period.

Expenditures

Operating Expenditures. In the non-OCS case, the operating budget is forecast on a per capita basis.

In the non-OCS cases, the operating budget is also forecast on a per capita basis. However, where major construction activities take place

onshore, it is assumed that construction workers in camps will not require the same expenditures as those resident in the community outside the camps. It is estimated that the expenditures required per employee resident in the construction camps will be approximately 1/5 as much as a worker residing outside the camp. Therefore, in calculating operating expenditures on a per capita basis 20 percent of the workers resident in construction camps will be counted.

Debt Service. Debt service is the amount necessary to pay or secure the payment of the principal and interest of bonds. In all cases only **existing** debt service requirements to maturity will be listed.

School Support. Funds provided to support local school districts are calculated on a per student basis. It is assumed that a proportionate share of the support of schools will be maintained for local, State and Federal support throughout the planning period.

Surplus or Deficit. In the non-OCS case and the OCS cases, the total of revenues is subtracted from the total of expenses to produce a surplus or a deficit of funds. A surplus represents funds available for additional capital improvements or additional operating expenditures. A deficit indicates the inability to provide for the same level of community services and to provide added capital improvements.
