CORRESPONDENCE INDEX

A. Comments from NC Department of Environment and Natural Resources Departmental Review

1)	Letter	11 May 2000	Doug Huggett (Division of Coastal Management) to JW Forman (Stroud Engineering)
2)	Memorandum	5 May 2000	Melba McGee (Environmental Review Coordinator, NCDENR) to Doug Huggett (Division of Coastal Management)
3)	Memorandum	27 Apr 2000	Franklin T McBride (Wildlife Resources Commission, Division of Inland Fisheries, Habitat Conservation Program) to Melba McGee (Environmental Review Coordinator, NCDENR)
4)	Memorandum	18 Apr 2000	David Taylor and James Patrick Monaghan Jr (Division of Marine Fisheries) to Melba McGee
5)	Memorandum	17 Apr 2000	Milt Rhodes (Division of Water Quality) to Melba McGee (Environmental Review Coordinator, NCDENR)
6)	Memorandum	13 Apr 2000	Stephen Hall (Division of Parks and Recreation, Natural Heritage Program) to Melba McGee (Environmental Review Coordinator, NCDENR)
7)	Memorandum	10 Apr 2000	Shannon Stewart, John Dorney (Division of Water Quality) to Milt Rhodes (Division of Water Quality)
8)	Memorandum	11 Apr 2000	Steve Benton (Division of Coastal Management) to Melba McGee (Environmental Review Coordinator, NCDENR)

B. Responses to NCDENR Agency Comments by Consultants for the Applicant

1)	Letter	13 Sep 2000	JW Forman Jr, PE (Stroud Engineering) to James Patrick Monaghan (Division of Marine Fisheries)
2)	Letter	13 Sep 2000	JW Forman Jr, PE (Stroud Engineering) to Franklin T McBride (NC Wildlife Resources Commission, Division of Inland Fisheries)
3)	Letter	13 Sep 2000	JW Forman Jr, PE (Stroud Engineering) to Milt Rhodes (Division of Water Quality)
4)	Letter	13 Sep 2000	JW Forman Jr, PE (Stroud Engineering) to Stephan Hall (Division of Parks and Recreation)
5)	Letter	13 Sep 2000	JW Forman Jr, PE (Stroud Engineering) to Shannon Stewart (Division of Water Quality, Non-Discharge Branch)

C. Comments by NCDENR Agencies Concerning Applicants Responses to Agency Review Comments

1)	Memorandum	24 Oct 2000	William Wescott, Coastal Coordinator (NC Wildlife Resources Commission, Habitat Conservation Program) to JW Forman (Stroud Engineering)
2)	Letter	6 Oct 2000	Milt Rhodes, SEPA Coordinator (Division of Water Quality) to JW Forman (Stroud Engineering)
3)	Memorandum	2 Oct 2000	Michael D Marshall, James Patrick Monaghan (Division of Marine Fisheries) to Melba McGee, Environmental Review Coordinator (NCDENR)
4)	Memorandum	30 Oct 2000	Stephan Hall (Division of Parks and Recreation) to Melba McGee, Environmental Review Coordinator (NCDENR)

D. Comments from North Carolina State Clearinghouse

1)	Intergovernmental Review Form	2 Feb 2001	North Carolina State Clearinghouse, Department of Administration
2)	Letter	13 Mar 2001	Michelle Duval and Daniel Whittle (Environmental Defense) to Doug Huggett (NCDENR)
3)	Letter	15 Mar 2001	Chrys Baggett (NC Department of Administration) to Doug Huggett (NCDENR)
4)	Letter	15 Mar 2001	Charles Peterson (University of North Carolina at Chapel Hill, Institute of Marine Science) to Doug Huggett (NCDENR)
5)	Letter	20 Mar 2001	Doug Huggett (NCDENR) to Coastal Science & Engineering and Stroud Engineering

E. Responses to Comments from NC Clearinghouse by Consultants for the Applicant

1) Letter	3 Apr 2001	Timothy W Kana, PhD (Coastal Science & Engineering LLC) to Doug Huggett (NCDENR, Division of Coastal Management)
2) Letter	4 Apr 2001	TW Kana, PhD (Coastal Science & Engineering LLC) to Doug Huggett (NCDENR, Division of Coastal Management)

F. Certification – 401 Water Quality

1) Letter	23 Mar 2001	Kerr T Stevens (NCDENR, Division of Water Quality) to Robert Murphy (Carteret County)

G. Comments from Federal Agencies on Permit Application ID 200000362

1) Letter	13 Apr 2001	William L Cox (USEPA) to Col James W DeLony (USACE-Wilmington)
2) Letter	20 Apr 2001	Andreas Mager Jr (NMFS) to Col James W DeLony (USACE-Wilmington)
3) Letter	1 Jun 2001	Garland Pardue (USFWS) to Col James W DeLony (USACE-Wilmington)

H. Responses to Comments from Federal Agencies by Consultants for the Applicants

1) Letter	25 Apr 2001	TW Kana, PhD (Coastal Science & Engineering LLC) to Col James W DeLony (USACE-Wilmington)
2) Letter	30 Apr 2001	TW Kana, PhD (Coastal Science & Engineering LLC) to Col James W DeLony (USACE-Wilmington)
3) Letter	24 May 2001	TW Kana, PhD (Coastal Science & Engineering LLC) to Garland Pardue, PhD (USFWS)

I. Comments from Nongovernmental Organizations and Individuals on Permit Application ID 200000362

1) Letter	17 Apr 2001	Mickey Sugg (USACE-Wilmington) to Pete Allen (Carteret County) recommending response to NGO comments
2) Letter	13 Apr 2001	Charles H Peterson, PhD (UNC-IMS) to Mickey Sugg (USACE-Wilmington)
3) Letter	12 Apr 2001	Jim Stephenson (NC Coastal Federation) to Mickey Sugg (USACE-Wilmington)
4) Letter	12 Apr 2001	Michel Duval (Environmental Defense) to Mickey Sugg (USACE-Wilmington)
5) Letter	10 Apr 2001	Don E Morris (Citizen) to Mickey Sugg (USACE-Wilmington)

J. Responses to Comments from Nongovernmental Organizations and Individuals on Permit Application ID 200000362 by Consultants for the Applicants

1) Letter and Attachment		
	27 Apr 2001	TW Kana, PhD (Coastal Science & Engineering LLC) to Mickey Sugg (USACE-Wilmington) (attachment responds to all correspondents in I)

K. Comments from Consultants to the Applicants to NC Division of Marine Fisheries Regarding Draft Environmental Plan

1) Letter	25 Apr 2001	TW Kana, PhD (Coastal Science & Engineering LLC) to Michael D Marshall (NCDENR, Division of Marine Fisheries)

L. Comments from Applicants to USACE Regarding Requirements under NEPA

1) Letter	8 May 2001	Pete Allen (Carteret County) to Col James W DeLony (USACE-Wilmington)
2) Letter	3 May 2001	C Reese Musgrave, Mayor (Town of Pine Knoll Shores) to Col James W DeLony (USACE-Wilmington)
3) Letter	3 May 2001	William L Fugate, Mayor (Town of Indian Beach) to Col James W Delony (USACE-Wilmington)
4) Fact Sheet	7 Aug 2001	Unsigned response from USACE-Wilmington to applicants on permit application status and time line

M. Additional Comments and Section 7 Endangered Species Consultation from NMFS on Permit Application ID 200000362

1) Letter	25 Jun 2001	Andreas Mager Jr (NMFS-St Petersburg) to Col James W DeLony (USACE-Wilmington)
2) Letter	~26 Jul 2001	Joseph E Powers, PhD (NMFS-St Petersburg) to Col James W DeLony (USACE-Wilmington)

N. Response to Additional Comments from NMFS on Permit Application ID 200000362 by Consultants for the Applicants

1) Letter	17 Aug 2001	JW Forman Jr, PE (Coastal Science & Engineering LLC) to Col James W DeLony (USACE-Wilmington)

O. Correspondence Related to Environmental Monitoring of the Project by the Applicants

1) Letter 18 Jun 2001 TW Kana, PhD (Coastal Science & Engineering LLC) to Mickey Sugg (USACE-Wilmington) with attachments as listed in a-j:
   a) Letter and report (omitting appendices) – UNC to Carteret County dated 10 May 2000
   b) Memo – CSE (Kana) to UNC (Peterson) dated 18 May 2000
   c) Letter – USACE (Harris) to Carteret County dated 28 Feb 2001
   d) Letter – UNC (Peterson) to CSE Baird dated 2 Apr 2001
   e) Proposal – Coastal Science Associates (Florey) to CSE dated 18 Apr 2001
   f) Memo – UNC (Peterson) submitted to NC Division of Marine Fisheries (unattributed) dated 9 May 2001
   g) Revised Proposal – CSA to CSE dated 28 May 2001
   h) Letter – UNC (Peterson) to Mickey Sugg (USACE-Wilmington) dated 3 Jun 2001
   i) Letter – CSE (Kana) to Town of Pine Knoll Shores (Musgrave) dated 8 Jun 2001
2) Letter 11 Jun 2001 Bart J Baca, PhD (CSA) to Kana (CSE)
3) Email Jun 2001 BJ Baca (CSA) to TW Kana (CSE) and revised proposal for environmental monitoring (dated Jul 2001)
4) Letter 17 Jul 2001 Charles H Peterson, PhD (UNC) to Ron Sechler (NMFS)
5) Letter 18 Jul 2001 TW Kana, PhD (CSE) to Ron Sechler (NMFS-Beaufort NC)
6) Letter 5 Aug 2001 Charles H Peterson, PhD (UNC) to Ron Sechler (NMFS-Beaufort NC)

P. Final Comments and Responses from Resource Agencies

1) Letter 20 Sep 2001 Garland Pardue (UFWS) to Col James W DeLony (USACE-Wilmington)
2) Letter 26 Sep 2001 Andreas Mager Jr (NMFS-St Petersburg) to Col James W DeLony (USACE)

Dear Sirs:

Enclosed please find a response from the Departments SEPA coordinator concerning the Bogue Banks beach renourishment Draft Environmental Impact Statement. The SEPA coordinator has indicated that several comments have been received requesting additional information or clarification, and that these issues must be addressed through a revision of the Environmental Document. Therefore, it is requested that you enter into negotiations with the various commenting agencies in an effort to resolve or address these issues. After such negotiations, a revised EIS document should be prepared which addresses the review agency concerns, and twelve (12) copies of the revised document should be submitted to this office, at which time I will transmit the documents to the SEPA coordinator for additional review.

Please feel free to contact me at (919) 733-2293 if you would like to discuss this matter further.

Sincerely,

Doug Huggett

MEMORANDUM

TO: Doug Huggett
Division of Coastal Management

FROM: Melba McGee
Environmental Review Coordinator

RE: #1046 Bogue Banks Restoration Plan, DEIS, Carteret County

DATE: May 5, 2000

The proposed project has been circulated and reviewed by our internal divisions.

Our review efforts raised a number of issues that will need to be addressed before this project is released for state review. After revisions have been made, I recommend the revised document be reviewed again internally prior to State Clearinghouse review.

Thank you for the opportunity to respond.

Charles R. Fullwood, Executive Director

MEMORANDUM

TO: Melba McGee
Office of Legislative & Intergovernmental Affairs

FROM: Franklin T. McBride, Manager
Habitat Conservation Program

DATE: April 27, 2000

SUBJECT: Comments for Bogue Banks Beach Restoration Plan, Draft Environmental Impact Study (DEIS), Carteret County. Project # 1046.

Staff biologists with the Wildlife Resources Commission have reviewed the DEIS. Our comments are provided in accordance with provisions of the Fish and Wildlife Coordination Act (48 Stat. 401, as amended; 16 U.S.C. 661 et. seq.), the Clean Water Act of 1977 (as amended) and the North Carolina Environmental Policy Act (G.S. 113A-1 et seq., as amended; 1 NCAC-25).

Carteret County is proposing to renourish 16.8 miles of oceanfront beaches in the towns of Pine Knoll Shores, Salter Path, Indian Beach and Emerald Isle. The identified sources of sand for this proposal are located offshore from the project site.

The DEIS indicates that erosion is to blame for loss of beach, dune and maritime forest habitats and a wide range of wildlife resources. If this document seeks to identify causes of lost wildlife resources and habitat then losses attributed to human disturbance, landscape alterations and development should also be included as contributing factors especially since this document indicates that Bogue Banks oceanfront has reached 90% build-out.

Recent studies by C. R. Donoghue "*The Influences of Swash Processes on Donax variablis and Emerita talpoida*" and C. H. Peterson, D. H. M. Hickson, and G. G. Johnson "*Short-term Consequences of Nourishment and Bulldozing on the Dominant Large Invertebrates of the Sandy Beach*" indicate that beach renourishment causes a severe depletion in numbers of macro invertebrates (shorebird food). Population recovery rates of macro invertebrates are dependent on recruitment from pelagic larval stocks and recruitment from neighboring beaches.

FROM: Milt Rhodes
Division of Water Quality

SUBJECT: Bogue Banks Beach Restoration Plan Environmental Impact Statement Document and FONSI, DENR# 1046, DWQ# 12652

The Division of Water Quality (Division) has reviewed the Draft Environmental Impact Statement document regarding the Restoration of Bogue Banks Beach and offers the following comments.

This document was reviewed by staff in the wetlands unit and planning branch of the Division for consistency with the State Environmental Protection Act. The full comments are attached to this letter, but in summary, these issues should be addressed in the final document.

1. Please supply the Division with a notification of the borrow area selection once it has been made.

2. The project must meet the turbidity standards set forth in the 401 Water Quality Certification for this project during construction.

3. It is desired that work be conducted between the months of November and April to limit the degree and severity of impact to environmental resources.

Thank you for the opportunity to comment. If you have questions regarding these comments, please contact Milt Rhodes at (919) 733-5083 x 366.

FROM: Stephen Hall SH

SUBJECT: DEIS – Beach Restoration Plan, Bogue Banks

REFERENCE: 1046

The assessment is well-written and appears to be quite thorough. It identifies several potential impacts, however, that are of concern to the Division:

- One of the proposed borrow areas is located within Bogue Inlet. As stated on p. 5-8, if this area is chosen as a source for dredge material, habitat for the piping plover (*Charadrius melodus*), federally and state listed as Threatened, may be lost. We strongly recommend that this area, along with any other areas located within the inlets or on the accreting ends of the banks, be excluded as potential borrow sites.
- Possible impacts to the loggerhead sea turtle (*Caretta caretta*), federally and state listed as Threatened, are also identified (p. 5-8). Impacts may result from the use of inappropriate dredge materials, changes in beach profiles, or from disposal activities taking place within the nesting or hatching periods. The use of nest relocations is proposed to mitigate for some of these impacts, but we regard this as the least desirable form of mitigation. Instead, we recommend that the standard measures supported by the US Fish and Wildlife Service and the US Army Corps of Engineers be followed regarding the (1) the types of sediments that are acceptable for disposal; (2) the beach profile created by renourishment. Beach renourishment should take place strictly in the off-season for sea turtle nesting -- November through April -- not as currently requested (p. 4-10) for the months of October and May.
- Use of the dredge spoils deposited at Brandt Island (p. 4-6) may potentially affect an undescribed butterfly that is currently known to exist only at Fort Macon State Park, Brandt Island, Radio Island, and Bear Island. Use of dredge materials stored in the large pit on Brandt Island would probably cause little impact, but we would be very concerned if any dredge materials are taken from areas of the island that have been stabilized by development of a grass cover.

MEMORANDUM

TO:	Milt Rhodes
THROUGH:	John Dorney, DWQ
FROM:	Shannon Stewart, DWQ
DATE:	April 10, 2000
SUBJECT:	Bogue Banks Beach Restoration Plan, Carteret County

Based on a review of the subject EIS, the Division of Water Quality has the following comments:

1. The EIS considers four possible borrow areas for the Bogue Banks Beach Restoration project. In section 3.16.1 of the EIS, it states that borrow area A provides the most promising deposits in terms of beach compatibility and potential yield of beach-quality sediments. Borrow Area A had the lowest R_A value, which indicated that approximately 85% of the deposit would be stable as beach fill in the project area. The other three potential borrow areas (B1, B2, and C) yielded R_A values substantially higher than borrow area A. As noted in the EIS, these areas would therefore require proportionately higher excavation volumes to achieve the same performance as borrow area A. The EIS also states that only a portion of borrow area A will be required to satisfy the nourishment volume requirements of this project – ample beach-quality sediments exist in this location.

   Section 2.3.1 of the EIS lists the selection of borrow areas as an "unresolved issue" at this point in the project. It states that "it will be uncertain until bids are received which combinations of dredge type and borrow area will yield the most cost-efficient project." The Division of Water Quality supports the use borrow area A as the exclusive source for beach-quality sediments for this project. As compared to the other three proposed borrow areas, the use of borrow area A as the sole source for beach sediments would require less material, would improve the durability of the nourishment project, would minimize changes in types and densities of nearshore species, and would reduce the rate of fill loses therefore minimizing turbidity in nearshore waters. Although borrow areas B1 and B2 may result in lower costs related to travel distances, they will have greater impacts on the nearshore environment in and around the project area.

   The Division of Water Quality would also like to request that when a decision is reached on the selection of a borrow area(s) appropriate documentation be provided for comment.

Re: Draft Environmental Impact Statement
Bogue Banks Beach restoration Plan
Project # 1046

Dear Mr. Monaghan:

The comments of your Division on the referenced EIS were greatly appreciated. Responses to the comments of the Division of Marine Fisheries are provided in this letter and the enclosures.

Enclosed with this letter is the "Final Report of The late fall 1999 assessment of benthic invertebrate and demersal fish resources in the offshore mining sites prior to sand mining." This report will replace the preliminary report included with the Draft EIS reviewed by your staff. Also enclosed are revised sections to the Draft EIS. On the revised pages, the replaced text is crossed out, and the revised text is in italics.

The original schedule for implementation of this project included placement of and on the beach during the coming winter months of years 2000 and 2001. Funding for that County wide project did not materialize as hoped. For that reason the scope of the project has been revised so that the municipalities of Emerald Isle, Pine Knoll Shores, Indian Beach and Salter Path (An unincorporated township of Carteret County) can implement nourishment projects as funding sources are developed. Nourishment projects in each of the communities will be implemented based on the design and constraints outlined in this EIS and any subsequent Major CAMA Permit issued based on this EIS. The Project description, Section 1.4 of the EIS has been revised to reflect this change. A copy of those revisions are included for your review.

Comment: In our review of the scoping document for this project (memorandum dated January 26, 2000) we requested that research be conducted to determine recovery times for benthic populations that are destroyed by pumping and depositing materials. This research has not been fully addressed in the EIS. We realize that sampling needs to continue through early fall for an accurate description of species diversity and species abundance to be completed. We cannot speculate as to what the potential impacts might be from the present EIS. ***We recommend that one complete year of field work be conducted in the offshore borrow areas and the nearshore intertidal deposit areas. Adequate time for data analyses, report preparation, and report review should be allowed and a complete review of these results should be made in the EIS.*** *If possible, data on the benthos should be collected from nearshore and intertidal areas of Fort Macon, Atlantic Beach, and Emerald Isle where pumping has occurred. We* *can provide the research design if requested. We also recommend that the particle size of the existing beach be the size pumped onto the beach since the literature indicates this will lessen recovery times.*

Response: The University of North Carolina, Institute of Marina Sciences, Charles H. (Pete) Peterson have completed the initial phase of the sampling meeting the criteria you have outlined. The results of those studies are provided in the attached report which will replace the preliminary report provided in the draft EIS. Physical and biological impacts and recovery will be monitored systematically following a sampling plan recommended by Dr. Peterson or recognized experts. Your input into that monitoring effort is requested. UNC-IMS has in their possession existing baseline data throughout Bogue Banks. We anticipate using these data when they become available in the published literature to compare construction and post-construction sampling. We requested these data for inclusion in the EIS but were informed that analyses are not available until published. Time is of the essence on this project. The severely eroded condition of the beach means any delay in implementation of a project could lead to higher property damages and losses. Given the existing body of research on impacts to benthic organisms and the natural variability of these systems, we believe that additional pre-nourishment sampling and research will not provide definitive results or allow prediction of impacts more accurate than can be deduced from the experiences in the literature. We believe that the proposed plan will result in reasonably rapid recovery because it will follow the practices discussed below.

There have been numerous studies of recovery of benthic fauna on nourished beaches. Many factors effect the recovery including grain size compatibility of nourishment sand with existing beach sand, seasonal relationship of nourishment to growth period of benthic fauna, depth of sand placed on the beach, levels of turbidity associated with various nourishment sand sources and ability of certain fauna to migrate vertically through the nourished sand. Monitoring of Phase one of the Myrtle Beach Renourishment Project (Jutte, Van Dolah and Levision, March 1999) found that benthic infauna largely recovered after two to three months. The study found that, in some cases, nourishment actually resulted in enhancement of biological assemblages.

The impact of nourishment on beach macro invertebrates has been shown to be highly variable. Virtually all published studies report some initial impact (either confirmed by direct sampling after nourishment, or by inference), However, recovery rates (compared to pre-nourishment densities) have been found the range from days to weeks (e.g. Jutte, et. al. 1999; Gorzelany and Nelson, 1987) to several years (eg. Cutler and Mahadeva, 1982). Studies by Donaghue (1999) at Pea Island (NC) and Peterson et. al.(2000) at Atlantic Beach (NC) quoted by the correspondent generally found longer recovery times the the majority of other researchers, including Van Dolah et/ al (1992) and Baca and Lankford (1987). A fundamental reason for the disparity in results among the various investigators is the extreme natural variability of population densities depending on seasons, variations in sediment compatibility between the natural beach and the nourishment sand, and the frequency of storms. It is generally accepted that the biological populations will recover more slowly if:

Nourished sands do not closely match the native sand grain size distribution,
Nourishment is performed during periods of peak larval recruitment,
The scale of the projects is large relative to the cross-shore dimension, and
Projects are repeated frequently, causing disruption of successive growing cycles.

No study has proven total loss of benthic populations due to nourishment or scraping. The concem is over the rate and scale of recovery compared to natural beaches. The proposed project design seeks to reduce impacts and accelerate recovery in the following ways:

- Selection of borrow area the most closely matches the desirable characteristics for the indigenous benthic fauna. Borrow area A has the best overfill ratios but is slightly coarser and has twice the shell content as the native beach. Borrow areas B1 and B2 have lower percentages of shell and slightly finer mean grain size (yielding moderately higher overfill ratios).Some investigators (eg. Peterson, 2000, personal communications) have suggested that borrow areas may be preferable for recruitment and recovery of beach organisms. Others (eg., Stewart, NCDENR-DWQ, comments) suggest borrow area A will yield sediments that produce fewer overall impacts on the nearshore environment. Regardless of which borrow area is selected, the differences compared to the natural beach, are considered relatively small because of the wide range of sediment sizes that occur between the foredune and inshore zone along Bogue Banks.
- Nourishment will be performed during periods of low biological recruitment periods (eg., late fall, winter and early spring months).
- The scale of the project in the cross-shore dimension is moderate (approximately 50 cy/ft), comparable to nourishment projects that have demonstrated rapid biological recovery such as Myrtle Beach (Baca, et.al, 1987; Jutte et. al, 1999)
- The project will be large enough given the low background erosion rate of the site to avoid frequent repeat nourishment every couple of years so that successive growth cycles are not interrupted as is the case now with frequent beach scraping (bull dozing).

The only means available to verify the impact of the nourishment on the Bogue Banks beach and borrow area fauna is to monitor the impacts through a program that includes characterization of both the physical and biological conditions before, immediately following and for a period sufficient to determine full recovery of the biological resources in the borrow area and on the beaches and to determine the physical performance of the nourishment project.

The Bogue Banks nourishment project will include a program of monitoring of impacts. Specific objectives of the monitoring will be as follows:

1. Document and quantify physical changes in the beach and nearshore zone,
2. Determine the ecological impacts and recovery rates of beach and nearshore biological resources following nourishment, and
3. Document the physical and biological impact and recovery of sand bottom habitats in the borrow area.

Comment: Another primary concern on this project is the time window for dredging. We strongly recommend that the time be shortened from October1 through May 15 to December 1 through March 31. This should reduce effects on recruitment of finfish and minimize effects on traditional beach fisheries.

It appears that, due to funding constraints, the project will have to be constructed in segments as funding becomes available in each of the individual municipalities on Bogue Banks. Construction windows may, therefore, be shortened. However, because of economic considerations and weather contingencies, the applicant wishes to have available the longest possible window for construction. By current state and federal policies, that window runs from November 1 (end of turtle nesting season) to May 15 (beginning of turtle nesting season) in North Carolina.

We believe that the responses provided herein should provide you and your staff with a better understanding of the Bogue Banks Project and the measures to be implemented as part of the project to minimize and to measure the physical and biological impacts of the project.

We would appreciate a timely review of the enclosed information and a response as to the adequacy of the EIS with the revisions indicated. That response should be made to this office to my attention.

If you have questions on any aspect of the project, please feel free to call me.

Sincerely,

STROUD ENGINEERING, P.A.

Re: Draft Environmental Impact Statement
Bogue Banks Beach restoration Plan
Project # 1046

Dear Mr. McBride:

The comments of your Division on the referenced EIS were greatly appreciated. Responses to the comments of the staff biologists with the Wildlife resources Commission are provided in this letter and the enclosures.

Enclosed with this letter is the "Final Report of The late fall 1999 assessment of benthic invertebrate and demersal fish resources in the offshore mining sites prior to sand mining." This report will replace the preliminary report included with the Draft EIS reviewed by your staff.

The original schedule for implementation of this project included placement of and on the beach during the coming winter months of years 2000 and 2001. Funding for that County wide project did not materialize as hoped. For that reason the scope of the project has been revised so that the municipalities of Emerald Isle, Pine Knoll Shores, Indian Beach and Salter Path (An unincorporated township of Carteret County) can implement nourishment projects as funding sources are developed. Nourishment projects in each of the communities will be implemented based on the design and constraints outlined in this EIS and any subsequent Major CAMA Permit issued based on this EIS. The Project description, Section 1.4 of the EIS has been revised to reflect this change. A copy of those revisions are included for your review.

Comment: The DEIS indicates that erosion is responsible for loss of beach, dune and maritime forest habitats and a wide range of wildlife resources. If this document seeks to identify causes of lost wildlife resources and habitat then losses attributed to human disturbance, landscape alterations and development should also be included as contributing factors especially since this document indicates that Bogue Banks oceanfront has reached 90 percent build-out.

Response: It is not within the scope of the draft EIS to identify causes of lost wildlife resources except for such impacts that might occur as a result of placement of sand on the beach from the designated borrow areas. Significant habitat losses can be attributed solely to erosion of the beach and the subsequent bulldozing of the beach undertaken to protect property from the ocean. With a stable berm fronting the dune as exist along the nourished beach areas of the Town of Atlantic Beach, the need for annual bulldozing of the beachfront would be eliminated allowing vegetation and the macro invertebrates to recolonize the beach, including the berm and dune face, and reestablish habitat that would otherwise be lost indefinitely.

This is illustrated by a survey of Sea Beach Amaranth conducted during August 2000 of the beaches of Bogue Banks from Bogue Inlet to Beaufort inlet. Twenty-three (23) plant individuals were identified along the entire island by the survey. Of those, 20 were located along the beach in portions of the Town of Atlantic Beach that have been nourished in the last ten years. The individual plants were found on the foredune at and above the dune toe. The stable beach that remains as a result of the nourishment projects in Atlantic Beach has created habitat for this endangered plant to flourish. On the remaining beach including Pine Knoll Shores, Salter Path, Indian Beach and Emerald Isle, only three individuals plants were identified. These were located 4 to 5 feet above the dune toe in Salter Path in an area were extensive beach scraping has occurred. It that area the dune is subject to loss because there is no significant berm width fronting the dune. The vegetation, dunes and dry beach areas that make up wildlife habitat on natural beaches require a long term stable beach for protection from the ocean. The nourishment project will provide that stability along the other beaches of Bogue Banks west of Atlantic Beach.

Of the approximately 335 miles of North Carolina's barrier islands from the Virginia border to Little River Inlet, only 143 miles or 43 percent is either developed or subject to development. The remaining 190 miles or 57 percent remains undeveloped and, for the most part, will remain so in perpetuity. A significant portion of the undeveloped barrier islands are accessible only by boat.

In Carteret County the numbers are even more dramatic. The County's barrier islands stretch from Ocracoke Inlet to Bogue Inlet, approximately 81 miles (measured on a County map). The undeveloped portions, from Beaufort Inlet to Ocrackoe inlet, make up 57 miles or approximately 70 percent of the total barrier island length. The developed portion of the County, Bogue Banks (excluding Fort Macon State Park), makes up 24 miles or approximately 30 percent of the County's total barrier island length. The Bogue Banks Project will not alter that distribution. Along the beach of Bogue Banks, the nourishment project will add the following:

Approximately 100 acres of dry beach (i.e., 16.8 miles, 50 feet wide)
Approximately 30 acres of stable dunes that evolve naturally by aeolian processes versus the unnatural bull dozing of coarse grained sand dunes that has occurred each year since 1995.

Comment: The reviewer referred to studies by C. R. Donahue and Peterson et. al. Indicating that beach nourishment causes a severe depletion of in numbers of macro invertebrates (shorebird food). Population recovery rates of macro invertebrates are dependent on recruitment from pelagic larval stocks and recruit from neighboring beaches.

Response: While these studies are important, the nourishment experience in the cases covered in those case studies differs greatly from that which is proposed at Bogue Banks.

Scale: The Pea Island nourishment site is only one mile long but received a total of approximately 500 c.y. / ft over seven years (versus (50 c.y. / ft. for the proposed project).
Frequency of Nourishment: The Pea Island site was nourished eight times between 1991 and 1997.
Sediment Grain size Compatibility: The Pea Island site received sand much finer than the natural beach (m_z=3.67 phi versus native beach 2.33 phi, Peterson, et. al, 2000).
Timing: Both studies involved beach fill placement during the active biological recruitment times in late spring. We anticipate beach fill operations for the Bogue Banks project to be during the optimal environmental windows as directed by the regulatory agencies via permit conditions.

Comment: We are very concerned for foraging shorebirds during all times of the year (breeding season, migration, wintering). North Carolina's coast is nesting habitat for species such as the willet, American oystercatcher, Wilson's plover, and piping plover and we often think of habitet for these as the most important to protect. However, our coast is also serves as very important wintering and migration habitat for many species of shorebirds. Therefore, we are not only concerned about beach renourishment during the breeding season, but throughout the entire year, especially when considering the cumulative impacts of large-scale renourishment projects. We do not believe that the direct and cumulative impacts to intertidal macro invertebrates and shorebirds have been adequately addressed in the DEIS.

Response: The assessment of the benthic invertebrate resources at Bogue Banks conducted by Peterson and Wells has been revised to include (enclosed for your review and inserted into the revised EIS as Appendix C) states that certain macro invertebrates and fish species are present along inshore and offshore areas at Bogue Banks. Therefore, dredging sand from offshore borrow areas and nourishing the shoreline may bury intertidal macrofauna and reduce the available food resource to birds that feed on these organisms. However, direct impacts to macro invertebrates associated with this project will be reduced for several reasons. Dredging and filling activities will occur largely during winter months, avoiding the larval recruitment period of many of these species, including mole crabs (early October) and coquina clams (spring and summer) (Donaghue, 1999). Additionally, studies have shown that intertidal macrofauna can recolonize a nourished area within one or two seasons (Ross and Lancaster, 1996; National Research Council, 1995; Reilly and Bellis, 1978), therefore, impacts will be temporary. Lastly, sand of similar grain size to the existing beach will be used to reduce changes in physical characteristics of the beach that may affect nourishment impacts on invertebrates (Donaghue, 1999; Peterson et al, 1999; Hackney et al, 1996).

Indirect impacts imposed on shorebirds that feed on macro invertebrates will be minimized as well. After impacts to macrofauna have occurred and numbers of these species are depressed, birds that prey upon these invertebrates, including the threatened piping plover, would likely move to adjacent undisturbed beach areas and other suitable feeding areas for the temporary period of population re-establishment. Because macro invertebrates recolonize rapidly, no long term impacts to these organisms or the shorebirds that prey upon them are anticipated with this project.

Comment: The large scale beach nourishment project will bury whole populations of intertidal macro invertebrates may preclude rapid recovery of those populations and does not allow for shorebirds to shift their foraging to nearby sites.

Response: There have been numerous studies of recovery of benthic fauna on nourished beaches. Many factors effect the recovery including grain size compatibility of nourishment sand with existing beach sand, seasonal relationship of nourishment to growth period of benthic fauna, depth of sand placed on the beach, levels of turbidity associated with various nourishment sand sources and ability of certain fauna to migrate vertically through the nourished sand. Monitoring of phase one of the Myrtle Beach Renourishment Project (Jutte, Van Dolah and Levision, March 1999) found that benthic infauna largely recovered after two to three months. The study found that, in some cases, nourishment actually resulted in enhancement of biological assemblages.

The impact of nourishment on beach macro invertebrates has been shown to be highly variable. Virtually all published studies report some initial impact (either confirmed by direct sampling after nourishment, or by inference), However, recovery rates (compared to pre-nourishment densities) have been found the range from days to weeks (e.g. Jutte, et. al. 1999; Gorzelany and Nelson, 1987) to several years (eg. Cutler and Mahadeva, 1982). Studies by Donahue (1999) at Pea Island (NC) and Peterson et. al.(2000) at Atlantic Beach (NC) quoted by the correspondent generally found longer recovery times the the majority of other researchers, including Van Dolah et/ al (1992) and Baca and Lankford (1987). A fundamental reason for the disparity in results among the various investigators is the extreme natural variability of population densities depending on seasons, variations in sediment compatibility between the natural beach and the nourishment sand, and the frequency of storms. It is generally accepted that the biological populations will recover more slowly if:

Nourished sands do not closely match the native sand grain size distribution,
Nourishment is performed during periods of peak larval recruitment,
The scale of the projects is large relative to the cross-shore dimension, and
Project are repeated frequently, causing disruption of successive growing cycles.

No study has proven total loss of benthic populations due to nourishment or scraping. The concern is over the rate and scale of recovery compared to natural beaches. The proposed project design seeks to reduce impacts and accelerate recovery in the following ways:

Selection of borrow area the most closely matches the desirable characteristics for the indigenous benthic fauna. Borrow area A has the best overfill ratios but is slightly coarser and has twice the shell content as the native beach. Borrow areas B1 and B2 have lower percentages of shell and slightly finer mean grain size (yielding moderately higher overfill ratios).Some investigators (eg. Peterson, 2000, personal communications) have suggested that borrow areas may be preferable for recruitment and recovery of beach organisms. Others (eg., Stewart, NCDENR-DWQ, comments) suggest borrow area A will yield sediments that produce fewer overall impacts on the nearshore environment. Regardless of which borrow area is selected, the differences compared to the natural beach, are considered relatively small because of the wide range of sediment sizes that occur between the foredune and inshore zone along

Bogue Banks.

Nourishment will be performed during periods of low biological recruitment periods (eg., winter and early spring months).

The scale of the project in the cross-shore dimension is moderate (approximately 50 c.y./ ft), comparable to nourishment projects that have demonstrated rapid biological recovery such as Myrtle Beach (Baca, et.al, 1987; Jutte et. al, 1999)

The project will be large enough given the low background erosion rate of the site to avoid frequent repeat nourishment every couple of years so that successive growth cycles are not interrupted as is the case now with frequent beach scraping (bull dozing).

The only means available to verify the impact of the nourishment on the Bogue Banks beach and borrow area fauna is to monitor the impacts through a program that includes characterization of both the physical and biological conditions before, immediately following and for a period sufficient to determine full recovery of the biological resources in the borrow area and on the beaches and to determine the physical performance of the nourishment project.

The Bogue Banks nourishment project will include a program of monitoring of impacts. Specific objectives of the monitoring will be as follows:

1. Document and quantify physical changes in the beach and nearshore zone,
2. determine the ecological impacts and recovery rates of beach and nearshore biological resources following nourishment, and
3. document the physical and biological impact and recovery of sand bottom habitats in the borrow area.

Comment: With a total project length (16.8) miles, this is one the longest beach nourishment projects in the last 20 years. The DEIS presents beach nourishment as a "sacrificial shore-protection technique". There are many examples of how beach nourishment provides at best only minimal protection from the encroaching sea and there are examples of the sand from beach nourishment being washed away within weeks of deposition. We question if this is a wise expenditure of public monies considering the cost of the renourishment, potentially short duration of the benefits and the adverse impacts to the fish and wildlife resources dependent on the project area.

Response: Beach nourishment is not a panacea for shore protection and beach management. Each location must be evaluated on its own merits as a candidate site for a successful nourishment project. For beaches with very high background erosion rates of 10 to 50 feet per year, the economics of beach nourishment will be very different from Bogue banks, which has background erosion rates of 1 to 3 feet per year (N.C. Division of Coastal Management, Long Term Average Annual Shoreline Change Rates, Updated through 1992). Carteret County is fortunate to have a beach nourishment project at Atlantic Beach that demonstrates convincingly the Bogue Banks is an excellent location for beach nourishment. The respondents are advised to drive the beach of Bogue Banks from west to east. From the healthy beaches at the west end of Emerald Isle to Atlantic Beach, the berm is narrow (in many places only a low tide beach exist), there is evidence if extensive structural damage to buildings and access decks and walkways, extensive loss of natural dune and adjoining maritime forest and underbrush where present, and evidence that at least 80 percent of the beach has been scraped to provide dune protection since the fall of 1999. The physical change in the beach shape upon entering the town limits of Atlantic Beach is dramatic. There is a wide berm, stable dunes with vegetation and little or no evidence of structural damage to ocean front buildings and decks. The performance of the nourished beach at Atlantic Beach provides physical evidence of a wider dry beach and reduced storm damage throughout the 1990's compared to exposed (non-nourished) beaches in the project area. The reviewer is referred to section 2.2.2 , Physical Impacts, of the draft EIS for a review of the physical factors that make Bogue Banks and excellent site for successful beach nourishment.

We are not aware of any beach nourishment projects constructed in North Carolina where the beaches have washed away in weeks following placement. If such projects do exist, please identify the projects so that the details of the projects can be investigated to determine the reasons for failure.

We believe that the responses provided herein provide you and your staff with a better understanding of the Bogue Banks Project and the measures to be implemented as part of the project to minimize and to measure the physical and biological impacts of the project.

We would appreciate a timely review of the inclosed information and a response as to the adequacy of the EIS with the revision indicated. That response should be made to this office to my attention.

If you have questions on any aspect of the project, please feel free to call me.

Sincerely,

STROUD ENGINEERING, P.A.

Re: Draft Environmental Impact Statement
Bogue Banks Beach restoration Plan
Project # 1046

Dear Mr. Rhodes:

The comments of your Division on the referenced EIS were greatly appreciated. Responses to the comments of the staff of the wetlands unit and the planning branch of the Division are provided in this letter and the enclosures.

Enclosed with this letter is the "Final Report of The late fall 1999 assessment of benthic invertebrate and demersal fish resources in the offshore mining sites prior to sand mining." This report will replace the preliminary report included with the Draft EIS reviewed by your staff. Also enclosed are revised sections of the Draft EIS. On the revised pages, the replaced text is crossed out, and the revised text is in italics.

The original schedule for implementation of this project included placement of and on the beach during the coming winter months of years 2000 and 2001. Funding for that County wide project did not materialize as hoped. For that reason the scope of the project has been revised so that the municipalities of Emerald Isle, Pine Knoll Shores, Indian Beach and Salter Path (an unincorporated township of Carteret County) can implement nourishment projects as funding sources are developed. Nourishment projects in each of the communities will be implemented based on the design and constraints outlined in this EIS and any subsequent Major CAMA Permit issued based on this EIS. The Project description, Section 1.4 of the EIS has been revised to reflect this change. A copy of those revisions are included for your review.

Comment: Please supply the Division with a notification of the borrow area selection once it has been made.

Response Three borrow areas have been selected for use in the project, areas, A, B1 and B2. These areas are proposed because they contain the beach-compatable sediments. Use of borrow area A will result in the lowest overfill ratios on the beach, the most durable fill, and will be the most cost effective to excavate using a hopper dredge, a technique preferred over others by some regulatory agencies. Borrow areas B1 and B2 contain somewhat finer material and will result in slightly higher overfill ratios. The higher overfill ratios will result in placement of more cubic yards of material to achieve the same adjusted beach profile and project durability. The additional costs associated with the additional sand volumes may be offset by the economies available due to the proximity of borrow areas B1 and B2 to the beaches.

Comment: The project must meet the turbidity standards set forth in the 401 Water Quality Certification for this project:

Response: Turbidity resulting from the disposal activities on the beach is addressed in section 5.9 of the Draft EIS. Results from two studies of turbidity associated with beach nourishment operations showed that, in both studies, turbidity did not exceed 25 ntu's outside the discharge area. Due to the low mud content of the borrow area sediments identified in borrow areas A, B1 and B2 (Appendix E, Table E6 of the Draft EIS), generally less than 4 percent, we believe that the project will be able to meet the requirements of the 401 Water Quality Certification.

Comment: It is desired that work be conducted between the months of November and April to limit the degree and severity of impact to environmental resources.

Response: It appears that, due to funding constraints, the project will have to be constructed in segments as funding becomes available in each of the individual municipalities on Bogue Banks. Construction windows may, therefore, be shortened. However, because of economic considerations and weather contingencies, the applicant wishes to have available the longest possible window for construction. By current state and federal policies, that window runs from November 1 (end of turtle nesting season) to May 15 (beginning of turtle nesting season) in North Carolina.

We believe that the responses provided herein should provide you and your staff with a better understanding of the Bogue Banks Project and the measures to be implemented as part of the project to minimize and to measure the physical and biological impacts of the project.

We would appreciate a timely review of the enclosed information and a response as to the adequacy of the EIS with the revisions indicated. That response should be made to this office to my attention.

If you have questions on any aspect of the project, please feel free to call me.

Sincerely,

STROUD ENGINEERING, P.A.

Re: Draft Environmental Impact Statement
Bogue Banks Beach restoration Plan
Project # 1046

Dear Mr. Hall:

The comments of your Division on the referenced EIS were greatly appreciated. Responses to the comments of the Division of Parks and Recreation are provided in this letter and the enclosures.

Enclosed with this letter is the "Final Report of The late fall 1999 assessment of benthic invertebrate and demersal fish resources in the offshore mining sites prior to sand mining." This report will replace the preliminary report included with the Draft EIS reviewed by your staff. Also enclosed are revised sections to the Draft EIS. On the revised pages, the replaced text is crossed out, and the revised text is in italics.

The original schedule for implementation of this project included placement of and on the beach during the coming winter months of years 2000 and 2001. Funding for that County wide project did not materialize as hoped. For that reason the scope of the project has been revised so that the municipalities of Emerald Isle, Pine Knoll Shores, Indian Beach and Salter Path (An unincorporated township of Carteret County) can implement nourishment projects as funding sources are developed. Nourishment projects in each of the communities will be implemented based on the design and constraints outlined in this EIS and any subsequent Major CAMA Permit issued based on this EIS. The Project description, Section 1.4 of the EIS has been revised to reflect this change. A copy of those revisions are included for your review.

Comment: One of the potential borrow areas is located within Bogue Inlet. As stated on p. 5-8, if this area is chosen as a source for dredge material, habitat for the piping plover (Charadrius melodus), federally and state listed as threatened, may be lost. We strongly recommend that this area, along with other areas located within the inlets or on the accreting ends of the banks, be excluded as potential borrow sites.

Response: The applicant agrees to delete the shoals in and around Bogue inlet as a potential source of borrow material for the beach nourishment project.

Comment: Possible impacts to the loggerhead sea turtle (Caretta caretta), federally and state listed as Threatened, are also identified (p. 5-8). Impacts may result from the use of inappropriate dredge materials, changes in beach profiles, or from disposal activities taking place within the nesting or hatching periods. The use of nest relocations is proposed to mitigate for some of these impacts, but we regard this *as the least desirable form of mitigation. Instead, we recommend that the standard measures supported by the US Fish and Wildlife Service and the US Army Corps of Engineers be followed regarding the (1) the types of sediments that are acceptable for disposal; (2) the beach profile created by renourishment. Beach nourishment should take place strictly in the off-season for sea turtle nesting-- November through April-- not as currently requested (p. 4-10) for the months of October and May.*

Response: To minimize impacts to nesting sea turtles in the project area, standard protocol adopted by the U. S. Fish and Wildlife Service and used in previous beach nourishment projects in North Carolina will be followed. This protocol includes the following guidelines:

1. Only beach quality sand suitable for sea turtle nesting, successful incubation, and hatchling emergence shall be used for beach nourishment on the project site. Furthermore, sand of similar grain size to the existing beach will be used to reduce any changes in physical characteristics of the beach that may affect nest survival.

2. Immediately after completion of the beach nourishment project and prior to the next three nesting seasons, beach compaction shall be monitored and tilling shall be conducted as required to reduce the likelihood of impacting sea turtle nesting and hatching activities.

3. Immediately after completion of this project and prior to the next three nesting seasons, monitoring shall be conducted to determine if escarpments are present and escarpments shall be leveled as required to reduce the likelihood of impacting sea turtle nesting and hatching activities.

4. Carteret County will ensure that contractors doing the beach nourishment and dredging work fully understand sea turtle protection measures.

5. Beach nourishment and dredging activities are planned to begin after November 1 and be completed before May 1. If any filling occurs after May 1, the pipeline will be placed along the landward edge of the berm.

6. If any beach nourishment or dredging activities take place during the period from May 1 through November 15, a standardized nest monitoring and relocation plan will be implemented in addition to the monitoring that already occurs. The plan incorporates monitoring of the beach disposal area each morning from the beginning of the nesting season until all equipment is removed from the beach and the relocation of any nests laid within the project area. Using standard nest relocation techniques, all nests will be located to a suitable nursery beach, agreed to prior to the start of relocation effort by the U.S. Fish and Wildlife Service and the North Carolina Wildlife Resources Commission. Hatching success of relocated nests will be monitored and reported.

7. Immediately after completion of this project and prior to May 1 for three subsequent years, sand compaction will be monitored in the area of restoration in accordance with a protocol agreed to by the Service, the State regulatory agency, and Carteret County. At a minimum, the protocol provided under 7a and 7b below will be followed. If required, the area will be tilled to a depth of 36 inches. All tilling activity must be completed prior to May 1. A report on the results of compaction monitoring will be submitted to the Service prior to any tilling actions being taken. An annual summary of compaction surveys and the actions taken will be submitted to the Service. This condition will be evaluated annually and may be modified if necessary to address sand

compaction problems identified during the previous year.

7a. Compaction sampling stations shall be located at 500-foot intervals along the project area. One station will be at the seaward edge of the dune/berm line (when material is placed in this area); one station will be midway between the dune line and the high water line; and one station will be located just landward of the high water line. At each station, the cone penetrometer shall be pushed to a depth of 6, 12, and 18 inches three times (three replicates). Material may be removed from the hole if necessary to ensure accurate readings of successive levels of sediment. Replicates will be located as close to each other as possible, without interacting with the previous hole and/or disturbed sediments. The three replicate compaction values for each depth will be averaged to produce final values for each depth at each station. Reports will include all 27 values for each transect line, and the final 9 averaged compaction values.

7b. If the average value for any depth exceeds 500 psi for any two or more adjacent stations, then that area will be tilled prior to May 1 of the following year. If values exceeding 500 psi are distributed throughout the project area but in no case do those values exist at two adjacent stations at the same depth, then consultation with the Fish and Wildlife Service will be sought to determine if tilling is required. If a few values exceeding 500 psi are present randomly within the project area, tilling will not occur.

8. Visual surveys for escarpments along the project area shall be made immediately after completion of the beach nourishment project and prior to May 1 for three subsequent years. Results of the surveys will be submitted to the Service prior to any action being taken. Escarpments that interfere with sea turtle nesting or that exceed 18 inches in height for a distance of 100 feet will be leveled to the natural beach contour by May 1. The Service will be contacted immediately if subsequent reformation of escarpments that interfere with sea turtle nesting or that exceed 18 inches in height for a distance of 100 feet occurs during the nesting and hatching season to determine the appropriate action to be taken. If it is determined that escarpment leveling is required during the nesting or hatching season, the Service will provide a brief written authorization that describes methods to be used to reduce the likelihood of impacting existing nests. An annual summary of escarpment surveys and actions taken will be submitted to the Service.

9. From March 1 through April 30 and November 1 through November 15, staging areas for construction equipment will be located off the beach to the maximum extent practicable. Nighttime storage of construction equipment not in use will be off the beach to minimize disturbance to sea turtle nesting and hatching activities. In addition, all construction pipes that are placed on the beach will be located as far landward as possible without compromising the integrity of the dune system. Temporary storage of pipes on the beach will be in such a manner so as to impact the least amount of nesting habitat and shall likewise not compromise the integrity of the dune systems.

These guidelines have been incorporated into the revised EIS in section 3.15. By planning to perform the majority of the project during off-season months, monitoring beach hardness, and relocating nests found in unsuitable habitat if project completion delays occur, impacts to nesting loggerhead sea turtles will be minimized.

Comment Use of dredge spoils deposited at Brandt Island (p. 4-6) may potentially affect an undescribed butterfly that is currently known to exist only at Fort Macon State Park, Brandt Island, Radio Island, and

Bear Island. Use of dredge materials stored in the large pit on Brandt Island would probably cause little impact, but we would be very concerned if any dredge materials are taken from areas of the island that have been stabilized by development of a grass cover.

Response: The applicant agrees to eliminate the dredge spoil islands at Brandt Island as a source of borrow material for the beach nourishment project..

We believe that the responses provided herein should provide you and your staff with a better understanding of the Bogue Banks Project and the measures to be implemented as part of the project to minimize and to measure the physical and biological impacts of the project.

We would appreciate a timely review of the enclosed information and a response as to the adequacy of the EIS with the revisions indicated. That response should be made to this office to my attention.

If you have questions on any aspect of the project, please feel free to call me.

Sincerely,

STROUD ENGINEERING, P.A.

Ms. Shannon Stewart
North Carolina Department of Environment and Natural Resources
Division of Water Quality, Non-Discharge Branch
1621 Mail Service Center
Raleigh, North Carolina 27699-1621

Re: Draft Environmental Impact Statement
Bogue Banks Beach restoration Plan
Project # 1046

Dear Ms Stewart:

The comments of your Division on the referenced EIS were greatly appreciated. Responses to the comments of the staff of the Non-discharge Branch of the Division are provided in this letter and the enclosures.

Enclosed with this letter is the "Final Report of The late fall 1999 assessment of benthic invertebrate and demersal fish resources in the offshore mining sites prior to sand mining." This report will replace the preliminary report included with the Draft EIS reviewed by your staff. Also enclosed are revised sections of the Draft EIS. On the revised pages, the replaced text is crossed out, and the revised text is in italics.

The original schedule for implementation of this project included placement of and on the beach during the coming winter months of years 2000 and 2001. Funding for that County wide project did not materialize as hoped. For that reason the scope of the project has been revised so that the municipalities of Emerald Isle, Pine Knoll Shores, Indian Beach and Salter Path (an unincorporated township of Carteret County) can implement nourishment projects as funding sources are developed. Nourishment projects in each of the communities will be implemented based on the design and constraints outlined in this EIS and any subsequent Major CAMA Permit issued based on this EIS. The Project description, Section 1.4 of the EIS has been revised to reflect this change. A copy of those revisions are included for your review.

Comments: Related to comment concerning impacts associated with selection of borrow areas.

Response: It appears that, due to funding constraints, the project will have to be constructed in segments as funding becomes available in each of the individual municipalities on Bogue Banks. Construction windows may, therefore, be shortened. However, because of economic considerations and weather contingencies, the applicant wishes to have available the longest possible window for construction. By current state and federal policies, that window runs from November 1 (end of turtle nesting season) to May 15 (beginning of turtle nesting season) in North Carolina.

Comment: Comment related to meeting the turbidity standards in the 401 Water Quality Certification for this project.

Response: Turbidity resulting from the disposal activities on the beach is addressed in section 5.9 of the Draft EIS. Results from two studies of turbidity associated with beach nourishment operations showed that, in both studies, turbidity did not exceed 25 ntu's outside the discharge area. Due to the low mud content of the borrow area sediments identified in borrow areas A, B1 and B2 (Appendix E, Table E6 of the Draft EIS), generally less than 4 percent, we believe that the project will be able to meet the requirements of the 401 Water Quality Certification.

Comment: Related to construction schedule:

Response: It appears that, due to funding constraints, the project will have to be constructed in segments as funding becomes available in each of the individual municipalities on Bogue Banks. Construction windows may, therefore, be shortened. However, because of economic considerations and weather contingencies, the applicant wishes to have available the longest possible window for construction. By current state and federal policies, that window runs from November 1 (end of turtle nesting season) to May 15 (beginning of turtle nesting season) in North Carolina.

We believe that the responses provided herein should provide you and your staff with a better understanding of the Bogue Banks Project and the measures to be implemented as part of the project to minimize and to measure the physical and biological impacts of the project.

We would appreciate a timely review of the enclosed information and a response as to the adequacy of the EIS with the revisions indicated. That response should be made to this office to my attention.

If you have questions on any aspect of the project, please feel free to call me.

Sincerely,

Raleigh, North Carolina, 27699-1601

Re: #1046 Bogue Banks Restoration Plan, Draft EIS, Carteret County

Dear Ms. McGee:

Please find attached letters from the commenting agencies from the initial review of the referenced draft EIS by the Department of Environment and Natural Resources. In all cases the letters indicate that revisions to the DIES and responses provided to each reviewer sufficiently address each reviewers concerns.

Copies of the letters from each reviewer are attached for your information. Also attached are copies of the initial review comments as provided by your office to Doug Huggett and subsequently to this office, and copies of the response letters to each reviewer from this office. All of this correspondence will be attached to the EIS with the index of correspondence.

It is important that review of the EIS proceed on a timely basis. Even though the referendum was voted down by County residents, the Towns of Pine Knoll Shores and Indian Beach are proceeding with preparations to construct a beach nourishment project during the dredging window of years 2001 and 2002. That project will be based on the findings and criteria set out in the referenced EIS.

Doug Huggett has agreed to contact me on the next steps we must take to complete review of the EIS.

If you have any questions concerning the enclosed documents or need additional information, please give me a call.

Sincerely,

STROUD ENGINEERING, P.A.

J. W. Forman, Jr., P.E.

MEMORANDUM

TO: J.W. Forman
Stroud Engineering

FROM: William Wescott, Coastal Coordinator
Habitat Conservation Program

William Wescott

DATE: October 24, 2000

SUBJECT: Bogue Banks Beach Restoration Plan: Comments regarding consultant responses and the final report of benthic invertebrate and demersal fish resources.

We requested a copy of a USACE study investigating the impacts beach nourishment had on benthic invertebrates. Our Coastal Coordinator in Washington received a copy of the study on October 23, 2000. After reviewing the study and consulting with coastal geologists we are able to respond to your September 13, 2000 letter.

Apparently benthic studies have been diligently undertaken to collect and identify the nearshore and offshore benthic communities that would be impacted by the proposed beach nourishment project. The inclusion of this information in the Final EIS will address our concerns regarding non-specific and incomplete data.

We remain concerned for foraging shorebirds during all times of the year (breeding season, migration, wintering). If beach nourishment occurs then nourishment activities should be scheduled to avoid peak biological activity of invertebrates. We still advocate that a better long-term solution for protecting beachfront development is to establish wider setbacks on all structures as they are rebuilt after being lost to the sea.

Thank you for the opportunity to comment on this project. We look forward to reviewing a complete EIS document. If you need to discuss these comments please call William Wescott at (252) 946-6481.

Dear Mr. Forman:

The Division of Water Quality (Division) has reviewed the responses to initial comments raised during agency review of the Bogue Banks Beach Restoration Plan Draft Environmental Impact Statement. The responses included in this letter submitted by Stroud Engineering and the modifications to the DEIS adequately address the Division's concerns regarding the project's impact to the surrounding environment. Please be advised that the project should meet the turbidity standard set forth in the 401 Water Quality Certification to be issued by the Division.

DATE: October 2, 2000

SUBJECT: 1046 -- Bogue Banks Beach Renourishment

This memo is in response to a letter from J.W. Forman, Jr., P.E., Stroud Engineering, dated September 13, 2000.

We have reviewed the applicant's response to our comments on the EIS. Based upon further review of the EIS and recent literature that has come to our attention we recommend the following:

1. **Continue monitoring the offshore borrow areas and nearshore intertidal deposit areas during the summer of 2001. Also, monitor these areas immediately following renourishment and for a period of time sufficient to determine recovery rates of the fauna.**

2. **A dredging window of November 15 through April 15.**

We appreciate the opportunity to comment on this project.

MEMORANDUM

TO: Melba McGee

FROM: Stephen Hall

SUBJECT: Response to Comments – DEIS – Beach Restoration Plan, Bogue Banks

REFERENCE: 1046

In our review of the DEIS, we had concerns about the potential for impacts to piping plovers (*Charadrius melodus*) and loggerhead sea turtles (*Caretta caretta*), both federally and state listed as Threatened. We also had concerns about the use of dredge spoil material from Brandt Island, the site of a colony of an undescribed and apparently very rare butterfly. The applicant (letter from J.W. Forman to S.P. Hall, 9/13/00) has addressed each of these concerns to our satisfaction.

RE: Bogue Banks Beach Restoration Plan – SEPA Draft Environmental Impact Statement

Please accept these comments regarding the proposed project on behalf of Environmental Defense, our 10,000 members in North Carolina and 300,000 members nationwide. In general, we have serious concerns regarding the large-scale, persistent and cumulative effects of this and related beach engineering projects, and the adequacy with which impacts from these projects are addressed. We recognize and acknowledge the efforts of the project sponsor and authors of the draft EIS to address the issues of highest controversy surrounding beach engineering, and offer the following comments regarding those issues for which we have particular concerns:

1) Cumulative and Long Term Impacts: In general, our dominant concern regarding beach engineering projects, particularly ones of such extensive spatial (and potentially temporal) magnitude, is the inadequate assessment of cumulative and long-term impacts to living marine resources and essential fish habitats. Specifically, the impacts of these projects are assessed on a piecemeal, or project-by-project basis, rather than as components of a statewide and regionwide beach engineering effort. We recognize that scientific studies examining the impacts of engineering operations on beach, intertidal and nearshore fauna are ongoing and not yet complete, but enough information exists to warrant a programmatic EIS on *all* of these activities for the North Carolina coast, if not the entire southeast region. We have requested such an evaluation of the Corps of Engineers (see Attachment 1) in a letter dated September 8, 2000. The Corps' response was that such an evaluation was too costly to undertake at the present time.

   Although the current project is proposed to be a one-time placement of sand, designed to "restore the sand deficit and provide for average yearly losses over a decade or so" (DEIS, Section 2.1, p. 2-2), it is clearly stated at the end of the introduction (Section 1.4, p. 1-3) that it is unlikely the entire project could be constructed within the same environmental window. Indeed, it appears that, given the funding needs of the communities, the project will stretch over several environmental windows. We are concerned about the downstream impacts of such discontinuous construction, which, as pointed out in Section 5.4.5 (page 5-2, second paragraph) are not insignificant.

www.environmentaldefense.org

2) Definition of Project Success: As acknowledged in Section 2.2.2 (p. 2-2) one of the major controversies with respect to beach engineering is the development of criteria, or lack thereof, for defining project success. Given the magnitude of resources required for the proposed project, there ought to be a clearly defined set of criteria by which to measure project success, particularly if state cost-share funds are obtained for any portion of the project as discussed in Section 2.3.3. The DEIS state in Section 2.2.2 that "Success will be defined in relation to how closely the postnourishment volume erosion rate compares with the estimated prenourishment volume erosions rate" (page 2-3), yet fails to identify a range of values which would constitute an acceptable or "successful" erosion rate. Although achievement of a certain rate of erosion may constitute success in an engineering sense, it may not necessarily translate into visible success for the project sponsors (i.e., the communities, and potentially state taxpayers if cost-share funding is obtained). Considering that this project is supposed to serve as "prototype" for future beach maintenance efforts (Section 2.1, page 2-1) and as a basis for determining a "long-range solution" from amongst three alternatives (Section 2.4, page 2-5), development of specific evaluation criteria by the project sponsors, rather than the contracted engineering company, would appear to be critical.

3) Project Purpose: Among the four stated objectives (Section 1.3, page 1-2) of the project is "preservation of the environmental, cultural and aquatic resources of the county". We maintain that this project as designed (mainly due to the extensive geographic scale) protects only the unnatural, i.e., manmade "environmental resources". The three remaining planning objectives are a more realistic statement of purpose. Beach engineering projects are rarely, if ever, consistent with protection of the natural environment, and we are unaware of any such projects that have enhanced the nation's living marine resources. We also disagree with the statement that Bogue Banks serves to draw human activity away from the more pristine shores of Shackleford and Core Banks. Although not accessible by vehicle, there is ample transportation available to these locations via public and private ferries, and certainly the number of privately owned boats anchored in Back and Core Sounds during the summer months does not indicate that the public is dissuaded from visiting these areas.

4) Consideration of Alternatives: The DEIS states that "Property abandonment and relocation at a large scale would leave the beach degraded for many years because it would necessarily become a piece-meal process" (page 1). Yet, as referenced previously, the DEIS indicates that if approved, project construction would itself be piecemealed. A retreat and relocation alternative can be planned to initially target those structures most at risk, and can be implemented gradually, rather than in one massive effort. Indeed, should this project be approved, development of a phased relocation and/or exit strategy should be considered, particularly if cost-share funding is obtained. Given that the community plans to reevaluate the costs and benefits of renourishment after a decade of monitoring (Section 2.2.2), development of such a strategy would be proactive. That being said, having once obtained the necessary approval for a beach engineering project (especially if other funding sources are obtained), it is highly likely that the local communities will naturally expect approval for a second project, at an even greater economic and environmental cost.

Also, under the no-action alternative in Section 4.2, page 4-2 one of the stated, yet unquantified, environmental impacts of this alternative is "chronic impacts to beach fauna". We presume that this would be the result of beach scraping. We disagree with this statement, as it implies that placement of dredged sand on the beach would *not* impact beach fauna and that beach scraping would not occur should the project move forward. Incidentally, we find it interesting that "loss of recreational beach" is listed as a quantifiable environmental impact, considering the subjective and intangible nature of the recreational experience, while no attempt is made to quantify the loss of biota.

5) Monitoring Program/Protocol: We applaud the commitment of the project sponsors to develop a comprehensive pre- and post-construction monitoring plan as outlined in Appendix C, and for initiating pre-project benthic monitoring. We feel that such efforts are absolutely necessary in order to assess project impacts accurately over the proposed 10-year project lifetime. We also feel that a periodic (once every three years), publicly available assessment of impacts should be conducted and the results used to adjust the implementation and maintenance of the project and develop a compensatory mitigation plan if warranted, especially if the communities elect to continue beach engineering as a management option. In light of the fact that environmental impacts are not quantified in the analysis of costs and benefits, we feel very strongly that the project sponsors be responsible for funding the monitoring program.

6) NC Marine Fisheries Commission Policies on Beach Dredge and Fill Activities: The North Carolina Marine Fisheries Commission (MFC) has statutory responsibility for protecting the marine and estuarine resources of North Carolina against impacts from both fishing and non-fishing threats. On November 16, 2000, the MFC approved a new policy for the protection of marine and estuarine resources under its authority from the effects of beach dredge and fill activities and related coastal engineering activities (copy attached). The Habitat and Water Quality Standing Advisory Committee of the NC Marine Fisheries Commission developed the policy in response to increasing number of beach engineering projects being developed and the inadequate consideration of cumulative and long-term impacts of these projects. This policy includes numerous issues that have so far not been adequately addressed in the DEIS.

In addition, the MFC shares responsibility under state law for the development of Coastal Habitat Protection Plans (CHPPs). The statutory goal of these plans is the "net enhancement" of the value to the coastal fishery of each habitat type. The Coastal Ocean CHPP is currently in pre-draft form; it will shortly be issued in public draft. That draft will include a set of policies and procedures to protect the marine and estuarine resources of North Carolina against development activities including beach engineering activities. The CHPP will then be formalized in regulation. The CHPP and its adjunct regulations will become a part of the state's federal coastal zone management plan.

Finally, we would like to explicitly state several requests regarding the Bogue Banks Renourishment DEIS:

- When will a programmatic EIS or comprehensive assessment of beach engineering projects be performed, at least for the state of North Carolina?
- What are the project sponsors' criteria for project success?
- Is there a contract with a research institution to continue the pre-construction benthic monitoring, develop post-project benthic monitoring, as well as develop a pre- and post-construction intertidal monitoring program?
- Should state cost-share monies be obtained, are there plans to proactively develop phased exit strategies in the event that beach engineering is not found to be a viable management alternative?

Until these questions and the other issues we have raised can be sufficiently addressed, we do not feel that the Bogue Banks Renourishment project should move forward. We repeat our request that a programmatic EIS be conducted, including full assessment of cumulative impacts of the multiple projects at various stages of design. We reiterate our willingness to discuss any of the issues that we have raised.

We thank you for the opportunity to comment on this very important project.

Sincerely,

Michelle Duval, Ph.D.

Dear Mr. Huggett:

Re: SCH File # 01-E-4300-0357; Draft Environmental Impact Statement Bogue Banks Beach Restoration Plan

The above referenced environmental impact information has been reviewed through the State Clearinghouse under the provisions of the North Carolina Environmental Policy Act.

Attached to this letter are comments made by State department(s) in the course of this review. The comment(s) need to be addressed in the Final Environmental Impact Statement. This document should be submitted to the State Clearinghouse upon completion for compliance with the North Carolina Environmental Policy Act.

Best regards.

Sincerely,

Chrys Baggett

Re: Bogue Banks Beach Restoration Plan

Dear Mr. Huggett:

I enclose here my comments on the Draft EIS for the Bogue Banks Beach Restoration Plan. I make these comments in my professional capacity as a coastal ecologist with the University of North Carolina at Chapel Hill. These opinions are derived from my 25 years of personal experience in quantitative monitoring of the major beach invertebrates on the beaches of Bogue Banks, my years of experimental analyses of how ecological processes on sand beaches are influenced by the physical character of the sediments, my personal experience with two beach nourishment projects at Fort Macon, my 30+ years of professional reading, research, and experience as a marine ecologist, my two decades of teaching barrier island ecology at Duke University and the University of North Carolina, and my recent experience as a member of the IRC charged with development of CHPPs, including the Coastal Ocean Habitat Protection Plan.

In my professional opinion, the proposed Bogue Banks Beach Restoration Plan is inadequately protective of the important natural resources of the intertidal beach and the coastal ocean, including especially the physical habitat and prey invertebrates required to sustain our recreationally and commercially important fisheries and the valued shorebirds of our beaches. Without (1) scientifically rigorous before-after monitoring of physical character of the sediments, impacts and recovery of the invertebrate prey, and consequences of turbidity and habitat change on the fishes, with required mitigation for any substantive impacts, (2) development of a state plan for assessing cumulative impacts based on results of a programmatic EIS covering all these sand mining and beach deposition projects along the entire coast of the state and beyond, as dictated by the range of the important fishes, (3) a match of sediment grain sizes to the natural sediments of the beach in a way that will protect the habitat value of the beach, and (4) restriction of the project to between Dec 1 and March 31 so as to minimize ecological damage and allow recovery to begin to develop during the ecologically significant spring-summer seasons, this project should not be granted a permit.

(1) Scientifically rigorous before-after monitoring of sediments, benthos, and fishes

The draft EIS is grossly deficient in its commitment to the monitoring that is necessary to evaluate the ecological impacts of the project and thereby allow the agencies to learn how to respond to future requests and how to condition projects to protect adequately the public trust resources. While it is true that monitoring of nourishment projects has been done in the past, this project is unique for its spatial scope, its application to pristine shores, and its context in the midst of potentially hundreds of miles of

similar projects coast-wide. Past beach nourishment projects have been done on short stretches of urbanized shore like Atlantic Beach, Wrightsville Beach, and North Topsail. The application to a pristine beach of such a length as to represent a significant fraction of the functional critical habitat for beach fishes, invertebrates, and shorebirds is unprecedented for North Carolina. Past monitoring projects attached to permit applications are almost uniformly poor scientifically, done merely to satisfy a regulatory burden in a way that typically produces inconclusive results. Monitoring should be designed up-front by and reviewed by professional statisticians so that the agency and the public can have reassurance that the important questions can be answered with adequate power to detect effects of ecological significance. That has not been done here. Here we are told that monitoring will be done by the Carteret County monitoring plan. There is no such plan, no detailed statistical design, and no binding commitment by the county, state, or the responsible party to funding such a project. In fact, the necessary before-project sampling has not even been done. In South Carolina projects, the offshore biology has been monitored before and after such projects in each of the four seasons of the year: this proposal includes pre-project monitoring of benthic invertebrates for only one season (autumn), yet the offshore fishery resources here are arguably even more important than off South Carolina. There are no data included on pre-project monitoring of the beach ecosystem and no design that could be evaluated statistically for its rigor and ability (power) to detect important changes. Granting a permit under such inadequacy is not in the public interest.

There is broad and essentially uniform consensus among the scientific community that the impacts of beach nourishment projects on fisheries through modification of their bottom and water column habitats are poorly understood. The monitoring that has been done for such projects in the past (1) has been too restricted to include all the potentially important impacts on fisheries, (2) has lasted for too short a time period to confidently demonstrate recovery, (3) has failed to meet standards of rigor and high power to detect large impacts, and/or (4) has been done for projects occurring on too small a scale to allow extrapolation to the cumulative effects of permitting many miles of beach nourishment. The impacts of concern include both phases of nourishment projects, the mining of sediments from the shelf and the deposition of sediments on the beach.

A minimally adequate monitoring design for either the mining site or the deposition site would include the following components. First, the monitoring design must begin with quantitative data taken before initiation of the project. Such "Before" observations must be made during each season of importance to the biota that comprise and use the habitat. A single year of such "Before" data is an absolute minimum necessary to make rigorous conclusions and multiple years of "Before" data are required to be completely comfortable in estimating the magnitude of effects with confidence. These "Before" data must include observations made in both the putative "Impact" areas and in "Control" areas that are sufficiently distant not to be affected by the project but sufficiently nearby and similar that they can serve to track conditions that would be expected in the "Impact" area in the absence of the project. The observations made during the "Before" period then need to be replicated in the "After" period in both the putative "Impact" areas and the "Control" areas. This monitoring needs to match the seasonal monitoring done during the "Before" period and needs to extend long enough in time to demonstrate recovery or allow inference of recovery with high statistical confidence. The "Control" area should have replication that involves statistically independent sites. This is preferable for the "Impact" areas too, but sometimes impossible because there may be only one project site. In any event, sufficient subsampling must be done at multiple locations to characterize the habitat and its utilization adequately. This monitoring design must be shown to be likely to have high statistical power to detect any magnitude of impact deemed important to fisheries biologists and managers. This requires an effective statistical design. Perhaps the best model for such rigorous project monitoring comes from the paper on BACI (Before-After-Control-Impact) designs by Stewart-Oaten et al. (1986: Ecology). Most monitoring associated with permits is incapable of statistically demonstrating even large impacts of the project with confidence because of inadequate statistical power in the design. The evaluation of cumulative impacts of beach nourishment on a large scale of tens of miles is a particular challenge, fundable perhaps only by creating a monitoring bank from contributions from multiple projects.

(2) Programmatic EIS for cumulative impacts and appropriate monitoring

Besides the needs to evaluate the impacts of this particular project on Bogue Banks, the responsible permitting authorities have a duty to evaluate the cumulative impacts of all such perturbations to the coastal ocean system. This requires first a programmatic EIS that applies the best scientific judgement, open to public review, analysis, and comment, as to cumulative impacts, especially on fishery populations and shorebirds. For a short stretch of urbanized shoreline, it is readily argued that most fish and shorebirds are mobile enough to move elsewhere to feed when their invertebrate prey resources are killed by beach nourishment. Similarly, when prey resources are mined along with sand from the offshore sand bodies, one can argue that the demersal fishes and crustaceans can feed elsewhere. But when projects are large enough and numerous enough and when projects are repeatedly done over time, then the potential for seriously limiting the production of fishes and birds greatly increases. Furthermore, if the physical sedimentary habitat is permanently altered or modified for the long term, then there is great potential for permanent limitation of the extent of critical fisheries habitat both on continental-shelf sand bodies (a limited habitat already in the southern portion of the state) and on intertidal beaches. Nowhere in this Draft EIS for Bogue Banks is there evidence that the public trust resources will be protected from cumulative spatial and cumulative temporal effects. Until such time that evidence exists, no permit should be granted for this project.

(3) Match of sediment grain sizes to protect habitat value of the beach

The recovery of natural ecological functioning of the beach habitat depends upon closely matching the sediment size distribution to that of the natural undisturbed beach. I have shown in a published paper based on study of a previous beach nourishment project on Bogue Banks (Peterson et al. 2000: Journal of Coastal Research) that the US ACOE requirements for matching sediment sizes are inadequate to allow recovery of function of the beach habitat within the following summer season. Incorporation of either too much shell (coarse material) or too much silt/clay (fine material) inhibits recovery. Too much shell inhibits burrowing by the beach invertebrates, which must burrow into the sediments to feed and avoid erosion and wave-transport off the beach face. Too much shell also prevents many shorebirds from feeding on the invertebrates that are present because coarse particles block the biomechanical ability of bills to extract invertebrate prey (see test in published paper by Quammen 1982: Marine Biology). Too much silt/clay likewise prevents sand burrowers from inhabiting a habitat that now lacks the interstitial spaces among sand grains and the penetrability required for burrowing. In addition, silt/clay is readily suspended causing enhanced turbidity, which clogs the filtration apparatus of these suspension-feeding beach invertebrates (mole crabs, coquina clams, some polychaetes, and amphipods) and inhibits surf fishes like pompano, bluefish, and Spanish mackerel from detecting their prey. We possess feeding data from experiments showing this feeding inhibition on pompano in the presence of elevated turbidity. The Bogue Banks project, as proposed in this Draft EIS, plans use of sediments that are much more dominated by shell fragments than the natural pristine Bogue Banks beaches. This will result in long-term (not just transient) reduction in beach invertebrate populations and thus habitat value for surf fishes and shorebirds. I base this judgement upon knowledge of the physical processes that affect sediments on the beach and upon my lab's survey of the biota of North Carolina beaches as a function of shell content. Silts and clays are gradually winnowed away from beach sediments as they become suspended in the water and make it turbid. Shell fragments, in contrast, are left behind to accumulate on beaches, and thus remain to degrade the beach habitat indefinitely until the next nourishment project is needed. Lower densities of the numerically and functionally important large burrowing invertebrates on shellier beaches are dramatic in our unpublished survey data. Thus, the choice to use shell-rich sediments in the Bogue Banks nourishment project will predictably degrade the critical habitat of the intertidal beach indefinitely. Such a poor match with pristine sediments should not be permitted.

(4) Restriction of the project to Dec 1 through March 31

Because of the seasonality of biological use and activity in both the subtidal sand body habitat and the intertidal beach habitat, sand mining and beach deposition should both be restricted to the colder months to minimize ecological injury and to speed up recovery in the next warm season. The draft EIS for the Bogue Banks project does not constrain the project adequately in light of what is known about biological seasonality to protect the functioning of these habitats. Our monitoring of beach invertebrates on Bogue Banks over a period of 25 years shows that the period of December 1 through March 31 is the proper window during which beach invertebrates like mole crabs and coquina clams have migrated to deeper waters, from which they can initiate recovery through migration and reproduction at the end of the project. Furthermore, our sampling of fish abundance at the sand bodies proposed for mining to conduct this Bogue Banks project demonstrated high abundances and high rates of feeding on bottom invertebrates of the sand bodies on November 29 and again in spring, with low levels in February after clod fronts had reduced water temperatures. The Draft EIS for Bogue Banks does not propose a time frame for the project that will adequately protect either of these habitats from the impacts of the project. A permit should not be granted until the window is narrowed to this Dec 1-March 31 season. Furthermore, the public is entitled to a commitment that such a window will be enforced by DCM: similar restrictions have not been enforced in the past and I have little confidence that they will be in the future, absent some new mechanism of assurance.

I trust that my concerns are clearly and fully enough articulated here. If any comments need further elaboration, please ask. In addition, if you need further information from our files, please ask.

Sincerely,

Charles H. Peterson

Dear Sirs:

This letter is in reference to the Bogue Banks Beach Restoration Plan Draft EIS (DEIS). As you may be aware, the DEIS completed its initial State Clearinghouse review on March 15th, 2001. It is my understanding that the State Clearinghouse has provided you with copies of the comments received by that office as of the March 15th deadline. In case this is not correct, I have provided a copy of these comments as well. In addition to these comments, an additional set of DEIS review comments were received in this office on March 16th, 2001. Although these comments were received one day after the official review period ended for the review, after discussion with the State Clearinghouse I have determined that it is appropriate and necessary that these comments be considered and addressed in Final Environmental Impact Statement (FEIS). Therefore, I must ask that you address all of the attached comments in the FEIS, and that 12 copies of the document be submitted to this office so that I may initiate the FEIS review process.

Please let me know if you have any questions concerning this matter. I may be reached at (919) 733-2293 or by e-mail at doug.huggett@ncmail.net.

Sincerely,

Doug Huggett

RE: Response to Comments dated 15 March 2001 from Dr. Charles H. Peterson, University of North Carolina Institute of Marine Sciences [Ref: EIS #01–E–0357] Bogue Banks Beach Restoration Plan (2049)

Dear Mr. Huggett:

I am writing on behalf of Carteret County and the Towns of Pine Knoll Shores and Indian Beach, in response to the above-referenced comments on the Bogue Banks nourishment project.

The correspondent has urged your agency to require that four conditions be met before a permit for the Bogue Banks nourishment is granted. I wish to outline herein how the applicant plans to meet certain of these conditions and to explain why others are not possible to achieve in any reasonable time or budget.

Dr. Peterson and his colleagues at UNC-IMS contributed valuable information and data in the development of the draft EIS under contract to Carteret County. They provided the initial biological samplings in November 1999 and February 2000, and prepared a detailed report which is Appendix C of the EIS.

Our project team has actively sought Dr. Peterson's guidance and recommendations for design of the project such that environmental impacts can be minimized. His contributions to the project have been important. We have also sought the advice of other experts [including Dr. Robert Van Dolah (SCDNR) and Dr. Bart Baca (Nova University)] and have reviewed the literature regarding impacts of dredging and beach fills on the fauna of similar project sites.

Early in the county's planning process (fall 1999), we were informed by Dr. Peterson that no quantitative biologic sampling data exist in and around our proposed borrow areas. As a result, the county, at its own initiative, contracted with UNC-IMS for a preproject monitoring that could be used as a baseline for future comparisons. The first of two planned samplings was completed by Dr. Peterson's group in November 1999. Detailed data from this survey are reported in Appendix C of the draft EIS.

UNC-IMS reportedly has completed numerous samplings of benthic organisms along the beach as part of a four-year study of the impacts of beach scraping. We requested relevant data from these samplings so they could be incorporated into the EIS but were informed by Dr. Peterson that they will not be available until one of his students completes a dissertation. As outlined in the draft EIS, we plan to use these data to estimate baseline beach conditions for the project when they become public.

Following are our responses to the four conditions outlined by Dr. Peterson.

Item 1) Rigorous before-after monitoring of sediments, benthos, and fishes.
The draft EIS (Appendix C) outlines the sampling protocols used by Dr. Peterson for his offshore surveys. The applicant proposes to follow up these samplings with additional benthic sampling in spring 2001 (preproject). Postproject sampling will be performed using similar sampling protocols and design in consultation with your agency and other reviewing agencies. Because it now appears that the project will be completed in several discrete segments by three towns and the county over several years, we are requesting guidance from NC DENR and National Marine Fisheries regarding what constitutes an acceptable level of biologic sampling. The Towns of Pine Knoll Shores and Indian Beach do not have unlimited resources to fund research that is more properly performed by universities or government agencies or that is more applicable to global concerns. However, the applicants realize the importance of sampling habitats over which their projects may produce direct and quantifiable impacts. Accordingly, we have recommended that the county and cooperating municipalities sponsor the following:

- A second preproject sampling of benthic organisms in spring 2001 in and around the planned borrow areas following the Peterson sampling design given in Appendix C of the draft EIS.
- Annual postconstruction sampling of benthic organisms in and around the borrow area(s) and beach for up to three years after completion of the Pine Knoll Shores and Indian Beach reaches on a schedule acceptable to state and federal agencies.

The results of Appendix C, as well as research published in the literature, suggest that quantification of impacts to fisheries by the proposed project is not possible by any reasonable amount of sampling of the water column for transient species. Such questions are global in nature and will require a major commitment of time and money to answer in any rigorous sense. We believe that the natural variation in pelagic species passing through and utilizing the borrow area(s) and beach is far too great to quantify impacts or prove cause and effect. This problem is not a straightforward sampling exercise. Therefore, the chance of any sampling schedule offering rigorous, predictive results is negligible.

Item 2) Programmatic EIS for cumulative impacts
The question of cumulative impacts is important and should be addressed in some manner by state and federal agencies. However, this is not a trivial exercise and certainly not one that can be accomplished in a reasonable amount of time. It will take years and millions of dollars to even begin to address this problem in any sort of rigorous way, given the wide range of variables that must be sampled, analyzed, modeled, and integrated. This is a global concern. I believe that years of effort would be required just to develop a scientific sample design or statistical model upon which professionals could agree. The question of cumulative impacts spans the disciplines of oceanography, geology, biology, chemistry,

CSE

water quality, fisheries, primary production, climate, rainfall, runoff, and anthropogenic inputs of man. This is not something that can be answered before the next damaging storm impacts Bogue Banks and, therefore, should not be a prerequisite for granting a permit for the project.

Item 3) Match sediment grain sizes.

The correspondent expressed concern about the shell percentage and advises that "high" shell content should not used. The draft EIS presents data for three borrow areas (A, B1, and B2). Borrow area A contains a deposit having about twice the shell content of the beach. Borrow areas B1 and B2 contain about the same 20 percent shell content as the native beach. As the draft EIS and permit application states in detail, the applicant proposes to use the particular combination of borrow areas that optimizes the match of grain sizes and costs of dredging. The applicant is continuing to collect borings in borrow areas B1 and B2 (beyond those reported in the draft EIS) in response to Dr. Peterson's recommendation to limit the shell percentage. In fact, more care has gone into the search for a good match of sediment types for this project than any previous nourishment along Bogue Banks. Other investigators have noted how poorly prior projects matched the sediments. (Atlantic Beach was too shelly and the Ramada Inn site was too fine.) The applicant believes that there is insufficient monitoring data from these prior projects to make any definite recommendations regarding shell content. If the agencies will provide quantitative criteria for nourishment sediment characteristics (specifically, a particular range of shell percentages) based on previously published studies, the applicant will strive to match them.

Item 4) Restrict the project to December 1 through March 31.

This restriction would be unprecedented, considering the number of nourishment projects that are completed during the biologically productive summer months. We are aware of no data or published reports that state these dates constitute the only acceptable window for dredging. The applicant has chosen to perform the work in cold-water months rather than request a permit for work in summer as other agencies have done. The period from around 1 November to around 1 May has been an accepted standard for construction outside the normal turtle-nesting period in many East Coast states. By shortening the window to only four months, it is highly unlikely that the project can be completed in one season. This means that equipment will have to re-mobilize and re-impact the project areas at considerable extra expense to the applicant.

If quantifiable data exist and state or federal agencies have a justifiable basis for establishing such a restrictive dredging window for the proposed project, the applicant is prepared to adjust the schedule. However, such restrictions should then be applied universally. I believe the schedule for dredging is important. However, to ultimately avoid any sense of arbitrariness, extensive biologic sampling on a monthly basis for many years should be performed by government agencies such that a sound basis for restricting the dredging window can be developed.

Finally, I would like to reiterate that what the applicant is proposing is a one-time project. It will be the first nourishment of Bogue Banks designed to match properly the texture of sediments in the borrow area with those of the native beach. The project will be performed in sections rather than in one complete pass over 16.8 miles such that adjacent areas have time to adjust and recover their biologic populations before the next sections are constructed. It will reduce the need for and frequency of beach scraping, a recurring adverse impact to biota in recent years. And it will allow dunes to build naturally with fine, windblown sediments that facilitate revegetation.

The present beach/dune system of Bogue Banks is not pristine. Its profile has been altered such that it is steeper and more vulnerable than the native beach to severe damage in storms. Coarse sand and pebbles common to the swash zone now reside in the foredunes, inhibiting revegetation. With loss of recreational beach has come a loss of turtle-nesting habitat and diminishment of a vegetative buffer between the ocean and development.

Bogue Banks is eroding, but not fast enough to create economic incentives to relocate. The proposed project, rather than continuing the present cycle of scraping after every storm, has a better chance of restoring the natural character of the beach and reducing the need to scrape. The project scale proposed by the applicant is sufficient to provide recreation and storm-protection benefits for at least one decade.

In closing, I wish to express my firm's commitment to executing the project in as environmentally sensitive a manner as practicable and reasonable. However, I do not believe it is possible for any project to achieve all four conditions recommended by Dr. Peterson. We will be happy to meet with your agency and UNC-IMS representatives at any time to develop an acceptable biological monitoring plan for the project.

Thank you for your consideration.

Yours truly,

Timothy W Kana PhD

RE: Response to Comments dated 13 March 2001 from Environmental Defense
Bogue Banks Beach Restoration Plan (2049) [SCH File #01-E-4300-0357]

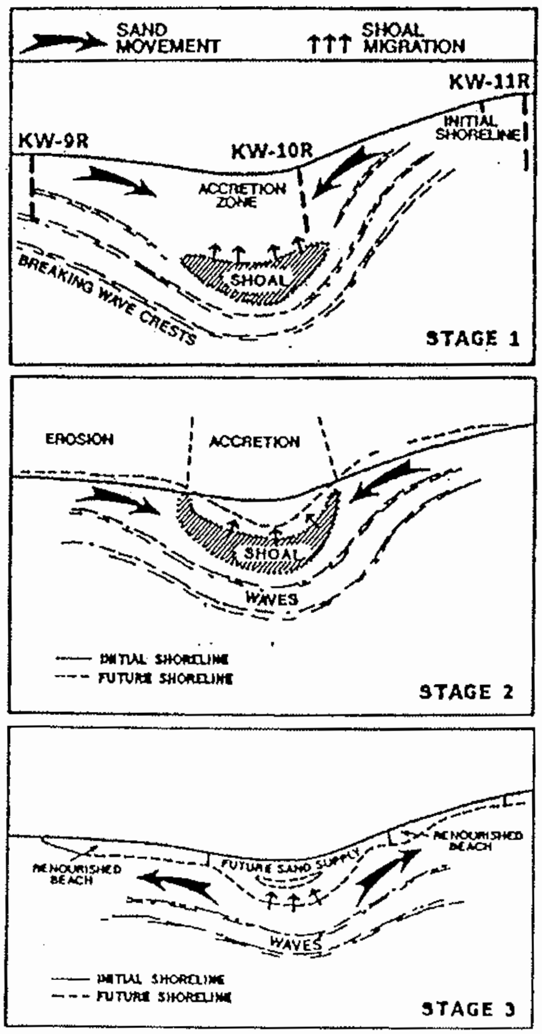
Dear Mr. Huggett:

This letter is in response to Environmental Defense comments dated 13 March 2001 on the above-referenced draft environmental impact statement.

Item 1) Concerns regarding cumulative and long-term impacts and schedule for construction
Response: The question of cumulative impacts is important and should be addressed in some manner by state and federal agencies. However, this is not a trivial exercise and certainly not one that can be accomplished in a reasonable amount of time. It will take millions of dollars to even begin to evaluate this problem in any sort of rigorous way, given the wide range of variables that must be sampled, analyzed, modeled, and integrated. This is a global concern. I believe that years of effort would be required just to develop a scientific sample design or statistical model upon which professionals could agree. The question of cumulative impacts spans the disciplines of oceanography, geology, biology, chemistry, water quality, fisheries, primary production, climate, rainfall, runoff, and anthropogenic inputs of man. This is not something that can be answered before the next damaging storm impacts Bogue Banks.

A growing body of research shows that borrow area dredging and beach nourishment produce short-term, temporary impacts (cf, Van Dolah et al, 1992; Jutte et al, 1999a; 1999b; referenced in the draft EIS, Appendix A). These can be minimized by proper matching of sediments and construction in colder months (as planned for the present project). After the project is complete, there will be nearly the same area of intertidal and offshore habitat available as before the project. It will simply be displaced seaward by the width of the new beach. Environmental studies of similar projects suggest impacted areas will recolonize rapidly. The primary questions for project monitoring are how fast will the borrow area and beach communities recover and how closely will the benthic populations match the native conditions. In theory, these should be easy questions to answer. But in reality, natural populations fluctuate over such wide ranges that there can never be assurance that a change in species numbers or diversity is due to anthropogenic impacts like dredging rather than some global impact such as water temperature change. Recently, South Carolina closed its spring shrimp fishery because the white shrimp larvae count was less than 5 percent of normal for this time of year. The decline was attributed to a prolonged cold snap where water temperatures fell below 45°F for more than 18 days. Such order-of-magnitude declines are common in natural systems and will occur off Bogue Banks as well, whether or not the project is constructed.

The correspondent expresses concern about downstream impacts if the project is performed discontinuously in sections and cites page 5-2 of the draft EIS. The study referenced (Roessler, 1998) relates to the possible effect of an offshore disposal mound near Beaufort Inlet encompassing nearly 30 million cubic yards. This artificial feature built over 30 years in connection with USACE navigation projects may have altered wave/current patterns along Atlantic Beach, although no historical data exist to prove this. The proposed project will not alter the nearshore bottom such that it changes the wave and current patterns to the detriment of downstream communities (cf, Appendix G). The scale of the borrow-area changes for the proposed project are dwarfed by changes around Beaufort Inlet and the offshore mound.



Regarding possible adverse end effects of the project, this will be minimized by tapering of the fill sections as described in the draft EIS and in responses to NCDENR comments in the correspondence section of the draft EIS. Adjacent unnourished areas will tend to benefit rather than suffer from the downstream spread of the beach fill. Many nourishment projects, in fact, are designed as "feeder" beaches whereby sand is placed every few years along an updrift reach in order to flow downcoast and nourish other sections (CERC, 1984). Probably the worst "end effects" occur in <u>natural</u> systems where shoals break free of inlets and bypass to the adjacent beach. As the process occurs, the beach in the lee of the shoal accretes rapidly while the adjacent sections erode. This has been documented in many places (cf, Kana et al, 1985; 1999) and is illustrated schematically in Figure A. The reason that natural shoal bypassing produces adverse end effects is because it tends to concentrate large volumes over short lengths of beach. The proposed project will spread sand relatively thinly and evenly along many miles of shoreline such that perturbations in the shoreline will be minimal.

FIGURE A.

CSE

Item 2) Definition of project success

As engineers for the applicant, my firm is developing quantitative criteria for defining project success. The key variable is the volumetric erosion rate. In our review of prior studies, we found no historical profiles or surveys which could be used as a rigorous basis for predicting this rate. The only data available were linear shoreline change rates (eg, movement of mean high water or vegetation lines) and limited sets of wading depth profiles (not comprehensive for the entire project area). We used these data to extrapolate volumetric changes and estimate approximate beach fill requirements for 5-year, 10-year, and 20-year periods (CSE Stroud, 1999). The applicant has initiated annual surveys of the nearshore and has obtained two sets of 110 profiles spanning the length of Bogue Banks. Each profile extends about 1,000 ft offshore and documents changes to the outer bar.

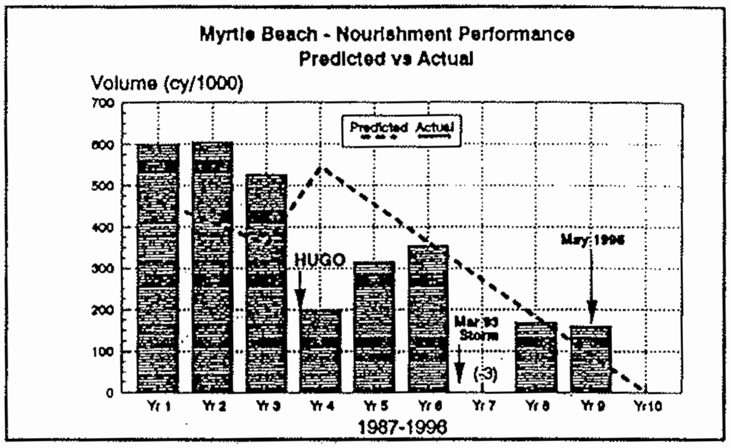
Enclosed is the first beach monitoring report covering the period June 1999 to June 2000. Also contained in the report are about 18 post-*Floyd* profiles from September 1999. The results show a range of erosion and accretion losses and provide more guidance for establishing project erosion rates. However, we consider these data to be insufficient to make any more refined long-term predictions because they only span one year. The applicant plans to resurvey the beach in June 2001 and update these data. As we have represented in the draft EIS, the anticipated volume losses are expected to be of the order 1-5 cy/ft/yr measured to closure depth. The rate will be closer to the high range if borrow areas B1 and B2 (less shelly deposits) are used and closer to the low range if area A (more shelly deposit) is used. Regardless of the rate, the applicant plans to perform annual surveys and quantify the fate of the beach fill such that a more rigorous erosion rate estimate can be developed for Bogue Banks over the next decade.

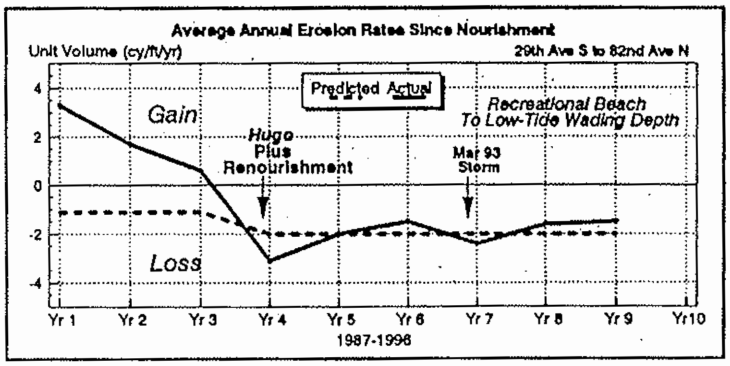
Figure B illustrates similar results for a project in Myrtle Beach (SC). In that particular project, the unit fill volumes were only about one-third the quantities proposed for Bogue Banks. Historical data suggest that Myrtle Beach and Bogue Banks have nearly equal long-term erosion rates.

CSE is in the process of developing "specific evaluation criteria" in consultation with the sponsoring communities. These will be particular to each borrow area(s). In general, the most appropriate criteria are volumetric erosion rates rather than some particular beach width because it is the littoral volume that is important in the long run. Short-term, beach-width fluctuations are poor predictive parameters because they are contour sensitive. For example, Hurricane *Floyd* produced a certain average dune recession (~12 ft) but matched it with seaward movement of mean high water (cf, CSE, 2000 – attached report).

CSE

FIGURE B.





Item 3) The correspondents question one aspect of the project purpose – "preservation of the environmental, cultural and aquatic resources of the county"

We disagree with the correspondent's contention that nourishment projects do not enhance or preserve the nation's living marine resources. It is well established that nourished beaches have restored turtle nesting habitat and vegetated dunes along many coasts that previously were armored with seawalls and had no such habitats (cf, National Academy of Sciences, NRC, 1990; 1995). Nearby Atlantic Beach is one such example. Others include Miami Beach (FL) and Myrtle Beach (SC). Pea Island (NC), a wildlife preserve, has received several inputs of nourishment to counter erosion and maintain protection to valuable back barrier habitats. Considering the biologic value of estuaries and lagoons, any soft solutions like nourishment that maintain the integrity of barrier islands will protect and preserve critical habitats to some degree.

The proposed project will reduce the need for and frequency of sand scraping. This will allow dunes to build gradually with appropriate-sized aeolian sand. Presently, most of the foredunes are composed of medium to coarse sand, pebbles, and shells, an unnatural sediment scraped from the surf zone after recent hurricanes. This is not enhancing the dune habitat.

While undeveloped Core Banks and Shackleford Banks are accessible by boat, only a tiny number of visitors (order of 1-2 percent) go there compared to the numbers visiting Bogue Banks. People want access to the shore. Carteret County strikes a model balance between less accessible beach preserves (~65 percent of shoreline) and accessible recreational beaches (~35 percent). Further, there are no roads through these preserves, unlike the Hatteras National Seashore.

4) Comment on consideration of alternatives regarding abandonment and relocation

The economics of nourishment versus property abandonment can always be refined. However, at present, they are skewed strongly in favor of maintaining the beach as described in detail in the draft EIS. The correspondents assert that the proposed project will be performed piecemeal just as property abandonment would be piecemeal. However, the definition of piecemeal is not the same in this case. Property abandonment would necessarily be done on a lot-by-lot basis with protracted delays and litigation likely. Nourishment, by contrast, is planned for long segments of beach that encompass hundreds of properties. The first segments planned (Pine Knoll Shores and Indian Beach/Salter Path) span over seven miles. This length would be considered a relatively long nourishment project by any standard (CERC, 1984). The Town of Emerald Isle is presently evaluating the feasibility of completing a three-mile project (Reach 3 and part of Reach 2) in 2002-2003. That reach encompasses nearly 200 properties. Each community must make careful decisions in the future regarding whether to continue nourishment or move toward abandonment. The problem now is that there are insufficient historical data to make this determination. The proposed project will offer an opportunity to establish on a site-by-site basis whether nourishment is viable for Bogue Banks. Evidence from the 1986 and 1994 nourishments of Atlantic Beach suggest overwhelmingly that it is viable in this setting. Further, some longtime opponents of coastal development such as Prof. Orrin Pilkey (Duke University) have stated that Bogue Banks is among the best candidate sites for nourishment in North Carolina.

Regarding the concern about beach scraping, the draft EIS makes clear that the proposed project will reduce the need for and frequency of sand scraping. We did not say it would eliminate it because certain contingencies may move property owners to demand scraping after a major storm. However, we expect the political pressure to scrape will be dramatically reduced after the projects just as it has been along Atlantic Beach. A tour of that site confirms that almost no sand scraping was performed after Hurricane *Floyd*, whereas the communities of Pine Knoll Shores, Indian Beach/Salter Path, and Emerald Isle scraped nearly the entire foredune.

5) Concerns regarding monitoring programs

The applicant is committed to a self-funded monitoring plan which will be developed in consultation with the appropriate regulatory agencies.

6) Concerns regarding proposed North Carolina Marine Fisheries Commission policies on beach dredge and fill activities

To the best of our knowledge, the referenced policies have not yet been certified by the state. The majority of issues raised by these new policies are addressed in the draft EIS. NCDENR has reviewed and approved the draft EIS. The applicants are striving to improve upon existing nourishment practice and work within the present regulatory framework. In fact, it will only be through properly designed and executed projects and long-term monitoring (as planned by the applicant) that state and federal

CSE

agencies can develop realistic and practical policies for protecting marine resources and maintaining the integrity of developed barrier islands via soft engineering solutions. The applicant expects to contribute knowledge regarding impacts after execution of the project such that our regulatory agencies may improve their management of coastal resources.

I hope the above responses adequately address the concerns raised by Environmental Defense. If you need additional clarification, please contact us at the earliest time.

Thank you for your consideration.

Yours truly,

Tim Kana

DWQ Project # 010324

APPROVAL of 401 Water Quality Certification and ADDITIONAL CONDITIONS

Mr. Robert Murphy
Carteret County Manager
Courthouse Square
Beaufort, NC 28516

Dear Mr. Murphy:

You have our approval, in accordance with the attached conditions and those listed below, to dredge 2.58 square miles of beach front for the purpose of conducting a beach renourishment project along Bogan Banks from Atlantic Beach/Pine Knoll shores to shipwreck Lane is Emerald Isle as described in your application dated March 5, 2001. After reviewing your application, we have decided that this fill is covered by General Water Quality Certification Number 3274. In addition, you should get any other federal, state or local permits before you go ahead with your project including (but not limited to) Sediment and Erosion Control, Coastal Stormwater, Non-Discharge and Water Supply Water shed regulations. **This approval will expire when the accompanying 404 or CAMA permit expires unless otherwise specified in the General Certification.**

This approval is only valid for the purpose and design that you described in your application except as modified below. If you change your project, you must notify us and you may be required to send us a new application. If the property is sold, the new owner must be given a copy of this Certification and approval letter and is thereby responsible for complying with all conditions. If total wetland fills for this project (now or in the future) exceed one acre, compensatory mitigation may be required as described in 15A NCAC 2H .0506 (h) (6) and (7). For this approval to be valid, you must follow the conditions listed in the attached certification and any additional conditions listed below.

1. DWQ staff recommended that the CAMA Permit be conditioned to address all issues raised in the EA or EIS.

If you do not accept any of the conditions of this certification, you may ask for an adjudicatory hearing. You must act within 60 days of the date that you receive this letter. To ask for a hearing, send a written petition, which conforms to Chapter 150B of the North Carolina General Statutes to the Office of Administrative Hearings, P.O. Box 27447, Raleigh, N.C. 27611-7447. This certification and its conditions are final and binding unless you ask for a hearing.

This letter completes the review of the Division of Water Quality under Section 401 of the Clean Water Act. If you have any questions, please telephone John Dorney at 919-733-9646.

Micheal F. Easley
Governor

Sherri Evans-Stanton, Acting Secretary
Department of Environment and Natural Resources

Wilmington, North Carolina 28402-1890

SUBJ: Carteret County: Nourishment of Bogue Banks Beaches
Action I.D. No. 200000362

Dear Colonel DeLony:

This is in reference to the above-listed public notice, dated March 16, 2001, to dredge and discharge approximately 8.0 million cubic yards of sand into wetlands and waters of the U.S. to nourish approximately 16.8 miles of beaches along the eastern shore of Bogue Banks Barrier Island, from Emerald Isle to Pine Knoll Shores, Carteret County, North Carolina. The stated purpose of the project is to restore the shoreline that has been severely damaged within the last five years from hurricanes and winter storms. Individual municipalities are expected to assume responsibility for execution of the nourishment project within a particular reach and to control the timing of implementation, scale, and scope of work, but the County is requesting a permit for the entire project so that the full scope of work can be coordinated.

The U.S. Environmental Protection Agency, Region 4, Wetlands Section (EPA), has reviewed this proposal and the Draft Environmental Impact Statement (DEIS) (dated October 31, 2000) for the project. We note that the preparers of the DEIS have made a commendable effort to address the majority of typical issues with beach nourishment, such as impacts to fauna from nourishment of sand with incompatible grain size, purpose and need, abandonment and relocation options, and impacts to the borrow sites (off-shore). The level of biological studies proposed for pre-project and post-project analysis is significantly better than other nourishment projects we have reviewed (most have no plans to conduct studies at all). However, we still have several concerns with the project as proposed, and with beach nourishment in general. At this time, we cannot recommend authorization of the project. Prior to consideration of project authorization, we recommend that the applicant address the resources agencies' comments on the DEIS and complete the final EIS.

EPA has been equivocal regarding the issue of pumping sand onto an eroding shoreface. Generally, we have not opposed beach nourishment when it provided a disposal site for a nearby, already authorized navigation project. The key factor, however, was whether or not biologically sensitive resources would be adversely affected through the use of this disposal method. As is usually the case, the value of adjacent structures, declining width of the recreational beach, and the perceived need to provide continued economic potential to shorefront property serve as the rationale for beach nourishment. The dollar value assigned to these factors in the benefits/costs calculations are almost always deemed to be greater than any environmental losses.

The DEIS states that the project is "an interim ten-year plan for the community - one that must be monitored carefully and used as a basis for formulating a long-range solution from among three alternatives: (1) no action, (2) abandonment and relocation, or (3) continued renourishment." However, providing wider beaches with no plans to curb shoreline development will only result in greater oceanfront development in ten years. With more development, and the likelihood that property values and tax income from these properties will be much higher in ten years, it appears that the long-range solution will be a foregone conclusion (continued nourishment or perhaps other even more harmful activities such as seawall construction). Because the stated erosion of the shoreline is so low, EPA believes there may be sufficient time *now* to conduct a more detailed analysis to formulate a long-range solution. We believe that a 50-year period may be a more a sensible timeframe to consider for shoreline changes and impacts to oceanfront properties. We believe that this is an appropriate planning period to use, because of the likely impacts from sea-level rise during this timeframe, and also because a long-term plan to abandon and/or relocate homes may be more acceptable when occurring over a 50-year period rather than a ten-year period.

EPA is concerned by the proposal for individual municipalities to complete the project. The public notice states that individual municipalities are expected to assume responsibility for execution of the nourishment project within a particular reach and to control the timing of implementation, scale, and scope of work. However, the EIS and other information presented with the public notice states a relatively specific time frame for construction, and also assumes the use of one dredge for the overall project. EPA believes that the implementation of this large project by as many as four separate entities may provide other challenges which have not been addressed by the EIS, such as coordination of dredging sites to avoid two different municipalities dredging the same area twice, ensuring compliance with the permit by the four additional entities and their contractors, and ensuring that most or all municipalities will complete the project (otherwise, erosion may increase in certain areas, or the longevity of the overall project may suffer). Because the project is being implemented by up to four separate municipalities, with potentially separate project schedules, we believe that it is imperative to prohibit activities during the sea turtle nesting season, and that the specific conditions of any authorization should be exceptionally clear and should reflect a potentially piecemeal completion of the project.

We suggest that a proposal for long-term measures include potential alternative mitigation for project impacts to the near-shore environment. For example, currently untreated nonpoint-source runoff from adjacent developed or hard surface areas could be redirected to some form of treatment within the project reach, prior to discharges to the ocean or sound. In our opinion, lessening the adverse consequences of storm water runoff in this sensitive/important environment could be beneficial. Moreover, water quality improvements would benefit recreational interests. This and other out-of-kind measures could be used for similar nourishment projects which are planned/authorized. Any measures which can lessen the impacts of increasingly pervasive shoreline development need to be examined. We note that the County, although interested in protecting the existing houses on Bogues Banks Island, has made no effort to halt oceanfront development. We recommend that the County and municipalities revise land use plans and improve zoning ordinances, specifically targeting the acquisition and/or preservation of developed and undeveloped lots to prevent future development. These preserved properties could become a network of greenspace and public beach access, enhancing the Bogue Banks experience for tourists and locals alike. Further, we recommend that greater avoidance of hazard areas by development, expanded use of setbacks for structures, and an overall lower development density would significantly reduce storm damage, without necessarily significantly affecting the tax base.

As pointed out by the U.S. Fish and Wildlife Service in their comments to the North Topsail Beach and Surf City nourishment projects (dated March 16, 2001), the addition of sediment from beach fill projects may threaten the sensitive nearshore habitats, particularly hardbottoms which are close to shore. Although the DEIS considers the impacts to hardbottom from dredging of the borrow areas, EPA could find no discussion of the potential impacts to nearshore hardbottom from sedimentation due to sand placement on nearby beaches. EPA recommends that the DEIS fully consider the adverse impacts that sedimentation (due to sand placement) could have on the hardbottom communities offshore, and the fisheries resources that they support.

At this time, EPA cannot recommend authorization, due to potential direct, secondary, and cumulative impacts of the proposed project. We recommend that all agency comments be addressed in the completion of the EIS for the project, prior to project authorization. Thank you for the opportunity to comment on this project. If you have any questions regarding these comments, please contact Kathy Matthews at the above address or by telephone at (404) 562-9373.

Sincerely,

William L. Cox, Chief

IN REPLY REFER TO April 26, 2001

Regulatory Division

Action ID. 200000362

Mr. Pete Allen, Manager
Carteret County
Courthouse Square
Beaufort, North Carolina 28516

Dear Mr. Allen:

Please reference Carteret County's application for Department of the Army (DA) authorization to conduct beach nourishment along 16.8 miles of Bogue Banks Barrier Island by discharging 8.0 million cubic yards of dredge material into Section 10 Navigable Waters and Section 404 waters of the Atlantic Ocean, in Carteret County, North Carolina.

In response to your proposal, our office has received comments from the National Marine Fisheries Service, by letter dated April 20, 2001 (copy enclosed), recommending against the authorization of your permit request. It is our suggestion that you revise your plans to satisfy the interests of the objecting agency.

It is the policy of the DA to provide an applicant the opportunity to furnish a proposed resolution or rebuttal to all objections from government agencies and other substantive adverse comments before a final decision is made on a proposed project. In this regard, I would appreciate receiving any comments that you have on this matter. If you intend to comment, please give your immediate attention to this matter, so processing of your permit application can be expedited.

If you have questions or comments, please contact me at (910) 251-4811 and I will assist you in coordinating with the review agencies.

Sincerely,

Mickey Sugg
Wilmington Regulatory Field Office

Colonel James W. DeLony
District Engineer, Wilmington District
Department of the Army, Corps of Engineers
P. O. Box 1890
Wilmington, North Carolina 28402-1890

Attention: Mr. Mickey Sugg

Dear Colonel DeLony:

The National Marine Fisheries Service (NMFS) has reviewed **Action ID No. 200000362**, dated March 16, 2001. According to the notice, Carteret County, c/o Mr. Robert Murphy, County Manager, proposes to dredge and discharge approximately 8.0 million cubic yards of predominately sand material for purposes of restoring approximately 16.8 miles of ocean beach between Emerald Isle and Pine Knoll Shores, in Carteret County, North Carolina. The stated purpose of the project is to restore oceanfront shoreline that has undergone erosion within the last five years as a result of hurricanes and winter storms. This letter is provided in accordance with provisions of the Fish and Wildlife Coordination Act (48 Stat. 401, as amended; 16 U.S.C. 661 et seq.) and Part IV.3(a) of the August 11, 1992, Memorandum of Agreement between our agencies. The NMFS hereby advises that components of the proposed work may result in substantial and unacceptable impacts to aquatic resources of national importance, and we provide grounds for determination that issuance of the requested permit must be denied, or the authorized work must be substantially modified, to protect those resources.

The proposed beach nourishment consists of placing dredged material at six locations (reaches). The final project elevation of the beaches would be approximately +8.0 feet mean low water. Approximately half of the dredged material, which would hydraulically excavated from three offshore bottom locations, would be deposited between the low water line and the outer bar located between 500 and 700 feet offshore. The offshore borrow sites (designated as sites A, B1, and B2) are located between 0.5 to 3.0 miles offshore in waters averaging -35 to -45 feet in depth. A hopper dredge or special suction dredge would be used to excavate the upper two to three feet of sediments and hydraulically pump it, via submerged pipeline, directly onto the designated beach area. The material would be deposited between the foredune and a temporary dike located 150-200 feet seaward of the foredune. The deposition area would be designed to allow coarser materials to settle before the fine sediments are washed into the surf zone. Once the material has settled, it would be distributed along the shoreline using equipment such as bulldozers and front-end loaders. Authorization is sought for use of any combination of reaches and borrow sites.

An interagency meeting and inspection of the project area is scheduled for May 11, 2001. An environmental analysis titled "Draft Environmental Impact Statement (DEIS), Bogue Banks Beach Restoration Plan" was sent to us by the applicant; however, normal procedures for review of the document and use of it for decision making have not been implemented. As a result, the NMFS has not formally reviewed or provided comments on the project with regard to procedures that are set forth in Regulations for Implementing the Procedural Provisions of the National Environmental Policy Act (NEPA) (40 CFR Parts 1500-1508).

The proposed project is located in an area identified as Essential Fish Habitat (EFH) for adult red drum (*Sciaenops ocellata*) which occur in the water column and surf zone, and larval and adult brown shrimp (*Farfantepenaeus aztecus*) and white shrimp (*Litopenaeus setiferus*) which occur on marine bottoms. Categories of EFH that would be impacted by this work include marine water column, sand bottom, and surf zone. These fishery resources and associated EFH are discussed in detail in documents prepared by the South Atlantic Fishery Management Council (SAFMC). Species under jurisdiction of the Mid-Atlantic Fishery Management Council (MAFMC) also occur in the project area. These species and their associated EFH include larvae, juvenile, and adult summer flounder (*Paralichthys dentatus*), which occur on marine bottom and in the water column and surf zone, and juvenile and adult bluefish (*Pomatomus saltatrix*), which occur in the water column and surf zone.

The project area also provides habitat for other species of commercial, recreational, and ecological importance, including Florida pompano (*Trachinotus carolinus*), southern kingfish (*Menticirrhus americanus*), Atlantic croaker (*Micropogonias undulatus*), spot (*Leiostomus xanthurus*), Atlantic menhaden (*Brevoortia tyrannus*), and striped mullet (*Mugil cephalus*). Several of these species serve as prey for king mackerel (*Scomberomorus cavalla*), Spanish mackerel (*Scomberomorus maculatus*), and cobia (*Rachycentron canadum*) which are managed by the SAFMC, and for highly migratory species (e.g., billfishes and sharks) that are managed by the NMFS. Detailed information on Federally managed fisheries and their EFH is provided in the 1998 amendments of the Fishery Management Plans of the South and Mid-Atlantic Regions and respectively prepared by the SAFMC and the MAFMC. The amendments were prepared in accordance with the Magnuson-Stevens Fishery Conservation and Management Act (MSFCMA) (P.L. 94-265). In addition, several of the above species are identified as species of "national economic importance" in accordance with Section 906(e)(1) of the Water Resources Development Act of 2986 (PL 99-602).

The NMFS is concerned that the project will adversely affect living marine resources and habitat, including EFH. Over the ten year life of the project, up to eight million cubic yards of material would be excavated from offshore borrow areas and approximately 2.58-square miles of nearshore sand bottom, that is designated as EFH, would be impacted. Notably, physical and biological conditions in these locations may be substantially changed and any return of pre-dredging conditions, including those that associated with ecological and productivity or trophic determinants, could require considerable time and may not occur.

Although a dredging strategy has been designed to encourage recolonization by benthic species, the actual extent of recolonization, and the composition and abundance of species that recolonize the area will not be known unless post-dredging monitoring is implemented. Slow recolonization or undesirable changes in the benthic communities could alter the local marine food web and reduce the overall value of the area as EFH for Federally managed species such as shrimp, red drum, and bluefish. Existing sample data from the project area indicates that it may serve as an important foraging site for species such as spot and Atlantic croaker and others that have significant commercial, recreational, and ecological importance. According to the public notice, sediments in borrow areas A, B1, and B2 have a low percentage of fine materials; however, the composite "overfill ratios" associated with sediments from areas B1 and B2 are 1.97 and 2.19, respectively. Based on this, it is anticipated that a large portion of this material is not expected to remain on the beach and will be redeposited in a 500-700-foot-wide section of the near shore zone. This level of displacement indicates that the material in these borrow areas, in fact, contain large components of fine material, and it is reasonable to conclude that sediment resuspension and greatly elevated levels of turbidity and sedimentation are possible in both the borrow and beach nourishment sites.

Suspended sediments can physically damage respiratory structures of benthic invertebrates and larvae and juvenile fishes. Species that rely on sight for feeding could experience a reduction in feeding efficiency due to poor visibility and they may need to relocate to less desirable habitat where nutritional needs are not met, or only partially fulfilled. While there are no established thresholds regarding the extent of ocean bottom that can be disturbed without modifying or reducing species abundance,[1] the known effects of dredging are such that work involving 2.58 square miles of submerged bottom has potential to be highly and significantly damaging to fishery resources and their habitat, including EFH.

Knowledge regarding impacts to fishery resources is also limited with regard to dredged material placement in the surf zone.[2] Larvae and juveniles of estuarine dependent species such as spot, Atlantic croaker, and summer flounder accumulate in near shore waters prior to passage through ocean inlets en route estuarine nursery areas. Because of the abundance of these species, and in view of the above mentioned concern over effects of suspended sediments and turbidity, potential for significant harm to living marine resources exists. Placement of dredged material in the surf zone also may eliminate or reduce numbers of ecologically important benthic invertebrate species such as donax (*Donax variabilis*) and mole crab (*Emerita talpoidia*).[3,4] These organisms are an important food for

seasonal resident surf zone species such as Florida pompano and southern kingfish.[5] The alteration of high utilization habitat for surf zone species is particularly significant in this case since up to half of the eight million cubic yards of excavated material would be deposited in this area. The estimated recovery time from beach nourishment activities is in the range of two months to four years for dominant surf zone invertebrates; however, the long-term effect of renourishment activities over a large area of near shore habitat (16.8 miles in this case) is unknown. In North Carolina, the magnitude of this impact may be even greater due to the relatively large number of beach renourishment and protection projects that are either planned or have been authorized. At this time, approximately 58 percent of the state's 320-miles of ocean beaches are subject to beach nourishment and protection activities.[6]

Although beach nourishment projects can be implemented so as to avoid periods of utilization by certain aquatic organisms, species of some fishes, invertebrates, sea turtles, and/or other marine organisms are almost always present and would be at risk. While restricting work to certain seasonal time frames or windows may provide meaningful mitigation in some situations, we note that in connection with this project the applicant seeks approval to work during periods of known high biological activity. Even if work is seasonally restricted, there is a high probability that continuation of dredging and disposal would be sought since high remobilization costs could be avoided and delays due to equipment failure and other problems are inevitable and are likely to necessitate schedule changes.

In connection with the Wilmington Harbor Improvement Project, the Corps of Engineers (COE) is currently funding studies that are aimed at examining the impacts of beach nourishment on early life history stages of fishes. In addition, the COE Engineering Research and Development Center, in cooperation with the National Ocean Service, Center for Coastal Fisheries and Habitat Research (CCFHR), plans to conduct studies at the Ocean Dredged Material Disposal Site near Wilmington and at the CCFHR laboratory in Beaufort, on the effects of various levels of suspended sediments and turbidity on larvae and juvenile fishes. When completed, these studies may help clarify fishery related impacts of dredged material placement in the surf zone and other locations. Unfortunately, these studies will not be completed in time for possible use in determining the level of impacts of the subject project on fishery resources and habitat, including EFH.

The applicant proposes to monitor the environmental impacts of the project; however, details concerning this effort were not provided in the public notice. Based on our experience in such matters, and on results of coordination with CCFHR personnel and Dr. Charles Peterson of the University of North Carolina Institute of Marine Science, it appears that a monitoring plan would only

[6] Rice, Tracy. US Fish and Wildlife Service. Raleigh, NC. April 12, 2001. Personal communication.

be meaningful if it employs a statistically valid sampling methodology for assessment of impacts and change in faunal composition and abundance.[7] Although the type and level of monitoring proposed at this time is unclear, we do not believe that a detailed statistical analysis is planned.

The high possibility that significant and adverse impacts to living marine resources and their habitat (including EFH) will result from this project, coupled with the relatively undetermined level and duration of those impacts, is of great concern. Based on this, we believe that the Department of the Army has little recourse but to withhold project authorization until a full evaluation of the project has been conducted in accordance with the NEPA and its implementation regulations. Although a draft environmental impact statement has been prepared, no effort has been made to conduct a NEPA review, or to ensure that other needed elements such as development and evaluation of reasonable alternatives; development of sequential mitigation; and opportunity for adequate public review, are adequate.

In view of the preceding, the NMFS recommends that Department of the Army authorization of the project not be granted until such time as the NEPA implementation provisions have been fully met. In fulfilling this requirement, we further recommend that the alternatives analysis include development and evaluation of a phased approach to the project. More specifically, the applicant should consider and evaluate performing a small portion of the desired project, thoroughly evaluating the environmental effects of this work, and then determining the feasibility and prudence of continuing the project. We also note that an EFH assessment, which is required in accordance with 50 CFR 600.920(g), and is specified in our April 17, 2000, "findings"letter to you, has not been received. We must advise that in the absence of this assessment and our response, your authorization of the proposed work would contravene the EFH conservation purposes of the MSFCMA and associated requirements involving coordination between our agencies.

Finally, this project area is within known distribution limits of Federally listed endangered and threatened species that are under purview of the NMFS. Therefore, in accordance with the Endangered Species Act of 1973, as amended, it is the responsibility of the appropriate Federal regulatory agency to review its activities and programs and identify any activity or program that may affect endangered or threatened species or their habitat. Determinations involving species under NMFS jurisdiction should be reported to our Protected Resources Division at the letterhead address. If it is determined that the activities may adversely affect any species listed as endangered or threatened and under NMFS purview, then formal consultation must be initiated.

Colonel James W. DeLony
District Engineer, Wilmington District
U.S. Army Corps of Engineers
Post Office Box 1890
Wilmington, North Carolina 28402-1890

Attention: Mr. Mickey Sugg

Dear Colonel DeLony:

The U.S. Fish and Wildlife Service (Service) has reviewed March 16, 2001, Public Notice Action ID No. 200000362, the October 2000 draft Environmental Impact Statement (EIS) for the Bogue Banks Beach Restoration Plan received by this office on February 22, 2001, and the draft Supplement to the Final EIS (Supplement) handed out by the applicant at the May 11, 2001, site meeting in Morehead City. Comments are not provided herein on the draft monitoring plan and will be submitted under separate cover. This is the report of the Service submitted pursuant to, and in accordance with, provisions of the Fish and Wildlife Coordination Act (48 Stat. 401, as amended; 16 U.S.C. 661 et seq.) and the Endangered Species Act of 1973 (87 Stat. 884, as amended; 16 U.S.C. 1531 et seq.).

The applicant, Carteret County, proposes to dredge sand and shell material and fill 90,000 linear feet of beachfront on Bogue Banks in Carteret County, North Carolina. Up to 8 million cubic yards of fill would be placed 8 feet above mean low water and below, and the sediment would be dredged from up to three sites located 0.5 to 3.0 miles offshore of Bogue Banks in 35 to 45 feet of water. The applicant proposes to construct the project in two phases: the first phase being 7.2 miles of beach fill along Pine Knoll Shores and Indian Beach in the winter of 2001-2002; and the second phase along 9.6 miles of Emerald Isle at an undetermined later date.

Based on the information provided in the application, we recommend the District Engineer not issue a permit for the proposed activities. We believe that the proposed activities, as presently configured, will have unwarranted adverse impacts on the nesting ability of Federally-protected sea turtles and other fish and wildlife resources. In addition, it is our opinion that the applicant has not satisfied the Environmental Protection Agency's 404(b)(1), 40 CFR §230.10(c), and National Environmental Policy Act (NEPA) guidelines as of this time.

The applicant's draft EIS contains a comprehensive economic evaluation of the relocation and rebuilding alternatives, but the document does not adequately address the project's impacts to fish and wildlife resources. Several of the project's details are unclear, sediment compatibility is not fully addressed, and the analysis of impacts to beach invertebrates is not complete. The Service refers the Corps to a recently prepared Environmental Assessment by Applied Technology & Management, Inc., for the Old Sound Creek Dredging Project at Tubbs Inlet (Action I.D. No. 200100552) as a model for an adequate NEPA document for beach fill activities. Get copy.

One facet of the proposed action that is not clear is the project's fill design. Page 4-7 of the draft EIS lists a fill volume of 50 cubic yards (cy) per foot, while page 5-2 states a desired volume of 175 cy/ft. During the May 11, 2001, site meeting Dr. Kana mentioned a 80 to 90 cy/ft volume. The magnitude of the beach fill will, in part, determine the magnitude of impacts to trust resources, and the applicant should better specify the fill volume to be used. Easy to clarify.

The draft EIS does not contain a maintenance plan but alludes to maintenance activities during the ten year project life. The Service recommends that a maintenance plan be prepared and circulated as a supplemental NEPA document for review prior to the issuance of any permit. Information on beach scraping, additional fill, and post-storm activities should be included in such a plan in order for the full scope of the project to be evaluated.

The draft EIS cites the offshore existing environment as containing high turbidity levels and patchy mud or clay areas that impeded visibility for divers. No additional information is described as to whether this condition is pervasive along the entire length of Bogue Banks, at what water depths, or if the hardbottom areas off of Emerald Isle have lower productivity levels (as compared to other hardbottoms in Onslow Bay in similar water depths and locations) because of existing suspended sediment loads in the water column. The EIS should be revised to elaborate on this aspect of the existing environment.

The sedimentation resulting from finer grain material washing off an artificial beach system is similar to, but distinct from, that produced by dredging, or naturally existing in the project area. Turbidity or suspended sediment loads are increased as the mined fill dewaters following placement on the beach, and finer sediments may be suspended and washed off the beach as long as fill material remains on the beach. The latter may lead to deterioration of nearshore habitat quality in the long-term. Studies on Bogue Banks and Wrightsville Beach have shown that nourishment sediment moves offshore artificially filled beaches (Reed and Wells 2000; Thieler et al. 1995). Riggs (1994, p. 17) states that sand placed on Wrightsville Beach has washed off the beach and buried extensive hardbottoms on the inner continental shelf near the federal storm damage reduction project. These hardbottoms were prime fishing locations, but are now significantly degraded due to a covering of two to six inches of sand. Hurme and Pullen (1988) concluded that increased turbidity levels from winnowing of fine sediments in beach fill can extend from a few months to seven years. The currently proposed design includes a high proportion of fine sediments, making this long-term impact a probable occurrence. The applicant states that the hardbottoms off of Bogue Banks are at least 1600 feet from the immediate project area, but provides no supporting evidence that this distance is an adequate buffer from project impacts.

Several beach fill studies had inadequate sampling designs that may have precluded detection of significant alterations in the populations or community parameters measured (Nelson 1991, 1993). The NRC (1995, p. 115) concluded that " . . . efforts should be directed toward obtaining a better understanding of functional changes in the trophic contribution of benthic assemblages to the fish and crustaceans species that rely on the benthos as a major food resource." Dr. Peterson has provided detailed information that would improve the sampling protocol for the proposed project to avoid this pitfall, and the Service reiterates those recommendations.

The effects of high turbidity levels on migrating organisms is unknown, but is potentially adverse. The Cape Lookout region is a migratory pathway for nationally important fish, marine mammals, birds and sea turtles. The placement of fine grained material on the project's beaches will produce an extensive suspended sediment plume in the nearshore waters, extending the indirect impacts of the action beyond the immediate project area and may harm or reduce the habitat quality for these migratory species. Moreover, the Corps noted (USACOE 1973, p. H-15) that it was possible that highly turbid water washing off of a potential project in Brunswick County would enter Lockwoods Folly Inlet during flood tides and create "injurious effects" on oyster-producing areas. Bogue Inlet will be approximately one mile from the project's construction area, and turbidity plumes may affect hardbottoms offshore the inlet as well as aquatic resources in Bogue Sound and the White Oak River estuary. The applicant has provided no detailed description of whether the high proportion of fine-grained sands in borrow areas B1 and B2 will be suspended similar to clay and mud sediments and elevate turbidity levels such that aquatic resources are harmed. The draft EIS states that borrow area B2 in particular has "poor quality material" (p. 3-16), yet as of this time that area is still proposed for use. While the documented mud and silt content for this project of less than 5% is half of the state standard of 10% maximum, recent projects on Oak Island that met that criteria exhibited up to 90 NTUs (nephelometric turbidity units) in field measured turbidity plumes (Ted Wilgis, pers. comm., May 10, 2001). The state water quality standard is 25 NTUs (unless elevated from natural conditions).

The applicant proposes to use all three borrow sites in whatever proportions are most practical in terms of project cost and engineering (p. 2-4 of the draft EIS). The Service cannot concur with this condition, which precludes a full evaluation of environmental impacts to trust resources. The available data indicate that none of the three sites are compatible with the native beach, and any mixture of the three sites will not make the overall fill more compatible.

The Service is highly concerned about the compatibility of the proposed mine material with the existing beach. The Public Notice (PN), draft EIS and Supplement do not provide adequate data on the sediment characteristics of the native beach for a full evaluation of the potential impacts to fish and wildlife resources. Following discussions at the May 11, 2001, site meeting, the applicant collected additional data on the native beach sediments and provided those to the Service on May 25, 2001.

The supplementary information indicates that borrow areas B1 and B2 are too fine and borrow area A has too much carbonate material. Figures E-10 and E-11 in the draft EIS show that site A contains 10-78% carbonate content, but less than 40% of the borrow material exceeds 2 millimeters in grain size. This indicates that roughly half of the carbonate fraction of the fill material is sand-sized or less, and not larger shell fragments. The native beach appears to have 20% carbonate content, and there are no data to show what proportion of this material is sand-sized versus larger shell fragments. Carbonate material breaks down faster than quartz and other inorganic sediments, making it more susceptible to chemical dissolution (USACOE 1995; USACOE 1998). If borrow area A is exclusively used for the project, the carbonate content of the beach would more than double. Carbonate material that is sand-sized or finer will be intermixed with the quartz sediments and not sort out with wave reworking of the fill. Over time this material may break down and/or dissolve, forming a carbonate cement that hardens the beach. Dissolution and cementation of the surface beach sediments has been reported on beach fill projects at Edisto Beach State Park, South Carolina, and Miami Beach, Florida. The Edisto Beach project differed from the native beach sediments by 11-34% (weight percent) in the fraction of sediments greater than 2 mm in size (an approximation for shell hash material) and doubled the percent material in the fine and very fine sand size fraction. The cementation problems in Miami have significantly impaired sea turtle hatchlings' ability to emerge from the nest chamber (Trish Adams, USFWS, pers. comm., 24 January 2001). A higher than background coarse-grained or carbonate fraction also inhibits the burrowing of beach infauna and the foraging of shorebirds (Peterson et al. 2000; Lindquist and Manning 2001; Alexander et al. 1993; Bowman and Dolan 1985).

Incompatible fill materials may adversely affect sea turtle nesting as well as the forage base for colonial waterbirds and migratory shorebirds, including the Federally-listed piping plover (*Charadrius melodus*). The draft EIS does not adequately address these impacts, and should be revised to incorporate information from and compliance with the United States Shorebird Conservation Plan 2000, Executive Order 13186 *Responsibilities of Federal Agencies to Protect Migratory Birds*, and bird census data on the project area's beaches.

The Service is concerned that the project, as currently proposed, will significantly harm the beach invertebrates along 16.8 miles of Bogue Banks. The applicant has not adequately addressed this issue, particularly the impacts of doubling the carbonate content of the beach substrate on beach invertebrates, foraging shorebirds and nesting sea turtles. At the May 11, 2001, site meeting the applicant requested additional information on the impacts of dredge and fill projects on invertebrates from the Service. Appendix A describes the salient research on this environmental impact from major dredge and fill projects.

These populations are a key facet of the coastal food web, and therefore decreased species abundances would reduce the prey base for shorebirds, surf fishes and beach macrofauna. Sediments from borrow areas B1 and B2 are significantly finer than the native sediments (50% losses are anticipated from the initial fill) and borrow area A has double the shell content of the existing beach. The Service is concerned that adverse impacts documented by Peterson et al.

where do they get this?

(2000) may be repeated and extended along 16.8 miles of beachfront. The length of the proposed project may prolong or prevent the recovery of beach invertebrate populations since undisturbed areas may be 3 to 5 miles away. Perpetual beach fill placement has the potential cumulative impact of permanently depressing beach invertebrate populations (Lindquist and Manning 2001).

The applicant proposes to use the natural sand bar offshore as a natural dike to hold the fill material close to the beach. The trough between the swash zone and an offshore bar provides valuable habitat to many benthic and pelagic resources. Figures attached to the state permit application show that this area would be filled with 2 to 10 feet of material, burying and substantially altering the substrate and water depth of the trough habitat. The applicant has not provided any description of the expected impacts to this habitat resulting from the proposed action.

Profile shape will be maintain as long as its a graded deposit

Offshore invertebrates are also impacted by dredge and fill projects. Removal of sand from the offshore borrow areas may permanently alter the physical characteristics of the areas and impact the benthic flora and fauna adapted to existing conditions. The proposed dredging methods are likely to reduce the adverse impacts to the borrow areas due to their shallow depth and intent to leave undisturbed areas between dredging furrows. The applicant has not provided sufficient information to document that the substrate within the furrows will not be changed to mud or rock outcrops, however. The majority of the cores taken in the borrow areas penetrated less than 3 feet of the seafloor, providing the Service with limited data on the strata underlying the borrow furrows.

The Service appreciates that the applicant conducted pre-project benthic surveys, but supports the recommendations of Drs. Peterson and Wells regarding the need to monitor this project for site-specific impacts following the project. The draft EIS states that wave height will be altered by 0.1 feet and the longshore sediment transport energy flux altered by 8-9%. These modifications to the hydrodynamic environment should be monitored to determine the level of resilience of the invertebrate populations, particularly those on the beach.

The timing of the proposed action on Bogue Banks is critical to avoiding and minimizing impacts to fish and wildlife resources. The applicant currently proposes to conduct construction between October 1 and May 15 (draft EIS, p. 4-10), which would impinge on the invertebrate recruitment seasons identified for the island (Reilly and Bellis 1978; Peterson et al. 2000; Lindquist and Manning 2001). The Service recommends that the work be scheduled from December 1 to March 31 instead, minimizing adverse impacts to the beach invertebrate populations, their migratory and resident faunal consumers, and nesting sea turtles and shorebirds.

The Service is concerned about the cumulative impacts that the proposed project might cause on Bogue Bank's coastal ecosystem. Cumulative impacts are not addressed in the applicant's October 2000 draft EIS. Approximately 176 miles of the 320 mile North Carolina shoreline is currently receiving or investigating beach disposal of dredged materials. The applicant recognizes the proximity of the project area to preserved beaches within Carteret County, but does not provide a state-wide contextual analysis. Eight million cubic yards of sediment will be dredged out of the benthic ecosystem and used to bury large portions of the nearshore benthic ecosystem while the applicant pursues a federal, 50 year project to do the same. Several studies have shown that nourishment sediment moves offshore the project beach (Reed and Wells 2000; Thieler et al. 1995), and that over time the need for sediments increases over the life of the project rather than decreases (Trembanis et al. 1998). The cumulative impacts of these dredge and fill projects is the wholesale manipulation of the continental shelf and its associated habitats. The perpetual artificial relocation of hundreds of millions of cubic yards of sediment from one place to another in North Carolina will lead to a long-term, far-reaching degradation of the seafloor and its hardbottom and sandy habitats.

The cumulative effects of the project on offshore fisheries may be the transformation of formerly preferred habitat into unsuitable or unusable habitat. This change could occur as a result of altered substrate characteristics, depth, or other physical parameters. The loss or degradation of this important fish habitat would adversely impact marine birds and marine mammals in addition to harming commercial and recreational fishermen that depend on these resources. The Service recommends that the monitoring plan incorporate detailed surveys of beach and nearshore fishermen to document positive or negative impacts to the local fishing community resulting from the project. Some of the beach seine fishermen on Bogue Banks may keep detailed records of their catches and commercial sales, which could provide data on pre-project conditions. Surveys should be conducted in project areas as well as control areas. North Carolina Division of Marine Fisheries' survey protocols and methodologies should be used by the applicant.

Due to the significant cumulative impacts and adverse environmental impacts, the Service recommends that the current proposed action be modified to avoid, minimize and mitigate anticipated adverse environmental impacts. There is no way to avoid significant impacts to fish and wildlife resources resulting from the proposed action due to the indirect and secondary impacts.

Adverse impacts could be minimized, however, by 1) conducting work during the recommended December 1 to March 31 period; 2) restricting the borrow area to those areas where the carbonate content and grain size more closely matches the native sediments; 3) avoiding construction around all known hardbottoms and site specific Essential Fish Habitat areas; 4) restricting the initial permit to Pine Knoll Shores and Indian Beach (the Emerald Isle phase would be subject to review by resource agencies after considering the monitoring results of phase one); 5) issuing the permit to have a finite life of one construction episode per community and no maintenance requiring new fill material; and, 6) reducing the length of the project to include gaps where beach construction activities would not be conducted and biological resources would find an undisturbed refuge from which to recolonize filled areas.

Finally, for those impacts that cannot be avoided or minimized, the Service recommends compensatory mitigation. Mitigation can be achieved via restoration, enhancement or preservation of similar habitat. For the proposed project, mitigation could be arranged by 1) relocating structures that are chronically and imminently threatened farther inland over time so the need for the proposed activity does not perpetuate indefinitely; 2) setting aside areas that allow overwash and levee/dune gaps (i.e., will not be bulldozed, designing a levee system that better approximates natural geomorphology); 3) not issuing any Corps permits for beach scraping for the ten year life of the project, albeit subject to modification following major storm events (i.e., hurricanes); or 4) purchasing oceanfront conservation easements or tracts at nearby coastal sites.

The applicant has stated that they are not familiar with methodologies allowing the valuation of intangible resources such as fish and wildlife, beach recreation and environmental damages. In order to calculate an appropriate level of compensatory mitigation, such a valuation is needed. The Service refers the Corps to the field of natural resource and environmental economics for valuation methodologies for intangible resources. Kopp and Smith (1993), Freeman (1993), Bergstrom and Cordell (1991), and Walsh et al. (1988) provide meticulous reviews of available methodologies. The Corps regularly uses the Contingent Valuation Method and the unit day value method in evaluating recreational benefits for federal storm damage reduction projects. The Department of Interior uses natural resource damage assessment methodologies to evaluate damages to trust resources. The National Park Service and the U.S. Forest Service utilize various general and specific recreational valuation techniques for visitation and use of their lands. The Center for Environmental and Resource Economics Policy at North Carolina State University, the Institute of Water Resources at the Corps, and the Coastal and Marine Studies Program at East Carolina University all have research and publications on various economic valuations of the North Carolina coastal system in particular. These sources could provide the necessary valuation methods for determining appropriate compensatory mitigation for the proposed action.

An EIS that complies with National Environmental Policy Act (NEPA) guidelines should be prepared as the permit review proceeds. It has become increasingly important to protect the ecological integrity of the barrier island ecosystem, including the intertidal and surf zones, and respond to changes in this environment with less environmentally damaging interventions. Furthermore, we are not likely to concur with the issuance of a permit that would permanently destroy or impair aquatic resources (i.e., the surf zone, water column, hardbottoms, sandy bottoms) designated as Essential Fish Habitat.

In accordance with the procedural requirements of the 1992 404(q) Memorandum of Agreement, Part IV.3(a), between our agencies, we are advising you that the proposed work may result in substantial and unacceptable impacts to aquatic resources of national concern. It is our opinion that the applicant has not satisfied the Environmental Protection Agency's 404(b)(1) nor the 40 CFR §230.10(c) guidelines as of this time. The latter states that "no discharge of dredged or fill material shall be permitted which will cause or contribute to significant degradation" of aquatic ecosystems. The Corps should address compliance with both of these sets of guidelines in the NEPA document.

The Service cannot concur with the project, as proposed, however we look forward to working further with the Corps and the applicant to modify the project to adequately protect fish and wildlife resources. The 16.8 miles of beachfront to be artificially filled would be the longest in North Carolina to date (the Dare County Beaches (Bodie Island Portion) federal project will be 14 miles long). The Corps should therefore use a precautionary approach when evaluating the project's impacts to fish and wildlife resources.

We appreciate the opportunity to provide comments. If you have any questions or comments, please contact Tracy Rice or John Ellis of my staff at (919) 856-4520, extensions 12 and 26 respectively.

Sincerely,

Garland B. Pardue, Ph.D.
Ecological Services Supervisor

APPENDIX A. Impacts to Invertebrate Fauna

When a beach is artificially filled, large volumes of sand are placed within the supralittoral and intertidal zones. Beach invertebrate populations are eliminated or greatly reduced. The direct, adverse impacts may be dramatic, but longer-term, indirect impacts related to altered beach characteristics and recruitment of a recovery population may have the greater impact on fish and wildlife resources that depend on beach invertebrates as a food source. Sand placement disturbs the indigenous biota inhabiting the subaerial habitats, which in turn affects the foraging patterns of the species that feed on those organisms (NRC 1995, p. 108).

Donoghue (1999) found the timing of beach fill placement, the time interval between fill placement episodes, the size and type of fill, and the compatibility of the fill material to the native sediments to be critical to the short- and long-term impacts to beach invertebrate populations. Fill placement during the invertebrate reproduction or recruitment periods in early spring and early fall depressed the populations of mole crabs and coquina clams for several months to years; ghost crab populations were similarly decreased as a result of fill placement on the beaches at Pea Island. The alterations to the geomorphology and sediment characteristics of the study beaches appear to be more controlling factors on invertebrate recovery periods than direct burial or mortality.

Peterson et al. (2000) documented beach invertebrate populations following dredge spoil disposal from Bogue Sound on the beaches of Bogue Banks to be reduced by 86-99% (compared to control beaches) 5 to 10 weeks following fill placement. The authors conclude that "Failure of *Emerita* and *Donax* to recover from nourishment by mid summer when they serve as a primary prey base for important surf fishes, ghost crabs, and some shorebirds may be a consequence of the poor match in grain size and high shell content of source sediments and/or extension of the project too far into the warm season" (Peterson et al. 2000, p. 368).

Reilly and Bellis (1978) state that species of beach infauna recruited from pelagic larval stocks, such as mole crabs and coquina clams, will recover if nourishment activity ends before larval recruitment begins in the spring. In the spring, recruitment begins with juveniles and adults approaching the beach. In the Bogue Banks project, nourishment extended from December until June, a time that included the March recruitment period of coquina clams. No increase in coquina clams occurred until approximately two months after cessation of nourishment, and populations failed to reach pre-nourishment numbers found during the winter. At the control site, coquina clams also decreased during the winter as they moved offshore. However, during March, numbers at the control site increased to high levels. The authors conclude that adult coquina clams were probably killed in their offshore wintering environment, and beach nourishment effects, most likely high turbidity, prevented normal pelagic larvae recruitment. The individuals that eventually arrived were post metamorphic adults likely to have diffused from area beaches via littoral drift.

Reilly and Bellis (1978) also found a complete absence of mole crabs within one week of the beginning of the nourishment project at Bogue Banks. Numbers were also reduced at the control site as adults moved offshore to spend the winter. Overwintering adult mole crabs returned to the control site in April, and the young of the year from pelagic larval stocks returned later in the spring. The return of mole crabs at Bogue Banks lagged one month behind that at the control site and then only young of the year mole crabs appeared at the nourished beach. The lack of adults at the nourished beach resulted in drastic reduction in overall biomass of mole crabs.

In addition, beach infauna are indirectly effected by the lack of internal structure in an artificially constructed beach as opposed to a natural beach. The fill material may vary significantly in its mineralogical composition, organic content, grain size distribution and sedimentary characteristics. Over the lifespan of the project, with the continual maintenance of an artificial beach, there will be a semi-permanent to permanent change in the beach, which supports an entire ecosystem.

While species which move on and off the beaches during their life cycle may recolonize the new beach in time, species spending their entire life cycles in the intertidal regions of the beach may be more severely impacted by massive sand placement (Hurme and Pullen 1988). *Haustorius* sp., an amphipod found on many beaches, recovered very slowly after the placement of beach fill on Bogue Banks (Reilly and Bellis 1978) and North Topsail Beach (Lindquist and Manning 2001).

Reilly and Bellis (1978) indicated that numbers of migrating, invertebrate consumers such as the speckled crab (*Arenaeus cribarius*), lady crab (*Ovalipes ocellatus*), ghost crab (*Ocypode quadrata*) and blue crab (*Callinectes sapidus*) were drastically reduced after nourishment activities. The authors conclude that this may be attributable to greater turbidity causing resident populations to move elsewhere, a change in beach slope and offshore bars making approach to the beach difficult, or more likely a reduction in the abundance of prey. Vertebrate consumers, such as fish and shorebirds, may also be adversely affected by a reduction in prey species. Lindquist and Manning (2001) found that Florida pompano (*Trachinotus carolinus*), a visually foraging surf zone fish, experienced a 40.5% decline in feeding on coquina clams and a 30% reduction in feeding on mole crabs during periods of elevated turbidity in a lab setting. Shelly material may also inhibit the foraging of shorebirds due to less efficient beak penetration into the substrate (L. Manning, pers. comm., May 8, 2001).

Coquina clams have been found to be "substrate sensitive" in their grain size preferences (Alexander et al. 1993). If the fill material significantly deviates from the native grain sizes, the ability of *Donax* spp. to burrow can be dramatically impaired. Bowman and Dolan (1985) found that mole crabs increase in abundance in specific grain sizes as well. Recent research on Bogue Banks has found that coquina clams have a decreased ability to burrow in sediment with a high shell content (Lindquist and Manning 2001). An impaired ability to burrow will increase the likelihood of invertebrates being washed out of their habitat and their susceptibility to predation.

Sand flowing onto the lower portion of the beach during the nourishment operation can affect habitat suitability and feeding by beach invertebrates beyond the immediate impact of sediment placement. Rakocinski et al. (1996) found that macrobenthic assemblages in nearshore, sandy-beach environments are less resilient to the impacts of beach construction projects than more diverse offshore assemblages. These nearshore assemblages respond to such projects with "decreased species richness and total density, enhanced fluctuations in those indices, variation in abundances of key indicator taxa, and shifts in macrobenthic assemblage structure" (Rakocinski et al. 1996, p. 326).

The recovery period for benthic communities that are lost to dredging is quite variable, ranging from a few months to several years (NRC 1995, MMS 1999). While the abundance and diversity of benthic fauna may return to pre-dredging values, several studies have documented changes in the species composition of the benthos that lasted more than a year, particularly in areas where bottom sediment composition was altered (Johnson and Nelson 1985, Bowen and Marsh 1988, Van Dolah et al. 1992, 1993, Wilber and Stern 1992). Benthic organisms inhabiting the potential offshore borrow areas serve as food for commercially important species and are essential in marine food chains.

Donoghue (1999) and Bowman and Dolan (1985) found that the dominant invertebrate species (i.e., coquina clams and mole crabs) are also influenced by hydrodynamic parameters. Abundances of coquina clams, for instance, are concentrated on the downdrift sides of beach cusps, and there is evidence that these clams surf from one beach cusp to another on the wave swash (Donoghue 1999). The abundance of these patches of clams decreases with smaller cusps and changes in the hydrodynamic conditions. The ability to maintain burrows and optimize filter feeding appears to be directly related to both grain size and hydrologic parameters, both of which can be drastically altered by an artificial beach fill project.

RE: Carteret County – Bogue Banks Beach Nourishment Project
Response to Comments dated 13 April 2001 from US Environmental Protection Agency (W.L. Cox) [SCH File #01-E-4300-0357; USEPA Action IC# 200000362]

Dear Colonel Delony:

I am writing on behalf of the applicants in response to comments dated 13 April 2001 from the US Environmental Protection Agency on the above-referenced project. The comments consist of eight paragraphs in a three-page letter. The following responses apply in order of the original paragraphs.

Paragraph 1
Response: No response needed.

Paragraph 2
Response: Our responses to comments from North Carolina state resource agencies have been incorporated into the final EIS. We will prepare responses to comments from other federal resource agencies as they are received as recommended by the correspondent.

Paragraph 3
Response: Many intangibles (including environmental impacts, recreational enjoyment, and lifestyle) are impacted by beach erosion and nourishment. We did not attempt to place any specific costs or benefits on such intangibles in our review of costs of the project, largely because there is no accepted method for valuing these factors. If the EPA has a particular methodology for assigning dollar values to such items, we will be happy to incorporate them into our analysis. It remains our contention that the cost of the project as quantified in the EIS will be far less than the cost of other alternatives over the next decade.

CSE

Paragraph 4

Response: This paragraph reflects the concern that the proposed project will encourage more oceanfront development over the next ten years. Presently, over 90 percent of the oceanfront is developed, leaving only a small percentage of lots subject to new development. The local communities are actively seeking opportunities to obtain additional oceanfront property for parking and beach access. In any case, relatively little additional oceanfront development is possible. Furthermore, all remaining barrier islands in Carteret County (approximately 55 miles of ocean shoreline) are already set aside as wilderness preserves with no vehicular access.

The applicant has been working for over three years to develop the present plan, obtaining input from representatives of many interests within the community, including environmentalists, developers, academicians, and political leaders. The proposed plan is based on consensus reached after many community forums and careful review of alternatives. A 50-year planning framework and project design life are considered desirable by the community and, in fact, are being evaluated by the US Army Corps of Engineers as part of a recently authorized feasibility study of Bogue Banks. However, the time required between authorization of this feasibility study and construction of a federal project is likely to be at least ten years. The community has determined that a decade is too long to wait for federally sponsored nourishment. Also, given the limited historical database (documented in the EIS), the applicant believes that a ten-year planning time frame is appropriate for this first nourishment. Experience with other communities has proved that a constructed project provides the best means of predicting future performance of larger scale projects such as the one envisioned by the USACE.

Paragraph 5 — Concern regarding multiple jurisdictions performing portions of the project without coordination

Response: The lead applicant (Carteret County) will coordinate production of plans and specifications such that environmental construction windows as prescribed in the permits are honored. The proposed borrow areas will be dredged once under the present project with later reaches avoiding the already dredged areas. Such coordination will be prescribed in contract documents. Copies of early construction plans (for the first reaches completed) will be shared with later contractors. As-built surveys will locate excavation areas used in each nourishment. Engineering reports will be prepared for each reach outlining the anticipated design life of that particular reach in the absence of other reaches being nourished or in conjunction with already nourished reaches, as applicable. Further, the county and local communities are committed to detailed monitoring and performance evaluation of each beach fill.

Paragraph 6 — Comment concerns nonpoint-source runoff and land planning

Response: The topography of barrier islands such as Bogue Banks forces most drainage toward the lagoon (Bogue Sound). Unlike mainland beaches such as Myrtle Beach, there is relatively little drainage toward the ocean. Furthermore, paved surfaces make up a small fraction of the land cover on Bogue

Banks. The sandy sediments that dominate the island have high percolation rates, aiding natural drainage.

The applicants are actively seeking opportunities to acquire additional oceanfront parcels for use as public access or conservation easements. Oceanfront development, which is nearly 90 percent built out, is subject to state setback regulations based on 30-year to 60-year erosion projections, depending on the type of building. With so much of the land already developed, the communities have chosen nourishment as the most viable alternative for (1) increasing separation between existing buildings and the sea, (2) reducing damages to properties due to storms and surges, (3) reducing the pressure for yearly beach scraping, (4) protecting and preserving existing barrier island habitats, and (5) providing improved recreational beach area for everyone. The project is attempting to apply best-management practices and a totally soft solution to coastal erosion as recommended by the National Academy of Sciences [NRC (1995) *Beach Nourishment and Protection*]. No other alternative provides comparable benefits commensurate with the project costs.

Paragraph 7 — Comment concerns potential impacts to hard-bottom communities
Response: The draft EIS addresses this concern in detail. Borrow areas will be situated at least 7,500 feet (ft) from the nearest hard bottom habitat (see Figure E1 of the EIS). Based on our analysis of profile closure depth and confirmed hard-bottom exposures, we believe the project will not produce a measurable increase in turbidity or exchange of sediment between the fill and offshore hard-bottom areas. The published reports of hard bottom (Hine and Snyder, 1985) and our preliminary borrow investigation (CSE Stroud, 1999) show hard bottom close to shore only around the westernmost project reach off Emerald Isle. The Hine and Snyder (1985) geologic map suggest the possible presence of hard bottom within 1,500 ft of the project shoreline between transects 10 and 28 (western Emerald Isle). If so, this would place hard bottom in less than 30-ft water depths just seaward of the outer bar. However, none of our cores in water depths less than 40 ft detected hard bottom (CSE Stroud, 1999).

The Hine and Snyder (1985) map is based on broad extrapolations from relatively sparse seismic and ground-truth data. No cores were obtained by them inside the 10-meter contour. (See Figure E2 of the EIS.) Based on our direct scuba observations of 140 sites off the project area, we believe a thin sand veneer occurs over the entire lower shoreface off Bogue Banks between the beach and the ~35-ft contour. The hard bottom confirmed at stations C18a1 and C18a2 (see Figure E5 of the EIS) is situated in water depths >40 ft about 4,500 ft offshore of transect 29 (see Annex E1, Table E1-D). This is believed to represent the most proximal outcrop of hard bottom off the project area. Because of its presence and the poor quality of sediments near it, the proposed borrow area B2 is terminated over two miles east of the Emerald Isle-West reach. In general, there is more sand and less hard bottom offshore of Bogue Banks compared to Topsail Beach or Surf City, based on reports available to date.

CSE

Paragraph 8 — Comment concludes with opposition to the project based on "potential direct, secondary, and cumulative impacts"

Response: The correspondent has not provided any quantitative analysis or reference to other nourishment projects demonstrating specific, permanent adverse impacts. If quantitative standards exist for certain concerns expressed by the correspondent, the applicants are prepared to modify the design and seek to achieve those standards.

I hope that the above-listed responses adequately address the US EPA's comments regarding the project. Please contact me if you need further information about any aspect of the project. Thank you for your consideration.

Yours truly,

Timothy W Kana PhD

Wilmington NC 28402-1890

RE: Carteret County – Bogue Banks Beach Restoration Project – USACE Action ID# 200000362]
Response to Comments dated 20 April 2001 from Andreas Mager, Jr. (NMFS)

Dear Mr. Sugg:

I am writing on behalf of the applicant in response to comments (dated 20 April 2001 from the National Marine Fisheries Service, Andreas Mager, Jr.) on the above-referenced project. Some of the concerns raised by NMFS match those of other agencies. Therefore, we direct you to our responses to comments from:

1) North Carolina Division of Marine Fisheries (18 April 2000 and 2 October 2000 comments; 13 September 2000 responses).
2) NCDENR-Wildlife Resources Commission (27 April 2000 and 24 October 2000 comments; 13 September 2000 responses).
3) University of North Carolina-Institute of Marine Sciences (15 March 2001 and 13 April 2001 comments; 3 April 2001 responses).
4) Environmental Defense (13 March 2001 and 12 April 2001 comments; 4 April 2001 responses).

Copies of these letters and responses are contained in the SEPA final EIS for the project, a copy of which has been delivered to your office. We believe the final EIS addresses all salient issues and presents a comprehensive evaluation of the project.

RE: Concerns Regarding Essential Fish Habitat
We have discussed the review required of essential fish habitats (EFHs) with NMFS representatives in Morehead City and St. Petersburg (FL). We are in the process of preparing the document and will submit it as required under NEPA. The habitats that are applicable include areas of offshore sand bottom, surf zone, and water column.

NMFS expresses concern that "physical and biological conditions in (the offsbore borrow areas) may be substantially changed . . .". The applicant is also concerned and has endeavored to design a project that will:

CSE

1) Only minimally change the bottom topography with shallow cuts of the order 2-3 feet.
2) Leave similar underlying sediments as are presently exposed at the surface.
3) Leave undisturbed "furrows" adjacent to the cuts from which recruitment can occur.
4) Match as closely as possible the grain size of the fill material with that of the beach.
5) Avoid dredging deposits containing >5 percent mud.
6) Perform work during colder months when biological productivity is lowest.

We are not aware of any nourishment project in the Southeast that followed the above protocols <u>and</u> produced long-term adverse impacts to essential fish habitat.

RE: Concerns Regarding Biological Monitoring
See previously referenced responses.

RE: Sediment Resuspension and Turbidity
Persistent turbidity results when discrete clay-sized particles are in suspension. Silt and fine sand has settling velocities orders of magnitude faster than clay. The "fines" referenced by the correspondent and reflected in overfill ratios consist mainly of sand-sized sediment. Clay-sized material will be a fraction of the "mud" fraction which will total no more than 5 percent of the borrow material.

Such concentrations of mud are ubiquitous in the nearshore zone and account for the chronic resuspension during storms and large seas. Species common to the area of Bogue Banks are adapted to order-of-magnitude variations in turbidity in the foreshore. The proposed project will not produce permanent elevated turbidity levels because the amount of clay-sized material that will be mobilized by dredging a 2.58-square-mile area is dwarfed by the volume of free mud on the ocean floor over other sections of the inner shelf in this setting. In fact, the applicant has chosen the borrow areas so as to avoid areas off Bogue Banks that have higher concentrations of mud on the sea floor.

RE: Potential Reductions in Important Surf Zone Species
The correspondent references two studies that indicate nourishment reduced populations of Donax and Emerita. These studies (Donaghue, 1999, and Peterson et al, 2000) describe impacts resulting from cases quite different than the proposed project. Donaghue observed declines at Pea Island on a beach that was nourished almost yearly over a seven-year period, leaving little time for recovery before the next fill in a one-mile reach. The Peterson et al study at Bogue Banks examined the impacts from placement on the beach of noncompatible, muddy sediments from Bogue Sound. Mean grain size was 3.67ϕ, which is nearly in the silt range and nearly an order of magnitude finer than the mean grain size in the project area. A review of the literature shows that where borrow sediments closely match the native beach and projects follow the six protocols listed previously in this letter, biologic and turbidity impacts tend to be exceedingly short-lived. References to other pertinent literature are given in Appendix A of the SEPA EIS for the project.

CSE

RE: Numbers of Nourishment Projects
We question the correspondents estimate of 58 percent of North Carolina beaches being considered for nourishment when only about 43 percent are developed. Further, Bogue Banks is the only developed barrier island for 52 miles to the east/north and for 21 miles to the west. In other words, the Cape Lookout region is not likely to experience chronic impacts of repeated nourishment activities.

RE: Schedule of Construction
The applicant has requested a November to April construction window to minimize the number of dredge mobilizations. The project will be performed in at least two phases with reaches 4, 5, and 6 (Indian Beach, Salter Path, and Pine Knoll Shores) scheduled for 2000-2001. Penalties will be imposed on the contractor if construction is incomplete prior to the end of the environmental window, assuming the applicants are granted permits with reasonable time conditions. We expect to work closely with NMFS to coordinate activities at the beginning and end of the construction window so as to avoid any commercial fishing activities in the surf zone in November or turtle nesting in April

RE: Proposed COE Turbidity Impact Studies
We encourage NMFS to review the historical literature on turbidity impacts on larvae and juvenile fishes. The Chesapeake Bay Institute of The Johns Hopkins University completed a series of controlled experiments in the 1970s investigating the question of turbidity impacts on fish egg-hatching success and fish larvae. We recall that these experiments showed no significant effects for the natural ranges of turbidity in the upper Chesapeake Bay (much higher suspended sediment levels than offshore Bogue Banks). Only the most extreme concentrations (above worst storm levels) showed some initiation of lethal effects (cf, Auld and Schubel, 1974; Schubel, 1977, p. 409; Sherk et al, 1974). These studies were funded by NSF, NMFS, and the State of Maryland.

RE: Proposed Monitoring
See response to Peterson letter and draft monitoring plan dated 25 April 2001 which we submitted to your office. Our proposed statistical analysis exceeds that which was initiated by Dr. Peterson as part of the applicant's SEPA EIS.

CSE

RE: "High Possibility" of Adverse Impacts
We disagree with this qualified statement and question its basis. In our opinion, the comment reflects a selective rather than comprehensive review of the literature, as noted above. Again, we believe that there are no known instances of prolonged adverse impacts of nourishment to indigenous organisms for projects that followed the six protocols previously listed. If such cases exist, we would like to obtain copies of any reports or documentation so that we may improve future projects.

In conclusion, we appreciate the correspondent's comments and concerns and have sought to address them by applying best-management practices to the design. In my opinion, the comments greatly overstate the potential for biological impacts based on a selective reading of the literature. Further, without quantitative standards and guidelines, the comments do not provide sufficient rationale for denying permits. Instead, more would be learned by proceeding with the initial reaches and carefully monitoring the physical and biological impacts of the project, as we are proposing. The applicant has no desire or motivation to degrade the shoreline or fishery on which the economy of Carteret County depends.

Thank you for your consideration.

Yours truly,

Tim Kana

RE: Carteret County – Bogue Banks Beach Restoration Project – Federal Action ID# 200000362]
Supplementary Information Requested by USFWS on 11 May 2001 (interagency meeting)

Dear Mr. Pardue:

I am writing on behalf of Carteret County and the Towns of Pine Knoll Shores, Indian Beach, and Emerald Isle in regard to the permit application for the above-referenced project. Representatives from your agency, Ms. Tracy Rice and Mr. John Ellis, attended an interagency meeting in Morehead City on 11 May 2001 and provided comments and requests for additional information. This letter and its attachments provide the information requested. These data are intended to supplement the information contained in the permit application and final EIS approved under the SEPA review process.

Work Accomplished

At the request of your agency, the Towns of Pine Knoll Shores and Indian Beach funded additional beach sediment collection and analyses as follows:

- 64 surficial sediment samples from Bogue Banks transect 48 (Emerald Isle) through transect 78 (Atlantic Beach). Sixteen, even-numbered transects were sampled along the dune face, top of berm, beach face, and low-tide terrace at low tide on 15 May 2001.

- 32 samples were analyzed in the laboratory by combining physical pairs from adjacent transects (eg, dune samples from transects 48 and 50 were combined physically, mixed completely, and a representative ~100-gram sample was tested for sediment properties). Samples were labeled B4850a for dune samples at transects 48 and 50, B4850b for berm samples, etc.

CSE

- Laboratory analysis of each sample consisted of:
  - Mechanical sieving at 0.25ϕ intervals.
  - Computation of grain-size distribution (GSD) parameters (mean, standard deviation, skewness, percent coarser than 2 mm, etc.).
  - Chemical analysis of the calcium carbonate fraction via acid reduction (dilute HCl) using a representative 20-gram sample.
  - Physical separation of the mud fraction (sizes passing the 230 ASTM sieve; ie, <0.0625 mm diameter) to determine the mud percent.
  - Size parameters were calculated by the Method of Moments and via graphic techniques of Inman (1952) and Folk and Ward (1957).

- Groups of samples were combined statistically using the raw weight percentages of each size fraction to calculate "composite" GSDs. Composites included:
  - CDUNE8 – composite of the eight dune tests (representing 16 physical samples).
  - CDUNE4 – composite of four of the dune tests (representing transects less altered by scraping).
  - CBERM8 – composite of the eight berm tests (representing 16 berm samples).
  - CBF8 – composite of the eight beach face tests, etc.
  - CLTT8 – composite of the eight low-tide terrace tests, etc.

- Overall beach composites were computed for all 32 tests ("COMP32") and 28 tests ("Comp28" which omits four of the dune samples).

- The composites from the 15 May 2001 sampling were compared with the June 1999 results. All new beach sediment data have been added to Table E3-Revised (EIS) and are attached to this letter. The 1999 "Native Beach" composite is compared with the 2001 composites at the bottom of Table E3.

- The "Native Beach" GSD was revised by averaging the results from the June 1999 and the May 2001 survey as follows (see Table E3 for additional details):
  - 1999 beach composite (20 samples) – mean = 0.302 mm
  - 2001 beach composite (28 samples) – mean = 0.298 mm
  - Revised native composite – mean = 0.300 mm

- Overfill ratios (RAs) for individual samples in three offshore borrow areas were recomputed using the revised native composite GSDs. These are given in Table E5-Revised. The typical change in RAs after this revision was ~0.01, or about 1 percent.

- Sediment characteristic maps of various textural parameters were updated for the three borrow areas. These include data from additional borings obtained between November 2000 and March 2001, which were in processing at the time of the interagency meeting.
  - Area A – ~76 cores
  - Area B1 – ~46 cores
  - Area B2 – ~42 cores

  Additional core data are given in Annex E1-Table E1-F (Appendix E to EIS).

- Results of the supplementary individual and composite GSDs (sample split weights, frequency, cumulative frequency, and statistics) are enclosed with this letter.

Borrow Area Delineation

As part of the final design for the Pine Knoll Shores and Indian Beach projects, we will optimize borrow areas A, B1, and B2 to effect a close match between the borrow sediments and the revised native beach sediments. This is an iterative process because of the number of variables involved and the natural variability of Bogue Banks' beach and offshore area. However, final decisions regarding exactly which portions of the borrow areas will be used cannot be made until all variables are known. These include the capabilities of each dredge of the winning construction bidder and the unit-volume bid price. (For example, if bid prices are lower than expected, more sand may be dredged, up to the maximum permitted volume.)

The final design will identify the optimal areas for excavations and will provide statistical composites for applicable groups of samples from borrow areas A, B1, and B2.

We anticipate collecting additional borings prior to any nourishment along Emerald Isle. The present data are focused in anticipation of construction along Pine Knoll Shores and Indian Beach reaches between November 2001 and April 2002. We request that your agency review these data in the context of the Pine Knoll Shores and Indian Beach reaches.

CSE

Supplement to the Biological Assessment

Also enclosed herein is a supplement to the biological assessment given in the EIS. Additional site visits and surveys have been performed since the EIS was prepared. The most recent survey was 14-15 May. The majority of Pine Knoll Shores and Indian Beach lacks any dry beach. Property owners are continuing to scrape the beach and rebuild the foredune. There are escarpments up to 8 feet high in some newly scraped dunes (see photo 1.4) and continued undercutting and mass wasting of vegetated dunes. In addition to the reduction of viable turtle nesting and seabeach amaranth habitat (see photos), even more habitable structures are imminently threatened than was reported in the EIS. We encourage you and your staff to visit the site and see the continued loss of dune and dry beach habitat. This is particularly noticeable upon leaving Pine Knoll Shores and traveling east along the beach into the Town of Atlantic Beach (which was nourished in 1986 and 1994 prior to five landfall hurricanes, see photo 1.6).

We appreciate the comments from your agency and hope you find the enclosed information responsive. Time is of the essence, and it is critical that we obtain your review of the project at the earliest time. Our project team and representatives of the county and towns would like to meet with you any time in the next two weeks and discuss these results in detail. Thank you for your consideration.

Yours truly,

Tim Kana

DEPARTMENT OF THE ARMY
WILMINGTON DISTRICT, CORPS OF ENGINEERS
P.O. BOX 1890
WILMINGTON, NORTH CAROLINA 28402-1890

IN REPLY REFER TO April 17, 2001

Regulatory Division

Action ID. 200000362

Mr. Pete Allen, Manager
Carteret County
Courthouse Square
Beaufort, North Carolina 28516

Dear Mr. Allen:

Please reference Carteret County's application for Department of the Army (DA) authorization to conduct beach nourishment along 16.8 miles of Bogue Banks Barrier Island by discharging 8.0 million cubic yards of dredge material into Section 10 Navigable Waters and Section 404 waters of the Atlantic Ocean, in Carteret County, North Carolina.

In response to your proposal, our office has received comments by letter (copies enclosed) from private organizations and individuals recommending against the authorization of your permit request. It is our suggestion that you revise your plans to satisfy the interests of the objecting individuals and organizations.

It is the policy of the DA to provide an applicant the opportunity to furnish a proposed resolution or rebuttal to all objections from government agencies and other substantive adverse comments before a final decision is made on a proposed project. In this regard, I would appreciate receiving any comments that you have on this matter. If you intend to comment, please give your immediate attention to this matter, so processing of your permit application can be expedited.

If you have questions or comments, please contact me at (910) 251-4811 and I will assist you in coordinating with the review agencies.

Sincerely,

Mickey Sugg
Wilmington Regulatory Field Office

Re: Bogue Banks Beach Restoration Plan

Dear Mr. Sugg:

I enclose here my comments on the Draft EIS for the Bogue Banks Beach Restoration Plan. I make these comments in my professional capacity as a coastal ecologist with the University of North Carolina at Chapel Hill. These opinions are derived from my 25 years of personal experience in quantitative monitoring of the major beach invertebrates on the beaches of Bogue Banks, my years of experimental analyses of how ecological processes on sand beaches are influenced by the physical character of the sediments, my personal experience with two beach nourishment projects at Fort Macon, my 30+ years of professional reading, research, and experience as a marine ecologist, my two decades of teaching barrier island ecology at Duke University and the University of North Carolina, and my recent experience as a member of the IRC charged with development of CHPPs, including the Coastal Ocean Habitat Protection Plan.

In my professional opinion, the proposed Bogue Banks Beach Restoration Plan is inadequately protective of the important natural resources of the intertidal beach and the coastal ocean, including especially the physical habitat and prey invertebrates required to sustain our recreationally and commercially important fisheries and the valued shorebirds of our beaches. Without (1) scientifically rigorous before-after monitoring of physical character of the sediments, impacts and recovery of the invertebrate prey, and consequences of turbidity and habitat change on the fishes, with required mitigation for any substantive impacts, (2) development of a federal or state plan for assessing cumulative impacts based on results of a programmatic EIS covering all these sand mining and beach deposition projects along the entire coast of the state and beyond, as dictated by the range of the important fishes, (3) a match of sediment grain sizes to the natural sediments of the beach in a way that will protect the habitat value of the beach, and (4) restriction of the project to between Dec 1 and March 31 so as to minimize ecological damage and allow recovery to begin to develop during the ecologically significant spring-summer seasons, this project should not be granted a permit.

(1) Scientifically rigorous before-after monitoring of sediments, benthos, and fishes

The draft EIS is grossly deficient in its commitment to the monitoring that is necessary to evaluate the ecological impacts of the project and thereby allow the agencies to learn how to respond to future requests and how to condition projects to protect adequately the public trust resources. While it is true that monitoring of nourishment projects has been done in the past, this project is unique for its spatial scope, its application to pristine shores, and its context in the midst of potentially hundreds of miles of

similar projects coast-wide. Past beach nourishment projects have been done on short stretches of urbanized shore like Atlantic Beach, Wrightsville Beach, and North Topsail. The application to a pristine beach of such a length as to represent a significant fraction of the functional critical habitat for beach fishes, invertebrates, and shorebirds is unprecedented for North Carolina. Past monitoring projects attached to permit applications are almost uniformly poor scientifically, done merely to satisfy a regulatory burden in a way that typically produces inconclusive results. Monitoring should be designed up-front by and reviewed by professional statisticians so that the agency and the public can have reassurance that the important questions can be answered with adequate power to detect effects of ecological significance. That has not been done here. Here we are told that monitoring will be done by the Carteret County monitoring plan. There is no such plan, no detailed statistical design, and no binding commitment by the county, state, or the responsible party to funding such a project. In fact, the necessary before-project sampling has not even been done. In South Carolina projects, the offshore biology has been monitored before and after such projects in each of the four seasons of the year: this proposal includes pre-project monitoring of benthic invertebrates for only one season (autumn), yet the offshore fishery resources here are arguably even more important than off South Carolina. Yet, for Bogue Banks, there has been sampling in the offshore mining areas only in one season. There are no data included on pre-project monitoring of the beach ecosystem and no design that could be evaluated statistically for its rigor and ability (power) to detect important changes. No monitoring of the surf fish abundance and gut contents/fullness is even mentioned or contracted. Granting a permit under such inadequacy is not in the public interest.

There is broad and essentially uniform consensus among the scientific community that the impacts of beach nourishment projects on fisheries through modification of their bottom and water column habitats are poorly understood. The monitoring that has been done for such projects in the past (1) has been too restricted to include all the potentially important impacts on fisheries, (2) has lasted for too short a time period to confidently demonstrate recovery, (3) has failed to meet standards of rigor and high power to detect large impacts, and/or (4) has been done for projects occurring on too small a scale to allow extrapolation to the cumulative effects of permitting many miles of beach nourishment. The impacts of concern include both phases of nourishment projects, the mining of sediments from the shelf and the deposition of sediments on the beach.

A minimally adequate monitoring design for either the mining site or the deposition site would include the following components. First, the monitoring design must begin with quantitative data taken before initiation of the project. Such "Before" observations must be made during each season of importance to the biota that comprise and use the habitat. A single year of such "Before" data is an absolute minimum necessary to make rigorous conclusions and multiple years of "Before" data are required to be completely comfortable in estimating the magnitude of effects with confidence. These "Before" data must include observations made in both the putative "Impact" areas and in "Control" areas that are sufficiently distant not to be affected by the project but sufficiently nearby and similar that they can serve to track conditions that would be expected in the "Impact" area in the absence of the project. The observations made during the "Before" period then need to be replicated in the "After" period in both the putative "Impact" areas and the "Control" areas. This monitoring needs to match the seasonal monitoring done during the "Before" period and needs to extend long enough in time to demonstrate recovery or allow inference of recovery with high statistical confidence. The "Control" area should have replication that involves statistically independent sites. This is preferable for the "Impact" areas too, but sometimes impossible because there may be only one project site. In any event, sufficient subsampling must be done at multiple locations to characterize the habitat and its utilization adequately. This monitoring design must be shown to be likely to have high statistical power to detect any magnitude of impact deemed important to fisheries biologists and managers. This requires an effective statistical design. Perhaps the best model for such rigorous project monitoring comes from the paper on BACI (Before-After-Control-Impact) designs by Stewart-Oaten et al. (1986: Ecology). Most monitoring associated with permits is incapable of statistically demonstrating even large impacts of the project with confidence because of inadequate statistical power in the design. The evaluation of cumulative impacts of beach nourishment on a large scale of tens of miles is a particular challenge, fundable perhaps only by creating a monitoring bank from contributions from multiple projects.

(2) Programmatic EIS for cumulative impacts and appropriate monitoring

Besides the needs to evaluate the impacts of this particular project on Bogue Banks, the responsible permitting authorities have a duty to evaluate the cumulative impacts of all such perturbations to the coastal ocean system. This requires first a programmatic EIS that applies the best scientific judgement, open to public review, analysis, and comment, as to cumulative impacts, especially on fishery populations and shorebirds. For a short stretch of urbanized shoreline, it is readily argued that most fish and shorebirds are mobile enough to move elsewhere to feed when their invertebrate prey resources are killed by beach nourishment. Similarly, when prey resources are mined along with sand from the offshore sand bodies, one can argue that the demersal fishes and crustaceans can feed elsewhere. But when projects are large enough and numerous enough and when projects are repeatedly done over time, then the potential for seriously limiting the production of fishes and birds greatly increases. Furthermore, if the physical sedimentary habitat is permanently altered or modified for the long term, then there is great potential for permanent limitation of the extent of critical fisheries habitat both on continental-shelf sand bodies (a limited habitat already in the southern portion of the state) and on intertidal beaches. Nowhere in this Draft EIS for Bogue Banks is there evidence that the public trust resources will be protected from cumulative spatial and cumulative temporal effects. Until such time that evidence exists, no permit should be granted for this project.

(3) **Match of sediment grain sizes to protect habitat value of the beach**

The recovery of natural ecological functioning of the beach habitat depends upon closely matching the sediment size distribution to that of the natural undisturbed beach. I have shown in a published paper based on study of a previous beach nourishment project on Bogue Banks (Peterson et al. 2000: Journal of Coastal Research) that the US ACOE requirements for matching sediment sizes are inadequate to allow recovery of function of the beach habitat within the following summer season. Incorporation of either too much shell (coarse material) or too much silt/clay (fine material) inhibits recovery. Too much shell inhibits burrowing by the beach invertebrates, which must burrow into the sediments to feed and avoid erosion and wave-transport off the beach face. Too much shell also prevents many shorebirds from feeding on the invertebrates that are present because coarse particles block the biomechanical ability of bills to extract invertebrate prey (see test in published paper by Quammen 1982: Marine Biology). Too much silt/clay likewise prevents sand burrowers from inhabiting a habitat that now lacks the interstitial spaces among sand grains and the penetrability required for burrowing. In addition, silt/clay is readily suspended causing enhanced turbidity, which clogs the filtration apparatus of these suspension-feeding beach invertebrates (mole crabs, coquina clams, some polychaetes, and amphipods) and inhibits surf fishes like pompano, bluefish, and Spanish mackerel from detecting their prey. We possess feeding data from experiments showing this feeding inhibition on pompano in the presence of elevated turbidity. No matter which sediment source is chosen from those surveyed off Bogue Banks, turbidity in the surf zone will result and will likely degrade fisheries through further loss of prey organisms and inhibition of feeding by visually oriented fishes. The Bogue Banks project, as proposed in this Draft EIS, plans use of sediments that are much more dominated by shell fragments than the natural pristine Bogue Banks beaches. This will result in long-term (not just transient) reduction in beach invertebrate populations and thus habitat value for surf fishes and shorebirds. I base this judgement upon knowledge of the physical processes that affect sediments on the beach and upon my lab's survey of the biota of North Carolina beaches as a function of shell content. Silts and clays are gradually winnowed away from beach sediments as they become suspended in the water and make it turbid. Shell fragments, in contrast, are left behind to accumulate on beaches, and thus remain to degrade the beach habitat indefinitely until the next nourishment project is needed. Lower densities of the numerically and functionally important large burrowing invertebrates on shellier beaches are dramatic in our unpublished survey data. Thus, the choice to use shell-rich sediments in the Bogue Banks nourishment project will predictably degrade the critical habitat of the intertidal beach indefinitely. Such a poor match with pristine sediments should not be permitted.

(4) Restriction of the project to Dec 1 through March 31

Because of the seasonality of biological use and activity in both the subtidal sand body habitat and the intertidal beach habitat, sand mining and beach deposition should both be restricted to the colder months to minimize ecological injury and to speed up recovery in the next warm season. The draft EIS for the Bogue Banks project does not constrain the project adequately in light of what is known about biological seasonality to protect the functioning of these habitats. Our monitoring of beach invertebrates on Bogue Banks over a period of 25 years shows that the period of December 1 through March 31 is the proper window during which beach invertebrates like mole crabs and coquina clams have migrated to deeper waters, from which they can initiate recovery through migration and reproduction at the end of the project. Furthermore, our sampling of fish abundance at the sand bodies proposed for mining to conduct this Bogue Banks project demonstrated high abundances and high rates of feeding on bottom invertebrates of the sand bodies on November 29 and again in spring, with low levels in February after clod fronts had reduced water temperatures. The Draft EIS for Bogue Banks does not propose a time frame for the project that will adequately protect either of these habitats from the impacts of the project. A permit should not be granted until the window is narrowed to this Dec 1-March 31 season. Furthermore, the public is entitled to a commitment that such a window will be enforced: similar restrictions have not been enforced in the past and I have little confidence that they will be in the future, absent some new mechanism of assurance.

I trust that my concerns are clearly and fully enough articulated here. If any comments need further elaboration, please ask. In addition, if you need further information from our files, please ask.

Sincerely,

Charles H. Peterson

RE: Bogue Banks Beach Nourishment – Action ID No. 200000362

Dear Mr. Sugg:

The following represents the comments of the North Carolina Coastal Federation (NCCF) on the permit request by Carteret County to dredge and discharge approximately 8 million cubic yards of material into Section 10 navigable waters and Section 404 waters to nourish approximately 16.8 miles of beaches along the eastern section of Bogue Banks barrier island from Emerald Isle to Pine Knoll Shores, in Carteret County, NC.

NCCF represents approximately 6,000 members across coastal North Carolina and participates actively in all facets of regulatory and environmental protection activities affecting the state's coast. NCCF has a long history of environmental advocacy regarding the beachfront of the Outer Banks and other segments of the North Carolina coastline, and appreciates the opportunity to submit these comments.

For the past couple of years, NCCF has publicized our Beach Renourishment Policy through our newsletters to its members and the general public, and comment letters to government agencies. This seven point policy (attached) outline the criteria we are committed to use to evaluate beach renourishment proposals. Comments submitted in this letter are based upon this policy.

First and foremost, we are requesting that the Corps of Engineers require Carteret County to prepare an Environmental Impact Statement (EIS) pursuant to the National Environmental Policy Act (NEPA) for this project. The nourishment of 16.8 contiguous miles of beaches is unprecedented on the North Carolina coast and would make it one of the longest stretches on the east coast. Due to its length, the project could have very significant primary, secondary and cumulative impacts upon biological resources that must be fully examined through a NEPA EIS before action on this permit can be taken. The preparation of an EIS under the NC Environmental Policy Act in no way eliminates the need for an EIS under NEPA. NEPA may serve as a substitute for SEPA; but SEPA

E-Mail: nccf@nccoast.org
www.nccoast.org

is not a substitute for NEPA. Inasmuch as the applicant has prepared a SEPA document, it should reduce the time necessary to prepare an EIS that meets NEPA requirements.

The permit application requests permit authority for ten years, which would allow maintenance and potential renourishment with this period. Irregardless of the model that projects the nourishment project will last ten years, it is likely that Bogue Banks would be renourished one or more times after severe storms during the ten year duration of the permit utilizing disaster relief funds provided by the Federal Emergency Management Agency. As a result, it will be necessary for the applicant to determine the environmental impacts of the project by projecting a worst-case scenario of severe storms and multiple reconstructions of the project necessary to maintain its ten-year lifespan. An alternative would be to grant a permit for a shorter duration of time, i.e. three years; or to condition the permit in such a way that prohibits renourishment within the ten-year period.

Second, we are requesting that a public hearing be held on the permit and on the Environmental Impact Statement required under NEPA. The public in Carteret County expressed their opposition to the expenditure of County funds on beach nourishment. In March 2000, Carteret County citizens rejected a county-wide referendum by a 73% to 27% margin that would have allowed the County to issue bonds to construct a beach nourishment project that is identical to the one described in this permit application. In this same referendum, the Town of Emerald Isle and the unincorporated area of Salter Path also voted against the bond issue. Both Emerald Isle and Salter Path are areas that could be nourished through this permit. Given this history, the Corps is faced with compelling circumstances that necessitate a public hearing in order to fully assess "the needs and welfare of the people" of Carteret County.

INADEQUATE CONSIDERATION OF ALTERNATIVES

The EIS submitted by the applicant as part of the SEPA process fails to adequately consider alternatives to the proposed project. This constrained view of alternatives is, in part, the result of the applicant's reliance upon inaccurate and unjustified assumptions. These assumptions also result in the benefits of the project being overstated and the costs being understated.

The applicant unjustifiably dismisses non-structural alternatives. The applicant concludes, without analysis or thoughtful discussion, that the only non-structural alternative is to relocate all the oceanfront structures, an endeavor the applicant estimates would cost almost $111 million. A non-structural alternative, however, does not necessarily entail relocation of all of the structures. No assessment is made of the alternative of a moderated retreat in which temporary, small-scale nourishment is used to reduce storm damage hazards in the short term while threatened structures are removed and either relocated or demolished. Further, Pine Knoll Shores, Indian Beach, Salter Path and Emerald Isle are distinctly different communities with unique development histories and patterns. As a result, a non-structural alternative must be evaluated on a community-by-community basis to determine its relative feasibility and cost, before folding these analyses in to an overall formula.

Prevailing public policy, and the law of the State of North Carolina, establish a policy of retreat from eroding shorelines through building relocation, building setbacks, development restrictions, and land use planning. 15 N.C.A.C. § 7H.0202(b), 7H.0306, 7H.0308. The primary purpose of the project is storm damage prevention and hazard reduction, not saving or relocating all existing structures. A genuine and open-minded analysis of alternatives must evaluate thoroughly the costs and benefits of a range of combinations of selective relocation, demolition, and temporary nourishment.

The applicant should be required to identify threatened structures that were grand fathered by the Coastal Area Management Act setback rule, i.e. were not in compliance with the rule when it was passed, and as a result could not be expected to survive long-term erosion rates on the oceanfront. The applicant also grossly exaggerates the cost of the retreat/relocation alternative by inflating the value of land beneath threatened structures as if the land was not threatened as well.

Because the applicant has not examined combinations of non-structural strategies of retreat, relocation, demolition. and temporary. short-term beach nourishment. the applicant has failed to comply with its duties under NEPA to give the project a "hard look" and to examine carefully all practicable alternatives.

ENVIRONMENTAL WINDOW UNACCEPTABLE

The environmental window requested by the applicant is unacceptable based on available monitoring data supplied by the applicant. If the applicant wishes to proceed with a window that extends from 1 November to 15 May, then it will be necessary for the applicant to conduct preconstruction monitoring during 2001-2002 to demonstrate that the environmental impact is not significant. Existing marine monitoring data of the borrow areas and invertebrate monitoring data from UNC Institute of Marine Sciences demonstrates that the environmental window for construction should be no wider than 1 December to 31 March.

The reason cited by the applicant for the wider window is to accommodate the completion of the project during two seasons. The applicant has divided the 16.8 mile project in to six stretches and has proposed constructing three stretches during each season. The Corps should require the applicant to consider constructing the project over three seasons in order to decrease the impact on marine and terrestrial fauna. In the Corps' "Projected Cost for Shore protection in North Carolina Over the Next 30 Years" (March 2000), the Corps wrote:

"Projects along Bogue Banks would be constructed in 3 phases with the first phase covering Pine Knoll Shores, the second phase covering all of Salter Path, Indian

Beach, and the eastern end of Emerald Isle. The third phase would cover the remaining portion of Emerald Isle."

One of the reasons the project should be segmented in to three or more sections is prevent harmful economic impacts on Carteret Counties sportfishing industry, which is second only to Dare County. The SEPA EIS correctly states, "The health of those activities (fishing, boat building, and outfitting and supply) is dependent on the health of the marine environment." The SEPA EIS does not quantify the impact of the sportsfishing industry in Carteret County nor does it adjust the economic impact of the project for the damage that would be done to this industry by expanding the environmental window. 5

MONITORING DATA AND PLAN INADEQUATE

The plan for monitoring the impact on environmental resources is incomplete and inadequate. The applicant did conduct some monitoring of fish abundance at the proposed borrow sites during the 1999-2000 season. The monitoring results demonstrated "high abundances and high rates of feeding on bottom invertebrates of the sand bodies on November 29 and again in the spring, with low levels in February after clod fronts had reduced water temperatures," according to Dr. Charles H. Peterson, who conducted the survey for the applicant. During the 2000-2001 season, the applicant conducted no monitoring of benthic invertebrates and fish abundance. At no time has the applicant conducted any monitoring of biological use and activity in the intertidal beach habitat.

The applicant has not produced a monitoring protocol, except to promise that a Carteret County monitoring plan will be utilized. No monitoring plan was included in the SEPA EIS. The Corp must require in its scoping meeting with the applicant that the Carteret County monitoring plan must accompany the draft NEPA EIS. It is insufficient and ineffective to simply establish a permit condition that monitoring will be conducted. The protocol and schedule for monitoring must be determined as part of the NEPA EIS process.

Preconstruction monitoring of marine and invertebrate activity is a necessity to establish a baseline on which to determine project impacts. The applicant missed an important opportunity in 2000-2001 to gather the necessary data to develop a baseline. It is unclear how the project can proceed during the 2001-2002 season without adequate and reliable baseline data. 10.

IMPACT TO MARINE RESOURCES

The Habitat and Water Quality Committee of the NC Marine Fisheries Commission approved a document entitled "Policies for the Protection and Restoration of Marine and Estuarine Resources from Beach Dredging and Filling in Large-Scale Coastal Engineering" in November 2000. (Attached) These policies were later adopted by the

NC Marine Fisheries Commission, which has statutory authority for protecting marine and estuarine resources. The document establishes seven policies related to large-scale beach dredge-and-fill and related projects. The SEPA EIS fails to adequately address and in most cases fails to address at all the seven policies. The seven policies must be addressed through the NEPA EIS that examines the potential impact of the project on Essential Fish Habitat as required by the Magnuson-Stevens Act.

MORE STUDY OF SAND SUITABILTY NEEDED

The applicant has selected three potential sand sources or borrow sites (A, B1 & B2). The applicant also requests flexibility in reach and borrow areas, with a clear preference towards maximizing the use of borrow area A. Borrow areas B1 and B2 have overfill ratios of 1.97 to 2.19 in order to retain sufficient sand on the beach. Borrow area A is a significantly courser grain size than borrow areas B1 and B2 and has an overfill ratio of 1.16. At the same time, borrow area A contains 44 percent carbonate material compared to 15 to 20 percent on the native beach. Mud percentage in borrow area A averaged about 4 percent in the upper 2.3 feet of the section. The mean grain size at borrow area A (0.51 mm) is significantly larger than the native beach (0.302 mm). The percent of sediment larger than 2 mm at borrow site A is 20.5 percent compared to about 5 percent on the native beach.

If the question is whether the sediment from borrow site A will stay on the beach, it is more likely to than borrow areas B1 and B2. However, the characteristics of borrow area A in terms of coarseness, large shell fragments, as well as mud composition should not qualify borrow site A as a suitable match for Bogue Banks beaches. Further study of borrow site A must be conducted to determine if the sand source could be made compatible with the native beach with the addition of a screening mechanism to sort out the largest particles and shell fragments and a filter mechanism to lower the mud content. Unless additional mechanisms are employed, it is premature to conclude that borrow site A is a suitable sand source.

Borrow area B2 appears to be the closest match to the native beach, although it too contained a relatively high percentage of mud (4.1 percent) and should be combined with a filtering mechanism to reduce turbidity. Borrow area B1 contained less mud, but its grain size was finer than the native beach which could reduce the project's longevity.

There are two unresolved regulatory issues that must be addressed before this project proceeds. First, based upon the mud and silt contents in the borrow sites, there is a serious question about whether the project can comply with the turbidity standard of the North Carolina Environmental Management Commission. The turbidity standard apples to dredging activities at the borrow areas as well as at the discharge site at the surf zone. NCCF recently has photographed large turbidity plumes associated with dredging activities at the Oak Island beach "sea turtle" project in Brunswick County currently being carried out the the Corps. Steps must be taken to prevent this type of impact from future projects. There also appears to be a real question about whether beach renourishment projects are in fact mining, and should be authorized by a Mining Permit from the NC Department of Environment and Natural Resources. This issue should be resolved to assure compliance with applicable mining standards.

FAILURE TO CONSIDER CUMULATIVE IMPACTS

The applicant's SEPA document gives inadequate attention to cumulative impacts. NEPA requires that the cumulative effects of this project be analyzed along with the effects of existing and potential projects. Cumulative impacts "can result from individually minor but collectively significant actions taking place over a period of time." 40 C.F.R. § 1508.7.

To conduct a valid cumulative impacts analysis, the applicant must look at not only the ongoing and potential projects listed in Table 6-1 of the Dare County EIS (attached), but at all other North Carolina beachfront sand disposal activities. In its 30-year economic forecast, the Corps includes three more proposed major nourishment projects not counted in the cumulative impacts figures: Topsail Beach, Surf City, and North Topsail Beach. Combined predicted shoreline lengths for these projects would add another 20.5 miles to the length of impacted beach.

Other current and proposed projects which need to be considered by the Corps in addition to the projects in Table 6-1 are:

PROJECT	AGENCY	TYPE OF PROJECT	STATUS	LENGTH
Topsail Beach	Corps of Engineers	Nourishment	Proposed	5.5 miles
Bogue Banks (three phases)	Corps of Engineers	Nourishment	Proposed	17 miles
Surf City	Corps of Engineers	Nourishment	Proposed	5 miles
North Topsail Beach	Corps of Engineers	Nourishment	Proposed	10 miles
Wilmington Harbor -- Bald Head Island	Corps of Engineers	Spoil disposal	Current	1 additional mile
Wilmington Harbor -- Caswell Beach/Oak Island	Corps of Engineers	Spoil disposal	Current	9.6 miles
Wilmington Harbor – Holden Beach	Corps of Engineers	Spoil disposal	Current	2 miles
Atlantic Intracoastal Waterway	Corps of Engineers	Expanded channel dredging with spoil disposal	Proposed	from Virginia to South Carolina state line
Drum Inlet/Core Banks	Corps of Engineers	Spoil disposal	Unscheduled	2 miles
Onslow Beach	Marine Corps at	Nourishment	Proposed	1 mile

(partially in the CBR System)	Camp Lejeune			
Mason Inlet Relocation --Figure Eight Island	New Hanover County	Spoil disposal	Proposed	2 miles
Figure Eight Island	Private	Nourishment	Current	2 miles
Long Beach Sea Turtle Restoration Project	Corps of Engineers	Nourishment	Proposed	2.3 miles
Lockwoods Folly River Environmental Restoration	Corps of Engineers	Possible dredging and disposal	Proposed	Unknown
			TOTAL	**59.4 miles known**

Adding these figures to those listed in Table 6.1 of the Dare County EIS yields an estimated total of 136 miles of shoreline slated for sand disposal, almost double the 76.7 miles in Table 6-1. The total is now close to 43% of the entire North Carolina coastline. It is important to note also that this total does not include the new Atlantic Intracoastal Waterway project length, which may place new sand disposal on numerous beaches up and down the entire length of the coast, according to an August 3, 2000 public notice.

In the absence of a programmatic EIS for the North Carolina coast, it is incumbent upon the applicant to conduct an analysis of the cumulative impact of its beach renourishment project on marine and terrestrial flora and fauna in conjunction with all other beach nourishment projects on the North Carolina coast that are underway or planned within the ten-year lifespan of the project.

In conclusion, we strongly recommend that the Corps fully review the environmental impacts of the Bogue Banks project by conducting a thorough Environmental Impact Statement (EIS) as required by NEPA and holding public hearings to gain input from citizens.

Sincerely,

Jim Stephenson
Program Analyst

NCCF Beach Renourishment Policy

NCCF will not object to a beach renourishment project if:

✓ (1) There is acceptable and adequate sources of sand available;
✓ (2) Project is properly planned, timed, and executed;
✓ (3) Habitat monitoring is done to evaluate the effects on fisheries habitat;
✓ (4) Project planners are completely forthcoming about the long-term financial costs of renourishment,
✓ (5) Financing arrangements place the burden on the people who benefit,
✓ (6) There is adequate public access (including parking) if county, state or federal funds are spent, and
✓ (7) Long-term planning is undertaken to address future beach protection when renourishment projects are no longer feasible either due to insufficient sand supplies or funding.

NORTH CAROLINA MARINE FISHERIES COMMISSION
DEPARTMENT OF ENVIRONMENT AND NATURAL RESOURCES

(B)

NORTH CAROLINA MARINE FISHERIES COMMISSION

POLICIES FOR THE PROTECTION AND RESTORATION OF MARINE AND ESTUARINE RESOURCES FROM BEACH DREDGING AND FILLING AND LARGE-SCALE COASTAL ENGINEERING

NORTH CAROLINA MARINE FISHERIES COMMISSION HABITAT AND WATER QUALITY STANDING ADVISORY COMMITTEE: NOVEMBER 6, 2000
NORTH CAROLINA MARINE FISHERIES COMMISSION: NOVEMBER 16, 2000

Policy Context

This document establishes the policies of the North Carolina Marine Fisheries Commission (Commission) regarding protection and restoration of the state's marine and estuarine resources associated with beach dredge and fill activities, and related large-scale coastal engineering projects. The policies are designed to be consistent with the overall habitat protection policies of the Commission, adopted April 13, 1999, as amended February 17-18, 2000, as follows:

> It shall be the policy of the North Carolina Marine Fisheries Commission that the overall goal of its marine and estuarine resource protection and restoration programs is the long-term enhancement of the extent, functioning and understanding of those resources.
>
> Toward that end, in implementing the Commission's permit commenting authority pursuant to N.C.G.S. §143B-289.52(a)(9), the Chairs of the Habitat and Water Quality Standing Advisory Committee, in consultation with the Commission Chair, shall, to the fullest extent possible, ensure that state or federal permits for human activities that potentially threaten North Carolina marine and estuarine resources:
>
> (1) are conditioned on (a) the permittee's avoidance of adverse impacts to marine and estuarine resources to the maximum extent practicable; (b) the permittee's minimization of adverse impacts to those resources where avoidance is impracticable; and (c) the permittee's provision of compensatory mitigation for all reasonably foreseeable impacts to marine and estuarine resources in the form of both informational mitigation (the gathering of base-line resource data and/or prospective resource monitoring) and resource mitigation (in kind, local replacement, restoration or enhancement of impacted fish stocks or habitats); and
>
> (2) result, at a minimum, in no net loss to coastal fisheries stocks, nor functional loss to marine and

estuarine habitats and ecosystems.

The findings presented below assess the marine and estuarine resources of North Carolina which are potentially threatened by activities related to the large-scale movement of sand in the coastal ocean and adjacent habitats, and the processes whereby those resources are placed at risk. The policies established in this document are designed to avoid, minimize and offset damage caused by these activities, in accordance with the laws of the state and the general habitat policies of this Commission.

Marine and Estuarine Resources At Risk from Beach Dredge and Fill Activities

The Commission finds:

1. In general, the array of large-scale and long-term beach alteration projects currently being considered for North Carolina together constitute a real and significant threat to the marine and estuarine resources of the United States and North Carolina.

2. The cumulative effects of these projects have not been adequately assessed, including impacts on public trust marine and estuarine resources, use of public trust beaches, public access, state and federally protected species, state critical habitats and federal essential fish habitats.

3. Individual beach dredge-and-fill projects and related large-scale coastal engineering activities rarely provide adequate assessment or consideration of potential damage to fishery resources under state and federal management. Historically, emphasis has been placed on the logistics of sand procurement and movement, and economics, with environmental considerations dominated by compliance with limitations imparted by the Endangered Species Act for sea turtles, piping plovers and other listed organisms.

4. Opportunities to avoid and minimize impacts of beach dredge-and-fill activities on fishery resources, and offsets for unavoidable impacts have rarely been proposed or implemented.

5. Large-scale beach dredge and fill activities have the potential to cause impacts in four types of habitats:

a. waters and benthic habitats near the dredging sites;
b. waters between dredging and filling sites;
c. waters and benthic habitats near the fill sites; and
d. waters and benthic habitats potentially affected as sediments move subsequent to deposition in fill areas.

6) Certain nearshore habitats are particularly important to the long-term viability of North

Carolina's commercial and recreational fisheries and potentially threatened by large-scale, long-term or frequent disturbance of sediments:

a. inlets;
b. the swash and surf zones and beach-associated bars; and
c. underwater soft-sediment topographic features, both onshore and offshore underwater hard-substrate topographic features.

7) Large sections of North Carolina waters potentially affected by these projects, both individually and collectively, have been identified as Essential Fish Habitats (EFH) by the South Atlantic Fishery Management Council (SAFMC) and the Mid-Atlantic Fishery Management Council (MAFMC). Affected species under federal management include:

a. summer flounder (various nearshore waters, including the surf zone and inlets; certain offshore waters);
b. bluefish (various nearshore waters, including the surf zone and inlets);
c. red drum (ocean high-salinity surf zones and unconsolidated bottoms to a depth of 50 meters);
d. several snapper and grouper species (live hard bottom from shore to 600 feet, and -- for estuarine-dependent species [e.g., gag grouper and gray snapper] -- unconsolidated bottoms and live hard bottoms to the 100 foot contour);
e. spiny dogfish (various coastal waters from the surf zone to 200 miles);
f. black sea bass (various nearshore waters, including unconsolidated bottom and live hard bottom to 100 feet, and hard bottoms to 600 feet);
g. penaeid shrimps (offshore habitats used for spawning and growth to maturity, and waters connecting to inshore nursery areas, including the surf zone and inlets);
h. coastal migratory pelagics (sandy shoals of capes and bars, barrier island and ocean-side waters from the surf zone to the shelf break inshore of the Gulf Stream; all coastal inlets);
i. corals of various types (hard substrates and muddy, silty bottoms from the subtidal to the shelf break);
j. calico scallops (unconsolidated bottoms northeast and southwest of Cape Lookout in 62-102 feet);
k. sargassum (wherever it occurs out to 200 miles);
l. many large and small coastal sharks, managed by the Secretary of the Department of Commerce (inlets and nearshore waters, including pupping and nursery grounds).

8) Beach dredge and fill projects also potentially threaten important fish habitats for anadromous species under federal, interstate and state management (in particular, inlets and offshore overwintering grounds), as well as essential overwintering grounds and other critical habitats for weakfish and other species managed by the Atlantic States Marine Fisheries Commission and the State of North Carolina. The SAFMC identified for anadromous and catadromous

species those habitats that have been EFH if there had been a council plan (inlets and nearshore waters).

9) Many of the habitats potentially affected by these projects have been identified as Habitat Areas of Particular Concern by the SAFMC. The specific fishery management plan is provided in parentheses:

a. all nearshore hard bottom areas (SAFMC, snapper-grouper);
b. all coastal inlets (SAFMC, penaeid shrimps, red drum, and snapper-grouper);
c. near-shore spawning sites (SAFMC, penaeid shrimps, and red drum)
d. well-known seafloor features, including the Point, Ten Fathom Ledge and Big Rock (SAFMC, snapper-grouper, coastal migratory pelagics, and corals);
e. pelagic and benthic sargassum (SAFMC, snapper-grouper);
f. sandy shoals of Cape Lookout, Cape Fear, and Cape Hatteras (SAFMC, coastal migratory pelagics) and;
g. Bogue Sound and New River Estuary (SAFMC, coastal migratory pelagics).

10) Habitats likely to be affected by beach dredge and fill projects include many being recognized in North Carolina Fishery Management Plans as important for state-managed species. Many of these habitats are in the process of being recognized as Critical Habitat Areas by the Commission, in either FMPs or in Coastal Habitat Protection Plans. Examples include:

a. inlets (Blue Crab FMP, Red Drum FMP, River Herring FMP);
b. oceanic nearshore waters (Blue Crab FMP, Red Drum FMP); and
c. many others as FMPs and CHPPs are adopted over the coming years.

11) Recent work by scientists in east Florida has documented exceptionally important habitat values for nearshore, hard-bottom habitats often buried by beach dredging projects, including use by over 500 species of fishes and invertebrates, and juveniles of many reef fishes. Equivalent scientific work is just beginning off North Carolina, but life histories suggest that similar habitat use patterns will be found.

Threats to Marine and Estuarine Resources from Beach Dredge and Fill Activities

The Commission finds that beach dredge-and-fill activities and related large-scale coastal engineering projects (including inlet alteration projects) threaten the marine and estuarine resources of North Carolina through the following mechanisms:

1. Direct mortality and displacement of organisms at and near sediment dredging sites;
2. Alteration of seafloor topography and associated current and waves patterns and magnitudes at dredging areas;

3. Alteration of seafloor sediment size-frequency distributions at dredging sites, with secondary effects on benthos at those sites;
4. Elevated turbidity and deposition of fine sediments down-current from dredging sites;
5. Direct mortality and displacement of organisms at initial sediment fill sites;
6. Elevated turbidity in and near initial fill sites, especially in the surf zone, and deposition of fine sediment down-current from initial fill sites;
7. Alteration of near-shore topography and current and waves patterns and magnitudes associated with fill;
8. Movement of deposited sediment away from initial fill sites, especially onto hard bottoms;
9. Alteration of large-scale sediment budgets, sediment movement patterns and feeding and other ecological relationships, including the potential for cascading disturbance effects;
10. Alteration of large-scale movement patterns of water, with secondary effects on water quality and biota;
11. Alteration of movement patterns and successful inlet passage for larvae, post-larvae, juveniles and adults of marine and estuarine organisms;
12. Alteration of long-term shoreline migration patterns (inducing further ecological cascades with consequences that are difficult to predict); and
13. Exacerbation of transport and/or biological uptake of toxicants and other pollutants released at either dredge or fill sites.

Commission Policies for Beach Dredge and Fill Projects and Related Large Coastal Engineering Projects

The Commission establishes the following general policies related to large-scale beach dredge-and-fill and related projects, to clarify and augment the general policies already adopted on April 13, 1999:

1. Projects should fulfill the Commission's general habitat policy by avoiding, minimizing and offsetting damage to the marine and estuarine resources of North Carolina;

2. Projects should provide detailed analyses of possible impacts to each type of Essential Fish Habitat (EFH), with careful and detailed analyses of possible impacts to Habitat Areas of Particular Concern (HAPC) and Critical Habitat Areas (CHA), including short and long term, and population and ecosystem scale effects;

3. Projects should provide a full range of alternatives, along with assessments of the relative impacts of each on each type of EFH, HAPC and CHA;

4. Projects should avoid impacts on EFH, HAPCs and CHAs that are shown to be avoidable through the alternatives analysis, and minimize impacts that are not;

5. Projects should include assessments of potential unavoidable damage to marine resources,

using conservative assumptions;

6. Projects should be conditioned on the avoidance of avoidable impacts, and should include compensatory mitigation for all reasonably predictable impacts to the marine and estuarine resources of North Carolina, taking into account uncertainty about these effects. Mitigation should be local, up-front and in-kind wherever possible;

1. Projects should include baseline and project-related monitoring adequate to document pre-project conditions and impacts of the projects on the marine and estuarine resources of North Carolina;

2. All assessments should be based upon the best available science, and be appropriately conservative so as to be prudent and precautionary; and

3. All assessments should take into account the cumulative impacts associated with other beach dredge-and-fill projects in North Carolina and adjacent states, and other large-scale coastal engineering projects that are ecologically related.

VIA FACSIMILE: 910-251-4025

RE: Action ID No. 200000362 - **Permit to Dredge and Discharge Material to Nourish Eastern Section of Bogue Banks**

Dear Mr. Sugg:

Please accept the following comments regarding the above-referenced matter on behalf of Environmental Defense, our 10,000 members in North Carolina and our 300,000 members nationwide. We have previously submitted comments on the Bogue Banks Beach Restoration Plan (attached) to the NC Division of Coastal Management and the NC State Clearinghouse and incorporate those comments by reference.

In general, we feel very strongly that the Corps' Wilmington District has an obligation under the National Environmental Policy Act (NEPA) to perform a new, comprehensive Environmental Impact Statement (EIS) for this project, particularly in light of the fact that a programmatic EIS has not been performed for the suite of beach engineering projects that is being proposed for the North Carolina coast. These projects and their impacts to coastal habitats and species do not exist in isolation from one another, yet that is precisely how the environmental impacts are evaluated. Given the number of such projects being proposed within the state, and the value of North Carolina's coastal habitats to commercially and recreationally important fish species all along the Atlantic seaboard, the NC Marine Fisheries Commission developed a policy for and a set of criteria by which beach engineering projects should be assessed (see attached). This policy also details the threats to marine and estuarine resources from dredge and fill activities.

We continue to maintain the need for thorough, scientifically defensible cumulative impacts analyses for this and all ongoing and proposed beach engineering projects. We have yet to see an analysis that adequately considers the long-term, cumulative impacts upon the coastal ocean ecosystem. Ideally, a statewide plan for assessing cumulative impacts should be implemented based upon the results of a programmatic EIS as described above. It should be designed in consultation with ecologists and biostatisticians to ensure that it has the proper statistical power to answer questions of biological relevance both spatially and temporally. Until such a plan can be designed, this project should not be permitted.

North Carolina Office · 2500 Blue Ridge Road · Suite 330 · Raleigh, NC 27607 · Tel 919 881 2601 · Fax 919 881 2607
New York, NY · Washington, DC · Oakland, CA · Boulder, CO · Austin, TX · Project Offices · Boston, MA · Los Angeles, CA
www.environmentaldefense.org

Finally, although we expressed our support of the applicant's stated intent to conduct a monitoring program as indicated in the draft EIS, we have learned through Dr. Charles Peterson of the University of North Carolina's Institute of Marine Sciences that indeed, there is no Carteret County monitoring plan; furthermore, that there is no commitment by any party—state, county or sponsor—to fund this critical portion of the project. The habitats, water column and marine organisms are all public trust resources and must be treated as such. The local project sponsors do not have the unmitigated right to impact these resources without sufficient documentation of such impacts simply because the residents have requested the project. Both the spatial and temporal extent of the Bogue Banks project warrant a statistically valid monitoring plan. Until a contract is in place to perform this monitoring, we strongly opposed permitting this project.

Thank you for the opportunity to comment on this important issue and for your consideration of our views.

Sincerely,

Michelle Duval, Ph.D.
Scientist

RE: Bogue Banks Beach Restoration Plan – SEPA Draft Environmental Impact Statement

Please accept these comments regarding the proposed project on behalf of Environmental Defense, our 10,000 members in North Carolina and 300,000 members nationwide. In general, we have serious concerns regarding the large-scale, persistent and cumulative effects of this and related beach engineering projects, and the adequacy with which impacts from these projects are addressed. We recognize and acknowledge the efforts of the project sponsor and authors of the draft EIS to address the issues of highest controversy surrounding beach engineering, and offer the following comments regarding those issues for which we have particular concerns:

1) Cumulative and Long Term Impacts: In general, our dominant concern regarding beach engineering projects, particularly ones of such extensive spatial (and potentially temporal) magnitude, is the inadequate assessment of cumulative and long-term impacts to living marine resources and essential fish habitats. Specifically, the impacts of these projects are assessed on a piecemeal, or project-by-project basis, rather than as components of a statewide and regionwide beach engineering effort. We recognize that scientific studies examining the impacts of engineering operations on beach, intertidal and nearshore fauna are ongoing and not yet complete, but enough information exists to warrant a programmatic EIS on *all* of these activities for the North Carolina coast, if not the entire southeast region. We have requested such an evaluation of the Corps of Engineers (see Attachment 1) in a letter dated September 8, 2000. The Corps' response was that such an evaluation was too costly to undertake at the present time.

   Although the current project is proposed to be a one-time placement of sand, designed to "restore the sand deficit and provide for average yearly losses over a decade or so" (DEIS, Section 2.1, p. 2-2), it is clearly stated at the end of the introduction (Section 1.4, p. 1-3) that it is unlikely the entire project could be constructed within the same environmental window. Indeed, it appears that, given the funding needs of the communities, the project will stretch over several environmental windows. We are concerned about the downstream impacts of such discontinuous construction, which, as pointed out in Section 5.4.5 (page 5-2, second paragraph) are not insignificant.

www.environmentaldefense.org

2) Definition of Project Success: As acknowledged in Section 2.2.2 (p. 2-2) one of the major controversies with respect to beach engineering is the development of criteria, or lack thereof, for defining project success. Given the magnitude of resources required for the proposed project, there ought to be a clearly defined set of criteria by which to measure project success, particularly if state cost-share funds are obtained for any portion of the project as discussed in Section 2.3.3. The DEIS state in Section 2.2.2 that "Success will be defined in relation to how closely the postnourishment volume erosion rate compares with the estimated prenourishment volume erosions rate" (page 2-3), yet fails to identify a range of values which would constitute an acceptable or "successful" erosion rate. Although achievement of a certain rate of erosion may constitute success in an engineering sense, it may not necessarily translate into visible success for the project sponsors (i.e., the communities, and potentially state taxpayers if cost-share funding is obtained). Considering that this project is supposed to serve as "prototype" for future beach mainrenance efforts (Section 2.1, page 2-1) and as a basis for determining a "long-range solution" from amongst three alternatives (Section 2.4, page 2-5), development of specific evaluation criteria by the project sponsors, rather than the contracted engineering company, would appear to be critical.

3) Project Purpose: Among the four stated objectives (Section 1.3, page 1-2) of the project is "preservation of the environmental, cultural and aquatic resources of the county". We maintain that this project as designed (mainly due to the extensive geographic scale) protects only the unnatural, i.e., manmade "environmental resources". The three remaining planning objectives are a more realistic statement of purpose. Beach engineering projects are rarely, if ever, consistent with protection of the natural environment, and we are unaware of any such projects that have enhanced the nation's living marine resources. We also disagree with the statement that Bogue Banks serves to draw human activity away from the more pristine shores of Shackleford and Core Banks. Although not accessible by vehicle, there is ample transportation available to these locations via public and private ferries, and certainly the number of privately owned boats anchored in Back and Core Sounds during the summer months does not indicate that the public is dissuaded from visiting these areas.

4) Consideration of Alternatives: The DEIS states that "Property abandonment and relocation at a large scale would leave the beach degraded for many years because it would necessarily become a piece-meal process" (page 1). Yet, as referenced previously, the DEIS indicates that if approved, project construction would itself be piecemealed. A retreat and relocation alternative can be planned to initially target those structures most at risk, and can be implemented gradually, rather than in one massive effort. Indeed, should this project be approved, development of a phased relocation and/or exit strategy should be considered, particularly if cost-share funding is obtained. Given that the community plans to reevaluate the costs and benefits of renourishment after a decade of monitoring (Section 2.2.2), development of such a strategy would be proactive. That being said, having once obtained the necessary approval for a beach engineering project (especially if other funding sources are obtained), it is highly likely that the local communities will naturally expect approval for a second project, at an even greater economic and environmental cost.

Also, under the no-action alternative in Section 4.2, page 4-2 one of the stated, yet unquantified, environmental impacts of this alternative is "chronic impacts to beach fauna". We presume that this would be the result of beach scraping. We disagree with this statement, as it implies that placement of dredged sand on the beach would *not* impact beach fauna and that beach scraping would not occur should the project move forward. Incidentally, we find it interesting that "loss of recreational beach" is listed as a quantifiable environmental impact, considering the subjective and intangible nature of the recreational experience, while no attempt is made to quantify the loss of biota.

5) Monitoring Program/Protocol: We applaud the commitment of the project sponsors to develop a comprehensive pre- and post-construction monitoring plan as outlined in Appendix C, and for initiating pre-project benthic monitoring. We feel that such efforts are absolutely necessary in order to assess project impacts accurately over the proposed 10-year project lifetime. We also feel that a periodic (once every three years), publicly available assessment of impacts should be conducted and the results used to adjust the implementation and maintenance of the project and develop a compensatory mitigation plan if warranted, especially if the communities elect to continue beach engineering as a management option. In light of the fact that environmental impacts are not quantified in the analysis of costs and benefits, we feel very strongly that the project sponsors be responsible for funding the monitoring program.

6) NC Marine Fisheries Commission Policies on Beach Dredge and Fill Activities: The North Carolina Marine Fisheries Commission (MFC) has statutory responsibility for protecting the marine and estuarine resources of North Carolina against impacts from both fishing and non-fishing threats. On November 16, 2000, the MFC approved a new policy for the protection of marine and estuarine resources under its authority from the effects of beach dredge and fill activities and related coastal engineering activities (copy attached). The Habitat and Water Quality Standing Advisory Committee of the NC Marine Fisheries Commission developed the policy in response to increasing number of beach engineering projects being developed and the inadequate consideration of cumulative and long-term impacts of these projects. This policy includes numerous issues that have so far not been adequately addressed in the DEIS.

In addition, the MFC shares responsibility under state law for the development of Coastal Habitat Protection Plans (CHPPs). The statutory goal of these plans is the "net enhancement" of the value to the coastal fishery of each habitat type. The Coastal Ocean CHPP is currently in pre-draft form; it will shortly be issued in public draft. That draft will include a set of policies and procedures to protect the marine and estuarine resources of North Carolina against development activities including beach engineering activities. The CHPP will then be formalized in regulation. The CHPP and its adjunct regulations will become a part of the state's federal coastal zone management plan.

Finally, we would like to explicitly state several requests regarding the Bogue Banks Renourishment DEIS:

- When will a programmatic EIS or comprehensive assessment of beach engineering projects be performed, at least for the state of North Carolina?
- What are the project sponsors' criteria for project success?
- Is there a contract with a research institution to continue the pre-construction benthic monitoring, develop post-project benthic monitoring, as well as develop a pre- and post-construction intertidal monitoring program?
- Should state cost-share monies be obtained, are there plans to proactively develop phased exit strategies in the event that beach engineering is not found to be a viable management alternative?

Until these questions and the other issues we have raised can be sufficiently addressed, we do not feel that the Bogue Banks Renourishment project should move forward. We repeat our request that a programmatic EIS be conducted, including full assessment of cumulative impacts of the multiple projects at various stages of design. We reiterate our willingness to discuss any of the issues that we have raised.

We thank you for the opportunity to comment on this very important project.

Sincerely,

Michelle Duval

NORTH CAROLINA MARINE FISHERIES COMMISSION
DEPARTMENT OF ENVIRONMENT AND NATURAL RESOURCES

NORTH CAROLINA MARINE FISHERIES COMMISSION

POLICIES FOR THE PROTECTION AND RESTORATION OF MARINE AND ESTUARINE RESOURCES FROM BEACH DREDGING AND FILLING AND LARGE-SCALE COASTAL ENGINEERING

NORTH CAROLINA MARINE FISHERIES COMMISSION HABITAT AND WATER QUALITY STANDING ADVISORY COMMITTEE: NOVEMBER 6, 2000
NORTH CAROLINA MARINE FISHERIES COMMISSION:

Policy Context

This document establishes the policies of the North Carolina Marine Fisheries Commission (Commission) regarding protection and restoration of the state's marine and estuarine resources associated with beach dredge and fill activities, and related large-scale coastal engineering projects. The policies are designed to be consistent with the overall habitat protection policies of the Commission, adopted April 13, 1999, as amended February 17-18, 2000, as follows:

> It shall be the policy of the North Carolina Marine Fisheries Commission that the overall goal of its marine and estuarine resource protection and restoration programs is the long-term enhancement of the extent, functioning and understanding of those resources.
>
> Toward that end, in implementing the Commission's permit commenting authority pursuant to N.C.G.S. §143B-289.52(a)(9), the Chairs of the Habitat and Water Quality Standing Advisory Committee, in consultation with the Commission Chair, shall, to the fullest extent possible, ensure that state or federal permits for human activities that potentially threaten North Carolina marine and estuarine resources:
>
> (1) are conditioned on (a) the permittee's avoidance of adverse impacts to marine and estuarine resources to the maximum extent practicable; (b) the permittee's minimization of adverse impacts to those resources where avoidance is impracticable; and (c) the permittee's provision of compensatory mitigation for all reasonably foreseeable impacts to marine and estuarine resources in the form of both informational mitigation (the gathering of base-line resource data and/or prospective resource monitoring) and resource mitigation (in kind, local replacement, restoration or enhancement of impacted fish stocks or habitats); and
>
> (2) result, at a minimum, in no net loss to coastal fisheries stocks, nor functional loss to marine and estuarine habitats and ecosystems.

The findings presented below assess the marine and estuarine resources of North Carolina which are potentially threatened by activities related to the large-scale movement of sand in the coastal ocean and adjacent habitats, and the processes whereby those resources are placed at risk. The policies established in this document are designed to avoid, minimize and offset damage caused by these activities, in accordance with the laws of the state and the general habitat policies of this Commission.

Marine and Estuarine Resources At Risk from Beach Dredge and Fill Activities

The Commission finds:

1) In general, the array of large-scale and long-term beach alteration projects currently being considered for North Carolina together constitute a real and significant threat to the marine and estuarine resources of the United States and North Carolina.

2) The cumulative effects of these projects have not been adequately assessed, including impacts on public trust marine and estuarine resources, use of public trust beaches, public access, state and federally protected species, state critical habitats and federal essential fish habitats.

3) Individual beach dredge-and-fill projects and related large-scale coastal engineering activities rarely provide adequate assessment or consideration of potential damage to fishery resources under state and federal management. Historically, emphasis has been placed on the logistics of sand procurement and movement, and economics, with environmental considerations dominated by compliance with limitations imparted by the Endangered Species Act for sea turtles, piping plovers and other listed organisms.

4) Opportunities to avoid and minimize impacts of beach dredge-and-fill activities on fishery resources, and offsets for unavoidable impacts have rarely been proposed or implemented.

5) Large-scale beach dredge and fill activities have the potential to cause impacts in four types of habitats:

    a) waters and benthic habitats near the dredging sites;
    b) waters between dredging and filling sites;
    c) waters and benthic habitats near the fill sites; and
    d) waters and benthic habitats potentially affected as sediments move subsequent to deposition in fill areas.

6) Certain nearshore habitats are particularly important to the long-term viability of North Carolina's commercial and recreational fisheries and potentially threatened by large-scale, long-term or frequent disturbance of sediments:

    a) inlets;
    b) the swash and surf zones and beach-associated bars; and

c) underwater soft-sediment topographic features, both onshore and offshore underwater hard-substrate topographic features.

7) Large sections of North Carolina waters potentially affected by these projects, both individually and collectively, have been identified as Essential Fish Habitats (EFH) by the South Atlantic Fishery Management Council (SAFMC) and the Mid-Atlantic Fishery Management Council (MAFMC). Affected species under federal management include:

a) summer flounder (various nearshore waters, including the surf zone and inlets; certain offshore waters);
b) bluefish (various nearshore waters, including the surf zone and inlets);
c) red drum (ocean high-salinity surf zones and unconsolidated bottoms to a depth of 50 meters);
d) several snapper and grouper species (live hard bottom from shore to 600 feet, and – for estuarine-dependent species [e.g., gag grouper and gray snapper] – unconsolidated bottoms and live hard bottoms to the 100 foot contour);
e) spiny dogfish (various coastal waters from the surf zone to 200 miles);
f) black sea bass (various nearshore waters, including unconsolidated bottom and live hard bottom to 100 feet, and hard bottoms to 600 feet);
g) penaeid shrimps (offshore habitats used for spawning and growth to maturity, and waters connecting to inshore nursery areas, including the surf zone and inlets);
h) coastal migratory pelagics (sandy shoals of capes and bars, barrier island and ocean-side waters from the surf zone to the shelf break inshore of the Gulf Stream; all coastal inlets);
i) corals of various types (hard substrates and muddy, silty bottoms from the subtidal to the shelf break);
j) calico scallops (unconsolidated bottoms northeast and southwest of Cape Lookout in 62-102 feet);
k) sargassum (wherever it occurs out to 200 miles);
l) many large and small coastal sharks, managed by the Secretary of the Department of Commerce (inlets and nearshore waters, including pupping and nursery grounds).

8) Beach dredge and fill projects also potentially threaten important fish habitats for anadromous species under federal, interstate and state management (in particular, inlets and offshore overwintering grounds), as well as essential overwintering grounds and other critical habitats for weakfish and other species managed by the Atlantic States Marine Fisheries Commission and the State of North Carolina. The SAFMC identified for anadromous and catadromous species those habitats that have been EFH if there had been a council plan (inlets and nearshore waters).

9) Many of the habitats potentially affected by these projects have been identified as Habitat Areas of Particular Concern by the SAFMC. The specific fishery management plan is provided in parentheses:

a) all nearshore hard bottom areas (SAFMC, snapper-grouper);
b) all coastal inlets (SAFMC, penaeid shrimps, red drum, and snapper-grouper);
c) near-shore spawning sites (SAFMC, penaeid shrimps, and red drum)

d) well-known seafloor features, including the Point, Ten Fathom Ledge and Big Rock (SAFMC, snapper-grouper, coastal migratory pelagics, and corals);
e) pelagic and benthic sargassum (SAFMC, snapper-grouper);
f) sandy shoals of Cape Lookout, Cape Fear, and Cape Hatteras (SAFMC, coastal migratory pelagics) and;
g) Bogue Sound and New River Estuary (SAFMC, coastal migratory pelagics).

10) Habitats likely to be affected by beach dredge and fill projects include many being recognized in North Carolina Fishery Management Plans as important for state-managed species. Many of these habitats are in the process of being recognized as Critical Habitat Areas by the Commission, in either FMPs or in Coastal Habitat Protection Plans. Examples include:

a) inlets (Blue Crab FMP, Red Drum FMP, River Herring FMP);
b) oceanic nearshore waters (Blue Crab FMP, Red Drum FMP); and
c) many others as FMPs and CHPPs are adopted over the coming years.

11) Recent work by scientists in east Florida has documented exceptionally important habitat values for nearshore, hard-bottom habitats often buried by beach dredging projects, including use by over 500 species of fishes and invertebrates, and juveniles of many reef fishes. Equivalent scientific work is just beginning off North Carolina, but life histories suggest that similar habitat use patterns will be found.

Threats to Marine and Estuarine Resources from Beach Dredge and Fill Activities

The Commission finds that beach dredge-and-fill activities and related large-scale coastal engineering projects (including inlet alteration projects) threaten the marine and estuarine resources of North Carolina through the following mechanisms:

1) Direct mortality and displacement of organisms at and near sediment dredging sites;
2) Alteration of seafloor topography and associated current and waves patterns and magnitudes at dredging areas;
3) Alteration of seafloor sediment size-frequency distributions at dredging sites, with secondary effects on benthos at those sites;
4) Elevated turbidity and deposition of fine sediments down-current from dredging sites;
5) Direct mortality and displacement of organisms at initial sediment fill sites;
6) Elevated turbidity in and near initial fill sites, especially in the surf zone, and deposition of fine sediment down-current from initial fill sites;
7) Alteration of near-shore topography and current and waves patterns and magnitudes associated with fill;
8) Movement of deposited sediment away from initial fill sites, especially onto hard bottoms;
9) Alteration of large-scale sediment budgets, sediment movement patterns and feeding and other ecological relationships, including the potential for cascading disturbance effects;
) Alteration of large-scale movement patterns of water, with secondary effects on water quality and biota;
11) Alteration of movement patterns and successful inlet passage for larvae, post-larvae, juveniles and adults of marine and estuarine organisms;

12) Alteration of long-term shoreline migration patterns (inducing further ecological cascades with consequences that are difficult to predict); and
13) Exacerbation of transport and/or biological uptake of toxicants and other pollutants released at either dredge or fill sites.

Commission Policies for Beach Dredge and Fill Projects and Related Large Coastal Engineering Projects

The Commission establishes the following general policies related to large-scale beach dredge-and-fill and related projects, to clarify and augment the general policies already adopted on April 13, 1999:

1) Projects should fulfill the Commission's general habitat policy by avoiding, minimizing and offsetting damage to the marine and estuarine resources of North Carolina;

2) Projects should provide detailed analyses of possible impacts to each type of Essential Fish Habitat (EFH), with careful and detailed analyses of possible impacts to Habitat Areas of Particular Concern (HAPC) and Critical Habitat Areas (CHA), including short and long term, and population and ecosystem scale effects;

3) Projects should provide a full range of alternatives, along with assessments of the relative impacts of each on each type of EFH, HAPC and CHA;

4) Projects should avoid impacts on EFH, HAPCs and CHAs that are shown to be avoidable through the alternatives analysis, and minimize impacts that are not;

5) Projects should include assessments of potential unavoidable damage to marine resources, using conservative assumptions;

6) Projects should be conditioned on the avoidance of avoidable impacts, and should include compensatory mitigation for all reasonably predictable impacts to the marine and estuarine resources of North Carolina, taking into account uncertainty about these effects. Mitigation should be local, up-front and in-kind wherever possible;

7) Projects should include baseline and project-related monitoring adequate to document pre-project conditions and impacts of the projects on the marine and estuarine resources of North Carolina;

8) All assessments should be based upon the best available science, and be appropriately conservative so as to be prudent and precautionary; and

9) All assessments should take into account the cumulative impacts associated with other beach dredge-and-fill projects in North Carolina and adjacent states, and other large-scale coastal engineering projects that are ecologically related.

12) Alteration of long-term shoreline migration patterns (inducing further ecological cascades with consequences that are difficult to predict); and
13) Exacerbation of transport and/or biological uptake of toxicants and other pollutants released at either dredge or fill sites.

Commission Policies for Beach Dredge and Fill Projects and Related Large Coastal Engineering Projects

The Commission establishes the following general policies related to large-scale beach dredge-and-fill and related projects, to clarify and augment the general policies already adopted on April 13, 1999:

1) Projects should fulfill the Commission's general habitat policy by avoiding, minimizing and offsetting damage to the marine and estuarine resources of North Carolina;

2) Projects should provide detailed analyses of possible impacts to each type of Essential Fish Habitat (EFH), with careful and detailed analyses of possible impacts to Habitat Areas of Particular Concern (HAPC) and Critical Habitat Areas (CHA), including short and long term, and population and ecosystem scale effects;

3) Projects should provide a full range of alternatives, along with assessments of the relative impacts of each on each type of EFH, HAPC and CHA;

4) Projects should avoid impacts on EFH, HAPCs and CHAs that are shown to be avoidable through the alternatives analysis, and minimize impacts that are not;

5) Projects should include assessments of potential unavoidable damage to marine resources, using conservative assumptions;

6) Projects should be conditioned on the avoidance of avoidable impacts, and should include compensatory mitigation for all reasonably predictable impacts to the marine and estuarine resources of North Carolina, taking into account uncertainty about these effects. Mitigation should be local, up-front and in-kind wherever possible;

7) Projects should include baseline and project-related monitoring adequate to document pre-project conditions and impacts of the projects on the marine and estuarine resources of North Carolina;

8) All assessments should be based upon the best available science, and be appropriately conservative so as to be prudent and precautionary; and

9) All assessments should take into account the cumulative impacts associated with other beach dredge-and-fill projects in North Carolina and adjacent states, and other large-scale coastal engineering projects that are ecologically related.

Colonel James W. DeLony
District Engineer, CESAW
U.S. Department of the Army, Corps of Engineers
Post Office Box 1890
Wilmington, North Carolina 28402-1890

Re: Continuous Beach Dredging and a Programmatic EIS for the Wilmington District

Dear Colonel DeLony:

We respectfully request that the U.S. Army Corps of Engineers prepare a programmatic Environmental Impact Statement (EIS) in connection with all beach dredging projects ("restorations," "renourishments," "beach erosion control," "beach disposal" and related projects) under the authority of the Wilmington District. The programmatic EIS should include an analysis of those currently undergoing review under the National Environmental Policy Act (NEPA) or under development for the district's area of responsibility. The analyses should also reflect the wide array of current projects for which adequate cumulative impacts analysis has not yet been conducted.

The current array of large-scale and long-term projects in this district is unprecedented. Projects are proposed for almost every developed beach area in the state. Major projects are proposed for Dare County beaches (a 13-foot dune and 50-foot beach berm along 14.8 miles of beach over fifty years with "renourishment" every three years involving up to 80 million cubic yards of sand), the "Highway 12" section of Dare County (Pea Island, Hatteras Island and Ocracoke Island), Brunswick County (details not yet available, but even more extensive beach "renourishment" over as much as 20 miles), Carteret County (16.8 miles of beach modification for which almost $30 million in public funding is being sought), and elsewhere. On-beach "disposal" is also proposed in connection with a variety of other projects, including the Wilmington Harbor deepening project.

These and related projects overlap significantly in their geographic and ecological contexts, and are very likely to cause serious and diverse cumulative impacts to both offshore and near-shore resources that could best be analyzed holistically. Practical alternatives that could reduce these and future cumulative impacts can most effectively be evaluated programmatically. Piecemeal analysis of environmental effects is almost certain to underestimate the degree of threat to publicly held marine and estuarine resources.

Artificial beach enhancement projects interact not only with other projects in terms of sand source areas, deposition areas and ultimate transport areas, but also collectively on the fishes and other organisms which use those habitats. Moreover, the impacts associated with the alteration of sand distribution and movement patterns also interact with other large-scale coastal engineering projects, including inlet modification projects like those at Oregon Inlet and Mason's Inlet, and various beach, harbor and channel maintenance activities. None of these can be appropriately assessed in isolation.

Furthermore, these projects together constitute a real and significant threat to the marine and estuarine resources of the United States and North Carolina. Large sections of the waters potentially affected by the projects, both individually and collectively, have been identified as Essential Fish Habitats (EFH) by the South Atlantic Fishery Management Council (SAFMC) and the Mid-Atlantic Fishery Management Council (MAFMC). Affected resources potentially include overfished species that are beginning to rebuild (e.g., summer flounder and bluefish), many species that are still in significant trouble (e.g., red drum, some snappers and groupers, spiny dogfish and black sea bass) and others which are fully fished and not able to stand further environmental stress (e.g., penaeid shrimps, coastal migratory pelagics, among others). The projects also stand to affect Essential Fish Habitats which have yet to be formally identified for anadromous species under federal management (but which clearly include inlets), as well as essential overwintering grounds and other critical habitats for striped bass, weakfish and other species managed by the Atlantic States Marine Fisheries Commission and the State of North Carolina.

Many of the habitats potentially effected by these projects have been identified as Habitat Areas of Particular Concern by the relevant federal fishery management councils: all near-shore hard bottom areas (SAFMC for snapper-grouper); all coastal inlets (SAFMC for penaeid shrimps, red drum, and snapper-grouper); near-shore spawning sites (SAFMC for penaeid shrimps, and red drum), the Point, Ten Fathom Ledge and Big Rock (SAFMC for snapper-grouper, coastal migratory pelagics, and corals); pelagic and benthic sargassum (SAFMC for snapper-grouper); sandy shoals of Cape Lookout, Cape Fear, and Cape Hatteras (SAFMC for coastal migratory pelagics); and Bogue Sound and New River Estuary (SAFMC for coastal migratory pelagics).

In 1998, administrative rules mandated by the 1996 reauthorization of the Magnuson-Stevens Fishery Conservation and Management Act designated all near-shore hardbottom and coral reefs of the southeast U.S., and the other habitats listed in the paragraph above, as Habitat Areas of Particular Concern, the highest level of Essential Fish Habitat. Under the Corps' current process, multiple large dredging and filling events will occur in these ssential Fish Habitat/Habitat Areas of Particular Concern without adequate study of short or long term impacts.

In a letter to the North Carolina Clearinghouse dated August 24, 2000 (attached hereto), the North Carolina Marine Fisheries Commission (MFC) concluded that the Dare County program constitutes a significant threat to state-managed marine and estuarine resources, and that its impacts cannot be adequately analyzed without a comprehensive assessment of impacts from the larger variety of such programs under development. The MFC is particularly concerned about cumulative impacts on surf-dwellers, on overwintering fish concentrations, and on the large suite of larval fishes which interact with the surf zone and inlets during their journeys into nurseries in the sounds. The SAFMC has expressed similar concerns about other projects in the region, and recently discussed the problem in detail at its Habitat and Environmental Protection Advisory Panel meeting in Charleston, SC. The MAFMC has expressed its concerns related to similar projects off New Jersey, and will be taking this matter up at Habitat Committee and Advisory Panel meetings in the near future.

In addition, the Jacksonville District COE received a letter dated June 27, 2000, signed by 70 Ph.D. scientists expressing concern over the continuing absence of detailed cumulative impact analyses in Corps EAs and EISs, despite more than 50 large offshore dredge and nearshore fill projects on the continental shelf of southeast and central Florida in the last 40 years. Over 500 marine species are known to use the nearshore reefs that can be buried by these projects, frequently as nursery areas. In addition, offshore dredge sites are often near reefs, and chronically elevated turbidity can have direct and indirect effects upon productivity across the shelf. Dozens of species are subject to diverse effects across the shelf areas affected by these massive dredge and fill projects. Fifteen North Carolina Ph.D. scientists signed that letter. Similar concerns exist with respect to impacts of large-scale and near-continuous dredging off North Carolina.

No other set of human activities comes close to posing the degree of threat to near-shore essential fish habitats as that posed by the activities under your management. Past NEPA assessments have not fully assessed the function of offshore and nearshore habitats affected by dredge and fill operations, the short-term impacts on the vast majority of species which utilize these habitats, nor the potential cumulative impacts across the affected shelf areas. Although some information related to these issues is newly available, several key references from the 1980's and early 1990's that expressed concern or questioned simplistic assumptions about effects have not been cited. A programmatic EIS focused on the North Carolina coast would provide the Corps with the opportunity to look systematically at past, present, and future effects of these large, semi-continuous dredging projects.

We recognize that beach management involves a complex mixture of many scientific disciplines and economic and political interests. However, the technical information is available and the administrative momentum is clear: a detailed, ecosystem-scale examination of cumulative impacts is necessary and will aid future project planning.

For these and additional reasons, a programmatic EIS on current and planned beach dredging projects along the North Carolina coast is urgently needed. The thorough development of such an EIS would provide all interested parties -- federal, state and local agencies, the scientific community, and national and state environmental organizations -- with a structured forum for proactively addressing the many environmental aspects of semi-continuous dredge and fill operations on the North Carolina coast and practical alternatives that would minimize impacts.

We would welcome the opportunity to further discuss the rationale for a programmatic EIS and its possible scope. We are therefore available to meet at the Wilmington District Office to discuss any aspect of this set of issues. We look forward to discussing these issues in further detail.

Yours truly,

REGULATORY
WILMINGTON FIELD OFFICE

Department of the Army
Corps of Engineers
Mr. Mickey T. Sugg

Your office is in receipt of an application from Carteret County, c/o of Robert Murphy, county Manager to nourish 16.8 miles of the Bogue Banks beaches. I wish to comment on that application.

The requirements of your office that all permits and comments from governing agencies be submitted before your agency will issue the permit have not been fulfilled. I submit the following observations.

1. The draft EIS statement has not been completed and presented for a public hearing as required. Enclosed is a copy of comments I submitted to the Division of Coastal Management on February 6, 2001 pertaining to the draft EIS. I specifically requested a public hearing on the document along with other proposals. I have received no communication from DCM.
2. I have not seen a public notice advertised in the local newspapers by CAMA regarding public comment or a public hearing as required by their procedures.
3. The issue of public Beach access to ACE standards has not been accomplished. The town of Pine Knoll Shores has only two public access points and parking is very limited. Emerald Isle has several public access points but very little parking. There is almost no public parking from the recently purchased regional facility west to the point. Most of the beachfront is blocked off by private gated communities.
   All issues of public access should be addressed before the permit is issued.
4. The County application proposes biological monitoring on board each dredge except January and February. The monitoring should take place at all times of operation.
   I request you consider my comments on SEC 5.18 of the attached Copy of comments to Mr. Doug Huggett of DCM . All monitors Must be highly qualified and paid by the State to avoid a conflict Of interest.

February 6, 2001

Mr. Doug Huggett
Division of Coastal Management

RE: EIS study. Proposed Bogue Banks Beach Nourishment.

I was able to perform a cursory layman's review of the above mentioned study to day after a legal notice was finally posted in the local paper January 24, 2001. The document was made available at four locations throughout Carteret county after I called the county managers office and then your office several times requesting information. As a layman I am not qualified to comment on the technical and scientific data that was in the report. I do feel I can comment on the common sense aspects of the document.

According to NCAC 25.06.04 the coastal agency may hold public hearings to increase public awareness, clarify issues, and gather additional public comment. The document was not adequately advertised for public display. Therefore I request your agency to withhold approval until such time that public hearings are held and the public has had ample time to view and comment on it.

Sec:2.0 page 21 states that bulldozing is detrimental to the beach environment. If the beach nourishment project is allowed to proceed will beach scraping be permitted in the years between applications of dredged sand?

Sec.2.2.1 page 21 states that funding for this project will be 64% local and 36% from other sources. What is the source of the 36% portion of the funding? Why is it not disclosed in this EIS? The citizens of Carteret County voted by a large majority that they were not in favor of using local funds to fund beach nourishment.

SEC.3.4.5 notes that the net long shore transport rates of sand are low. 3.4.6 states that erosion is due to storm events. No mention is made of the fact that most scientists attribute the increased erosion to an increased rate of sea level rise. The sea level rise in turn causes the beaches to move naturally in response. Why was this aspect of the issue not addressed? At best the nourishment will be short lived and the damage to the environment will have already been done.

SEC 3.15.3 notes that endangered Loggerhead and Green turtles are the two most common types found in this area. Although their presence is mostly in the warm months; they are present at times in the winter

I request your consideration of the above statement and assurance that all the requirements of your agency have been met before issuing the permit to proceed. I also request a public hearing be conducted in Carteret County.

Sincerely yours,

Don E. Morris

RE: Carteret County – Bogue Banks Beach Restoration Project
Response to Comments – USACE Action ID# 200000362]

Dear Mr. Sugg:

I am writing on behalf of Carteret County and the Towns of Pine Knoll Shores, Indian Beach, and Emerald Isle in response to comments on the above-referenced project from:

1) Don E. Morris (dated 10 April 2001)
2) Environmental Defense (Michelle Duval and Daniel Whittle) (dated 12 April 2001)
3) NC Coastal Federation (Jim Stephenson) (dated 12 April 2001)
4) University of North Carolina-Institute of Marine Sciences (Charles Peterson) (dated 13 April 2001)

We appreciate the opportunity to address the correspondents' concerns in the attachments to this letter. In some cases, the comments duplicate those submitted to NC CAMA in the course of the SEPA review process. Therefore, the present response references certain earlier responses we have made and incorporated into the final EIS. We will be happy to meet with any of the correspondents and discuss their concerns in more detail.

Thank you for your consideration.

Yours truly,

D E White for TWK

ATTACHMENT
Response to Comments — USACE Action ID# 200000362

1) Response to Morris Letter

The draft EIS has been reviewed, commented upon, revised, and finalized by all required state agencies. To the best of our knowledge, the reviews have followed all state requirements with respect to public notices and requests for comments. Further, the proposed project has been presented to the community in essentially the same form as given in the EIS during at least ten community forums since fall 1999. Widely publicized, public forums were held at four sites around Carteret County prior to the county referendum in March 2000 and at county council meetings and town council meetings at the affected towns. Also, several workshops were conducted over the past two years involving representatives of state and federal resource agencies in which the Bogue Banks project was discussed in detail. In addition, there has been extensive press coverage and explanation of the project in connection with council meetings and the bond referendums.

The proposed project will be funded locally with no federal contribution. The applicant (county and towns) is actively seeking to comply with all ACE standards as if this were a federally funded project. To this end, the Town of Pine Knoll Shores recently acquired centrally located oceanfront property with space to accommodate 100 vehicles.

The applicant expects to comply with all conditions placed on the permits including schedules and requirements for on-board biological monitoring.

Regarding comments in an associated letter dated 6 February 2001 from Mr. Morris to Doug Huggett (CAMA), these are addressed in the draft and final EIS. It is now likely that nearly 100 percent of the project will be funded by the applicant towns through special tax districts.

2) Response to Environmental Defense Letter

Attached is a copy of our response to Environmental Defense's 13 March 2001 comments (which accompanied the 12 April letter) on the SEPA draft EIS for the project.

Because the NEPA and SEPA requirements are essentially the same, we believe the existing EIS addresses all salient concerns. Only one item is incomplete under NEPA requirements – preparation of the EFH report, which is in preparation and will be submitted in May to NMFS and USACE. We wish to reiterate that assessment of cumulative impacts for all pending North Carolina projects is not a trivial exercise. An appropriate place to start, however, may be to look at the experience in other states. South Carolina, for example, has nourished approximately 60 miles of its coast (30 percent) since 1980. South Carolina Department of Natural Resources has worked closely with the US Army Corps of Engineers and South Carolina Coastal Council (now SCDHEC-OCRM) to evaluate environmental impacts of many of these projects. A general conclusion of these studies, according to Dr. Robert F. Van Dolah (SCDNR) is that the impacts to flora and fauna are short-lived on the beach with recovery typically occurring in weeks to months. Borrow area recovery rates are much more variable (as is the physical nature of the areas) and may require up to several years, although some recovered in one season.

There are no documented cases that we are aware of in the Southeast where dredging for nourishment produced a permanent or even short-lived biologic desert. The question is, rather, when and how similar are benthic populations on the beach and in borrow areas after nourishment. The evidence from states that have nourished high percentages of their coast indicate biologic recovery is relatively rapid (order of the life cycle for individual species), and the ensuing species diversity is similar to predredging conditions. Dredging does not directly impact pelagic species because they are mobile and can avoid dredges, so it is reasonable to assume that if benthic populations recover rapidly, the local fishery will not be adversely impacted. This is why other states tend to focus nourishment impact monitoring on the benthic species. We are aware of no statistically valid methods of quantifying impacts to fisheries due to nourishment projects. If there is a way to quantify the effect of dredging and distinguish it from such direct impacts to fisheries as commercial trawling and recreational fishing, we would appreciate a reference in the literature from the correspondent.

The Towns of Pine Knoll Shores and Indian Beach anticipate funding environmental monitoring surveys as a condition of the permits for the first reaches scheduled for

CSE

construction. They are working closely with the resource agencies to design a program that will provide meaningful, quantitative results.

Carteret County initiated and is continuing to fund the first island-wide physical monitoring surveys of Bogue Banks. Data collected in June 1999, September 1999 after Hurricane *Floyd*, and June 2000 provide the most comprehensive measure of sand losses to date. Data such as these are critical for evaluating the feasibility of nourishment and developing correlations with biologic impacts. It is through such monitoring that the project sponsors have determined that nourishment is feasible and will result in fewer adverse impacts to existing dune and turtle nesting habitats (than the present policy of doing nothing or sand scraping after every storm) and fewer adverse impacts to the local tax base than property abandonment, relocation, or condemnation. The applicant has demonstrated in the EIS/permit application a commitment to completing the project based on sound, scientific study and careful site-specific monitoring. Included in this effort was baseline biologic monitoring by Dr. Peterson at UNC-IMS (Appendix C of the EIS).

3) **Response to NC Coastal Federal Letter**

Speaking on behalf of the applicant, we believe that the SEPA EIS exceeds existing practice for locally funded nourishment projects and is as comprehensive as necessary for a project of this scope. The EIS has been thoroughly reviewed and approved by all state resource and clearinghouse agencies. Further, it introduces substantial new geotechnical, survey, and environmental data for the site, obtained at the applicant's expense. The EIS, in other words, is not simply a recitation of existing data and information.

We cannot predict the renourishment cycle because many intangibles would affect it. However, the correspondent greatly overstates the concern about multiple nourishments being required. It is true that the applicant may seek reimbursement in the event of a major storm, but for such funds to be forthcoming, two basic criteria would have to be met:

CSE

1) Beach damage is so severe that buildings remain imminently threatened.
   and
2) Reimbursement would only apply to the portion of the nourishment sand lost during the storm.

Without the project, the communities may seek emergency dune restoration, relocation, and rebuilding funds from FEMA after major storms. With the project, the level of damages is likely to be reduced and less funds required to restore sand volume losses than to rebuild or relocate structures. Atlantic Beach's experience during the past five years demonstrates how nourishment reduces property damages and, therefore, the outlay for storm disaster relief. Further, the applicant's post-storm surveys after Hurricane *Floyd* (see attached report entitled "Survey Report 2000 – Bogue Banks, North Carolina"; CSE, 2000) show that *Floyd* caused volumetric erosion to the upper beach and dunes within the project area that was a small fraction of the planned nourishment volume. Therefore, the scale and cost of renourishment after major storms over a ten-year period are likely to be much smaller than the initial nourishment cost. After small storms, the nourished beach will be left to rebuild naturally and no remedial measures are anticipated. Nourishment will reduce the pressure to scrape the dunes back into place after storms in the project area, just as it has done along Atlantic Beach.

Three referendums have been held for the project. The county-wide referendum in March 2000 failed. The Pine Knoll Shores and Indian Beach referendums in March 2001 and April 2001 (respectively) passed by a greater than 2:1 margin. The EIS outlines in detail the substantial financial contribution that Bogue Banks makes to Carteret County.

RE: Consideration of Alternatives — We disagree with the correspondent. While many different nonstructural scenarios are possible, the one suggested by the Coastal Federation is infeasible. It contradicts a most fundamental tenet of shore protection, which is consistency and uniformity of protection whether the choice is to armor, to nourish, to construct groin fields, or to set back buildings. The applicant has chosen a soft solution–nourishment– based on sufficient data which demonstrate this to the most viable alternative. Nourishment longevity is proportional to the square of the project length. Therefore, if only short reaches are nourished, the fill will not provide much more protection than sand scraping provides at present (because the pockets of fill will quickly spread alongshore). To restore a sand deficit of a certain volume, one has to add that volume, not a fraction of it.

Carteret County is a model for coastal zone management in North Carolina. Less than 33 percent of its ocean shoreline is developed and accessible by car. The rest is held in trust as part of the Cape Lookout National Seashore. Bogue Banks is the only generally accessible beach in the county. There are 53 miles of undeveloped barrier islands to the east and north, and 21 miles of undeveloped barrier islands to the west. Bogue Banks has low erosion rates, making it (in the words of Prof. Orrin Pilkey, Duke University) among North Carolina's best candidate sites for nourishment. Further, the proposed project will be locally, not federally, funded. Nourishment of Atlantic Beach demonstrates, on a site-specific basis, the feasibility and likely longevity of a project of the scale proposed. That reach also proves that future property damage will likely be reduced significantly by nourishment.

RE: Environmental Window — The correspondent requests an environmental window of 1 December to 31 March based on the opinion of one expert, Dr. Peterson. Please see our response to this concern in our letter dated 3 April 2001 regarding Dr. Peterson's comments. On behalf of the applicant, we met with NC Division of Marine Fisheries and Dr. Peterson on 5 April 2001 and discussed the concern regarding this issue. We understand the concern regarding November construction relates principally to the fall finger mullet fishery. Apparently, this fishery involves setting nets at access points near the Atlantic Beach/Pine Knoll Shores town line and catching fish migrating east to west from Beaufort Inlet. The applicant is willing to begin the first reach (Pine Knoll Shores) at the central or western end so as to stay several miles away from the commercial fishermen in November.

At present, about 40 percent of the project (Pine Knoll Shores East and West, and Indian Beach/Salter Path) is slated for construction between November 2001 and April 2002. The second phase would most likely involve Emerald Isle East and portions of Emerald Isle Central at least one year later. In short, it appears likely that the project will be constructed in two or more phases as recommended by the correspondent.

CSE

RE: Monitoring Data and Plan — The applicant is working closely with the resource agencies to develop a rigorous environmental monitoring plan following recommendations by Dr. Peterson, experts at SCDNR, Dr. Bart Baca (CSA), and standard practice in other southeast states. A copy of the draft plan was forwarded to USACE on 25 April. We disagree with Dr. Peterson's opinion that identification of samples to the "family" level is sufficient and instead have proposed identification to "species" level so that scientifically defensible statistics may be produced. Because the initial reaches funded for nourishment represent only 42 percent of the total project length, we have proposed monitoring before and after construction of 50 percent of the stations established by UNC. We anticipate that future reaches will involve monitoring of additional stations around the time of their funding and construction. The draft monitoring plan for the PKS-IB-SP reaches represents a financial commitment of >1 percent of total project costs added to what the applicant has already spent for baseline biological studies.

RE: Impact to Marine Resources — The applicant addresses this concern in our letter dated 4 April 2001 to Environmental Defense. We are also in the process of preparing a report on potential impacts to essential fish habitat (EFH) and have discussed this requirement with NMFS representatives in Morehead City and St. Petersburg (Florida)

RE: Sand Suitability Studies — The applicant has obtained over 140 borings in and around the proposed borrow areas. Approximately 25 of these were obtained as recently as February 2001 and are not yet reported in documents. However, the EIS provides detailed data from 90 borings in or immediately adjacent to borrow areas A, B1, and B2. We believe that the density of borings presented in the EIS far exceeds other geotechnical studies to date for nourishment projects in North Carolina. When our additional borings obtained recently are added, the average density of cores will be approximately 25 per square mile. We are using these data to further refine the borrow areas such that the closest possible match with the native beach is obtained. Presently, it appears some mix of sediments from borrow areas B1, B2, and A will yield the optimum size distribution.

CSE

We disagree with the correspondent's contention that the coarse, shelly material in borrow area A should be screened off before placement of the remaining sediment on the beach. We are aware of no documentation that confirms sediments with 40-45 percent shell material will be detrimental to beach organisms. North Carolina beaches contain a wide range of sediment sizes and textures in the cross-shore dimension, as well as regionally varying mean grain sizes and sediment textures. The mix of sediments in the proposed borrow areas will sort naturally upon placement, just as the native sediments do.

Concerns about high shell percentage were expressed by Dr. Peterson (see our response to his comments), and we suspect that the Coastal Federation is basing their comment on Peterson's opinion. Whether or not high shell percentages (order of 40-45 percent of the material) are lethal to organisms or result in lower densities of organisms in the surf zone has not been proved by rigorous studies. Peterson's limited observations (derived from cursory investigations at Atlantic Beach) are insufficient to prove cause and effect. If the resource agencies have specific standards for shell content, grain size, and mud percentages that must be met, we will strive to meet them. In the meantime, we will continue to refine the borrow areas such that mud percentage is minimized, shell content falls within the natural range for North Carolina beaches, and the overfill ratios are a low as possible. The applicant has no desire to place high percentages of mud on the beach. (A defacto standard in many jurisdictions is 15 percent clay-silt.) Our first choice for dredging equipment is self-loading hopper dredges because a portion of the fines will be decanted back to the water column near the borrow area before placement on the beach.

The EIS addresses potential turbidity and sediment transport in Appendix G and in Sections 3.14, 3.16, and 5.16. Construction activities will cause temporary elevation of turbidity levels immediately around the dredge and at the discharge points on the beach. These elevated levels will not persist and will fall within the natural range of turbidity for the area. For "large" plumes to persist, there has to be exceedingly high percentages of disaggregated clay in the sediments. Dredging in fluff mud in estuaries is commonly associated with long-duration, large-scale plumes. Such conditions, however, do not exist around the proposed borrow areas.

CSE

RE: Cumulative Impacts — We have addressed this issue in responses to the Peterson comments and Environmental Defense comments.

RE: NCCF Beach Renourishment Policy — The applicant comes as close to satisfying all seven policies of the NCCF as any nourishment project ever attempted in North Carolina.

1) Borrow areas defined in detail and continuing to be optimized by a dense network of borings.

2) Project is being scheduled for cold weather months, and our project planning team has extensive project experience.

3) Habitat monitoring was initiated by the applicant during early planning and will continue as the project is constructed.

4) The applicant has discussed costs openly in numerous community forums and has presented details in the EIS.

5) The project will be locally funded with the largest burden (>50 percent) placed on oceanfront owners.

6) All communities involved maintain public access to their beaches and are actively seeking opportunities to increase access.

7) The EIS details the planning that has gone into the project and will be required after ten years to reevaluate whether to continue. Further, the USACE has initiated a long-term study for beach restoration of Bogue Banks.

Finally, the applicant (at its own initiative) established the first systematic monitoring of the beach and inshore zone to quantify erosion rates. This latter effort is ultimately the most important determinant of costs of projects and whether or not future projects will be feasible and economic.

4) **Response to University of North Carolina Letter**
See attached response dated 3 April 2001.

RE: Pine Knoll Shores and Indian Beach Nourishment Projects
Draft Environmental Plan

Dear Mike:

As we discussed with you, Rick Monaghan, and Dr. Peterson on 5 April at your office, we have prepared a "strawman" environmental monitoring plan for the above-referenced projects. I would like for you to review the plan with your staff, Dr. Petersen, and others of your choosing, and let us know what changes if any may be required.

The specific scope of work is based on several factors, as follows:

- Recommendations by Dr. Peterson in Appendix C of the final EIS for the Bogue Banks nourishment project.
- Recommendations by Dr. Bart J. Baca (president of Coastal Science Associates, Jacksonville, FL, and Columbia, SC) with whom we plan to contract and perform the study.
- Recommendations and standard practice of South Carolina Department of Natural Resources (care of Dr. Robert F. Van Dolah).
- Authorizations by town officials to fund the indicated scope of work up to four times (ie, four samplings and analyses) to be scheduled at your office's discretion.
- The fact that the anticipated projects for Pine Knoll Shores and Indian Beach represent less than 50 percent of the entire Bogue Banks project area.

The scope of work entails quantitative sampling of the borrow areas and beach using a representative suite of stations established by UNC-IMS. The consensus recommendation for schedule appears to be a spring and fall preproject sampling and a spring and fall postproject sampling. Four monitoring periods will entail a major financial commitment by the community commensurate with overall project costs. Further, I believe what we are proposing

CSE

in this plan greatly exceeds the environmental monitoring that has been performed in connection with other locally funded projects in North Carolina.

If you have any questions about our proposed scope of work or need information on CSA's qualifications, I will be happy to forward them. In the meantime, thank you for your consideration.

Yours truly,

Tim Kana

US Army Corps of Engineers, Mr. Mickey Sugg

DRAFT

Environmental Monitoring Plan

Town of Pine Knoll Shores and Town of Indian Beach
Beach Nourishment Project

The following draft plan was prepared by Coastal Science Associates, Inc (CSA*i*) (c/o Dr. Bart J. Baca and Mr. Stephen R. Florey) based on their understanding of the general requirements of North Carolina's Division of Marine Fisheries and prior experience with similar projects.

Background

The intent of the proposed ecological study is to assess the existing biological conditions of the of benthic invertebrates at the proposed offshore borrow areas for the Bogue Banks beach nourishment project located in Carteret County, North Carolina.

The ecological study will include benthic sampling and analysis from offshore borrow areas and near by controls. CSA*i* proposes to use 50 percent of the stations previously sampled by UNC's Institute of Marine Sciences (UNC-IMS). Benthic sampling will be conducted at the beaches that have been proposed to be nourished. Benthic samples will also be collected on one of the adjacent unnourished beaches to act as a control.

CSA*i* recommends that four sampling events be performed to assess the recovery of the borrow sites and beach nourishment activities. Two sampling events (spring-fall) should be conducted prior to the dredging event, and two sampling events (spring-fall) should be conducted after the nourishment activities have been completed. Based on the information provided, CSA*i* proposes the following scope of services.

Task 1. Field Collection of Benthic Samples

The proposed borrow area to be sampled is located approximately 2 miles south of Salter Path/Indian Beach, Carteret County, North Carolina. The depths in the sampling area range from 35 feet (ft) at the inshore areas to 47-49 ft in the offshore areas.

The proposed sampling will produce a total of 100 core samples (50 percent of the stations originally sampled by UNC-IMS in fall 1999) from both the offshore borrow areas and control areas. Cores will be collected by divers using a cylindrical corer (9.9 cm in internal diameter). All station locations will be selected from the previous study performed by UNC-IMS. All stations will be located by Differential Global Positioning System (DGPS). All benthic samples collected will be sieved in the field through a 0.5-mm stainless steel sieve bucket. All sediment and organisms retained in the bucket will be preserved in 10 percent buffered formalin with Rose Bengal stain.

In addition, four stations will be sampled on the proposed beach to be nourished. Two stations will be sampled within the project area, and two will be sampled outside the project area to act as controls. A total of 12 cores will be collected along the beach. Every attempt will be made to perform the sampling at the same station locations as the Lisa Manning report (NC Sea Grant, April 2000).

Task 2. Laboratory Methods

Once samples have been transported to the laboratory, core sediment samples will be carefully re-sieved through a 0.5-mm stainless steel sieve bucket and screen. This sediment reduction will expedite the sorting process. The remaining sediments and organisms will be placed in labeled, double-ziplock bags and initially preserved in 10 percent buffered formalin solution with Rose Bengal stain. Organisms will be allowed to harden for 48 hours and then will be transferred to 80 percent ethanol alcohol. After the hardening period, the organisms will be placed in sorting trays and submersed/ diluted in de-ionized water to minimize any volatile alcohol vapor production during identification.

Organisms will then be sorted and enumerated in the laboratory and identified to the lowest possible taxon (species level in most cases) with the aid of a variable power dissecting microscope (Bausch & Lomb) and/or a compound microscope (Swift or Bristol). Organisms will be identified by an experienced biologist utilizing various identification keys for organisms expected to be collected (eg, Abbott, 1974; Bousfield, 1965; Bynum and Fox, 1977; Dover, 1979; Fauchald, 1977; Fox and Bynum, 1975; Gosner, 1978; Heard, 1982; Kaplan, 1988; Morris, 1975; Ruppert and Fox, 1988;

Uebelacker and Johnson, 1984; Williams, 1984). Species identified for each station will then recorded on a laboratory bench sheet (per EPA, 1989).

Task 3. Data Analysis

Benthic data from the borrow area and control site will be statistically compared to evaluate changes in faunal abundance and number of species present among sites and over time. Analysis will include variance testing (ANOVA) or the nonparametric Kruskai-Wallis test, as necessary. Comparison among specific treatment groups will be completed using the Student-Newman-Keuls test (parametric and unparametric designs). Diversity indices will be computed for each area (all samples combined) using Shannon's diversity index (H), species richness (SR) and evenness (J). Changes in overall community composition among sites and seasons can be evaluated using a proportional similarity coefficient (Bray-Curtis) with flexible sorting strategy and a cluster intensity (ß) of -0.25.

Task 4. Reporting

A report for each of up to four (4) sampling events (including details of field data collection, data presentation, analysis, and conclusions/results) will be submitted to North Carolina Division of Marine Fisheries within 120 days following completion of the fieldwork.

May 8, 2001

Colonel James W. DeLony, District Engineer
U. S. Army Engineer District, Wilmington
Post Office Box 1890
Wilmington, North Carolina 28402

Re: Bogue Banks SEPA Final EIS
Carteret County/Pine Knoll Shores Nourishment Project
Action ID# 200000362

Dear Colonel DeLony:

It is very troubling to hear that your office may require a full NEPA review of the referenced project. If this review is required, the Towns of Pine Knoll Shores and Indian Beach, and the unincorporated community of Salter Path, will not be able to construct their planned beach nourishment projects as scheduled during the winter of years 2001 and 2002.

The most troubling aspect of this news is that compliance with the SEPA process with the State of North Carolina is nearly complete and the State is nearing a point of being ready to issue permits for the project. Since the State SEPA process is as mandated by NEPA, we fail to see the justification for this second tier of redundant review. We fail to see how an additional level of procedural review will expose or cause to be investigated any additional environmental impacts not identified under the federally mandated SEPA process.

The Towns of Pine Knoll Shores and Indian Beach and Carteret County (for the unincorporated Salter Path area) are prepared to implement beach nourishment projects in their respective communities with dredging to begin in November of this year. These communities are justifying the nourishment project based on threats to the valuable oceanfront properties and recreational resources that currently exist. Additional delays could further endanger property and could represent significant financial impacts to the economy of this County and these communities.

It is our understanding that the Corps has the authority to limit or not invoke the NEPA process for the project. We would question what federal interests are involved in the project that would invoke a full NEPA review of the project. This question is especially relevant since the SEPA process has been fully complied with. The Bogue Banks project is a local project with locally justified benefits funded entirely with local funds.

Our consultants advise me that there are three federal agencies with jurisdictional authority over the environmental aspects of the project: EPA, U. S. Fish and Wildlife Service (FWS) and National Marine Fisheries Service (NMFS). The jurisdiction of these agencies involves wetlands, endangered species, and fisheries coordination. We are currently working to complete the Essential Fish Habitat Assessment required by NMF. The biological assessment required by FWS for endangered species coordination is included in the SEPA EIS. Additionally, the plan for monitoring impacts to fisheries and benthic resources in the borrow and deposition areas is currently being reviewed by the Division of Marine Fisheries and NMFS. We anticipate finalizing that plan in the next two weeks.

We request that you make a full assessment of the work done to date and permit the project based on the SEPA EIS and any additional coordination with the three federal agencies that is required. We are confident that we can complete the required agency coordination in a time period that will permit construction to begin during November of this year.

Please do not invoke what seems to be a purely procedural NEPA process of redundant reviews that will cause delays to this very important project.

I look forward to your response.

Sincerely,

Pete Allen,
County Manager

RE: Bogue Banks SEPA Final EIS
Carteret County/Pine Knoll Shores Nourishment Project
[Action ID# 200000362]

Dear Colonel Delony:

I am disturbed to learn at this late date that your office may require a full NEPA review on our project in response to comments from the National Marine Fisheries Service. If this review is required, we cannot construct our project next winter, and we will lose one year. Properties will remain imminently threatened in Pine Knoll Shores.

I believe that I made it clear in my last correspondence to you that time is of the essence. It disturbs me that we are just now learning of this possibility three months after submitting our permit application to your office. Our consultants also requested guidance from your office and CAMA regarding these procedures more than 1½ years ago in December 1999.

As you are aware, we have completed the SEPA review and have submitted the final EIS to your office. We followed the regulatory procedures and permitting path that your office and the state advised us to follow in December 1999. This included preparing an EIS rather than an EA on the project. There are no significant issues remaining, and all state agencies have accepted our EIS.

As I understand it, there are no extraordinary problems associated with our project which might elevate the review requirements to the full NEPA process. We are not impacting endangered species or permanently changing air or water quality. The only outstanding federal requirement not contained in the SEPA EIS, I am told, is a brief report on Essential Fish Habitat (EFH). Our consultants are completing this and will submit it to your office this month as per instruction from NMFS.

I have been told that most beach nourishment projects are performed without an EIS. I find it incredulous that the SEPA EIS would be considered insufficient in this case. I am told that the state is ready to move forward with our permits so that we have sufficient time to secure a contractor for this winter. If it is your intent to delay a decision on our project until fall, tell me now so we will not waste any more time in trying to initiate a project in November.

Our community is solidly behind this project, and we are not asking the federal government for any assistance with funding. I am at a loss to know what agency needs more time to review and comment on this project after the extensive local and regional press it has received.

Please let me hear from you on this matter.

Yours truly,

C. Reese Musgrave, Mayor

Re: Bogue Banks SEPA Final EIS
Carteret County/Indian Beach Nourishment Project
(Action ID# 200000362)

Dear Colonel Delony:

The county informed me this week that your office is considering requiring full NEPA review of our nourishment project. I do not understand why this is necessary after we have gone through the SEPA process and have submitted a complete EIS on the project. If NEPA review is required, why were we not informed of this in February when our permit application was submitted?

This concerns me because we cannot build our project next winter if we have to wait for another comment period. We are solidly behind the project and do not feel we have the time to wait any longer. We expect to get new sand and have our properties protected next year. We are not asking for federal money.

We have tried to work with the Corps and have waited patiently for your Section 111 study. If you require full NEPA review, we will suffer another unnecessary delay. I am having trouble understanding why you need another comment period after every agency has already commented.

The state is ready to make their decision. We are ready to protect our homes. If you plan to deny our permit, tell us now so that we may pursue other remedies.

Sincerely,

W. L. Fugate

William L. Fugate, Mayor

Fact Sheet
Carteret County Beach Renourishment Permit Application

Date: August 7, 2001

Subject: Summary on the permit status for the Carteret County 16.8 mile Bogue Banks Beach nourishment permit application, Action ID 200000362.

1) On February 5, 2001, our office received a copy of the permit application, dated January 29, 2001, to dredge and pump approximately 8.0 million cubic yards of sand along 16.8 miles of Bogue Banks Beaches, starting at Pine Knoll Shores and terminating in Emerald Isle, Carteret County, NC.

2) The permit application was considered incomplete because of uncertainty as to who was the applicant, the county or the towns or both. After clarification from the towns and county, the application was considered complete on March 14, 2001. A Public Notice was issued on March 16, and responses were received from all Federal agencies as well as environmental organizations and a few citizens. The comments were mailed (April 17 and April 26) to the County to provide them an opportunity for rebuttal comments.

3) Telephone calls were made to Frank Rush, Assistant County Manager; Mayor Reese Musgrave, Pine Knoll Shores, and Bill Forman, applicant's consultant, on May 1, to explain the Federal NEPA process and potential requirements. The differences between the SEPA and NEPA processes were discussed and explained. In addition we explained that the "State EIS" document does not meet our Federal EIS requirements and there was no coordination of the "State EIS" with us or the other Federal review agencies. At the initial scoping meeting in October of 1999, we had requested that the "State EIS" be circulated to the Federal agencies for review. This never occurred.

4) A scoping meeting was held May 11, 2001 with all the applicants, National Marine Fisheries Service (NMFS), US Fish and Wildlife Service (USFWS), and other interested parties to discuss the proposal and the "State EIS". Issues of discussion were the following: cumulative impacts of beach (re)nourishment along the NC coast, Essential Fish Habitat (EFH), sand compatibility sampling- concerns with too much carbonate material, the need for additional beach sampling transects, the monitoring report, cost of additional sampling and monitoring, and Threatened and Endangered species- the need to include a detailed comparison of current habitat for turtles and sea beach amaranth vs the post-construction habitat, and the value of using data from Atlantic Beach. We discussed the NEPA process and how the Federal agencies did not receive the "State EIS" until the permit application was made.

5) Essential Fish Habitat consultation was initiated on March 16 via Public Notice. The consultant provided a copy of the EFH assessment and proposed monitoring report. On

May 21, a letter was sent to NFMS requesting comments on the applicant's EFH assessment, the EIS, and the proposed monitoring report.

6) A copy of the Threatened and Endangered Species Biological Assessment (BA) was mailed to USF&W Service on April 25. The BA was also included in the "State EIS" that was sent to them in March. On May 18, a letter was sent to the Service initiating formal consultation.

7) We determined that the economics and the sand compatibility results should be reviewed in house to verify study methodology and to ensure their accuracy. A copy of the sand compatibility study was given Geo-Tech on April 27, and the economic analysis was given to our economist on May 14. The economic analysis has been confirmed. We are awaiting information on the sand compatibility from Geo-tech.

8) On June 14, a meeting was held to discuss U.S. Fish & Wildlife Service's concerns with the project and the submitted Biological Assessment (BA). Comments from USFWS were discussed. The consultants brought data and samples from 60 additional sand borings and discussed their findings. USFWS disagrees with the compatibility of the material-too much shell content. We were told that the BA is incomplete and formal consultation would not begin until completed document is submitted (Disclosed in their June 12 letter- received in our office on the 19th).

9) Also on 14 June, letters were sent to Mr. Pete Allen, County Manager: a) informing him of our NEPA responsibilities and that we would be determining if an EA or EIS will be required w/in the next 60 days, and b) furnishing the USFWS comments on their proposal.

10) On June 20, a meeting was held at NMFS's office. NMFS expressed concerns that the project boundaries (in relationship to the borrow sites & which site will he used w/ which reach) were not well defined, and the exact amount of material needs to be included. Also, there is a need to identify the dredging technique. This information was discussed by the county representatives. The monitoring plan was discussed.

11) On July 16, a follow-up meeting was held at NMFS's office to discuss the monitoring plan. A copy of the NMFS June 25 letter that expresses their concerns regarding NEPA requirements, sand compatibility results, monitoring plan, and EFH (w/ EFH recommendations) was distributed and discussed. CSE (the county's consultant) distributed copies of the revised monitoring plan. The county needs to identify goals in the monitoring plan and describe the plan in detail.

12) The updated BA was sent, by CSE, to NMFS in St. Petersburg, Florida and to USFWS on July 13. NMFS has sent us a letter (dated July 26-Biological Opinion (BO)) stating that formal consultation is not necessary provided hopper dredge guidelines are implemented. The NMFS letter was faxed to the County and Mr. Forman.

13) On August 6, we decided that an EA would be sufficient at the present time to satisfy our NEPA requirements. This decision was relayed to the County and the consultants on August 7.

14) On August 7, I spoke with USFWS regarding the timeframe for submitting their BO. They stated that they could produce it by mid-September. It doesn't appear that there will be any outstanding issues involved with endangered species. We asked that a copy of any mitigation recommendations be sent so that we can forward them to the applicant. This will help them get started on implementing the recommendations.

15) We are awaiting information from Geo-tech and Environmental Branch regarding the sand compatibility study. Environmental has stated that they would draft a report.

16) To date needed information from the applicant: a) a completed EA, b) updated and approved monitoring plan, and c) response to NMFS concerns with EFH consultation, d) a Section 401 Water Quality Certification from the State, and e) a CAMA permit. With USFWS BO (projected in mid-September) and this information, the projected time frame for the issuance of a permit could be mid to late October.

June 25, 2001

Colonel James W. DeLony
District Engineer, Wilmington District
Department of the Army, Corps of Engineers
P. O. Box 1890
Wilmington, North Carolina 28402-1890

Attention: Mr. Mickey Sugg

Dear Colonel DeLony:

This responds to your May 21, 2001, request for additional comments concerning plans by Carteret County, c/o Mr. Robert Murphy, County Manager, to renourish beaches located on Bogue Banks in Carteret County, North Carolina (**Action ID No. 2000003620**). You specifically ask for comments concerning the Draft Environmental Impact Statement (DEIS); the May 31, 2001, revised monitoring plan for pelagic fish and invertebrates; and the May 15, 2001, Essential Fish Habitat (EFH) Assessment. The project involves dredging of up to 2.58 square miles of ocean bottom and deposition of up to 8 million cubic yards of dredged material on ocean beaches. Approximately 1,400 acres of intertidal and subtidal beach habitat along 16.8 miles of ocean beach between Emerald Island and Pine Knoll Shores, in Carteret County, North Carolina would be altered by the project.

By letter dated April 20, 2001, the National Marine Fisheries Service (NMFS) commented on anticipated impacts of the project on living marine resources, including EFH. In that letter we recommended against project implementation due the severity of anticipated impacts. Subsequent to that, we participated in a May 11, 2001, interagency meeting with the applicant to discuss our concerns. Many of the issues raised in our April letter remain unresolved.

DRAFT ENVIRONMENTAL IMPACT STATEMENT

The status of the Corps of Engineers' (COE) determination regarding compliance with procedural requirements of the National Environmental Policy Act (NEPA)(40 CFR Parts 1500-1508) needs to be resolved. It appears that granting Department of the Authorization in this case would constitute a major Federal action due to subsequent effects on the human environment. We also believe that the project is not consistent with NEPA requirements which require sequential mitigation of impacts. As pointed out in earlier reports, less damaging alternatives and impact reduction opportunities exist.

At the May 11 meeting, Coastal Science and Engineering, LLC (CSE), the applicant's consultant, provided a copy of the Draft Supplement to Bogue Banks Beach Nourishment Plan, Final Environmental Impact Statement (FEIS). The document is dated May 8, 2001, and responds to our April 20, 2001, letter. Considering that issues related to compliance with the NEPA implementation regulations are uncertain, submission of the FEIS seems premature. We also note that material provided in the FEIS does not resolve concerns raised in our initial report on the project. Although a line-by-line review of the DEIS has not been prepared, the following issues need to be addressed:

1. Sediment compatibility between the proposed borrow sites and Bogue Banks beaches was discussed at the May 11 meeting and additional sediment analysis data, as requested by the U.S. Fish and Wildlife Service (FWS), were provided. Based on coordination with the FWS, and on information provided in their letter dated June 1, 2001, the suitability of the excavated sand for beach use remains questionable. Sediments in borrow Sites B1 and B2 are exceptionally fine grained and material at borrow Site A has excessive carbonate levels. Excessive amounts of carbonates can form a carbonate cement and may harden the beach to a point where use by burrowing invertebrates may be limited. Although we agree that deposition of compatible material during winter months would allow reestablishment of invertebrate populations, the DEIS gives no assurance that these conditions will be met. Lacking either an acceptable plan of action or reasonable evidence of only minor effects we remain concerned that the project could adversely effect 16.8 miles of intertidal habitat and fauna that supports commercially and recreationally important fishery resources. We also note that Appendix A of the FWS' letter contains and excellent overview of research related to the impacts of dredging and filling associated with beach nourishment. This information should be incorporated into the environmental documents for the project.

2. The DEIS and other information provided by the applicant is confusing in terms of the amount of material that would be placed on the beach and the length of beach to be nourished. For example, the DEIS indicates that a fill volume of 50-cubic yards of material per liner foot is planned. At the May 11 meeting 80 to 90-cubic yards per linear foot of beach was mentioned. Accurate volumetric and linear amounts of material to be deposited on the beach need to be provided.

3. The DEIS notes that maintenance work may be required during the ten year life of the project, but a plan for maintaining the project is not provided. The frequency and magnitude of anticipated maintenance should be addressed in the FEIS and if project maintenance is anticipated, details concerning this work should be developed and provided for agency review prior to granting Federal authorization of the project.

4. Borrow sites B1 and B2 contain sediments with high levels of fine grain material that is subject to protracted resuspension during dredging and disposal activities. If plans to use these sites are retained then possible effects on subadult fish and invertebrates, EFH, and other living marine resources should be identified in the FEIS.

5. The DEIS states that up to 50 percent of the material placed on the beach will end up offshore, but the document does not adequately address the potential for, and effects of, long-term resuspension and transport of material to offshore areas that support hardbottom habitat. The DEIS

concludes that since hardbottoms are located no closer than 1600 feet from work sites on Bogue Banks no impacts are anticipated. No basis is given for the conclusion that this distance is sufficient to preclude project related impacts.

6. It is unclear whether coordination with our Protected Resources Division has been conducted. As presently proposed, use of a hopper dredge could occur in areas that support sea turtles. As noted in our April 20, 2001 letter, determinations involving species under NMFS jurisdiction should be reported to our Protected Resources Division. If the proposed activities may adversely affect any species listed as endangered or threatened, then formal consultation must be initiated.

REVISED MONITORING PLAN

Previously identified deficiencies in the original monitoring plan were discussed in considerable detail at the May 11 meeting. The revised monitoring plan titled, "Revised Environmental Services Proposal: Bogue Banks Beach Restoration Project, Bogue Banks , North Carolina," addresses some of our concerns. Coordination with staff at the NOAA Center for Coastal Fisheries and Habitat Research (CCFHR) and Dr. Charles Peterson of the University of North Carolina, Institute of Marine Science indicates that the revised plan still would not provide the statistical analysis needed to adequately evaluate project related impacts on living marine resources. The enclosed letter, dated June 3, 2001, from Dr. Peterson to Mr. Mickey Sugg of your Regulatory Division, outlines our concerns. Development of an acceptable monitoring plan is a key element of the proposed project and authorization of the should be withheld pending fulfillment of this need.

EFH ASSESSMENT

The applicant prepared EFH Assessment, dated May 10, 2001, provides an adequate description of Federally managed species and EFH found in the project area. The NMFS does not agree, however, with the applicant's determination that the proposed dredging and disposal of dredged material in EFH will minimally impact these species and habitats. Consequently, the issues and concerns identified in our April 20, 2001, letter remain valid. As currently proposed, the applicant would have almost unlimited flexibility regarding the use of borrow sites, nourishment locations, and dredging techniques. This flexibility could preclude the use of more environmentally prudent actions that would reduce levels of adverse impact to EFH. Other potential impacts to EFH include:

Marine Water Column EFH

The range of potential impacts of off shore dredging and disposal on Bogue Banks beaches are not adequately described in the EFH Assessment. In our comments on the DEIS we noted that use of hopper dredges in areas having fine sediments (e.g., borrow sites B1 and B2) could be problematic due to high suspension rates of this material. Regardless of the dredging technique used, exceptionally high levels of suspended sediments could damage or kill early life history stages of Federally managed species.

Surf Zone EFH

Discharging material dredged from borrow sites B1 and B2 on to Bogue Banks beaches would result in elevated turbidity levels. Related effects of this are largely undetermined with regard to subadult fish and invertebrates, including federally managed species, but could be significant and adverse. The FEIS states that the NMFS selectively reviewed data concerning impacts of turbidity and suspended sediments on fishery resources. This is not accurate and the concerns we identified regarding the uncertain status of the impacts of beach nourishment on fishery resources found in the surf zone are well supported. Although we continue to have significant concerns regarding possible impacts on EFH and associated fishery resources, we believe that the project could be modified to address those concerns. Changes regarding dredging techniques (e.g., specified use of a hydraulic dredge), identification and use of specific locations within the borrow sites where compatible sand exists, and setting limits on beach locations that would be impacted during dredging cycles would reduce the level of our concerns.

Hardbottom EFH

The EFH Assessment notes that the various borrow and disposal sites are located between 1600 and 6500-feet from the nearest hard bottom habitat and that mechanisms for natural transport of fine sediments to these sites are do not exist. Studies perfomed on Bogue Banks and Wrightsville Beach have shown that sediment from nourished beaches has moved offshore and buried hardbottom habitat. Unless the applicant's conclusion regarding this issue can be substantiated, we continue to believe that hardbottom habitat could be adversely affected by the project.

Seasonal Restrictions on Dredging

Seasonal restrictions on dredging can reduce project specific and cumulative impact of dredging and beach disposal of dredged material. However, the dredging window (November 1 - April 15) proposed by the applicant is unacceptable because it impinges on recruitment seasons for surf zone dwelling invertebrates and estuarine dependent species which begins as early as January. While some species are at risk during any season, the proposed dredging window does not sufficiently reduce impacts to fishery resources.

Monitoring Plan

The EFH Assessment states that the proposed monitoring plan will address the project's impacts on Federally managed species. We disagree and refer to our May 31, 2001, comments concerning the adequacy of the revised monitoring plan. The physical and biological conditions and construction techniques that would allow beach nourishment to take place with only minimal impact to EFH must be demonstrated. A properly designed and implemented monitoring plan is also needed for determination of the role of this project in connection with other similar activities.

The NMFS strongly believes that a phased approach to this project would allow impact measurement and would provide opportunities for inclusion of modifications that are needed to preclude significant harm to living marine resources and EFH. If performed in phases, Phase I could include the work on Pine Knoll Shores and Indian Beach (7.2-miles) and would include impact monitoring. Authorization of subsequent work would be contingent upon successful completion of the initial phase in compliance with permit conditions and based on the outcome of environmental monitoring. The monitoring results would be used to develop a plan for Phase II which would include the Pine Knoll Shores portion of the project.

In view of the preceding, the NMFS recommends that Department of the Army authorization of the project not be granted unless it is in accord with the following EFH recommendations:

EFH Conservation Recommendations

1. The timing of the proposed action is critical to protecting EFH and associated fishery resources. Therefore, in order to avoid and minimize potential adverse impacts all dredging and disposal activities for beach nourishment shall be limited to the period between November 15 and March 1 of any year.

2. Adverse impacts to EFH can be avoided and minimized if sand sources have low levels of fine grained materials and carbonates and are otherwise compatible with existing sediment on the beach that is to be nourished. Therefore, criteria shall be established to ensure that material placed on beaches is compatible with that which currently exits on the beach.

3. The monitoring plan for this project should utilize statistically valid sampling procedures. The proposed monitoring shall be modified to include such procedures and shall be subject to review and approval by the COE and review agencies prior to project start up.

4. In order to avoid and minimize adverse impacts to EFH and associated fishery resources the project plans should be revised to identify a the exact location for extraction of borrow material, the specific type of dredging equipment to be used, and exact location of beach segment where the material will be deposited. Based on the information provided, adjustments will be developed as needed to preclude significant harm to living marine resources and EFH.

5. In recognition of this being the largest beach nourishment project ever proposed in North Carolina a phased construction approach and monitoring of fishery resources and habitat is needed. Therefore, phased construction and monitoring shall be required and implementation of subsequent work phases shall be contingent upon successful demonstration that significant environmental harm has not occurred and adequate monitoring, as needed for determination of individual work related and cumulative effects on living marine resources and EFH are determined.

Pursuant to Part IV.3(a) of the 1992 404(q) Memorandum of Agreement (MOA) between our agencies, we advised by letter dated April 13, 2001, that the proposed work will substantially and unacceptably impact nationally important aquatic resources. The information provided herein supplements our earlier report and is provided in accordance with, and in continuance of the cited MOA provisions. We further note that provisions concerning your responsibilities pursuant to Section 305(b)(4)(B) of the Magnuson-Stevens Fishery Conservation and Management Act requires your office to provide a written response to this letter within 30 days of its receipt and at least 10 days prior to final approval of the action. A preliminary response is acceptable if final action cannot be completed within 30 days. Your final response must include a description of measures to be required to avoid, mitigate, or offset the adverse impacts of the activity. If your response is inconsistent with our EFH Conservation Recommendations, you must provide an explanation of the reasons for not implementing those recommendations [50 CFR Section 600.920(j)].

Please direct related comments or questions to the attention of Mr. Ron Sechler at our Beaufort Facility. He can be reached at 101 Pivers Island Rd, Beaufort, North Carolina 28516, or at (252) 728-5090.

Sincerely,

for Andreas Mager, Jr.

REGULATORY
WILMINGTON FIELD OFFICE

Colonel James W. DeLony
District Engineer
Wilmington District
Army Corps of Engineers
Department of the Army
P.O. Box 1890
Wilmington, NC 28402-1890

Dear Colonel DeLony:

This responds to your July 5, 2001, letter and July 2001 Environmental Assessment (EA) on the Bogue Banks Beach Renourishment Project, Carteret County, North Carolina (Corps of Engineers permit application number 200000362), submitted to the National Marine Fisheries Service (NMFS), Habitat Conservation Division, Beaufort, North Carolina, by Dr. Timothy W. Kana of Coastal Science and Engineering LLC (preparers of the EA) and forwarded to NMFS Southeast Regional Office, Protected Resources Division. Our comments are rendered pursuant to the interagency consultation requirements of section 7 of the Endangered Species Act (ESA) on the potential project impacts to federally-listed species under NMFS purview, of proposed beach renourishment activities in Carteret County. We have assigned number I/SER/2001/00783 to this consultation; please refer to it in future correspondence on this activity.

The applicants (Carteret County, and the towns of Pine Knoll Shores, Indian Beach, and Emerald Isle) propose to excavate by hydraulic dredge up to 6.7 million cubic yards of beach-quality sediment from ocean borrow areas situated 0.5 to 3.0 miles offshore of Bogue Banks to renourish approximately 16.9 miles of Carteret County beaches between the towns of Pine Knoll Shores and Emerald Isle. A hopper-type dredge (or dredges) would be the most likely method employed for sand excavation from the offshore sites. Construction activities are planned to occur between November and April. Federally-listed sea turtles, whales, and shortnose sturgeon may be present in the action area.

A hopper dredge is likely to be used for most of the proposed activity; therefore, NMFS concurs with the conclusions of the EA that the project may affect listed species under NMFS purview that may be present. Hopper dredges are known to occasionally take sea turtles and sturgeon, and pose a collision risk to whales. Construction during November through April will minimize dredge interactions with migratory and nesting sea turtles by avoiding the peak period of sea turtle abundance in the action area. Observers aboard the hopper dredges will minimize the chances of dredge collisions with migrating whales. Because of foraging habits, it is unlikely that shortnose sturgeon will occur at the offshore dredging sites.

The potential for adverse effects to listed species from hopper dredging of offshore sand borrow areas for beach renourishment activities proposed to be permitted by the Corps for this project is covered by an existing NMFS biological opinion to the Corps. On September 25, 1997, NMFS issued a Regional Biological Opinion to the Corps' South Atlantic Division on the continued hopper dredging of channels and borrow areas in the southeastern United States, including offshore borrows areas off North Carolina. That opinion analyzed hopper dredging effects on sea turtles, whales, and shortnose sturgeon, and included non-discretionary reasonable and prudent measures, and implementing terms and conditions, to minimize potential interactions with these federally-listed marine species.

Since the Wilmington District will require NMFS-approved endangered species observer coverage aboard the hopper dredge (to watch for whales, sea turtles, and sturgeon) and must abide by all the other terms and conditions, including incidental take limits, established in the 1997 Regional Biological Opinion, NMFS believes that any adverse effects to listed species have been adequately considered and minimized, and no further consultation is necessary.

This concludes consultation responsibilities under section 7 of the ESA for the proposed action. Consultation should be reinitiated if new information reveals impacts of the identified activity that may affect listed species or their critical habitat, a new species is listed, the identified activity is subsequently modified or critical habitat determined that may be affected by the identified activity.

We appreciate the opportunity to comment and work with the Corps of Engineers, Wilmington District. Please contact Eric Hawk, fishery biologist, at (727) 570-5312, or by e-mail at eric.hawk@noaa.gov, if you have any questions or if we may be of further assistance.

Sincerely,

Joseph E. Powers, Ph.D.
Acting Regional Administrator

File: 1514-22 f.1. NC

HOP297

R. L. VanAntwerp
Brigadier General, U.S. Army
Division Engineer
South Atlantic Division, Corps of Engineers
Room 313, 77 Forshyth St., S.W.
Atlanta, Georgia 30355-6801

Dear Brigadier General VanAntwerp;

Enclosed is the regional biological opinion concerning the use of hopper dredges in channels and borrow areas along the Southeast U.S. Atlantic coast. This biological opinion amends the regional opinion conducted in 1995, and supersedes the interim biological opinion issued on April 9, 1997. The opinion recognizes the efforts of the Corps of Engineer's (COE) South Atlantic Division (SAD) to minimize sea turtle takes through application of new technology such as draghead deflectors, seasonal dredging windows, termination of projects in which high rates of turtle takes are observed, and elevated staff effort to identify and resolve site-specific problems. Despite these major efforts and continuing plans by the COE to improve the effectiveness of the rigid draghead deflector and to resolve dredging schedules to reduce the likelihood of sea turtle interactions, NMFS believes that further sea turtle takes are likely in future years. However, we believe that these takes are not likely to jeopardize the continued existence of any species. An annual incidental take, by injury or mortality of 35 loggerheads 7 Kemp's ridleys, 7 green turtles, 2 hawksbills, and 5 shortnose sturgeon is listed in the incidental take statement appended to the enclosed opinion. This annual take level can be monitored over fiscal years to be consistent with project contracts.

I appreciate your continued commitment to reduce sea turtle takes associated with dredging in your Division. COE Division and District staff have facilitated the excellent working relationship that exists between our offices within the SAD. We look forward to continuing these cooperative efforts in sea turtle conservation.

Sincerely,

Hilda Diaz-Soltero
Office Director
Office of Protected Resources

Endangered Species Act - Section 7 Consultation

Biological Opinion

Agency: U.S. Army Corps of Engineers, South Atlantic Division

Activity: The continued hopper dredging of channels and borrow areas in the southeastern United States

Consultation Conducted By: National Marine Fisheries Service, Southeast Regional Office

Date Issued: ____________

Background

Hopper dredging in channels and borrow areas along the southeastern coast of the United States during the spring of 1997 resulted in an unanticipated high rate of loggerhead turtle take. The number of takes quickly approached the incidental take level established in the regional biological opinion (BO) issued to the Army Corps of Engineers (COE) on August 25, 1995. A formal consultation considering the take rates as well as the dredging locations and conditions was conducted and an interim biological opinion (IBO) was issued on April 9, 1997 and is incorporated herein by reference. The IBO concluded that continued hopper dredging during the 1997 fiscal year was likely to take additional sea turtles but was not likely to jeopardize the continued existence of any species. The incidental take, by injury or mortality, of seven (7) documented Kemp's ridleys, seven (7) green turtles, two (2) hawksbills, sixteen (16) loggerhead turtles, and five (5) shortnose sturgeon was set pursuant in the IBO. This modification added 15 loggerheads to the annual incidental take level, bringing the 1997 fiscal year total incidental take level to 35 loggerheads.

The history of Endangered Species Act (ESA) Section 7 consultations on the deployment of hopper dredges to maintain the depths of southeastern channels is discussed in the August 25, 1995 BO and is incorporated herein by reference. Although no endangered sea turtles have been taken in any channel dredging projects during the 1997 fiscal year, 28 loggerheads have been taken, including 9 loggerheads taken subsequent to the issuance of the IBO (Table 1).

During 1997, the COE responded to high rates of sea turtle takes by assessing each dredging project, modifying draghead deflectors when apparently necessary, conducting relative abundance surveys and relocation trawling, and ultimately ending a number of projects prior to completion (Kings Bay, Brunswick Harbor, Savannah Harbor, Morehead City).

1991 Biological Opinion

Two hundred twenty-five sea turtle takes, including 22 live turtles, were documented between 1980 and 1990 in the Southeast channels despite limited observer coverage in most channels throughout most of that decade (Table 2a.). Seventy-one of these turtles were taken in four months of dredging in the Canaveral ship channel in 1980, the first year in which observers were required. Twenty-one were observed in over two years of dredging in the Kings Bay Channel in 1987–1989, after observers were first deployed on dredges in that channel. Observers were required on most hopper dredges after 1989. Documented takes of turtles on dredges in Brunswick and other Southeast U.S. channels indicated that sea turtles were vulnerable to hopper dredges in all southeastern channels during warmer months. These observations resulted in the Section 7 consultation that concluded with a BO issued on November 25, 1991.

The November 1991 BO was the first cumulative area consultation between NMFS and COE's South Atlantic Division (SAD) regarding hopper dredging. The BO considered hopper dredging in channels from the Canaveral in Florida through Oregon Inlet, North Carolina. The 1991 BO concluded that continued unrestricted hopper dredging in Southeast U.S. channels could jeopardize the continued existence of listed sea turtles. The Opinion established a reasonable and prudent alternative to unrestricted hopper dredging which prohibited the use of a hopper dredge in the Canaveral ship channel, and from April 1 through November 30 in other southeastern channels north of Canaveral. An incidental take level was established based on assumptions that takes would be significantly reduced due to limited dredging windows, but that water temperatures in some years would result in turtle presence in channels during December and March. Observers were required on dredges equipped with outflow and/or inflow screening in March and December. The presence or absence of turtles in December would determine the further need for observer coverage into January. The documented incidental take of a total of five (5) Kemp's ridley, green, hawksbill or leatherback turtle mortalities in any combination of which no more than two (2) are Kemp's ridley, or fifty (50) loggerhead turtle mortalities was set. The Opinion anticipated that seasonal restrictions on hopper dredging would be adjusted on a channel-by-channel basis as better information on turtle occurrence was collected. Additionally, the development and testing of a draghead deflector was promoted.

1995 Biological Opinion

Between 1992 and 1995, only 16 sea turtle takes were documented (Table 2b.), including three that were alive when collected during dredging operations in the SAD under the dredging windows established in the November 1991 BO (see above). During that period COE developed a rigid draghead deflector that appeared to be effective during videotaped dredging trials using mock turtles, as well as during experimental dredging associated with trawling in the Canaveral Channel. COE also completed a study of six Southeast channels to determine seasonal abundance and spatial distribution of these turtles. A discussion of the findings can be found in the COE report entitled "Assessment of Sea Turtle Abundance in Six South Atlantic U.S. Channels" (Dickerson et al. 1994), summarized in the 1995 BO. Based on the new information, COE requested expanded dredging windows and observer requirements. NMFS considered their request and developed alternative dredging windows and observer requirements and added requirements for the use of hopper dredges in borrow areas along the east coast.

After 1995, COE districts within the SAD generally required observers in some channels, such as Kings Bay, throughout the winter, beyond the new monitoring windows. SAD hopper dredge projects were initially conducted in the middle of the dredging windows, when nearshore waters were cool. During 1996, only nine sea turtle takes, including one green turtle and eight loggerheads, were documented (Table 2c.). No more than three takes occurred in any project. The new dredging windows and draghead deflector requirements appeared to provide good protection to sea turtles.

Hopper dredging operations contracted for the 1997 fiscal year were planned for early in the calendar year, however a number of operations were not begun until late winter. Beginning on March 2, 1997, loggerhead takes occurred in Kings Bay at rates higher than previously observed. Six turtles were taken in four days of dredging. While consulting with NMFS regarding this unprecedented rate of loggerhead takes, a COE specialist from the Waterways Experiment Station proposed some modifications to the draghead with the potential to reduce sea turtle takes. Relocation trawling was also initiated, beginning March 9,1997; however, as can be seen on Table 2, these efforts did not preclude further sea turtle takes in Kings Bay. Dredging was terminated on March 12, 1997, with only 53 percent of the project completed.

Table 1 lists the sea turtle takes observed in hopper dredges throughout the SAD during 1997, as well as the steps taken by COE to reduce the likelihood of takes. Deflector dragheads were re-engineered to fit specific dredges wherever possible and relocation trawling was initiated. Dredging was terminated prior to completion of projects in Kings Bay, Brunswick Harbor, Savannah Harbor and Charleston Harbor. Consultation was reinitiated to consider the effects of the remaining hopper dredging projects anticipated for the 1997 fiscal year. In addition to those specific projects listed in the resulting April 1997 IBO, dredging at Reach II of the Myrtle Beach dredge disposal area is likely to begin before the fiscal year ends. Despite ongoing dredging at the Oregon Inlet, no sea turtle takes have been documented since May 15.

Proposed Activity

This consultation addresses the use of hopper dredges in channels and borrow areas along the Atlantic portion of COE's SAD within the existing dredging windows (Table 3). Channels dredged by hopper dredges include: Oregon Inlet, Morehead and Wilmington Harbors, Charleston, Port Royal and Savannah harbors, Brunswick, Kings Bay, Jacksonville, St. Augustine and Ponce de Leon inlets, West Palm Beach, Miami and Key west channels. Borrow areas that may be dredged by hopper dredges include areas off of Dade County Florida and Myrtle Beach South Carolina.

Draghead deflectors will be used on all projects and observers will be required at least during those periods identified in Table 3. Year-round observer coverage will likely be required by the COE for most channels, particularly those with histories of high sea turtle catch rates such as Kings Bay. Within the South Atlantic Division, the COE will try to schedule dredging of the highest risk areas (Canaveral, Brunswick, Savannah, and Kings Bay) during periods when nearshore waters are coolest -- after December 15 but well before March. Priority for winter dredging will also be given to areas that have substrates that reduce the efficiency of the deflector (Wilmington Harbor channel, Reach 1 of Myrtle Beach). Completion of all projects during the cold-water months will be attempted when possible.

Listed Species and Critical Habitat

Listed species under the jurisdiction of the NMFS that may occur in channels along the southeastern United States and which may be affected by dredging include:

Threatened:

(1) the threatened loggerhead turtle - Caretta caretta

Endangered:

(1) the endangered right whale - Eubalaena glacialis
(2) the humpback whale - Megaptera novaeangliae
(3) the endangered/threatened green turtle - Chelonia mydas
(4) the endangered Kemp's ridley turtle - Lepidochelys kempii
(5) the endangered hawksbill turtle - Eretmochelys imbricata
(6) the endangered shortnose sturgeon - Acipenser brevirostrum

Green turtles in U.S. waters are listed as threatened, except for the Florida breeding population which is listed as endangered.

Additional endangered species which are known to occur along the Atlantic coast include the finback (Balaenoptera physalus), the sei (Balaenoptera borealis), and sperm (Physeter macrocephalus) whales and the leatherback sea turtle (Dermochelys coriacea). NMFS has determined that these species are unlikely to be adversely affected by hopper dredging activities.

Information on the biology and distribution of sea turtles can be found in the 1991 and 1995 BOs, which are incorporated by reference. Channel specific information has been collected by COE for channels at Morehead City, Charleston, Savannah, Brunswick, Fernandina and Canaveral, and is presented in detail in COE summary report entitled "Assessment of Sea Turtle Abundance in Six South Atlantic US Channels" (Dickerson et al., 1994) and in the COE Biological Assessment.

There is no significant new information regarding the status of these species that has not been discussed in the BOs that have been incorporated by reference (March 12, 1997 and August 25, 1995).

Assessment of Impacts

The Biological Opinion issued in 1991 contained strict dredging windows that appeared to be very effective at limiting the number of sea turtles taken by hopper dredges during channel maintenance dredging in the Southeast U.S. along the Atlantic coast. Between 1991 and 1995, no more than 8 turtles were taken in any year, and many of those taken were released alive. Studies conducted by the COE (Dickerson et al., 1994) documented turtle distribution and abundance in six channels that suggesting the existing windows were accurate. However, the COE requested expansion of existing windows to lessen the burden of maintenance dredging while testing and further developing a rigid draghead deflector design. The deflector was effective at pushing aside mock turtles when tested during 1994, and preliminary field trials in the Canaveral shipping channel had encouraging results. NMFS considered this new information, presented by the COE in a biological assessment forwarded to NMFS in November 1994. The resulting BO, issued August 25 1995 expanded dredging windows and modified observer requirements.

Only 9 sea turtle takes were documented in 1996, suggesting that the expanded dredging windows and the deflector requirements provided protection to sea turtles that was similar to the previously more-restrictive windows. However, the COE's internal policy resulted in conduct of most of the hopper dredging projects during months when coastal waters were still cold, consistent with the previous dredging. The increased rate of take observed during 1997 and discussed below suggests that the restriction of hopper dredging to months when nearshore waters are cold remains the best method for minimizing sea turtle takes.
Unfortunately, a number of dredging projects contracted for early 1997 in the SAD but not restricted to mid-winter months, were delayed into the Spring. This delay coincided with a unseasonably warm winter, when the waters of Kings Bay reached 60°F in early March. The incidental take of nine loggerheads in Kings Bay over only 11 days of dredging indicated that the nearshore abundance of loggerheads was high, apparently higher than during the late 1980's when observers were first deployed on hopper dredges in Kings Bay.

There were other indicators of high nearshore sea turtle abundance along the Southeast U.S. Atlantic coast during 1997. Commercial shrimp trawling conducted without the use of turtle excluder devices (TEDs) offshore of South Carolina and Georgia between May 15 and July 15 resulted in sea turtle catch rates higher than previously documented. Sixty nine sea turtles were taken in 29 days of shrimping off of South Carolina, including 65 loggerheads, 3 ridleys and 1 leatherback. Forty-six sea turtles were taken in 17 days of towing off of Georgia. The sea turtle catch per unit effort (CPUE) for this operation is about 0.35 turtles per hour of trawling, standardized to 100 feet (30.5 m) of total headrope length fished. The CPUE (same units) for commercial shrimp trawling in the 1970s and 1980s reported by Henwood and Stuntz (1987a) was only 0.0487. Loggerhead turtles were the predominant species reported by Henwood and Stuntz and have also been predominantly observed in this study. They account for most of the increase in overall CPUE. The CPUE for loggerheads alone has been greater than 0.30 turtles per hour, while the value reported in Henwood and Stuntz was 0.0456 turtles per hour. The rates of taking for leatherback and Kemp's ridley turtles in the Atlantic study area have also been higher than anticipated.

The high relative density of sea turtles during 1997 may be due to an unseasonably warm winter or other factors contributing to annual variations in abundance, due to an actual increase in the abundance of benthic immature sea turtles in the loggerhead population, or due to a combination of these factors. Trends in the status of loggerheads are generally identified at the nesting beach, when the most accessible life stage, adult nesting females, can be counted. Because they mature at 20 to 30 years of age, increases or decreases in the abundance of benthic immature loggerheads as determined by incidental captures in nearshore waters would not be observed for decades. While nesting beach surveys suggest that the South Florida population of loggerheads increased and now appears to be stable, increases have not been apparent on nesting beaches of Georgia and South Carolina. Further work on the development of multi-year in-water sampling sites is needed to identify trends in multiple age-classes of the loggerhead population.

The COE noted that 14 of the 28 takes that occurred during 1997 were on the same dredge, the Eagle. The high rate of takes, particularly on this dredge, suggested that the deflecting draghead was not installed properly or was not being operated properly. Takes occurred in a number of the 1997 dredge projects during clean-up. Ridges left behind after the initial dredging are leveled during clean-up, but the draghead passes over troughs. Takes occurring during clean-up may be difficult to avoid since the draghead deflector must remain hard on the bottom to be effective.

The COE has been conducting meetings between districts within the SAD to discuss the results of assessments of channel conditions and dredge inspections. They have determined that the draghead deflector has not been working properly due to poor education of the dredge operators on its proper use, and due to poor tailoring of the deflector to specific dragheads. Increased efforts to educate dredge operators are planned. Additionally, since fewer than 10 private hopper dredges operate within SAD, engineers that have designed the conceptual deflector will be sent to the dredges to insure that the deflectors are adapted to each draghead and that the operators understand how to use the deflector effectively.

Cumulative Effects

"Cumulative effects" are those effects of future state or private activities, not involving Federal actions, that are reasonably certain to occur within the action area of the Federal action subject to consultation. These are discussed in detail in the biological opinions incorporated by reference.

Conclusion
NMFS believes that the elevated rate of observed sea turtle takes by dredges in the southeastern United States during March of 1997 was likely due to increased abundance of loggerheads in nearshore waters due to an unseasonably warm winter. There is no way to predict whether similar conditions will be encountered in upcoming seasons. Over the past six years, the COE's SAD has continuously expressed a commitment to minimize sea turtle takes, and has conducted research and taken repeated steps to further this goal. Repeated termination of dredging operations due to high sea turtle takes during 1997 confirms their commitment to avoid sea turtle takes. Further efforts to educate the dredging industry and recruit their interest and involvement in avoiding sea turtle takes are necessary and are planned by the COE. Additionally, the COE has committed to additional efforts to improve the effectiveness of the deflecting draghead. The sea turtle deflector should be tailored to each hopper dredge draghead and the dredge operators should be fully trained in the operation of the draghead to ensure proper use and improve effectiveness. Improvements in operator and deflector performance are necessary prior to reliance on the draghead as a mechanism for reducing sea turtle takes.

NMFS anticipates that the COE's interest in improving the performance of the deflector, their commitment to limit the use of hopper dredges in channels of high sea turtle abundance during periods when nearshore waters are likely to be cold, and their overall goal of further reducing sea turtle takes during hopper dredge activities will minimize the interactions of hopper dredges with sea turtles. However, annual variation in the abundance of sea turtles in some channels and borrow areas make it likely that sea turtle takes will still occur. Additionally, overall increases in loggerhead and Kemp's ridley populations are anticipated due to TED requirements that have reduced the mortality rates of benthic lifestages of these species. Lastly, in some years high levels of hopper dredging activity may be necessary. For example, termination of projects prior to completion during FY 1997 may result in an increase in the number and length of hopper dredging projects necessary for channel maintenance during FY 1998. Therefore, NMFS believes that up to 35 loggerheads may be taken by injury or mortality, as well as 7 Kemp's ridleys, 7 green turtles, 2 hawksbills, and 5 shortnose sturgeon. These takes are not likely to jeopardize the continued existence of these species and the ongoing commitment by the COE to further minimize takes may reduce the likelihood of sea turtle takes in the future even if nearshore sea turtle abundances increase.

Conservation Recommendations
Pursuant to section 7(a)(1) of the ESA, conservation recommendations are made to assist COE in reducing or eliminating adverse impacts to loggerhead, green, and Kemp's ridley turtles that result from hopper dredging in the southeastern United States. The recommendations made in the 1995 BO are pertinent to this consultation as well, and therefore remain valid. Further recommendations are given below.

- Because of the possibility of annual variation in water temperatures, sea turtle abundance, and hopper dredging demand, NMFS has retained the dredging windows established in the 1995 BO. However, the COE has expressed a commitment to deploy hopper dredges during cold-water periods in channels with high sea turtle abundance or with substrates that render the deflector ineffective. NMFS appreciates the COE's commitment to do this, and recommends that the SAD priority list be finalized and distributed to the Districts and NMFS prior to the initiation of dredging during FY 1998.

- The COE should work with the dredging industry to insure their understanding of the importance of sea turtle conservation and to increase the industry's interest in minimizing sea turtle takes.

- Greater than 50% of the loggerheads taken in North Carolina may be from the northern nesting assemblage of loggerheads. While recent loggerhead nesting beach surveys did not identify a decline in the number of nesting females on beaches north of Cape Canaveral, increases observed in the south Florida nesting assemblage have not been noted. High sea turtle catch rates during only the early weeks of the wood debris clean-up conducted by COE off Cape Fear during 1997, as well as preliminary work conducted in North Carolina, suggest that turtles may be abundant in North Carolina channels primarily during migration into and emigration out of North Carolina inshore waters. The COE should work with the NMFS Beaufort Laboratory and the North Carolina Division of Marine Fisheries to document the movements of sea turtles off North Carolina during spring and fall months. Results from these studies may provide insights into further safe dredging windows to minimize the likelihood of takes of loggerheads from the more vulnerable northern nesting assemblage. Summer windows would reduce the pressure to complete all SAD hopper dredging during cold-water periods.

- The COE should investigate further modifications of the draghead to minimize the need for clean-up. Some method to level the peaks and valleys created by dredging would reduce the amount of time dragheads are removed from the bottom sediments.

Incidental Take Statement

Section 7(b)(4) of the Endangered Species Act (ESA) requires that when a proposed agency action is found to be consistent with section 7(a)(2) of the ESA, and the proposed action may incidentally take individuals of listed species, NMFS will issue a statement that specifies the impact of any incidental taking of endangered or threatened species. It also states that reasonable and prudent measures, and terms and conditions to implement the measures, be provided that are necessary to minimize such impacts. Only incidental taking resulting from the agency action, including incidental takings caused by activities approved by the agency, that are identified in this statement and that comply with the specified reasonable end prudent alternatives, and terms and conditions, are exempt from the takings prohibition of section 9(a), pursuant to section 7 of the ESA.

Based on the high rate of sea turtle takes observed during of 1997, increases in the Kemp's ridley population, possible increases in the benthic lifestages of loggerhead populations, annual variation in nearshore abundance of sea turtles and hopper dredge demands, the NMFS anticipates that hopper dredging in the Southeast U.S. Atlantic area of the SAD may result in the injury or mortality of sea turtles and shortnose sturgeon. Therefore, a low level of incidental take, and terms and conditions necessary to minimize and monitor takes, are established. The annual (by fiscal year) documented incidental take, by injury or mortality, of seven (7) Kemp's ridleys, seven (7) green turtles, two (2) hawksbills, thirty-five (35) loggerhead turtles, and five (5) shortnose sturgeon is set pursuant to section 7(b)(4) of the ESA.

To ensure that the specified levels of take are not exceeded early in any project, COE should reinitiate consultation for any project in which more than one turtle is taken within 24 hours, or once five or more turtles are taken. The Southeast Region, NMFS, will cooperate with COE in the review of such incidents to determine the need for developing further mitigation measures or to terminate the remaining dredging activity.

Section 7(b)(4)(c) of the ESA specifies that in order to provide an incidental take statement for an endangered or threatened species of marine mammal, the taking must be authorized under section 101(a)(5) of the Marine Mammal Protection Act of 1972 (MMPA). Since no incidental take in the Atlantic Region has been authorized under section 101(a)(5) of the MMPA, no statement on incidental take of endangered right whales is provided.

The reasonable and prudent measures that the NMFS believes are necessary to minimize the impact of hopper dredging in channels and borrow areas in the southeastern United States have been discussed with COE. The following terms and conditions are established, in addition to those identified in the 1995 BO, to implement these measures and to document the incidental take should such take occur.

1. The COE's draghead deflector engineer that assistant in this design design should inspect the rigid draghead deflector annually to ensure that the deflector has been tailored appropriately to each draghead. Additionally, the inspector should assess whether the dredge operator appears to be familiar with the operation of the draghead deflector and provide necessary training where appropriate.

2. If the rigid draghead deflector appears to be ineffective in Wilmington Harbor and slows the dredging project such that the amount of time the hopper dredge will be deployed is increased, the deflector should be removed from the draghead for that channel.

3. The COE should develop an educational/training program for dredge operators to increase their understanding of how the draghead deflector works and why it is necessary.

SOUTH ATLANTIC COAST HOPPER DREDGING (Calendar Year 97)					
Project	Dredge Period	Approximate Amount of Work Completed	Turtle Takes	Mitigative Measures Taken	Remarks
Kings Bay	3/1/97 to 3/12/97	Removed 437,000 out of 821,000 cy Approximately 53% completed.	L 3/2/97 L 3/4/97 L 3/5/97 L 3/6/97 L 3/6/97 L 3/6/97 L 3/8/97 L 3/8/97 L 3/12/97	Sea turtle deflecting draghead used. Jacksonville Dist. specialist inspected deflector on 3/6/97. Relocation trawling started 3/9/97. Extensive, ongoing consultation with NMFS as takes occurred. All work terminated 3/12/97 due to high take levels even though relocation trawling had become operational.	Water temp. 57 to 58 F. Dredge Eagle 1. Two takes in one batch on 3/6/97 and 3/8/97. Contract required removal of relatively small veneer of material. Most takes occurred through starboard dragarm. Rapidity of takes was a surprise to all concerned.
Brunswick Harbor	2/6/97 to 3/19/97	Removed 975,400 cy Work stopped at 50% completion	L 3/9/97	Sea turtle deflecting draghead used. Sea turtle abundance, based on visual observations, prompted termination of work because of potential for unacceptable levels of entrainment.	Water temp 63 F. Dredge RN Weeks. Historic abundance of sea turtles and high levels of entrainment in 1991 was part of the reason for termination of work.
Savannah Harbor	3/4/97 to 3/22/97	Removed about 545,500 cy, or about 52% of what could have been dredged	L 3/14/97 L 3/22/97 L 3/22/97	Sea turtle deflecting draghead used. Dredging terminated so as not to take any more sea turtles.	Water temp. 63 F. Numerous sea turtles sighted. Dredge Ouachita was 'skimming' high areas to bring depth to acceptable levels quickly before leaving for urgent work in Mississippi River.
Charleston Harbor	3/14/97 to 3/26/97	Bid qty 900,000 cy Req. qty 408,000 cy Removed qty 350,000 cy About 39% completed	L 3/19/97 L 3/20/97 L 3/21/97 L 3/25/97 L 3/26/97	WES expert / developer of sea turtle deflecting draghead system, conducted onboard Inspection and made recommendations. Some changes to draghead and dredging operation made. Relocation trawling performed.	Water temp. 61 F. Dredge Eagle 1.
Myrtle Beach borrow area (Phase 1)	9/15/96 to 5/13/97	Bid qty 2.5 million cy Work completed	L 4/15/97 L 5/04/97 L 5/09/97	Sea turtle deflecting draghead used. Relative abundance trawling on 3/28-29/97, with 12 hours of "nets in water", yielded one loggerhead. Trawling on 5/8 thru 5/13/97 yielded no sea turtles.	This is one of 3 phases / reaches of total project. Part of work in all phases is by pipeline dredge. Total quantity of material to be dredged is about 6 million CY
Morehead City Harbor	4/25/97 to 5/16/97)	About 120,000 cy removed out of about 1,720,000 cy About 7% of work completed	L 4/27/97 L 4/30/97 L 5/01/97 L 5/02/97 L 5/15/97 L 5/15/97	Sea turtle deflecting draghead. Relocation trawling began 5/8/97 and continued until termination of dredging. One loggerhead captured on 5/9/97. Nighttime trawling performed 5/10 & 5/11 with no turtles captured. Because of concern over extensive takes, dredging terminated with only 7 % of work done.	Dredge Manhatten Island

Wilmington Harbor (interior Channels)	2/14/97 to 3/13/97	About 217,300 cy removed Work completed	No takes		Dredge McFarland
MOTSU	3/14/97 to 4/3/97	About 60,000 cy removed Work completed	No takes		Dredge McFarland
Wilmington Harbor (Ocean Bar)	4/3/97 to 4/30/97	About 300,000 cy Work completed	L 4/07/97	Sea turtle deflecting draghead.	Dredge RN Weeks
Dade County Beach (Miami Reach)	3/30/97 7/20/97 (estimate)	About 380,00 of 475,000 cy completed as of 6/6/97	No takes	Based on past dredging and anecdotal information about sea turtlesin area, takes are not anticipated.	

L = Loggerhead cy = cubic yards

TABLE 2a. Sea turtle takes (includes live, injured and killed) observed on hopper dredges prior to the regional consultation. Observers were not required on all projects until 1989, after which extensive monitoring was required.

Colonel James W. Delaney, District Engineer
U. S. Army Engineer District, Wilmington
Post Office Box 1890
Wilmington, North Carolina 28402-1890

Attention: Mr. Mickey Sugg

Re: Bogue Banks Beach Restoration Project
Responses to National Marine Fisheries Service letter of June 25, 2001

Dear Colonel Deloney:

This letter is in response to comments in the June 25, 2001 letter to your office from Southeast Regional Office of National Marine Fisheries Service concerning plans to nourish 16.8 miles of ocean shoreline located in Carteret County, North Carolina (Action ID No. 2000003620). This letter addresses specific comments in the referenced letter.

In reference to the last sentence of the first page of the referenced letter, if the agencies know of less damaging alternatives and impact reduction opportunities that do not significantly alter the scope and costs of the project and are supported by quantitative research data, we request that those opportunities be revealed as soon as possible. Additionally, the Corps of Engineers has been implementing beach nourishment projects in North Carolina for over fifty years. We would expect to be held to the same standards of environmental protection in project implementation as applied to Corps of Engineers' projects.

Item 1. Sediment Compatibility:

We continue to disagree with the position of U. S. Fish and Wildlife Service that the sands proposed as beach fill material are not compatible. The Geotechnical Engineering Branch of the Corps of Engineers, Wilmington District, is currently reviewing the sand compatibility data. We expect that their review will be in agreement with our assessment of the borrow area sediments. It is an error to state that borrow sediments in borrow area B1 and B2 are exceptionally fine grained. As shown by the records of borings taken in the borrow areas and summarized in figures E8a, E8b and E9a (CSE, July 2001) mean grain size for composite samples from the borrow area A was 0.51 to 0.54 mm (coarse sand), 0.28 mm (medium sand) for borrow area B1 and 0.31 mm (medium sand) for borrow area B2. This compares with mean grain sizes for the native beach material composite samples of 0.30 mm (see table 5, Biological Assessment, July, 2001).

Percent mud for sand samples from borrow areas B1, B2 and A proposed for use does not exceed 4 percent. The standard the Corps of Engineers uses for beach compatible sand is 10 percent mud content (percent passing the No. 200 sieve).

The accepted standard for quantifying compatibility is the overfill factor, R_A (CERC 1984). This is a measure of how similar a borrow sediment is to the native beach. Section 3 of the Biological Assessment reports R_A=s for individual borrow samples ranging from <1.02 to >10.0 with means of about 1.15 in revised borrow area A, 1.58 in revised borrow area B1, and 1.50 in revised borrow area B2. As shown in Section 4 of the Biological Assessment, by combining sediments from borrow area A with those in borrow areas B1 and B2 in proportions of approximately 1:2, a composite R_A of about 1.3-1.35 results. Shell content for an example composite of 62 borings is approximately 32 percent (see Biological

Assessment, Table 5 and Appendix A). A further advantage of the borrow areas chosen is the slightly broader size distribution than the native sediment. This is important from an engineering standpoint because it means the borrow sediment will be more stable and last longer, a primary goal of the project. Borrow areas with narrow size distributions will generally not perform as well even if the mean grain size matches the native sediment (USACE 1995a).

The example composite size distribution of 62 borings from borrow areas A, B1, and B2 is expected to be modified favorably after placement on the beach because of the following factors:

- Construction by hopper dredge (the 95 percent most probable dredging method) will eliminate nearly all mud before pump-out onto the beach (D. Hussin, Great Lakes Dredge & Dock, pers. comm., April 2001), thus shifting the mean grain size to a slightly coarser value.

- Shell material in the cores contains high proportions of friable thin shell (eg, *Donax* sp.) which will be broken into smaller shell hash fragments in the swash zone, narrowing the size distribution.

- Natural sorting in the littoral zone of a broad distribution of sediments will maintain the distinct difference between the offshore bar (fine sand), beach face (medium to coarse sand and shell), and dune (fine sand). Presently, there are portions of the profile such as the horns of beach cusps containing >70 percent shell material.

The proposed borrow areas have been selected to provide sediments that are compatible with the native beach. The borrow materials identified for this project are more compatible than sands placed on Atlantic Beach or Pine Knoll Shores by the Corps of Engineers as part of past nourishment projects. This project meets a higher standard, but at the same time, should not be held to a higher standard than Corps of Engineers projects.

With reference to the calcium carbonate content of the sediments, none of the sediments to be dredged and placed on the beach are highly reactive. While calcium carbonate material breaks down much faster than quartz and feldspar, the process is not rapid. Shell fragments from the borrow area would require many decades to centuries to break down completely and dissipate from the beach as well as an overburden to provide pressure to consolidate the sand. Cementation is not likely to occur, because the fill will be placed within the active surf zone and will not contain high proportions of muddy material. Hydraulic fills have the advantage of producing a slurry that runs down the profile during construction. Fine-grained material is selectively sorted and winnowed in the surf during placement. The natural flooding of the beach by different wave and storm events provides a periodic washing of the sand that flushes the calcium carbonate from the sands. Reports of sites (eg, Edisto Beach, SC) where cementation may have occurred generally involved placement of unwashed sediments above the spring swash line where the periodic flushing does not occur.

With regard to re-establishment of beach organisms essential to health of recreational and commercial fish species, There have been numerous studies of environmental impacts of beach nourishment projects over the past 20 years. The majority of beach nourishment projects have had no long-term environmental effects when compatible, low silt/clay materials are used, when borrow sites are properly selected, and when proper timing is adhered to.

Lankford and Baca (1989) and Baca et al (1991) published two articles summarizing the findings of available literature relative to the severity of impacts from various forms of beach nourishment. They found that impacts to beach sites were few and short-lived but that impacts to borrow sites were more long-lived (Table 9).

TABLE 9. Impacts to various communities as a result of different types of beach nourishment methods. (H = high impacts M = medium impacts L= low impacts)

IMPACTS	TO BEACH OR BORROW SITE	OFFSHORE DREDGING	NEARSHORE DREDGING	SHOAL SCRAPING
Benthic macro-invertebrates	Borrow	M	H	M
Reefs and hardbottoms	Borrow	M	M	L
Fisheries	Borrow	M	M	L
Turtle nesting	Beach	L	L	L
Bird nesting	Beach	L	L	L
Diversity/richness	Borrow	M	H	L
Commercial/recreational value	Borrow	M	H	L

Macro-invertebrates, diversities, and commercial/recreational values were impacted by nearshore dredging. Importantly, however, "high" is relative as these impacts were not significant or long-lived in most cases (reviewed in Lankford and Baca 1989). In a recent South Carolina study comparing predredging (CSA 1999) and postdredging impacts (CSA 2000) on offshore areas, although impacts were noticeable, they had virtually disappeared after one year.

Most of the monitoring studies of beach nourishment projects in the southeastern United States show that macro-invertebrate community recovery is rapid once dredging and filling have ceased (Saloman 1974, Cutler and Mahadevan 1982, Naqvi and Pullen 1982, Gorzelany 1983, Reilly and Bellis 1983, Gorzelany and Nelson 1987, Hurme and Pullen 1988). Within the caveate of proper borrow-site selection and compatible, low silt/clay material, there is no research which contradicts this statement. Recent experience with Florida and New Jersey projects also supports these findings.

In recent years, there have been a few papers published which suggest possible long-term and/or significant impacts to certain species (eg, Donaghue 1999, Peterson et al 2000). These papers have been selectively referenced by the agencies as evidence of unacceptable impacts to biological resources due to nourished beaches. Some clarification of the exact nature of the nourishment projects upon which these studies were based is appropriate. These studies (Donaghue, 1999, and Peterson et al, 2000) describe impacts to populations of *Donax* and *Emerita* for nourishment cases quite different than the proposed project. Donaghue observed declines at Pea Island on a beach that was nourished almost yearly over a seven-year period, leaving little time for recovery before the next fill in a one-mile reach. The Peterson et al study at Bogue Banks examined the impacts from placement on the beach of highly non-compatible, muddy sediments from dredging of the Atlantic Intracoastal Waterway on the north side of Bogue Sound. Mean grain size of the fill was 3.67φ, 0.070 mm (very fine sand), which is nearly in the silt range and nearly five times finer than the mean grain size proposed for this Bogue Banks project.

These papers do illustrate practices to be avoided in the implementation of a beach nourishment project that results in the minimum impacts to biological resources, i.e., frequent re-nourishment and nourishment with non-compatible fine sediments.

Item 2. Clarification of the Project Schedule and Nourishment Quantities:

The proposed project consists of excavating by hydraulic dredge up to 6.7 million cubic yards of beach-quality sediment from ocean borrow areas situated 0.5 to 3.0 miles offshore of the project area. Sediment would be pumped onto the beach between the toe of the existing dune and the low water line and shaped by bulldozers into a profile that closely matches the natural beach. Approximately 50 percent of the excavations would be deposited by run-out from the discharge point between mean low water and the outer bar (~500 ft offshore). Typical fill sections would add ~44 to 113 cubic yards per linear foot (cy/ft) of beach and advance the shoreline 50 to 125 ft. The work would be performed in phases covering all or portions of each of six designated reaches according to the following schedule (subject to local funding availability).

- ***Phase I*** (funding approved) - Reaches 4, 5, and 6 - Towns of Pine Knoll Shores and Indian Beach - 7.2 miles - up to 3.1 million cubic yards* - November 2001 to April 2002.

- ***Phase II*** (subject to funding) - Reach 3 and eastern half of Reach 2 - Town of Emerald Isle - 3.0 miles - up to 1.7 million cubic yards* - November 2002 to April 2003.

- ***Phase III*** (subject to funding) - Reach 1 and western half of Reach 2 - Town of Emerald Isle - 6.7 miles - up to 1.9 million cubic yards* - November 2003 to April 2004 (or later environmental window).

As described above, the proposed project has been revised in anticipation of phased construction over at least three years (i.e., three environmental windows). Three borrow areas (A, B1, and B2) will be used, but excavations will be limited to specific areas within A, B1, and B2 (shown on Figs 26-27 of the Biological Assessment). Fill sections will involve up to the indicated volumes given in the permit application but may be less depending on final construction bids because the project funding is fixed. Representative fill sections are given in the permit application. The fill sections shown in the permit application indicate a base fill volume (based on the ~4.5 million cubic yard volume deficit) and an additional "overfill" volume representing the additional quantity needed to match the performance of the native beach. The final project volume and section volumes cannot be known with certainty until bids are received and compared with the budget available for each phase. Based on best-available information, the proposed project will be executed as follows.

Phase I - Reaches 4, 5, and 6 - Towns of Pine Knoll Shores and Indian Beach (transects 48-77). See sheets 3d, 3e, 3f, 7, 8, and 9 of the permit application.

Dates of Construction: 1 November 2001 through 30 April 2002.

Borrow areas: B1, B2, and A within the revised areas and sections shown in Figures 26-30 of the Biological Assessment. Approximately 65 percent of the fill will be obtained from B1 and B2 and 35 percent will be obtained from A.

Estimated Phase I volumes:

	Initial Base Volume (cy)	Advance Nourishment Plus Overfill Volume (cy)	Total Volume (cy)
Reach 4	550,000	440,000	990,000
Reach 5	480,000	240,000	720,000

Reach 6	905,000	445,000	1,350,000
Phase I Total			3,060,000

Phase I dimensions:

	Depth of Cut (ft)	Volume Cubic Yards (%)	Areas (acres / sq. miles)
Borrow area A	~2	1,071,000 (35)	332 / 0.52
Borrow areas B1 and B2	~3	1,989,000 (65)	411 / 0.64
Phase I Total		3,060,000 (100)	743 / 1.16

Beach Area	Length (ft)	Avg. Unit Volume (cy/ft)	Estimated Added Dry Beach Width (ft)	Estimated Added Dry Beach (acres)
Reach 4	13,400	73.9	82	25.2
Reach 5	8,800	81.8	91	18.4
Reach 6	15,400	87.7	97	34.3
Phase I Total	35,600(~7.1 miles)			77.9

Inshore (Surf Zone) Areas	Average Width Impacted by Direct Filling (ft)	Area (acres)
Reach 4	525	161
Reach 5	510	103
Reach 6	525	186
Phase I Total		450

Time required for construction: ~153 days (at 20,000 cubic yards per day average)

Average production per day: ~250 ft

Fill sequence (anticipated):

Begin Phase I in Reach 5 - Pine Knoll Shores West to avoid November surf fishery in Atlantic Beach
Fill Reach 5 @ ~1,800 ft per week (impacted areas)
Fill Reach 6 - Pine Knoll Shores East
Fill Reach 4 - Indian Beach
End Phase I

Type of equipment and construction sequence: Hydraulic dredge

There are an estimated 20 self-propelled hopper dredges and one shallow-cut suction dredge certified to perform work of this type in the U.S. Therefore, there is a 95 percent probability that the type of equipment used will by a self-propelled hopper dredge. Hopper dredges excavate borrow areas, then travel to an inshore site about 1,000 ft offshore where they connect to a temporary pipeline. From there, slurry of sediment and water is pumped to shore and distributed in sections along the beach. Sediment is discharged parallel to the shore and semi-contained by low berms. The slurry runs alongshore and down-profile, carrying finer grained sediments into the surf where it is mixed and sorted by waves. Clay-sized particles dissipate beyond the surf zone and silts and very fine sands tend to settle beyond the outer bar. The balance settles in the trough or in the new berm. After completion of ~1-2 miles, the landing pipe from offshore is moved to a new locality. The area just filled is graded to the final slopes (matching the natural beach elevation and slopes above high water) and then left to adjust naturally. Typically, a given 1-2 mile reach is only impacted by construction activities for approximately one month, and then the operation moves to another reach.

Phase II - Reach 3 and portions of Reach 2 - Emerald Isle East and Emerald Isle Central (ie, Indian Beach/Emerald Isle town line at transect 48 to ~30th Street at transect 34). See sheets 3b, 3c, 5, and 6 of the permit application.

Anticipated dates for construction: 1 November 2002 through 30 April 2003.

Borrow areas: B1, B2, and A within the revised areas and sections shown in Figures 26-30 of the Biological Assessment. Approximately 65 percent of the fill will be obtained from B1 and B2 and 35 percent will be obtained from A.

Estimated Phase II volumes:

	Initial Base Volume (cy)	Advance Nourishment Plus Overfill Volume (cy)	Total Volume (cy)
Reach 3	970,000	485,000	1,455,000
Reach 2 (east part)	150,000	75,000	225,000
Phase II Total	1,120,000	560,0000	1,680,000

Phase II dimensions:

	Depth of Cut (ft)	Volume Cubic Yards (%)	Areas (acres / sq. miles)
Borrow area A	~2	588,000 (35)	182 / 0.285
Borrow areas B2 and B1	~3	1,092,000 (65)	226 / 0.353
Phase II Total		1,680,000 (100)	408 / 0.638

Beach Area	Length (ft)	Avg. Unit Volume (cy/ft)	Estimated Added Dry Beach Width (ft)	Estimated Added Dry Beach (acres)
Reach 3	12,900	112.8	125	37.0
Reach 2 (east part)	2,800	80.4	89	5.7
Phase II Total	15,700(3.0 miles)			42.7

Inshore (Surf Zone) Areas	Average Width Impacted by Direct Filling (ft)	Area (acres)
Reach 3	575	~170
Reach 2 (east part)	475	~30
Phase II Total		200

Time required for construction: ~112 days (at 15,000 cubic yards per day average)

Average production per day: ~140 ft

Fill sequence (anticipated):

Begin Phase II at east end of Reach 3 (Indian Beach/Emerald Isle town line at transect 48)
Fill Reach 3
Fill eastern 2,800 ft of Reach 2 ending at 30th Street (~transect 34)
End Phase II

Type of equipment: Hydraulic dredge

Phase II (Reach 3 and part of Reach 2) represents 17.9 percent of the total project length and 25.1 percent of the total project volume.

Phase III - Remainder of Reach 2 from 30th Street (transect 34) to Ebb Tide Drive (transect 25) and all or portions of Reach 1 (Ebb Tide Drive to Shipwreck Lane, transect 8) - Central and Western Emerald Isle.

Anticipated dates for construction: 1 November 2003 through 30 April 2004.

Borrow areas: B1, B2, and A within the revised areas and sections shown in Figures 26-30. Approximately 65 percent of the fill will be obtained from B1 and B2 and 35 percent will be obtained from A.

Estimated Phase III volumes:

	Initial Base Volume (cy)	Advance Nourishment Plus Overfill Volume (cy)	Total Volume (cy)
Reach 2 (west part)	617,000	308,000	925,000
Reach 1	753,000	282,000	1,035,000
Phase III Total	1,370,000	590,000	1,960,000

Phase III dimensions:

	Depth of Cut (ft)	Volume Cubic Yards (%)	Areas (acres / sq. miles)
Borrow area A	~2	686,000 (35)	212 / 0.33
Borrow areas B2 and B1	~3	1,274,000 (65)	263 / 0.41
Phase III Total		1,960,000 (100)	475 / 0.74

Beach Area	Length (ft)	Avg. Unit Volume (cy/ft)	Estimated Added Dry Beach Width (ft)	Estimated Added Dry Beach (acres)
Reach 2 (west part)	11,700	79.1	88	23.6
Reach 1	23,700	43.7	49	26.7
Phase III Total	35,400(6.7 miles)			50.3

Inshore (Surf Zone) Areas	Average Width Impacted by Direct Filling (ft)	Area (acres)
Reach 2 (west part)	425	114
Reach 1	425	231
Phase III Total		345

Time required for construction: ~130 days

Average production per day: 270 ft

Fill sequence: To be determined upon review of conditions around time of construction

Type of equipment: Hydraulic dredge

Phase III (Reach 1 and the west part of Reach 2) represents 39.9 percent of the total project length and 29.3 percent of the total project volume.

Summary

Phase I: Reaches 4, 5, and 6 - 3,060,000 cy - Nov 2001 - Apr 2002
Transects 48 to 77 (Pine Knoll Shores and Indian Beach town limits)
37,600 linear feet (7.1 miles)

Phase II: Reach 3 and 2,800 ft of Reach 2 - 1,680,000 cy - Nov 2002 - Apr 2003
Transects 34 to 48 (eastern Emerald Isle, 1st Street to 30th Street)
15,700 linear feet (3.0 miles)

Phase III: Reach 1 and remainder of Reach 2 - 1,960,000 cy - Future
Transects 8 to 34 (western and central Emerald Isle, Shipwreck Lane to 30th Street)
35,400 linear feet (6.7 miles)

Totals: Reaches 1 through 6 - 6,700,000 cy
Transects 8 to 77 [Shipwreck Lane (Emerald Isle) to Atlantic Beach town line)
88,700 linear feet (16.8 miles)

See Appendix B of the Biological Assessment, the Permit Application, for detailed maps and cross-sections of the proposed project.

Item 3. Maintenance Work to the Project During Its Ten year Life:

The frequency and magnitude of the maintenance work that might be required to the project is dependent solely upon the frequency of Hurricane and extreme storm events with winds and waves that cause significant damage to the project. Naturally, the frequency and magnitude of these events cannot be predicted. If maintenance dredging and beach filling are required, it would be done under the guidelines established in the state and federal permits for the proposed project. The time of year, borrow area location, and other criteria set forth in the permits would be followed. The Corps of Engineers and the N.C. Division of Coastal Management would also have to approve any maintenance work because it would represent a deviation from the three phased implementation plan for the project.

Item 4. Fine Grained Materials in Borrow Areas B1 and B2:

It is an error to identify materials in borrow areas B1 and B2 as having high levels of fine grained materials. Fine-grained materials that produce elevated turbidity levels are those sediments with very low settling velocities (i.e., clays and silts). As previously stated in the SEPA EIS and Biological Assessment, the proposed borrow area tests an average of less than 4 percent mud (percent passing the No. 200 sieve). Fine and very fine sand in the borrow areas produce short term increases in suspended sediment and is generally not considered to result in adverse impacts to biota given settling times that are much shorter than the silt and clay sediments.

In the New Jersey Study (USACE, 2001) turbidity measurements indicated that the effects of beach fill operations on short-term turbidity appeared to be limited to a relatively narrow swash of beach front (less than 500 m). Borrow sediments in the New Jersey project contained a silt and clay fraction generally less than 10 percent by weight. The clay/silt fraction in the sediments proposed for nourishment of Bogue banks is 4 percent or less.

Another finding in the New Jersey study was that measurements of turbidity at stations located far from the filling operations showed that maximum NTU values measured near the fill operations did not appear to be outside the range that organisms would be exposed to during periods of high wave energies. This agrees with the EIS that turbidity associated with the nourishment operations will probably not exceed background levels during periods of high wave energy at the beach.

Van Dolah et al. (1992) assessed turbidity conditions associated with a beach nourishment project at Hilton Head, South Carolina. They concluded that elevated turbidity was restricted to a small area near the discharge point during periods of active nourishment operations. Van Dolah et al. (1994) reached similar conclusions for a study of beach nourishment effects at Folly Beach, South Carolina. The spatial extent of the turbid plume in this study, as determined by measurements of NTUs, extended approximately 1,000 m (~3,300 feet) in the direction of longshore current a distance of 15m (~49 feet) from shore, and 500 m (~1,650 feet) at a distance of 30 m (~98 feet) from shore. Turbidity levels varied depending on local wind and wave conditions. During periods of calm winds and seas, turbidities of about

100 NTUs were measured near the discharge. With strong winds and turbulent waves, turbidities increased to 200 NTUs within 300 m (~984 feet) of the discharge. Van Dolah et al. (1994) stated that background turbidities approached 100 NTUs during episodes of storm generated turbulence. They concluded that, "Although dredge effluent does increase turbidity levels in the immediate vicinity of the outfall, there are many other factors such as local weather and wave energy that will also produce this effect. The turbidity levels found at Folly Beach during nourishment and the dispersal of the sediment plume were not considered unusual or severe relative to normal fluctuations of background levels."(USACE, 2001).

Item 5. Offshore Movement of Fill Sediments:

The shape and slope of beach profiles evolves in relation to wave energy and sediment grain size (Bascom 1951; Komar 1976). Tide range also plays an important role because it controls the elevations over which waves act on the profile. Where sediments are uniform across the foreshore, there tends to be less topography, particularly in the fine to very fine sand ranges. But in settings like Bogue Banks where there is a relatively broad range of sediment grain sizes, profiles have more complex morphology. Bars and troughs are more common and berms tend to be more mobile (Hayes 1976). By using a graded deposit of similar-sized sediments from borrow areas A, B1, and B2, waves will adjust the nourished profile to a morphology similar to the existing beach. Nourishment will displace the profile seaward (including the offshore bar and trough) and not simply infill the trough as depicted on reference cross-sections in the permit application.

If a narrow, borrow size distribution were used, the resulting profile would be more uniform. The profile illustrations in the permit application are idealized to show the relative scale of the fill sections. These are easier to visualize than a complex profile that will develop across the littoral zone to closure depth (approximately -30 ft NGVD).

Hardbottom impacts are addressed below.

CSE has collected sediment cores over a grid offshore of the project area covering some 16 miles along shore and 2.5 miles offshore of the project area (See figure 5, EIS, Appendix E). In only two locations was exposed hard bottom discovered, at the location of cores C20a1 and C20a2, offshore of Emerald Isle, reach 2. These locations are 4000 and 13,000 feet from the beach respectively, well outside the littoral zone. There is no research to support the claim of NMFS that fine sediments from the nourished beach will bury and adversely impact the hard bottom habitats. The contrary may be true based on findings of the New Jersey study. The New Jersey study (USACE, 2001) found that the turbid plume from the nourishment operations area extended less than 500 m (1,640 feet) in the direction of longshore transport in the swash zone and dispersed rapidly across the surf zone. The proposed fill materials contain such a small percentage of clay and silt sized sediment that relocation of these sediments from the offshore zone to the littoral zone should not result in an increase in the rate of change of movement of fine sediments in the offshore area.

Item 6. Coordination with NMFS Protected Resource Division:

Endangered species coordination with the Protected Resource Division was completed on July 26, 2001 with a letter from Joseph E. Powers, Acting Regional Administrator, National Marine Fisheries Service, St. Petersburg, Florida, to Colonel James W. Deloney, District Engineer, Wilmington District.

Hardbottom EFH Impacts:

With regard to hardbottom impacts, the closure depth, the depth that defines the seaward limit of sediment transport in the littoral zone, has been estimated at –30 feet, NGVD. The bottom seaward of the closure depth remains dynamic but to a much lesser degree than the littoral zone. There is ongoing redistribution of muddy surficial sediments in the offshore areas associated with suspension and settling related to waves and local currents. Exposed hardbottom areas are, more than likely, ephemeral, subject to periodic burial and exposure by free mud layers that are known to exist and move around over sandy and hard bottoms in deeper water well beyond the depth of closure (i.e. the cross-shore advection limit of the fill).

Seasonal Restrictions on Dredging:

It is proposed that the Bogue Banks project honor existing protocols outlined in the regional Biological Opinion of 1997 between the NMFS and the Corps of Engineers for the Southeastern coast of the United States. From the standpoint of NMFS, hopper dredging would be permitted year round as long as the dredge intakes are equipped with turtle exclusionary devices and monitors are stationed on the dredges. NMFS imposes no seasonal restrictions on hydraulic dredge operations. Even though these operational criteria are valid for the offshore, or intake, portions of the project, restrictions on the upland work are more restrictive. The protocol for the upland, beach, work will require that dredging be based on the protocol agreement between the Corps of Engineers and the U. S. Fish and Wildlife Service. These restrictions require that no work be performed on the beach after May 1 due to the potential for nesting sea turtles, and after April 1 in areas where there is a potential for nesting piping plovers. It is upon these restrictions and upon negotiations with the N. C. Division of Marine Fisheries during preparation of the SEPA EIS, that the proposed window of November 1 to April 30 was based. We feel that, as long as the criteria outlined in the Regional Biological Assessments are met, the proposed dredging window remains valid.

Monitoring Plan:

The Monitoring plan is in the process of being revised in accordance with the comments from the meeting at NMFS at Pivers Island on July 16, 2001. The results of the June sampling of beach and borrow area resources are being evaluated in order that design of the study can be modified so the results will be statistically significant. The comments provided by Charles H. (Pete) Peterson in his letter of 3 June, 2001 will be addressed in the Monitoring Plan to be submitted following this letter. We are insisting that the final plan provide specific details of the plan that will enable the plan to be used for compliance purposes by the Corps of Engineers.

The applicants agree to a phased implementation of the project as described under item 2 above. The applicants will not agree to make the implementation of phases 2 and 3 contingent upon the outcome of the environmental monitoring of phase 1. This is an unreasonable requirement without precedent on Corps of Engineers projects. This requirement subjects the co-applicant municipality, Emerald Isle, to the possibility that their project cannot be performed while Pine Knoll Shores and Indian Beach gain the benefits of a protective beach. Further, in keeping with best management practices, the applicants have defined the entire scope of the work instead of submitting piece meal applications for various reaches. The criteria and need for nourishment is uniform and rational for the six reaches. There is no basis, in our opinion, to hold one or more reaches to a different standard than others.

EFH Conservation Requirements:

1. Timing of Dredging and Filling: This is addressed above under Seasonal Restrictions on Dredging.

2. Sand Compatibility: We feel that there has been adequate evidence provided to the federal agencies that the borrow material proposed for use is compatible. The monitoring plan will include sampling of post dredging beach sediment samples to verify that this criteria is being met. We also feel that a review of the sand compatibility by the Corps of Engineers will confirm the evidence presented to date.

3. Monitoring Plan Statistical Validity: The Monitoring plan in preparation will include analyses of data from the June Sampling event and a plan design based on statistical analyses of that data that will ensure that results are statistically significant.

4. The exact locations of the borrow areas to be used is addressed in item 2 above.

5. The Bogue Banks project is a large project and will have impacts on aquatic resources. We feel that adequate evidence has been presented to the federal agencies that the project will be implemented in such a manner as to minimize the impacts and to quantify impacts to some important resources. Additionally, we feel that sufficient information has been referenced on the results of the studies of others on the biological impacts of beach nourishment to provide a level of confidence that the proposed project is being implemented using "Best Management Practices" developed as a result of those studies. Finally, the project is being implemented based on existing dredging protocols developed based on regional Biological Opinions of the NMFS and USFWS in conjunction with the Corps of Engineers.

As indicated above, the applicants prefer a phased implementation of the project as described under item 2 above. The applicants will not agree to make the implementation of phases 2 and 3 contingent upon the outcome of the environmental monitoring of phase 1. This is an unreasonable requirement without precedent on Corps of Engineers projects or other projects that we are aware of.

This response was prepared by Coastal Science and Engineering, Morehead City. Comments related to this response should be directed to CSE at the address shown above.

RE: Carteret County – Bogue Banks Beach Restoration Project – USACE Action ID# 200000362]
Biological Monitoring

Dear Mickey:

I am writing to update you on the status of our plans for biological monitoring of the above-referenced project. Following is a chronology of events in this regard and copies* of relevant correspondence and reports. The purpose of this file is to document for your agency the efforts that the applicants have made to initiate biological monitoring of the project.

October 1999	– Carteret County contracted with UNC-IMS (Dr. Peterson) to design a monitoring program and perform initial offshore sampling. Beach sampling not contracted because of ongoing but incomplete study by IMS student.
November 1999	– Fall borrow area sampling by IMS.
February 2000	– Supplementary fish samplings by IMS.
6 March 2000	– Draft SEPA EIS submitted to NCDENR
21 March 2000	– County funding referendum fails – limited funds available to continue with EIS/permitting.
* 6 April 2000	– (received by CSE 5 April 2001) Beach sampling study: "Effectiveness of Beach Bulldozing Against Shoreline Erosion and the Impacts of Bulldozing on Biological Resources" by Peterson, Wells, Manning, and Conaway.
* 10 May 2000	– Draft IMS report on initial fall-winter samplings (7 pp + appendices).
* 18 May 2000	– CSE comments on draft IMS report (6 pp).
11 September 2000	– Revised IMS biological monitoring report submitted (13 pp + appendices) incorporated into EIS as Appendix C.

CSE

16 October 2000 – CSE contracted by Town of Pine Knoll Shores for final design of reaches 5 and 6 of county plan.

31 October 2000 – Second draft EIS submitted incorporating comments and responses to NCDENR reviews.

29 December 2000 – CSE contracted by Town of Indian Beach for final design of reach 4 of county plan.

24 January 2001 – Permit application for county project (six reaches, 16.8 miles) submitted to CAMA and USACE.

* 28 February 2001 – USACE informs Carteret County that the permit application should include individual municipalities as co-applicants.

16 March 2001 – Public notice issued by USACE on Bogue Banks permit application (Action ID 200000362).

* 2 April 2001 – Dr. Peterson informs CSE that he can no longer be engaged in the environmental monitoring of Bogue Banks.

4 April 2001 – Final SEPA EIS incorporating comments and responses from all state agencies.

10 April 2001 – Town of Pine Knoll Shores establishes a budget NTE $150,000 for biological monitoring in connection with reaches 5 and 6.

* 18 April 2001 – Coastal Science Associates Inc (CSA) (Dr. Bart Baca) submits draft proposal for pre and postmonitoring within budget parameters established by Pine Knoll Shores.

* 9 May 2001 – (received by CSE and CSA on 18 May) Dr. Peterson's comments on draft CSA monitoring plan submitted to NC Division of Marine Fisheries.

11 May 2001 – Interagency meeting with USACE, USFWS, NMFS, applicants, CSE, CSA, and Dr. Peterson.

* 28 May 2001 – Revised CSA biological monitoring proposal received by CSE.

* 3 June 2001 – Dr. Peterson's comments on revised CSA monitoring proposal.

* 8 June 2001 – CSE letter to Pine Knoll Shores recommending authorization of initial spring sampling immediately.

CSE

11 June 2001 – Pine Knoll Shores authorizes initial spring sampling following CSA's revised proposal plus modifications as outlined in 8 June letter by CSE.

16 June 2001 – CSA initiates offshore and beach sampling as outlined in their revised proposal and CSE's 8 June letter.

CSA representatives will be available this week to meet with NMFS in Morehead City and discuss the specific sampling and analysis plan. The work that we are initiating this month will follow standard methodology and accepted protocols for statistical design.

CSA has completed environmental monitoring projects for many nourishment projects (eg, Myrtle Beach, Pawleys Island, Seabrook Island, and Hunting Island) and has had to comply with requirements of the States of Florida and South Carolina, as well as other jurisdictions in regard to sampling design and analyses. I am asking that your agency advise us as soon as possible on any specific sampling requirements of the federal government for the proposed project so that we can develop an appropriate scope of work and budget. We anticipate accomplishing a significant level of monitoring commensurate with the overall scope of the project.

Thank you for your consideration.

Yours truly,

Timothy W Kana PhD
Project Director

Dear Bob and Tim:

Please find enclosed our Final Report on the "Bogue Banks beach renourishment project: Late fall 1999 assessment of benthic invertebrate and demersal fish resources in the offshore mining sites prior to sand mining." We have included Appendices with all the raw data to allow any future recalculations or analyses. Because no subsequent spring sampling has taken place, the report is quite descriptive and does not involve any analysis of impacts. The assessment should serve well as a late fall baseline for assessing impacts of any future mining of sediments at the proposed borrow areas.

Please direct any questions to us if clarifications are necessary.

Sincerely,

Pete

1. Background

There are several environmental issues relating to the benthic habitat and biological resources that arise in considering a beach renourishment project for Bogue Banks. The most significant include: (1) impacts to and recovery of the benthic invertebrate community at the borrow areas; (2) potential impacts to commercially or recreationally important demersal fishes and crustaceans in part because of these effects on their benthic invertebrate prey; (3) impacts to and recovery of the benthic invertebrate community on the intertidal and shallow subtidal beach; and (4) potential impacts to commercially and recreationally important fishes in the surf zone and/or shorebirds in large part because of these effects on their benthic invertebrate prey and because of enhanced turbidity along the shoreline.

Each of these issues deserves evaluation and requires some field monitoring before and after renourishment to evaluate the resulting impacts. Because the benthic invertebrate community at the offshore borrow sites changes across the seasons, it is appropriate to sample in multiple seasons (fall and spring) both before and after the renourishment project to assess impacts and recovery. Because renourishment was originally planned for winter 2000-2001, an initial set of samples was collected in the late fall of 1999 to provide fall baseline data to characterize the benthic invertebrate community at the prospective offshore borrow sites and at nearby control sites that were not planned to be mined prior to any disturbance from the renourishment project. This report includes a description of results from an analysis of the fall 1999 samples. We also include here a complete analysis of composition of surface sediment samples in each of the borrow sites and control sites so as to characterize the sedimentary habitat in which the invertebrates live. Sedimentary habitat is the prime factor that controls abundance and composition of soft-bottom invertebrate communities. The invertebrate sampling needs to be repeated in a spring prior to any sand mining, and then possibly in fall and spring of each year after mining until sufficient recovery has been documented. Sediment sampling must also be repeated after the mining has occurred to evaluate potential impacts on the sedimentary habitat and subsequent recovery, but an annual frequency should suffice for monitoring of sediment character.

The test of the impact of removing sand from the three "Borrow Areas" A, B1, and B2 (Fig, 1) requires the use of a BACI (Before-After-Control-Impact) experimental design. Samples from impact (Borrow) areas will be compared with those from control (undisturbed) areas both before and after the sand is removed. (Control areas would have no sand removed but would otherwise be affected by all other impacts, i.e. storms, shrimping, etc., that affect the impact area.) These samples taken before the removal of the sand can be compared with identically conducted samplings made after sand mining to evaluate impacts. In addition, the design also calls for spring sampling both before and after the removal of sand to assess the seasonal component, for a minimum of 4 sampling periods to complete the assessment of impacts. This report describes only the first of those samplings. The study does not include any spring sampling of the Borrow Areas or any sampling of the intertidal beaches.

Assessment of the significance of the offshore mining of sands for the renourishment also involves evaluation of potential impacts on demersal fishes and crustaceans at the borrow site. Impacts could occur directly during sand mining and indirectly through modification of the prey community. This effect on prey could last for some unknown time. The fish and crustacean community also changes seasonally so sampling is needed to document presence and relative abundance of demersal fish and crustaceans and to describe their utilization of benthic invertebrate prey. Trawl sampling was first conducted in late fall 1999, coincident with the sampling of the benthos. We conducted one additional trawl sampling in early February 2000 to document over-winter use of the Borrow Areas by fishes. This should be repeated in one or more springs to document the date of seasonal return of fishes to the site. Our analysis includes not only the information on fish and crustacean abundances on the two dates but also a description of their diet from gut contents in the late fall 1999 collection.

No sampling has yet taken place to serve as the before-renourishment monitoring data for the intertidal invertebrates of Bogue Banks beaches or for sea turtles. The invertebrate community of the intertidal beaches is › strongly seasonal and dynamic within the warm season that sampling to provide baseline information should occur throughout the warm season, with subsequent identically designed sampling to assess potential impacts and recovery but after the project has been completed. The complete design for such beach monitoring would include "before and after" sampling of control beaches where no renourishment occurs.

2. Description of Sampling and Analytic Methodologies

A. Benthic Prey Resources

Two hundred core samples were collected during late fall of 1999 (12-22 November) to characterize the invertebrate macrofauna at all three prospective borrow sites and at control sites near each borrow site (Fig. 1). Ten replicate core samples were taken at each of six sites in Borrow Area A and at each of two sites from Borrow Area B-1 and Borrow Area B-2. Ten replicate cores were also taken at each of ten control sites: six around Borrow Area A and two near each Borrow Area B site. Exact locations of each site were determined using a handheld GPS with differential receiver (Table 1). Water depths ranged from 35 feet at the inshore sites and 47-49 feet at the offshore sites. Cores were taken by divers using a cylindrical corer 9.9 cm in internal diameter (each covering a surface area of 76.4 cm^2) with 500-µm mesh across the top to prevent loss of surface animals. Replicates were haphazardly positioned at each systematically distributed (see Fig. 1) sample station within a 3-m^2 area. All core samples were taken to a depth of 10 cm. After being transported to the boat, the contents were emptied from the core tubes into plastic bags, labeled, and sealed. Immediately upon returning to the lab, the material from the cores was sieved through a 500-µm mesh. Material retained on the sieve was preserved in a 5% aqueous solution of buffered formalin. Rose Bengal vital stain was added to the samples to facilitate sorting. After a week, the formalin was drained off through a 500-µm sieve and replaced with 70% ethanol. Subsequently, animals were separated from detritus by hand picking and identified to family. Several benthic impact studies including especially those by Warwick (1988) of IMER in Plymouth, England have demonstrated that analysis of response at the level of family preserves all the information about community patterns without the high costs of proceeding to species-level.

At the same time that the macrofaunal cores were taken, divers collected three 2.65cm-diameter cores to a depth of 2 cm at each site to sample the meiofauna (fauna smaller than 0.5mm and greater than 0.063mm). These samples were iced onboard ship, preserved in the lab with a 5% aqueous solution of formalin, and archived for possible analysis, if required.

Benthic sled sampling was used to collect belt transect samples of larger, more sparsely distributed animals such as hermit crabs and sand dollars. The sled has matching steel blades on both the top and the bottom so that it functions properly no matter how it lands on the bottom. To produce a belt transect, the sled (25 cm tall with a 63 cm wide blade) was towed 15.8 m along the bottom by a line extending to the boat and sampled the top 6 cm of sediment. Sediment passes through the 6 mm mesh and larger organism are retained. A taut-line buoy attached to the sled allowed for accurate positioning along the marked course. We sampled only on a flat-calm day (9 December 1999) at sea to prevent the sled from bouncing and to control its positioning. Using this sled, we took 40 belt transect samples of 10 m^2 each. This design yielded two replicate belt transect samples at each of the 20 sampling sites (Fig. 1). Animals found in the sled samples were identified, counted, and recorded. Species not immediately identifiable in the field were collected and returned to the lab for identification.

B. Demersal Fish and Crustaceans

In order to provide a semi-quantitative characterization of demersal fishes and crustaceans, including commercially or recreationally important species, that occupy the potential borrow areas and may conceivably be impacted directly by dredging operations or indirectly by loss of their benthic invertebrate prey, we sampled the demersal species of the three borrow areas. Replicate trawl samples were taken on 29 November 1999 and again on 4 February 2000 from the R/V Capricorn using timed 20-minute otter-trawl tows at 4.02k/hr with a 12.3-m otter trawl. Thus the trawl would cover 16,492 m^2 of bottom area if there were no currents. The actual bottom area covered varied according to wind and tidal currents during any specific tow, which is why tows were standardized by time and speed rather than distance covered. These trawl samples were distributed as follows: 4 in Borrow

Area A and 2 in each of Borrow Areas B-1 and B-2. The contents of each tow were identified to species, counted, and recorded. In addition, stomachs of up to 20 replicate individual fish of the most abundant species were removed, and preserved by formalin injection onboard ship during. Stomach contents for up to twenty of the eight most common fish species from the November trawl survey were identified (when possible) and divided into major taxonomic group (e.g. polychaete, decapod, bivalve, etc.). Fish guts were examined from both inshore areas and offshore areas when possible. The divided categories were then weighed to the nearest 0.0001 g. Detailed inspection of some of the diet remains allowed identification to the family, genus or species level of some of the gut contents.

C. Sediments

At each site where macrofaunal cores were collected, divers also took core samples for grain-size analysis of sediments. Composite bottom samples were obtained at each of the ten Borrow Area sites and each of the ten control sites. Using PVC sampling tubes (16.5 cm [6.5 in] long and 2.5 cm [1 in] wide), divers collected 3 replicate samples of the upper 2 cm of the bottom within a 3-m^2 area at each of the twenty sites. Sample tubes were tightly capped, then brought to the surface and returned to the laboratory for analysis. Loss of fine-grained material, which can occur with conventional grab samplers, is minimized by using diver collections. Samples were assumed to be representative of the surficial material in which most of the macrofauna live.

In the laboratory, the replicate sediment samples were combined in a single container, then washed three times to remove salts and placed in a drying oven. After recording the bulk sample weight, a Calgon dispersant was added and the fine-grained (mud) component (by definition less than 0.063 mm diameter) was rinsed through a #230 mesh wet sieve. The remaining material (sand + gravel/coarse shell) was reweighed and prepared for sieve analysis. Prior to sieving the sand-sized fraction, the gravel/coarse shell fraction (by definition more than 2 mm in diameter) was removed with a #10 mesh sieve and weighed. A Tyler mechanical splitter was used to obtain a 25 g subsample of the remaining material (sand) which was then sieved at ¼ phi intervals (Carver 1971).

Each sieve stack was placed in a mechanical ro-tap for 20 minutes. Individual sieve fractions were weighed and recorded. Small amounts of fine-grained sediment that had not previously washed through the wet sieve were collected in a pan at the bottom of the sieve stack and, for computational purposes, were included with the wet-sieved material. Percentages of gravel/coarse shell, sand, and fine-grained sediment were computed from the bulk sample weights, and percentages of each size fraction in the sand range were computed from the 25 g splits that were sieved. Mean and standard deviation were computed using Excel software and mean phi values were converted to millimeters using the standard conversion, phi = $-\log_2(\text{mm})$, where mm corresponds to the intermediate diameter in mm (Folk 1974).

3. Results

A. Benthic Invertebrate Resources

Table 2 (2a for per-core results and 2b normalized to per square meter) presents the results of analyses of the 200 core samples taken to describe the benthic macrofauna at the three Borrow Areas and the surrounding Controls for each. Total macrofaunal densities were slightly greater at the offshore sites (14.1 invertebrates per core at Borrow Area A and 9.3 per core averaged over nearby Control sites) than at the inshore sites (9.7 invertebrates per core averaged over Borrow Areas B-1 and B-2 and 6.6 per core averaged over nearby Control sites. Results suggest slightly higher macrofaunal abundances in the Borrow Areas than in their respective Control Areas (Fig. 2). The polychaetes accounted for 65 % to 75 % of the total macrofauna in these late-fall 1999 samples. Other common groups in order of abundance were bivalve molluscs, nemerteans, small crustaceans, and echinoderms (see Appendix for all raw data).

Table 3 (3a for per-belt transect results and 3b normalized to per square meter) describes the results of analysis of all 40 belt transects for larger benthic invertebrates. The inshore sites revealed higher numbers of these larger invertebrates than the offshore sites. Borrow Area A contained 3.1 larger invertebrates per $10m^2$ belt transect and its nearby Control sites averaged 2.8, as compared to the average of Borrow Areas B-1 and B-2, which was 0.7 and their nearby control sites of 1.2 (Table 3). No consistent difference appeared between Borrow and Control Areas in this data set (Fig. 3). Gastropods were the most common taxon represented in these samples.

B. Demersal Fish and Crustaceans

Trawl sampling detected relatively large number of demersal fish occupying the seafloor habitat during late fall, declining by early February (Table 4 presents the results of trawling for fishes and crustaceans on 29 November 1999 and Table 5 presents the 4 February 2000 results). In November, offshore areas were dominated by spot, which accounted for more than 50% of total catch and was sufficiently abundant there to create a pattern of slightly higher fish densities offshore than inshore. In addition to spot, pinfish, pigfish, and croaker were the most common species offshore. Inshore fishes were dominated by croaker, silver perch, silversides, pinfish, and sea mullet.

The abundance of most fish species had decreased by 4 February. This February sampling took place after a 3-week cold spell, the first prolonged cold weather of the winter of 1999-2000. The contents of these February 2000 samples (Table 5a,b) contrasted with those of November 1999 (Table 4a,b), showing an average reduction in catch by 81.3%. Catch in February from inshore stations was 41.3% and of offshore stations 3.7% of the corresponding catches in November. The abundances of two commercially and recreationally important species, spot and croaker, which made up 50.8% of the fall catch, dropped by 98.9% and 99.8% respectively. In February, pinfish, menhaden, and silversides made up 96.4% of the total catch. Spot, croaker, pigfish, sea mullet, and silver perch all showed large declines from November to February in both inshore and offshore areas. Pinfish catch in offshore areas was greatly reduced in February compared to November; however, inshore catches of pinfish were similar across dates. Two species of fish, menhaden and southern flounder (both found only in the inshore area), were more abundant in February than in November.

Examination of the stomach contents of the eight most abundant fish (croaker, gray trout, pinfish, pigfish, sea mullet, silver perch, silversides, and spot) demonstrated that many of the benthic invertebrates found in core samples and belt transects were major diet items of these fish (Table 6). Only about half of all stomachs examined were empty, with some variation among species. Major prey species for croaker and pinfish included polychaete worms, bivalves, and occasionally small shrimp (primarily grass shrimp, *Palaemonetes* sp.) and crabs (primarily pinnotherid crabs). Shrimp (both *Palaemonetes* sp. and penaeids) and to a lesser degree portunid crabs were the primary prey species found in the stomachs of gray trout. Sea mullet prey items were dominated by pinnotherid and portunid crabs and large polychaete worms. Small grass shrimp and other bottom-dwelling crustaceans (amphipods and isopods) were the dominant prey found in silver perch stomachs. Pigfish stomachs contained primarily polychaetes with an occasional grass shrimp present. Some polychaetes and small crustaceans (isopods, cumaceans, and amphipods) were found in the stomachs of spot, but stomachs were relatively empty compared to other species. Finally, silversides fed primarily on harpacticoid (benthic dwelling) and calanoid (planktonic) copepods.

Comparisons between stomach contents of fish collected from inshore and offshore locations were possible for six of the eight species that were caught in abundance in both areas (croaker, gray trout, pinfish, silver perch, silversides, and spot). Examination of the data revealed no consistent pattern in either the proportion of empty stomachs or major prey items between the two areas.

C. Sediments

Data are summarized in Table 7; individual size frequency curves and histograms are provided in Figure 4. With the exception of two treatment sites in Borrow Area A, sands comprised at least 90% of the bottom sediment by weight. In all cases, muds comprised less than 4% of the sediment by weight. Visual inspection of the samples revealed that the coarse fraction, typically less than 8% by weight, was comprised primarily of coarse shell fragments. Using the Wentworth size scale (Folk 1974), mean grain size in 80% of the samples was classified as fine sand and 20% as either medium or coarse sand. Values for standard deviation showed that 85% of the samples were moderately or moderately well sorted. Reed and Wells (2000) found similar sediment distribution patterns off Fort Macon, Atlantic Beach and Pine Knoll Shores, NC, in samples taken at 36 locations during each of two sampling periods, fall 1996 and spring 1997. Their samples showed muddier sediments occurring in the offshore areas but no significant seasonal variations in mean size or sorting.

4. Discussion

The benthic invertebrates occupying the bottom in both the inshore and offshore Borrow Areas represent species that are indeed being consumed by demersal fishes, such as spot, croaker, pinfish, pigfish, and sea mullets. Our gut examinations revealed that feeding was active and intense on the benthos in late November. Compared to other gut data, the percentages of empty stomachs in this data set are quite low. The densities of benthic invertebrates (6-16 individuals per 76.4-cm^2 core) are similar to those found occupying sandy bottoms in the Beaufort Inlet in December 1994 (Peterson et al. 1999), which were around 10 individuals per 76.4 cm^2 core (the same used in this study). The Beaufort Inlet samples were taken at a depth of 26-36 feet, similar to the inshore sites sampled in this study. Both surveys showed a general dominance by polychaetes. No other sampling of benthic invertebrates is truly comparable to these because of differences in sieve mesh size, water depth, reef proximity, geography, or sedimentology. Nevertheless, we present some benthic macrofauna data in Tables 8 (total macrofauna) and 9 (major taxa) from these other studies for contrast. Densities of benthic infauna in cores at the Borrow Areas in late November during our sampling period and in the earlier Beaufort Inlet study are lower than those observed near hard-bottom reefs off Wrightville Beach (Posey and Ambrose 1994) and those observed by Van Dolah (1994) in finer sediments off Hilton Head, South Carolina (Table 8). For those taxa reported in Posey and Ambrose (1994), bivalves, gastropods, scaphopods, amphipods, isopods, polychaetes, and echinoderms, densities were higher than in our sampling of the Borrow Areas (Table 9).

Belt transects for larger invertebrates revealed a similar dominance by gastropod molluscs in our new data set from the Borrow Areas and in our earlier Beaufort Inlet study. These larger invertebrates were slightly more common in the Beaufort Inlet than in the study areas sampled here (Table 10). Greater echinoderm (sand dollar) densities occurred in the vicinity of the Beaufort Inlet. The only other analogous data set on larger invertebrates comes from Dahlgren et al. (1994), although they report only some taxa from belt transects near hard-bottom reefs off Wrightsville Beach. Dahlgren et al. (1994) reported belt transect data (Table 10) for several classes of echinoderms near the same reefs studies by Posey and Ambrose (1994). Dahlgren et al. (1994) observed higher densities of holothuroids (sea cucumbers) than we document in the Borrow Areas but similar densities of echinoids (sand dollars) and stelleroids (sea stars) (Table 10). The difference in sea cucumber densities is likely also a consequence of the finer sediments in the site studied by Dahlgren et al. (1994).

Our fish sampling revealed high densities of many fishes, dominated by species of substantial value to commercial and recreational fisheries of North Carolina and neighboring states. These fishes were actively feeding on the benthic macrofauna. Shrimp catches were low, although commercial shrimp trawling was being conducted in the immediate vicinity of all the Borrow Areas at the time of our sampling in late fall 1999. Many species of demersal fish of the estuaries of North Carolina and the Southeast generally are known to exit the sounds and estuaries in the fall on route to offshore sites for overwintering. The precise locations of these overwintering sites are not completely described, but our sampling indicates that this area off Bogue Banks is utilized in abundance during late fall by spot, croaker, pigfish, pinfish, silver perch, and sea mullet. Subsequent sampling during early February revealed emigration of these fishes to unknown locations as the weather became cooler. We have been unable to find any comparable semi-quantitative data on demersal fish abundances in shallow shelf habitats off the Carolinas; however, the densities observed in late November 1999 were judged by our boat captain, who has operated this trawl routinely for 25 years, to be similar to densities in spring, summer, and fall around Beaufort Inlet (J. Purifoy, pers. com.).

Our sampling is appropriately designed to serve as the fall baseline data set for the Borrow Areas in contemplation of a monitoring scheme to assess impacts of and recovery from the sand mining for beach renourishment. This includes not only the benthic macrofauna and demersal fishes but also the sediments on the sea floor. Because the macrofauna is so closely tied to sediment character, the evaluation of any changes in surface sediment character after mining is critical to interpreting the impacts on and recovery of benthic invertebrates and probably also fishes. The monitoring of the offshore Borrow Areas that we anticipate includes another analogous sampling in a spring season to provide baseline data for that season of the year. The standard deviations in our initial data set on infauna at the Borrow Areas suggest that we will have sufficient statistical power to detect about a 20% change in total infaunal density. Analyses of densities of individual families will be less powerful, but an ordination analysis on the entire community data set will have power similar to that of the test of total infaunal density.

In addition, baseline sampling of the nourishment sites and control sites on the beach itself would also need to be conducted prior to sand mining, but during the warm months when the intertidal beach is used by macrofauna. We already possess a substantial amount of data on abundances of intertidal beach invertebrates from all along Bogue Banks from 1997-1999 from studies conducted by L. Manning (unpubl.: see Table 11 for an example data set). This information can be incorporated into an assessment design to evaluate the potential consequences of the renourishment on the beach system, allowing contrasts between the multiple summers before renourishment and the summer or summers afterwards as one means of assessing impact and rate of recovery. In addition, sampling should be conducted at control sites that do not receive sand from the project to allow detection of interannual change unrelated to the project, but the design for this assessment will need to be finalized after the scope and timing of the project is defined.

MEMO May 18, 2000

TO: Dr. Charles Peterson and Dr. John T. Wells

FROM: Dr. Timothy Kana

RE: Bogue Banks Beach Restoration Project
Environmental Monitoring Report and Draft EIS Comments

Thank you for forwarding your draft final report dated May 10, covering the fall 1999 environmental surveys and which consisted of 7 pages of text, 4 figures, 11 tables, and appendices. We appreciate your work in getting this first sampling completed. I am writing on behalf of the CSE Baird and Stroud Engineering.

We have reviewed your draft and offer the following comments, questions, and recommendations for revisions. I am enclosing comments from NCDENR received on May 12 concerning our draft EIS (which contained your preliminary report of 28 January as Appendix C). Some of DENR's comments are related to benthic impacts. Therefore, I would like your help in addressing certain items (referenced below). We need to receive your revised final report as soon as possible, preferably by June 1. Following are our comments.

Comments from CSE Baird and Stroud

1) Please see the attached memorandum dated 20 January for guidance and incorporate those revisions as applicable.

2) We want you to re-organize "1. Background" because your draft mixes recommendations, sample design, methods, and opinions, and does not reference previous related studies. Divide the information appropriately in the following headers/subheaders:

   Introduction/Purpose (i.e., done in anticipation of Bogue Banks beach renourishment project under contract to county; to address environmental issues of concern quantitatively; represents first sampling of four planned; intended to characterize existing conditions before the project; why this is important)

   Previous Benthic Studies (reference literature)
   – Site specific to Bogue Banks area (summarize prior results and findings)
   – Related regional studies (summarize results and findings)
   The results and findings should specify for the respective studies rates of recovery or a finding of no recovery, if that is the case.

CSE

Sample Design (summarize the overall sample design noting how your study goes beyond previous work to sample demersal fish and assess potential impacts and provide baseline conditions) [Methods (subheader), Results (subheader), Discussion (subheader) to follow logically here]

Conclusions and Recommendations for Future Monitoring (This is where the "recommendations" in your "1. Background" should be placed.)

3) *RE: Literature Review* – We assume that you can draw on your extensive experience and previous studies to provide a synopsis of the relevant literature on benthic impacts (offshore borrow areas and nourishment areas) and rates of recovery for similar sites, noting which studies may be at odds with Reilly and Bellis (1983) or Peterson et al. (1999), etc., and what factors may have produced different results (e.g., too much mud, high frequencies of sand scraping, etc.). Your draft final report does not provide context or reflect what you know about the subject.

NOTE: If we are going to do a nourishment project along Bogue Banks, the county (and regulatory agencies) are looking to all of us for recommendations on how to do it right. The question for us is not whether to nourish but how to do it with the least environmental impact. The EIS states that there will be direct impacts to organisms and many will be killed. This is unavoidable. Your review of the literature should provide appropriate biological context. What studies proved rapid (<1 year), slow (<10 years), or no recovery (>10 years)? How will our sampling design isolate the effects of dredging the bottom from the effects of seasonal climate change, normal trawling operations through the area, etc.? What are the life cycles of the dominant species found in the proposed borrow areas or on the beach?

4) *RE: Methodology* – We suggest that you begin Section 2A by stating that replicate cores (for benthics) were obtained at 20 stations, ten of which are within proposed borrow areas A, B1, and B2, and ten in nearby control areas. At each station, ten replicate samples were collected to provide a statistical sampling following established protocols (?ref?). Thus, a total of 200 individual samples were obtained and analyzed (results in appendices). Leading the section with "200 samples" may suggest to casual reviewers that we sampled 200 sites. The only relevance of this number is whether ten replicates per station and the number of stations are representative and adequate to characterize the area.

CSE

Under demersal fish (or related literature review), you should note that no protocols exist for such sampling in connection with nourishment projects since none have been done in North Carolina (or regionally, if that is true). The sampling plan is therefore based on what? You will note in certain agency comments as well as your own (early in our planning for the project) that there are concerns for the fish. Are these concerns based on any previous data? If so, we should cite them. If not, we should emphasize that this sampling is unprecedented in order to reinforce our claim that we are serious about quantifying environmental impacts and reducing the amount of damage as much as possible.

6) *RE: Statistical Analysis* – Please provide statistical measures of species diversity, species richness, etc., as we requested in our January 20 comments on the interim report, so that these data can be normalized and compared objectively with future data sets. It would be useful to provide abbreviated tables showing summaries by higher taxa (e.g., bivalves, gastropods, amphipods, etc.) and corresponding histograms similar to Figure 2.

can't do power analysis

It is premature to indicate your ability "to detect a 20 percent change" in total infaunal density. Even if this were true, it is misleading because totals can be obtained by many combinations of species. We assume some species are better food sources than others, if for no other reason than their food mass is greater. Our hope should be that a diverse suite of species returns rapidly. Is there any literature that states what benthic species are more desirable? If so, can we do anything to encourage recruitment of these species after dredging? Given the exceedingly high standard deviations for most species and the possibility of ten-fold differences in seasonal abundance (according to many other studies), we need to be careful about setting standards for comparison.

7) *RE: Results* – Please provide summary pie charts or histograms of species composition (sorted by higher taxa) at the borrow and control sites to facilitate review by the agencies and aid in future comparisons. The figures in your draft final report are inadequate.

Provide reference to the sediment data that CSE Baird/Athena Technologies collected in and around the borrow areas (text section 3.16 and appendix E of the draft EIS) and note how these results are similar to or different from your data.

We would like to have more "examples" of beach/intertidal data included in your report from Lisa's work. In particular, it will be helpful to have some of her comparative data at select stations showing abundances during different seasons or pre and post scraping. The results section is the appropriate place to reference it. We realize that these data are still being analyzed, but some respondents in the agencies appear to be referencing this work in their comments.

8) *RE: Discussion* – The discussion should lead with a summary and comparisons of what is on the bottom rather than what is eating the bottom. Then it should progress logically from macrofauna to epifauna to the fish. Where comparisons with other studies are made, provide specific results in the text [e.g., Posey and Ambrose (1994) found (species) diversity __ percent higher than your study].

Why was species abundance generally higher in the proposed borrow areas than the control areas? From an ecological standpoint, which borrow areas are preferable for dredging? How do these benthic sampling results correlate with surficial grain size? Areas B1 and B2, after dredging, will tend to expose fine sand whereas area A will tend to leave coarser shelly sand and mud. Which is preferable for benthic recovery?

Will newly exposed substrate recolonize after dredging, and if so, what can we do to accelerate recolonization? Is there a difference between recolonization after hopper dredging versus traditional cutterhead dredging? Will a shallow cut (1-3 ft thick) favor recolonization compared to a deep cut (~10 ft thick)? Your report needs to relate the sampling results to the nourishment project and offer practical guidance to the county as well as the regulatory agencies.

Your assessment of demersal fish is important. If we dredge A or B, does that mean the fish will not come back next year? What is known about migratory patterns of fish over borrow areas? What factors cause fish to move on to other areas? Do benthic or fish populations fluctuate by orders of magnitude from season to season because of life-cycle timing, timing of fish grazing, temperature, rainfall/runoff, or trawling operations? How will one-time dredging modify these cycles? How would yearly dredging (same general area) modify these cycles? If there will be impacts to the local fishery due to dredging A and B, will it be proportional to the area dredged? What is the natural variation in fish populations and will the impact from nourishment be detectable? If it cannot be quantified, then so state.

You refer to "other gut data" but give no reference. Also, you refer to fish "feeding was active and intense" in late November without defining intense. In the third paragraph of the discussion, you refer to "high densities" of fish of "substantial value" without defining high density or substantial.

9) *RE: Conclusions and Recommendations* – To the extent you can apply your extensive experience and results of the first sampling analyses, we ask you to draw conclusions to assist the agencies in their review. If you know that no amount of sampling can prove cause and effect of dredging for any aspect of the work, please state. Similarly, if you know there will be unrecoverable impacts, please specify what they will be so we are sure to include them in the EIS.

   Your recommendations for follow-up sampling are good and should be consolidated at the end. I encourage you to write to the Carteret County Council immediately and emphasize to them how important a summer sampling will be for the EIS. This is an opportunity for you to fund students over the summer and help the county keep the project planning on track.

RE: Formatting – Please resubmit the text with minimum one-inch margins and bold the **HEADERS** and **Subheaders**.

Agency Comments (see attached comments)

NC Wildlife Resources Commission (dated 27 April)

- Please provide us with a copy of the Donaghue paper and Peterson et al. paper referenced in the comment (4th paragraph). We would appreciate your response to this concern.
- Will nourishment by dredge from A or B introduce spoil onto the beach that might attract foraging shorebirds?

NC Division of Marine Fisheries (dated 18 April)

- As expected, they would like to see one year of field surveys. Can you provide at least one year's worth of data for representative intertidal sites such as you reference for the 1997-1999 data collections by Lisa?

NC Division of Water Quality (dated 10 April)

- They prefer borrow area A as the exclusive sediment source. Is this consistent with your assessment of benthic impacts? (Would overall impact be greater or less if we reduce the number of borrow areas, but necessarily dig deeper?)

CSE

Finally, we would also like to receive a copy of the following references you cited: Day et al. (1971), Peterson et al. (1999), Warwick (1988). If you or Lisa Manning have some related papers on intertidal beach communities, we would also like to have them for review. The only paper we have from your group is Hickerson and Peterson (1992).

Please call if you have any questions about these comments. If you would like to discuss these comments with the county, I will be happy to come up on short notice and lend support. Your work is a key element of the EIS. This is an opportunity to showcase the research that UNC is doing and to demonstrate its relevance to the community. That is why we encourage you to make these changes.

IN REPLY REFER TO

February 28, 2001

Regulatory Division

Received
28 Feb 01

Carteret County
C/o County Manager
Courthouse Square
Beaufort, North Carolina 28516

Dear Sir:

I am replying in reference to you application for a Major CAMA Permit for Bogue Banks Beach Nourishment dated January 24, 2001. We have reviewed the application and accompanying EIS. The EIS refers to project construction and maintenance activities that would be conducted by the individual local governments within Carteret County. Therefore, to insure that permit conditions and requirements are associated with the appropriate local governments, we recommend that you amend your application by including the local governments as co-applicants. We can still utilize your EIS and cumulative impacts information to address the combined projects.

I am considering your application as incomplete until I receive a reply to this letter clarifying the applicant, who is responsible to insure that the terms and conditions of any authorization(s) are met. We would next want to conduct a scoping meeting with all the co-applicants and the appropriate resource agencies as quickly as possible to expedite your application. The project manager for this activity is Mr. Mickey Sugg of my staff and he can be reached at (910) 251-4811.

Sincerely,

Keith A. Harris
Chief, Wilmington Regulatory Field Office

11:50 am

Dear Tim and Bill:

I was asked at the end of last week to serve as advisor to the NC Division of Marine Fisheries of DENR on what should be contained in the monitoring plans for the Pine Knoll Shores and other beach nourishment projects. It appears to me that continuing to work on the actual monitoring project as an ecological collaborator with you and your engineers would represent a conflict of interest. Consequently, I felt compelled to send you this note to indicate that I do not wish to be engaged in the monitoring of Bogue Banks.

I can suggest other benthic ecologists who would be capable of conducting the ecological monitoring. They include: Dr. Bill Kirby-Smith of the Duke University Marine Lab, Dr. Terry West of the Biology Department of East Carolina University, and Dr. Martin Posey of the Department of Biological Sciences of UNC-W.

I am pleased to make available to you or to the person with whom you contract to do this work any information that we have on the benthic and fish biology of Bogue Banks. As you know, much of the information is a raw data form, but some final copies of reports and a lot of raw data are at your disposal.

Sincerely,

Pete

Comments:

Dear Dr. Kana:

Please find attached the draft proposal for the Bouge Banks Beach Nourishment project. The sampling and analysis are what we have performed in South Carolina at the direction of Bob Van Dolah for numerous beach nourishment projects. We can accommodate any sampling plan that the NC Marine Fisheries wants us to perform, but this should at least be the minimum permit requirements for monitoring. Please call me to discuss any question you might have.

Sincerely,

Stephen R. Florey

RE: **Environmental Services Proposal**
Bouge Banks Beach Restoration
Bouge Bank, North Carolina
CSA*i* Proposal No. 01-132-EA

Dear Dr. Kana:

Coastal Science Associates, Inc. (CSA*i*) is pleased to submit this proposal to Coastal Science & Engineering, LLC (CSE) to perform the above referenced study as outlined in your letter dated April 6, 2001. This agreement is made as of April 18, 2001 by and between CSE, LLC (Client) and CSA*i*.

Background

The intent of the proposed ecological study is to assess the existing biological conditions of the of benthic invertebrates at the proposed offshore borrow areas for the Bouge Banks Beach Renourishment Project, located in Carteret County, North Carolina.

The ecological study will include benthic sampling and analysis from offshore borrow areas and near by controls. CSA*i* proposes to only use 50% of the stations previously sampled by the Institute of Marine Service, UNC. Benthic sampling will also be conducted at the beaches that have been proposed to be nourished. Benthic samples will also be collected on one of the adjacent un-nourished beaches to act as a control.

Otter trawls may also be performed to assess the demersal fish and invertebrate populations around the borrow areas and along the beach. CSA*i* recommends that four sampling events be performed to assess the recovery of the borrow sites and beach nourishment activities. Two sampling events should be conducted prior to the to dredging (Spring-fall) event, and two sampling events should be conducted after the nourishment activities have been completed (spring-fall). Based on the information provided, CSA*i* proposes the following scope of services:

TASK 1. Field Collection of Benthic Samples

The proposed borrow area to be sampled is located approximately 2 miles south of Salter

Path/Indian Beach, Carteret County, North Carolina. The depths in the sampling area range from 35 feet at the inshore areas, to 47-49 feet in the offshore areas. The proposed sampling will produce a total of 100 core samples (50% of the stations originally sampled by UNC in Fall 1999) from both the offshore borrows areas and control areas. Cores will be collected by divers using a cylindrical corer 9.9 cm in internal diameter. All station locations will be selected form the previous study performed by the Institute of Marine Sciences, UNC. All stations will be located by Differential Global Positioning System (DGPS). All benthic samples collected will be sieved in the field through a 0.5 mm stainless steel sieve bucket. All sediment and organisms retained in the bucket will be preserved in 10% buffered formalin with rose bengal stain.

In addition, four stations will be sampled on the proposed beach to be nourished. Two stations will be sampled within the project area and two will be sampled outside the project area to act as controls. A total of twelve corers will be collected along the beach. Every attempt will be made to perform the sampling at the same station location as the Lisa Manning report (NC Sea Grant, April 2000).

Task 2. Laboratory Methods

Once samples have been transported to the laboratory, core sediment samples will be carefully re-sieved through a 0.5 mm stainless steel sieve bucket and screen. This sediment reduction will expedite the sorting process. The remaining sediments and organisms will be placed in labeled, double-ziplock bags and initially preserved in 10 percent buffered formalin solution with Rose Bengal stain. Organisms will be allowed to harden for 48 hours and then transferred to 80 percent ethanol alcohol. After the hardening period, the organisms will be placed in sorting trays and submersed/diluted in de-ionized water to minimize any volatile alcohol vapor production during identification.

Organisms will then be sorted and enumerated in the laboratory and identified to the lowest possible taxon (species level in most cases) with the aid of a variable power dissecting microscope (Bausch & Lomb) and/or a compound microscope (Swift or Bristol). Organisms will be identified by an experienced biologists utilizing various identification keys for organisms expected to be collected (e.g., Abbott, 1974; Bousfield, 1965; Bynum and Fox, 1977; Dover 1979; Fauchald, 1977; Fox and Bynum, 1975; Gosner, 1978; Heard, 1982; Kaplan, 1988; Morris, 1975; Ruppert and Fox, 1988; Uebelacker and Johnson, 1984; Williams, 1984). Species identified for each station will then recorded on a laboratory bench sheet (per EPA, 1989).

Task 3. Data Analysis

Benthic data from the borrow area and control site will be statistically compared to evaluate changes in faunal abundance, and number of species present among sites and over time.

Analysis will include variance testing (ANOVA), or the non-parametric Kruskai-Wallis test, as necessary. Comparison among specific treatment groups will be completed using the Student-Newman-Keuls test (parametric and unparametric designs). Diversity indices will be computed for each area (all samples combined) using Shannon's diversity index (H), species richness (SR) and evenness (J). Changes in overall community composition among sites and seasons can be evaluated using a proportional similarity coefficient (Bray-Curtis) with flexible sorting strategy and a cluster intensity (ß) of -0.25.

Task 4. Reporting

Report for each sampling event, including details of field date collection, data presentation, analysis, and conclusions/results will be submitted to NC marine Fisheries within 120 days following completion of the field work portion of the work.

Response to CSE monitoring proposal of 25 April 2001 for Bogue Banks Nourishment Project

Charles H. Peterson, PhD

9 May 2001

This proposal fails to incorporate almost all of the substantive recommendations presented in the 5 April meeting of Mike Marshal, Rick Monaghan, Pete Peterson, Tim Kana, and Bill Foreman. Specifically, here are the shortcomings:

(1) There is no sampling of the surf fish by beach seine, comparing abundances, gut fullness, and gut prey contents in nourished and control areas during the summer season following nourishment. If benthos does not recover during that first summer, then this fish utilization monitoring should be continued until recovery has been demonstrated.

(2) The numbers of samples are presented for the benthic sampling of the offshore mining site and the numbers of sampling dates (4), but absolutely no statistical power analysis is provided to justify what magnitude of impact could be detected from such a sampling. Absent power to detect important effects, monitoring is less than worthless because it falsely implies an ability to assess impacts when the exercise is inconclusive by design. This analysis can be based on variability information available in the earlier IMS-UNC study.

(3) The spring sampling date (April) originally proposed for pre-project sampling of offshore benthos has already passed. So is this proposal designed for a winter 2002-3 project? This is unresolved.

(4) Beyond mention of 4 beach stations to be drawn from the Lisa Manning sites, there is no adequate design provided to describe the methodology of the intertidal beach sampling. Included in this absence of information is a total lack of attention to power of the design to detect effects of various magnitudes. Thus, this sampling design like that of the offshore benthic sampling fails to meet the standards of excellence of the discipline and may be less than useless to understanding impacts and recovery.

(5) The follow-up sampling is proposed for two sampling dates independent of whether recovery has been demonstrated. This is inappropriate, failing to continue monitoring if biological resources are still impacted.

Background

The purpose of this proposed ecological study is to assess the existing biological communities of benthic invertebrates and fish at the proposed Bogue Banks Beach Renourishment Project, located in Carteret County, North Carolina. This is a revised proposal, based on a public and agency meeting held May 11, 2001, at which recommendations were given from the UNC Institute of Marine Sciences (IMS), the U.S. Fish & Wildlife Service, the National Marine Fisheries Service, the U.S. Army Corps of Engineers, the North Carolina Department of Environment and Natural Resources, North Carolina Coastal Federation, and others. The general recommendation was to put more emphasis into fisheries surveys and impacts, and less into macroinvertebrate species identification.

The ecological study will include benthic sampling and analysis for proposed borrow and nourishment sites, and fish sampling and analysis for proposed nourishment sites, including reference sites. CSA*i* proposes to use up to 50% of the stations previously sampled by IMS (2000). Two sampling events (pre- and post-) are proposed in the first year, with an additional sampling event for each of the next three years. The scope of work is as follows.

TASK 1. Field Collection of Benthic Samples

The proposed borrow area to be sampled is located approximately 2 miles south of Salter Path/Indian Beach, Carteret County, North Carolina. The depths in the sampling area range from 35 feet at the nearshore areas, to 47-49 feet in the offshore areas. **A power analysis will be conducted following a review of previous studies conducted by IMS and based on preliminary sampling.** Assuming individual sample core size is appropriate, this analysis will determine the correct sample number to obtain an estimate of mean density of a species population within +/-10%. The proposed sampling will produce a useful number of core samples (50% of the stations originally sampled by UNC in Fall 1999) from both the offshore borrow areas and control areas.

All borrow station locations will be selected from the previous study performed by IMS. In addition, four stations will be sampled on the proposed beach to be nourished. Two stations will be sampled within the project area and two will be sampled outside the project area to act as references/controls. The number of cores will be determined in the above preliminary sampling. Every attempt will be made to perform the sampling at the same station location as in the Lisa Manning report (NC Sea Grant, April 2000). All stations will be located by Differential Global Positioning System (DGPS). Cores will be collected by SCUBA diving or wading using a four inch PVC cylindrical corer with an internal diameter of 9.9 cm (sampling an area of 77 sq cm). Benthic samples collected will be sieved in the field through a 0.5 mm stainless steel sieve bucket. All sediment and organisms retained in the bucket will be preserved in 10% buffered formalin with rose bengal stain.

Nearshore fish sampling will also be conducted at the four beach sample sites. This will consist of three hauls of a 100' beach seine at each of the sites. Species, numbers, and life stage will be field-determined to the extent possible; fish requiring further examination will be subsampled and preserved in 10% buffered formalin. A subsample of each of the more common species will be placed on ice for immediate gut content and volume/weight analysis at the nearby IMS laboratory.

Samples will be preserved as above, properly labeled inside and outside of the containers, and transported to the laboratory for identification using proper quality assurance/quality control procedures.

Task 2. Laboratory Methods

Once samples have been transported to the laboratory, core sediment samples will be carefully re-sieved through a 0.5 mm stainless steel sieve bucket and screen. This sediment reduction will expedite the sorting process. The remaining sediments and organisms will be placed in labeled, double-ziplock bags and initially preserved in 10 percent buffered formalin solution with Rose Bengal stain. Organisms will be allowed to harden in formalin for 48 hours and then transferred to 80 percent ethanol alcohol. After the hardening period, the organisms will be placed in sorting trays and submersed/diluted in de-ionized water to minimize any volatile alcohol vapor production during identification.

Organisms will then be sorted and enumerated in the laboratory and identified to a minimum of family level with the aid of a variable power dissecting microscope (Bausch & Lomb) and/or a compound microscope (Swift or Bristol). Organisms will be identified by experienced biologists using various identification keys (e.g., Abbott, 1974; Bousfield, 1965; Bynum and Fox, 1977; Dover, 1979; Fauchald, 1977; Fox and Bynum, 1975; Gosner, 1978; Heard, 1982; Kaplan, 1988; Morris, 1975; Ruppert and Fox, 1988; Uebelacker and Johnson, 1984; Williams, 1984). Taxa identified for each station will be recorded on a laboratory bench sheet (per EPA, 1989).

Gut contents will be analyzed at the nearby IMS laboratory; contents will be removed, weighed, volume determined, sorted, and identified. Depending on degree of degeneration, samples may alternatively be preserved in 10% formalin and washed for analysis. Organisms will be separated into general groups (e.g., penaeid shrimp, portunid crabs, etc.).

Task 3. Data Analysis

Organism data from the borrow area and control site will be statistically compared to evaluate changes in faunal abundance, and number of species present among sites and over time. Besides standard statistics, analyses will include variance testing (ANOVA), and equivalent parametric tests. Comparison among specific treatment groups will be completed using the Student-Newman-Keuls test (parametric design). Diversity indices will be computed for each area (all samples combined) using Shannon's diversity index (H), Margalef's species richness (SR) and evenness (J). Changes in overall community composition among sites and seasons can be evaluated using a proportional similarity coefficient (Bray-Curtis) with flexible sorting strategy and a cluster intensity (ß) of -0.25.

Task 4. Reporting

A report for each sampling event, including details of field data collection, data presentation, analysis, and conclusions/results will be submitted to CSE and the Towns, for review and dissemination to the reviewing agencies/groups, within 120 days following completion of the field work.

FAX-(190)-251-4025

Daer Mr Suggs:

At the request of Mr. Bill Foreman of CSE, I address my comments on the 31 May 2001 Revised Biological Monitoring Proposal for the Bogue Banks Beach Nourishment Project to you. As you are aware, I have provided earlier comments to the applicant in person, through written response, and verbally at the scoping meeting in Morehead City.

The Revised Biological Monitoring Proposal fails to meet the most fundamental of the requests that I advocated in all three previous forums. Even as a Master's Degree student project, this proposal would receive a failing grade. I detail its shortcomings here, consistent with my earlier comments.

(1) Despite the availability of data to do so, this proposal does not conduct the standard statistical power analyses required to demonstrate whether the proposed monitoring of benthic invertebrates (either in the mining areas or on the beach) has the intrinsic capability of detecting impacts of any magnitude, let alone the 10% change that is claimed. Furthermore, the discussion of power that is incorporated fails to recognize the statistical basis of the design of the data collection. Only by replicating stations not by replicating samples at stations are degrees of freedom (independent replicates) enhanced to increase power. Without a proper power analysis, the design for offshore sampling at the mining sites and the design for sampling beach impacts cannot be justified as adequate to inform the public or the regulators. The proposal slavishly maintains a commitment to half the original offshore stations and only 4 beach stations without providing the necessary power analysis to demonstrate the adequacy of the design.

(2) All work on offshore benthic communities of the shelf in the Southeast, including recent work completed by Posey of UNC-W for the Wilmington US ACOE project, demonstrates the strong seasonality of the offshore benthic community. All previous monitoring projects have therefore sampled in multiple seasons, usually all four seasons as in the South Carolina studies done recently for Myrtle Beach and Hilton Head. The Carteret County plan in the Draft EIS for the Bogue Banks Beach Nourishment Project proposes sampling at two seasons, spring and fall. This new monitoring plan backs away even from that minimal

commitment to include but one sampling of the mining sites and controls per year. That reduction in scope of information gathering is utterly unjustified and fails to protect the public trust interest in an important fisheries habitat. This project should be required to sample at least in spring and fall before the start of the project and again on those identical biannual schedules afterwards until recovery is demonstrated with adequate statistical power.

(3) The specific sampling design for the beach sampling is not provided for review to ascertain its suitability. The need to control for elevation on shore and perhaps for sedimentological variables is not addressed. Preliminary data from Manning's work and in the Peterson et al. (2000) paper from JCR are sufficient to allow the applicant to fashion a specific design and conduct analysis of its power to detect impacts of various magnitudes. This has still not been done. The months and years proposed for sampling are not specified. Again, sampling needs to control for dramatic seasonal variation. Furthermore, monitoring should continue until recovery is demonstrated with a statistically powerful design. Sampling that cannot detect change is a waste of effort and misleading to the public, who justifiably expect that regulators are requiring something meaningful in the way of monitoring of impacts from permitted projects.

(4) I need to clarify one position that I took toward the end of the scoping meeting in Morehead City. While I am convinced that the identification to family level is an appropriate cost savings for the offshore benthic community monitoring at the mining site, the beach macrobenthos is far less diverse. There, species-level identification is not costly and definitely needs to be done to distinguish the two species of *Donax* clams. They are among the three most valuable prey items for surf fish and shorebirds on the beach and the two species of *Donax* engage in rather different dynamics, requiring their numbers to be distinguished in the monitoring. Note too that if species are not identified in the offshore sampling, then species diversity indices cannot be computed, as is inconsistently proposed in this revised monitoring plan.

(5) I applaud the inclusion of beach seining and gut contents analysis for surf fishes. Nevertheless, this component too is vague as to sample size and includes no power analysis to demonstrate whether it can detect impacts of a given magnitude.

While these comments represent my ongoing concerns with the adequacy of the monitoring plans proposed, they exclude the one important issue that I also am convinced needs to be addressed by the state and federal regulators. That is the issue of cumulative impacts on fisheries habitat and fish themselves from the enhanced numbers of nourishment projects statewide. This single applicant cannot be expected to design and conduct those studies, but the state and federal agencies can be. Furthermore, the separate projects that together may exert cumulative impacts of importance should be expected to share in funding those studies, even at the expense of some level of monitoring at each individual project. Here adequate environmental stewardship and leadership at state and federal levels are needed.

Sincerely,

C.H. Pete Peterson

RE: Coastal Engineering Services in Connection with a Beach Nourishment Project Along Pine Knoll Shores, North Carolina [2049]
Recommendations for Immediate Preproject Biological Sampling (Proposed Task 5B)

Dear Mayor Musgrave:

As you know, we have submitted two draft biological monitoring plans to state and federal agencies (18 April and 31 May) for their review and approval. So far, we have not received any agency recommendations or directives of what is required as a condition of permits. The comments we have received (on 11 May at the interagency meeting and on 3 June) were from Dr. Charles Peterson, consultant to North Carolina Division of Marine Fisheries. It does not appear that anything we submit will be entirely satisfactory to Dr. Peterson unless your community is willing to spend much more money on this work (beyond the approximately $150,000 that we understand you are able to apply toward biological monitoring at present).

We have proposed, through our consultants [Coastal Science Associates, Inc (CSA) – Dr. Bart Baca], up to four samplings plus an initial sampling for certain "power" analyses. CSA's revised proposal follows standard practice and is sufficiently adequate to assess impacts in our opinion. Further, it could be modified at a later date to adjust to preliminary findings and results of earlier samplings. As to when these samplings should occur remains debatable, but it appears that "spring" and "fall" samplings before nourishment will be required. It also remains debatable what the specific scope of work should be with respect to number of stations, number of samples, etc.

I am concerned that we could go round and round with Dr. Peterson indefinitely about the scope of work. Meanwhile, time is of the essence. Therefore, I wish to make the following recommendations and request action from your council at the earliest time.

CSE

1) Pine Knoll Shores should assume that the regulatory agencies will require two prenourishment biological samplings – one now and one in the fall prior to the planned November 2001 construction startup.

2) The initial sampling should be performed within the next ten (10) days and should follow Dr. Baca's latest proposal (enclosed).

3) CSA should double the number of offshore benthic stations to 20 for this first sampling to match all of Dr. Peterson's November 1999 stations. Half of the samples would be analyzed under this agreement as per CSA's present proposal, and half would be held in reserve should all 20 stations be required as a condition of the permits.

4) The Town of Pine Knoll Shores should authorize CSE and CSA to initiate field sampling immediately with costs not to exceed $30,000 for initial work.
(In the event that the Town of Indian Beach agrees to a similar proposal, we recommend that 70 percent be paid by Pine Knoll Shores and 30 percent be paid by Indian Beach on a pro-rata basis).

5) The Town of Pine Knoll Shores should continue to negotiate a mutually acceptable scope of work for biological monitoring with the regulatory agencies.

The above-listed recommendations will provide us with samples that can count later as a "spring" prenourishment sampling. CSA (Dr. Baca) is prepared to mobilize immediately, collect and preserve the specimens, and perform the initial sampling analyses. The extra ten (10) stations sampled (beyond CSA's present proposal) would not be analyzed until the town reaches agreement with the agencies regarding the scope of biological monitoring required for the entire project.

I am particularly concerned that if the agencies rely primarily on Dr. Peterson for guidance, the monitoring will remain open-ended. This is fiscally irresponsible. CSA's monitoring follows standard practice and will therefore be directly comparable to other studies of beach nourishment impacts. Certain of Peterson's recommendations are impractical and will not result in any definitive, quantitative conclusions about impacts. Further, he and some of the commenting agencies seem to be focusing on a select few studies that showed adverse impacts and ignoring the growing body of rigorous monitoring studies that confirm rapid recovery for most projects of this type.

If you have any questions about these recommendations, please call me or Bill Forman, and feel free to discuss the specific work plan with Dr. Baca (954-797-1185) at any time. Thank you for your consideration.

Yours truly,

Timothy W Kana PhD

Re: Bogue Banks beach nourishment

Dear Tim:

Having received two reviews on our submittal of a revised monitoring plan for the above project, I find it necessary to make a few comments. Although Dr. Pete Peterson's letter is unprofessional and charged with emotion, I will conversely address his acrid comments with objective facts, to wit:

(1) The data mentioned by Dr. Peterson as available are not recent enough to use in the upcoming project, nor are they suitably quantitative, for power analysis. For example, a Peterson et al. report (cover letter date April 6, 2000) describes February 1998 benthic sampling which is non-random, non-stratified, combining replicate cores, lacking proper identification of organisms, and using a sieve size which is inappropriate for macro-invertebrates (1mm *vs* the 0.5mm standard). In addition, the variability in organism abundance tied to changing seasonality precludes the use of a two-year old winter study to establish sample numbers for other seasons. The Final Report submitted by Peterson and Wells (September 11, 2000) has similar problems as the above but also provides a list of organisms which cannot be used for analyses. Common names are used for families, some of which could represent 10 or more species; some families have only one genus or species and therefore would automatically provide higher levels of taxonomic identification. In addition, as I discussed with Dr. Peterson, some organisms are known as opportunists which frequently occur in larger numbers than normal following nourishment; however, since they often belong to families with more evenly-distributed, less opportunistic species there is no way of observing this effect when only families are used. Diversity indices, species richness, and similar measures cannot be applied to these data.

For the above reasons, and as recommended by Green (1979; # 5 of his "Ten Principles"), we recommended preliminary sampling to establish the appropriate number of replicate samples. That power analysis study is an extra cost of $14,000, hardly an avoidance of quantitative sampling protocols. Through this preliminary study, a planned over-sampling effort (as Dr. Peterson might call "slavish"), satisfactory replicate numbers can be determined. For example, we can obtain the proportion of a given species in a population, selecting our probability of detecting it in subsequent samples at 90-95%, and determine the sample size *n*. There are several (other) methods available to conduct power analyses, but none are mentioned in any studies by Peterson et al. which we reviewed, although he stresses it in his reviews of our methods.

(2) As per discussions at a meeting held in Morehead, we looked for ways to cut sampling costs and slavishly assumed that extending the number of annual samplings (and reducing taxonomic efforts) was more important to the beach nourishment opponents than multi-seasonal sampling. However, we also prefer multi-season sampling.

(3) As stated above, the preliminary work done by Peterson and Manning cannot be used because of poor design and focus on a few of the larger invertebrates. The touted Peterson et al. (2000) JCR paper uses a sieve size of 3mm to sample macro-invertebrates which effectively eliminates a large percent of polychaetes, amphipods, and macro-invertebrate larvae, which can make up 90% or more of a beach sample, thus biasing the sample to make the data useless and unreliable. Donax clams and mole crabs are not always the most common, nor the most important, organisms in intertidal areas. No conclusions about the environmental effects of beach nourishment should rely on this bias sampling.

On the second point, as I mentioned at our Morehead meeting, the homeowner cannot be held hostage to an unending monitoring program. The agencies must have the knowledge and experience to agree on some manner of beach nourishment which they can assume, based on voluminous literature, will have little or no long-term negative environmental effects. And if it does have an effect, then we can mitigate for it or redesign future nourishment. The scientific fact remains, that if compatible material is used, and if the proper seasons are selected, then beach nourishment impacts are short-lived.

(4) Dr. Peterson states that identification to family is appropriate for offshore but not for beach samples. That is a variance from our meeting discussions and reflects the inadequate sampling techniques used by researchers in the past. As stated, macro-invertebrates are undersampled and standard macro-invertebrate protocol is ignored in some previous studies.

(5) The fish gut content analysis was one of the studies added to our monitoring plan based on comments from Dr. Peterson and his cohort agencies. At the Morehead meeting Dr. Peterson offered his nearby laboratory for our use since gut contents must be analyzed quickly. However, because of Dr. Peterson's outspoken opposition to this project, and his insistence on the use of sub-standard methods for macro-invertebrate surveys, we must find another nearby location. Our samples will be preserved to enable third party review if necessary.

The second comment letter, that of the U.S. Fish and Wildlife Service, does not go into sampling details but "reiterates those recommendations" of Dr. Peterson. However, their reliance on Peterson et al. (2000) and similar work reduces the credibility of their statements considering the problems we discussed with the sampling methods.

I will discuss our plan with you further, and we are excited that sampling can begin soon to meet seasonal deadlines. However, we must be careful that we do not follow guidelines which will subject our study to criticism from the scientific community. We should not be held to localized methods which purport to investigate national trends, thus reversing years of credible research. We will modify our study plan to maintain the standard of quality required by our state Quality Control certifications, while adding the needed focus on fisheries impacts. Sampling will be a stratified randomized design, with adequate replication to detect effects, in order to prove or disprove the null hypothesis that the beach nourishment had no long-term effects on borrow or fill site macro-invertebrates, or on fill site macro-invertebrates and nearshore fish.

Sincerely,

Bart Baca, Ph.D.

Dear Ron:

I enclose my review of the revised monitoring proposal for the Bogue Banks Nourishment Project presented to agency personnel and in document form at a meeting in Beaufort yesterday on July 16, 2001. I apologize for my conflict that prevented me from attending the actual presentation. I did have access to the full set of illustrations to aid in my review of the revised plan.

I am sorry to report that I found only some and, in my judgement, insufficient progress on key issues that I addressed in my review of the previous monitoring plans. The attached formal review explains my reasons for reaching this conclusion.

Sincerely,

Pete Peterson

Review of July 2001 Bogue Banks Beach Restoration Project
Monitoring Plan from Coastal Sciences Associates

By

Charles H. Peterson
UNC Institute of Marine Sciences
17 July 2001

I have examined the revised monitoring plan for the Bogue Banks Beach Nourishment project and present my reactions here to how well the revision addresses previously unanswered questions. Overall, the revised plan does not adequately provide the necessary detail about sampling design to be able to judge the plan scientifically adequate.

(1) The problem of power to detect potential impacts in the design remains. The proposers report something that they term results of a power analysis, but those results are not responsive to the issue. They report that 10 replicates per site was adequate to capture over 90% of the species. This may be so (no results are provided as support), but it is irrelevant. This monitoring study that is proposed will not make measurements at the species level. Even if it did, species counts do not reflect the value of the benthos as prey for surf fishes, crabs, and shorebirds. Densities (or biomass even better) of the two taxa that contribute over 95% of the biomass of the community, *Donax* spp. and *Emerita talpoida*, are the variables that must be estimated well to be able to detect impacts of importance to the predators that use the benthic macrofauna. Power is estimated very simply from any adequate pilot data, which the proposers now have, and the result is expressed in the form of curves that show how the probability of demonstrating an impact of a given size (20% for example) at an alpha of 0.05 varies as a function of replication (here as a function of numbers of sample sites) and other aspects of the sampling design. That has not been done. Consequently, the public and the resource agencies have no assurance for either the mining site or the beach deposition site that even a large impact of the project could be detected.

(2) The proposal makes a point to commit to using the previous locations sampled by Peterson et al. for the mining sites and by Peterson and Manning for the beach deposition sites. Yet, there is no statistical ANOVA design presented that incorporates those earlier sampling results into it to allow that earlier work to be used most effectively to help interpret impacts and recovery. The beach sampling is to be done using 0.5 mm mesh instead of the 1mm mesh used by Peterson and Manning. That major difference prevents comparisons among these data sets. Why would such a change be made? There is no discussion or justification of changing methods in mid stream. I presume that the sampling of the beach that has already been done in June used that 0.5 mm mesh, so that it has become impossible to compare to earlier samplings of Peterson and Manning.

(3) The dates (even seasons) of all samplings are unacceptably vague. Seasonality is a major determinant of benthic community composition and densities, so season must be controlled in any test of recovery. The sampling schedule for beach invertebrates should involve sampling during the warm season when abundances are high and importance to feeding surf fishes, crabs, and shorebirds is great. That is not assured. The failure to specify dates of sampling threatens ability of the entire design to estimate recovery rate. For example, a pre- and post-project sampling are proposed in the first year. Does first year mean first calendar year (i.e., 2001) or first fiscal year (June 2001-May 2002)? If it means first calendar year, the project does not begin until around December and does not end until around April, so there is no possible way to conduct a "post-project" sampling in the first calendar year. If it means first fiscal year, then the post-project sampling must occur in May, a month that does not hold month constant in the pre- and post-project periods. That design would prevent initial impact from being estimated because the difference between pre-project and post-project samples would confound seasonality with impact. This problem becomes even worse in successive

years because recovery rate must be judged against initial densities in the pre-project period, so month needs to be held constant for that comparison.

(4) This proposal still deviates from the commitment made in the Draft EIS for the Bogue Banks Nourishment Project in its monitoring of the mining sites. That EIS reported that a Fall and a Spring monitoring would be done prior to and after the project. Such a design could overcome the seasonality of this system adequately to estimate impacts to and recovery from the project. This monitoring proposal makes no mention of a Spring sampling before the project commences. It also does not specify season (month) of sampling for the subsequent post-project sampling in a design that assures that seasonality will not intrude to confound interpretation and does not replicate the Spring-Fall pattern. The numbers of stations (sites) to be sampled in the offshore monitoring are reduced to 15 from those 20 originally taken by Peterson et al in the single Fall 1999 sampling. No indication is given of which stations are to be dropped and whether the resulting design still can estimate impacts at all Borrow Areas. Furthermore, the modified design violates a cardinal rule in statistical design of monitoring by failing to maintain a balanced design of equal numbers of replicates for control and impact stations. This has negative effects on the power of the design to detect impacts and should be avoided.

(5) The proposal identifies Emerald Isle as a region within the project area. At the scoping meetings, concerns about cumulative impacts were addressed by the proposers by saying how the Emerald Isle portion of the area covered by the Bogue Banks draft EIS was not part of this project and would remain outside the project area. Why is it thus included as within the project area? This inconsistency prevents one from analyzing the adequacy of location of sample sites on the beach.

(6) Furthermore, the proposal reports that the previous Peterson and Manning beach sites will be used if possible. What would make this impossible? Which sites exactly will be used? If those sites are not used, what sites will be and why?

(7) The beach samples are to be taken by SCUBA diving and wading. The Peterson and Manning samples were all taken at low tide by walking on dry beach or in the swash. If tidal stage of sampling will be closer to high water for this monitoring, comparability with previous samples will be jeopardized.

(8) The details of the fish sampling are not sufficiently complete to allow evaluation of the adequacy of this component of the monitoring design. The mesh size of the seine is not given. The date (month) of sampling is not specified. It should be in late summer, when the surf fish demands on benthic prey are greatest and their abundances highest. The distance towed is not specified. Whether samples are day or night is not addressed. The critical need to seine during very low swell conditions is not mentioned. The problem of sampling on different days or at different times and tidal stages at different sites is not identified and defended. It is unclear what response variables will be measured. It should be abundance of each species of fish captured, perhaps subdivided by size class. What life stage implies is unclear. Methods for gut contents and "volume" analysis are not provided. Is gut fullness to be measured? How? That is not clear. How many fish will be examined and of which species?

(9) As I mentioned in my last review, species richness and diversity indices cannot be computed when animals are not identified to species, so that part of the data analysis section is inconsistent with the methods provided. ANOVA is a parametric test, as opposed to the implication made in the Data Analysis section. Non-metric MDS is a far more discriminating means of conducting multivariate analysis of community composition than the old-fashioned cluster analyses.

Re: Beach nourishment impacts

Dear Tim:

After reviewing southeast literature, I noticed you guys had already covered most of what I had to say. At any rate, based on experience over the last 15 or so years, it is my opinion, and that of many other researchers, that beach nourishment projects have no long term environmental effects when compatible, low silt/clay materials are used, when borrow sites are properly selected, and when proper timing is adhered to. Following is a listing of some of our beach nourishment projects used to formulate our opinions:

· Indian River County Beach. Hardbottom surveys of fish, benthos, invertebrates, and flora for beach nourishment project. Applied Technology and Management, Gainesville, FL.
· Martin County Beach Nourishment. Nearshore benthic and artificial reef monitoring for assessment of long-term impacts to fish and macroinvertebrates. Applied Technology and Management, Gainesville, FL.
· Longboat Key Beach Nourishment. Nearshore benthic and artificial reef monitoring for assessment of long-term im-pacts to fish and macroinvertebrates. Applied Technology and Management, Gainesville, FL.
· City of Key West. Analyses of macro-invertebrate communities on Smathers and Rest Beaches for beach renourishment project. Post, Buckley, Schuh, and Jernigan, Miami, FL.
· John U. Lloyd beach nourishment project. Long-term specimen identification for determining impacts of a large beach nourishment project using offshore dredging. John U. Lloyd State Park, Dania, FL.
· Daufuskie Island beach nourishment. Monitoring surficial sediments and macrobenthic infauna assemblages at the proposed offshore borrow areas. Applied Technology and Management, Mt. Pleasant, SC.
· Seabrook Island beach nourishment project. Environmental surveys for determination of impacts resulting from shoal dredging for beach nourishment. Seabrook Island POA, Charleston, SC.
· Hunting Island beach- nourishment project. Environmental surveys for determination of environmental impacts of beach nourishment. SC Department of Parks, Recreation, and Tour-ism, Columbia, SC.

· Palmetto Dunes beach nourishment project. Collection, identification and report relative to the environmental effects of shoal scraping for a beach nourishment project on Hilton Head Island. Palmetto Dunes, Hilton Head, SC.
· Hog Inlet beach nourishment project. Collection, identification and report relative to the environmental effects of shoal scraping for a beach nourishment project on North Myrtle Beach. Coastal Science & Engineering, Columbia, SC.
· Pawleys Island Beach Nourishment. - Macroinvertebrate surveys for determination of environmental impacts. Town of Pawleys Island, SC.
· Myrtle Beach nourishment project. Long-term macroinvertebrate and turbidity studies conducted before and after major sand nourishment. Myrtle Beach, SC.
· Seabrook Island environmental study. A five-year study of the effects of a beach nourishment dredging project on the coastal vegeta-tion, birds, and other natural resources. Seabrook Island Company, Charleston, SC.

We published two symposia presentations on these projects and the literature relative to the severity of impacts from various forms of beach nourishment (Lankford and Baca 1989, Baca et al. 1991). We found that impacts to beach sites were few and short-lived but that impacts to borrow sites were more long-lived (see Table 1).

Table 1. Impacts to various communities as a result of different types of beach nourishment methods (H=high, M=medium, L=low impacts).

Impacts To Beach or Borrow Site Offshore Dredging Nearshore Dredging Shoal Scraping
Benthic macroinvertebrates Borrow M H M
Reefs and hardbottoms Borrow M M L
Fisheries Borrow M M L
Turtle nesting Beach L L L
Bird nesting Beach L L L
Diversity/richness Borrow M H L
Commercial/recreational value Borrow M H L

Macroinvertebrates, diversities, and commercial/recreational values were impacted by nearshore dredging; importantly, however, "high" is relative as these impacts were not significant or long-lived in most cases (reviewed in Lankford and Baca 1989). In a recent South Carolina study comparing pre- (CSAi 1999) and post-dredging impacts (CSAi 2000) on offshore areas, although impacts were noticeable, they had virtually disappeared after one year.

Most of the monitoring studies of beach nourishment projects in the southeastern U.S. show that macroinvertebrate community recovery is rapid once dredging and filling have ceased (Saloman 1974, Taylor Biological Co. 1978, Culter and Mahadevan 1982, Naqvi and Pullen 1982, Gorzelany 1983, Reilly and Bellis 1983, Gorzelany and Nelson 1987, Hurme and Pullen 1988). Within the caveate of proper borrow site selection and compatible, low silt/clay material, there is no research which contradicts this statement.

Our experience with the above Florida projects confirms this also. Over the years we have seen that the few papers published which indicate long term and/or significant impacts stand out and are easier to publish because of their rarity. Editors/reviewers have indicated they are not interested in the more usual "no impacts of nourishment papers".

Sincerely,
Bart Baca, Ph.D.

July 2001

Background

The purpose of this proposed ecological study is to assess the existing biological communities, and to assess impacts on benthic invertebrates and fish, at the proposed Bogue Banks Beach Renourishment Project, located in Carteret County, North Carolina. This the second revised proposal, based on a public and agency meeting held May 11, 2001, at which recommendations were given from the UNC Institute of Marine Sciences (IMS), the U.S. Fish & Wildlife Service, the National Marine Fisheries Service, the U.S. Army Corps of Engineers, the North Carolina Department of Environment and Natural Resources, North Carolina Coastal Federation, and others. The general recommendation was to put more emphasis into fisheries surveys and impacts, and less into macroinvertebrate species identification.

The ecological study will include benthic sampling and analysis of proposed borrow and nourishment sites, and fish sampling and analysis of proposed nourishment sites, including reference sites. CSA*i* proposes to use the stations previously sampled by IMS in all cases possible. Two sampling events (pre- and post-) are proposed in the first year, with an additional sampling event in each of the next three years.

A power analysis was conducted following a review of previous studies conducted by IMS and based on the initial spring (June) sampling. The analysis determined that 10 replicates per site was adequate to capture over 90% of the total species (beach and borrow stations). The proposed sampling should produce a useful number of core samples (including stations originally sampled by UNC in Fall 1999) from both the offshore borrows areas and control areas. The scope of work is as follows.

TASK 1. Field Collection of Samples

Beach Site Sampling

Five stations will be sampled on the proposed beach to be nourished. Three stations will be sampled within the project area (Emerald I., Indian Beach, Pine Knoll Shores) and two will be sampled outside the project area to act as references/controls. Three transects will be sampled at each station, and five elevations will be sampled at each station corresponding to elevations used by Peterson et al. studies (1999, 2000). Every attempt will be made to perform the sampling at the same station location as in the Lisa Manning report (NC Sea Grant, April 2000). All stations will be located by Differential Global Positioning System (DGPS). Cores will be collected by SCUBA diving or wading using a 10.2 cm (four inch) cylindrical corer with an internal diameter of 9.9 cm (sampling an area of 77 cm^2). Benthic samples collected will be sieved in the field through a 0.5 mm stainless steel sieve bucket. All sediment and organisms retained in the bucket will be preserved in 10% buffered formalin with rose bengal stain.

Nearshore fish sampling will also be conducted at the beach sample sites. This will consist of three hauls of a 100' beach seine at the sites (one at each beach) and three at controls. Species, numbers, and life stage will be field-determined to the extent possible; fish requiring further examination will be subsampled and preserved in 10% buffered formalin. Guts of a subsample of each of the more common species will be placed on ice for gut content and volume analysis at a nearby laboratory.

Borrow Site Sampling

The proposed borrow areas have been shown in the EIS and other submittals. Sites are designated as A (offshore), B1, and B2 (both nearshore). Sample sites previously used in work by Peterson et al. (1999, 2000) will be sampled in all cases possible. All stations will be located by Differential Global Positioning System (DGPS). Ten cores will be taken at each site for a total of 150 cores. Cores will be collected by SCUBA diving using a 10.2 cm (four inch) cylindrical corer with an internal diameter of 9.9 cm (sampling an area of 77 cm^2). Benthic samples collected will be sieved in the field through a 0.5 mm stainless steel sieve bucket. All sediment and organisms retained in the bucket will be preserved in 10% buffered formalin with rose bengal stain.

A summary of proposed monitoring sampling protocols is as follows:

Beach Site invert samples	**Beach Site invert replicates**	**Invert Device**	**Sieve**	**Beach Fish sampling**	**Other sampling**
3 transects per each of 3 beach sites (Emerald I., Indian B., Pine Knoll) + 3 for each of 2 controls	3 cores at each of 5 elevations (strata) per transect; total 225 total cores	77 cm^2	0.5mm	100'x6'x1" beach seine, 3 hauls for sites and 3 for controls; 10% gut content analysis	Ghost crab burrows - 4m wide section on each upper transect
Borrow Site inverts	**Borrow reps**			**Borrow fish**	
15 sites - 9 inside, 6 controls: B2 and B1 (2 each), and near-shore half of A	10 cores from each; 150 total	77 cm^2	0.5mm	None	None

Task 2. Laboratory Methods

Samples will be preserved as above, properly labeled inside and outside of the containers, and transported to the laboratory for identification using proper quality assurance/quality control procedures.

Once samples have been transported to the laboratory, core sediment samples will be carefully re-sieved through a 0.5 mm stainless steel sieve bucket and screen. This sediment reduction will expedite the sorting process. The remaining sediments and organisms will be placed in labeled, double-ziplock bags and initially preserved in 10 percent buffered formalin solution with Rose Bengal stain. Organisms will be allowed to harden in formalin for 48 hours and then transferred to 80 percent ethanol alcohol. After the hardening period, the organisms will be placed in sorting trays and submersed/diluted in de-ionized water to minimize any volatile alcohol vapor production during identification.

Organisms will then be sorted and enumerated in the laboratory and identified to a minimum of family level with the aid of a variable power dissecting microscope (Bausch & Lomb) and/or a compound microscope (Swift or Bristol). Organisms will be identified by experienced biologists using various identification keys (e.g., Abbott, 1974; Bousfield, 1965; Bynum and Fox, 1977; Dover, 1979; Fauchald, 1977; Fox and Bynum, 1975; Gosner, 1978; Heard, 1982; Kaplan, 1988; Morris, 1975; Ruppert and Fox, 1988; Uebelacker and Johnson, 1984; Williams, 1984). Taxa identified for each station will be recorded on a laboratory bench sheet (per EPA, 1989).

Task 3. Data Analysis

Organism data from the borrow area and control site will be statistically compared to evaluate changes in faunal abundance, and number of species present among sites and over time. Besides standard statistics, analyses will include variance testing (ANOVA), and equivalent parametric tests. Comparison among specific treatment groups will be completed using the Student-Newman-Keuls test (parametric design). Diversity indices will be computed for each area (all samples combined) using Shannon diversity index, Margalef's species richness and evenness. Changes in overall community composition among sites and seasons can be evaluated using a proportional similarity coefficient (e.g., Bray-Curtis) with flexible sorting strategy and a cluster intensity (ß) of -0.25.

Task 4. Reporting

A report for each sampling event, including details of field data collection, data presentation, analysis, and conclusions/results will be submitted to NC Department marine Fisheries within 120 days following completion of the field work portion of the work.

RE: Carteret County – Bogue Banks Beach Restoration Project – Federal ID# 200000362]
Environmental Monitoring Plan [2049-5]

Dear Ron:

Thank you for meeting with Dr. Baca, Bill Forman, and me on Monday. I appreciate your time and the input that we received on the environmental monitoring plan from Larry Settle, Rick Monaghan, and Mickey Sugg. Since April, we seem to be making small steps toward resolving the plan. However, I am writing to reiterate that we need to make some big steps immediately; otherwise, Phase I will not be possible in winter 2001-2002.

I am writing with these recommendations which I believe are consistent with previous comments.

1) Environmental monitoring should be performed twice per year using June and November as the baseline months – June because of our initial samples by CSA last month and November because of UNC's fall 1999 baseline.

2) Offshore benthics should be sampled at 15 stations within and around borrow areas A, B2, and B2 with a minimum number of replicates as recommended by Larry and Bart. (Peterson and CSA sampled 10 replicates, but it appears from the initial data that seven may be adequate.)

3) Beach benthics should be sampled at 15 stations (5 strata) as shown on the map we provided on Monday at your offices.

4) Beach seining for gut analysis should be sampled at five of the beach stations (three treatment and two control) as described on Monday.

5) Statistical analyses should include comparisons of organism densities using graphics recommended by Larry and Bart.

6) Postproject sampling should be performed twice per year (June and November) following each phase of construction. We anticipate the following schedule of sampling whereby post-Phase I also serve as pre-Phase II, etc.

June 2001	Initial preproject / power analysis sampling
November 2001	Pre Phase I

CSE

June 2002	Post Phase I
November 2002	6 month / post Phase I / pre Phase II
June 2003	12-month post-Phase I / post Phase II
November 2003	18-month post-Phase I / 6-month post Phase II / pre Phase III
June 2004	24-month post-Phase I / 12-month post Phase II / post Phase III
November 2004	30-month post-Phase I / 18-month post Phase II / 6-month post Phase III
June 2005	Contingency postproject sampling
November 2005	Contingency postproject sampling

Funds are presently committed for Phase I sampling (five events). Future phases will provide for a minimum of five additional sampling periods, budgeted as part of the soft costs for the Emerald Isle reaches (subject to funding for construction).

Because of the sequencing of construction, particular sections of the beach will be nourished each month. Therefore, contemporaneous sampling in June and November will represent a sequence of months after completion. This will give us some idea of the rate of recovery along the beach (ie, for a section nourished in February, the June and November samplings are "3-months" and "9-months" after; the "6, 12, 18-month" intervals above are nominal, in other words).

It remains our opinion that the goal of the monitoring should be to document what organisms are present before the project and what are present six months to two years after the project. If recovery follows the experience at most other nourishment sites, the above-listed scope and schedule should be more than adequate to determine that. We are recommending two contingency sampling periods in 2005 if data indicate the populations have not returned to levels similar to unnourished sections within two years. We request that no further sampling be required once two successive periods demonstrate recovery as defined by quantitative measures agreeable to your reviewers and feasible under Dr. Baca's sampling plan.

Please let us know immediately if this extended sampling schedule is acceptable. We need to move on with this. Thank you for your consideration.

Yours truly,

Tim Kana

Dear Ron:

I write in response to the letter sent to you on 18 July by Dr. Tim Kana containing suggested modifications of the proposed monitoring proposal for the Bogue Banks Nourishment Project. It is unclear from this letter whether Dr. Kana had yet received my review sent to you on 17 July about continuing deficiencies in the monitoring because no reference was made to my comments and none of the substantive issues in my review was addressed in Dr. Kana's letter.

There is little need for me to repeat my comments of the 17 July review. None of the concerns has been fully addressed. Even the issue of timing of sampling, which is more completely provided in Kana's letter, is incompletely presented. Specifically, was the offshore area sampled in June 2001 by Baca to provide two pre-project samplings? That is not clear and, if it has not been done, that contradicts the commitment made in the Draft EIS. Most critically, there is no mention of the problem of power to detect impacts and thus no progress in providing the necessary statistical information that would insure that the sampling design can detect those effects of most significance to protecting essential fish habitat and its function.

Sincerely,

CH Pete Peterson

CERTIFIED MAIL
RETURN RECEIPT REQUESTED

Carteret County
c/o Dave Clark, County Engineer
Courthouse Square
Beaufort, NC 28516

RECEIVED
AUG 08 2001
CSE

Dear Sirs:

Please reference your application request under the Coastal Area Management Act to undertake the Bogue Banks Beach Nourishment Project. Processing of your application, which was received by the Division's Morehead City regional office on February 9, 2001, was placed on administrative hold on April 30, 2001 pending completion of a North Carolina Environmental Policy Act (NCEPA) review. Barring any unforeseen circumstances, I expect the NCEPA review to be concluded within the next few days. However, it has been determined that an additional piece of information will be required prior to the Division resuming processing of your application. This additional information item is summarized below:

1) In a June 20, 2001 letter to this office, the N.C. Division of Marine Fisheries has stated that

   "The Division of Marine Fisheries is unable to adequately review this project becuse of the lack of specificity in the revised Biological Monitoring Plan. We recommend that the application process be put on hold until a satisfactory Biological Monitoring Proposal, with specifics, is in hand and approved as an integral part of the total project."

   I concur with the Division of Marine Fisheries that the requested information is essential in making a determination on the significance of any impacts to fisheries resources. Therefore, the Division must place processing of your permit application in abeyance until such time as this office obtains written notification from the Division of Marine Fisheries that the requested information has been submitted. It is my understanding that your agents are in the process of working this matter out with DMF staff, so I am hopeful that this issue will have minimal impact on the timeline for this Division taking final action on your application. Should you wish to discuss this matter further with Division of Marine Fisheries staff, you should contact Mr. Rick Monaghan at (252) 726-7021.

As required by T15A:07J.0204(d), during the pendency of any termination of processing, the permit processing period will not run. Upon receipt by this office of the requested information, the Division of Coastal Management will resume processing of the application at the point where it was terminated. If you have any questions concerning this matter, please feel free to contact me at (919) 733-2293.

Sincerely,

Doug Huggett
Major Permits Coordinator

FISH AND WILDLIFE SERVICE
Raleigh Field Office
Post Office Box 33726
Raleigh, North Carolina 27636-3726

September 20, 2001

Colonel James W. DeLony
District Engineer, Wilmington District
U.S. Army Corps of Engineers
Post Office Box 1890
Wilmington, North Carolina 28402-1890

Dear Colonel DeLony:

The U.S. Fish and Wildlife Service (Service) has reviewed your July 2001 Biological Assessment (BA) for the Bogue Banks Beach Nourishment Project in Carteret County, North Carolina, and its potential impacts on Federally-listed threatened and endangered species. Our comments are provided in accordance with section 7 of the Endangered Species Act of 1973, as amended (16 U.S.C. 1531-1543; Act). Please note that additional correspondence on this project is forthcoming pursuant to technical assistance under the Fish and Wildlife Coordination Act, specifically with regards to our concerns on sediment compatibility.

The proposed project consists of excavating, by hydraulic dredge, up to 6.7 million cubic yards of sediment from ocean borrow areas situated 0.5 to 3.0 miles offshore of the project area. Sediment would be pumped onto the beach between the toe of the existing dune and the low water line and shaped by bulldozers into a profile that closely matches the natural beach. Approximately 50 percent of the excavations would be deposited by run-out from the discharge point between mean low water and the outer bar (approximately 500 feet offshore). Typical fill sections would add approximately 44 to 113 cubic yards per linear foot of beach and advance the shoreline 50 to 125 feet. The work would be performed in phases covering all or portions of each of six designated reaches according to the following schedule: (1) Phase I (Reaches 4, 5 and 6) - Towns of Pine Knoll Shores and Indian Beach, 7.2 miles and up to 3.1 million cubic yards, (2) Phase II (Reach 3 and eastern half of Reach 2) - Town of Emerald Isle, 3.0 miles and up to 1.7 million cubic yards, and (3) Phase III (Reach 1 and western half of Reach 2) - Town of Emerald Isle, 6.7 miles and up to 1.9 million cubic yards. The proposed work is scheduled to occur between November 2001 and April 2002 for Phase I, November 2002 to April 2003 for Phase II, and November 2003 to April 2004 for Phase III.

The material proposed for disposal on the oceanfront beach has the potential to impact Federally-listed species, such as loggerhead (*Caretta caretta*), leatherback (*Dermochelys coriacea*), Kemp's ridley (*Lepidochelys kempi*), hawksbill (*Eretmochelys imbricata*) and green sea turtles (*Chelonia mydas*), and seabeach amaranth (*Amaranthus pumilus*). However, based on the information provided in your BA and implementation of the following conservation measures, we could concur with a determination that the proposed project is "not likely to adversely affect" any Federally-listed endangered or threatened species, their formally designated critical habitat, or species currently proposed for Federal listing under the Act. Please note, continuation of formal consultation with the Federal action agency and the preparation of a biological opinion will be required if any of the following conditions cannot be implemented. Formal consultation may also be required if: (1) new information reveals impacts that may affect listed species or critical habitat in a manner not previously considered; (2) this action is subsequently modified in a manner that was not considered in this review; or, (3) a new species is listed or critical habitat determined that may be affected by the identified action.

1. The project must be conducted during the period when sea turtle nesting and hatching and seabeach amaranth germination are not likely to occur (i.e., November 16 through April 30). Note that activities that cannot be completed during this period may be subject to formal consultation which would take an estimated minimum of 135 days, and no activities are permitted during the formal consultation process and the preparation of a biological opinion.

2. All fill material placed on beaches must be sand that is similar to that already existing at the beach site in both coloration and grain size distribution. All such fill material must be free of construction debris, rocks, organic materials, or other foreign matter and shall not contain, on average, greater than 10 percent fines (i.e., silt and clay; passing the # 200 sieve) and shall not contain, on average, greater than 5 percent coarse gravel or cobble, exclusive of shell material (retained by the # 4 sieve). Note that this is a region-wide guideline for reducing potential adverse effect to sea turtles. The Service has sediment compatibility concerns related to other fish and wildlife resources that are being discussed with the Corps and which may be addressed in subsequent Fish and Wildlife Coordination Act correspondence.

3. A daily, early-morning sea turtle nest monitoring program must be implemented. The monitoring program should continue for six years after initial sediment disposal occurs and should include sea turtle nesting success (i.e., nests and false crawls) and hatching or emergence success during the sea turtle nesting and hatching season (May 1 - November 15) of each year. This monitoring program is intended to address our concerns with potential sediment incompatibility and its affects on nesting sea turtles. Please note, these beaches may already be surveyed on a regular basis by volunteers participating in the North Carolina Wildlife Resources Commission's Sea Turtle Volunteer Program. It is possible that the collection of this data might be coordinated through the volunteer program.

4. Immediately after completion of sediment placement on beaches and prior to April 1 for three subsequent years, sand compaction must be monitored in the placement area. At a minimum, the protocol provided under 4a and 4b below shall be followed. If required, the area shall be tilled to a depth of 36 inches. All tilling activity should be completed prior to April 1 so that they can be evaluated prior to the sea turtle nesting and hatching season and the seabeach amaranth germination period (May 1 through November 15). A report on the results of compaction monitoring shall be submitted to the Service prior to any tilling actions being taken. An annual summary of compaction surveys and the actions taken shall be submitted to the Service. Note that the requirement for compaction monitoring can be eliminated if the decision is made to till regardless of post-construction compaction levels. Also, out-year compaction monitoring and remediation are not required if placed material no longer remains on the beach.

   4a. Compaction sampling stations shall be located at 500 ft (152 m) intervals along the placement area. One station shall be at the seaward edge of the dune line (when material is placed in this area), and one station shall be midway between the dune line and the high water line (normal wrack line).

At each station, the cone penetrometer shall be pushed to a depth of 6, 12, and 18 inches three times (three replicates). Material may be removed from the hole if necessary to ensure accurate readings of successive levels of sediment. The penetrometer may need to be reset between pushes, especially if sediment layering exists. Layers of highly compact material may lay over less compact layers. Replicates shall be located as close to each other as possible, without interacting with the previous hole and/or disturbed sediments. The three replicate compaction values for each depth shall be averaged to produce final values for each depth at each station. Reports shall include all 18 values for each transect line, and the final six averaged compaction values.

4b. If the average value for any depth exceeds 500 psi for any two or more adjacent stations, then that area shall be tilled prior to April 1 (to allow time for inspection/evaluation before the sea turtle nesting season). If values exceeding 500 psi are distributed throughout the placement area but in no case do those values exist at two adjacent stations at the same depth, then consultation with the Service shall be required to determine if tilling is required. If a few values exceeding 500 psi are present randomly within the placement area, tilling shall not be required.

5. Sand compaction data must be collected on beaches scheduled for sediment disposal prior to the disposal operation following the protocols described above. Such pre-disposal beach compaction data would establish a range of values for areas in which sea turtles actually nest. These data would form a valuable baseline for comparison with post-disposal compaction values and could influence the necessity for post-disposal tilling.

6. Visual surveys for escarpments along the project area must be made immediately after completion of the sediment placement and prior to April 1 for three subsequent years. Results of the surveys must be submitted to the Service prior to any action being taken. Escarpments that interfere with sea turtle nesting or exceed 18 inches in height for a distance of 100 ft (30 m) must be leveled to the natural beach contour by April 1. The Service shall be contacted immediately if subsequent reformation of escarpments that interfere with sea turtle nesting or exceeding 18 inches in height for a distance of 100 ft (30 m) occurs during the nesting and hatching season to determine the appropriate action to be taken. An annual summary of escarpment surveys and actions taken shall be submitted to the Service. Out-year escarpment monitoring and remediation are not required if placed material no longer remains on the beach.

7. Seabeach amaranth surveys will be conducted for a period of three years along the entire project (Phase I, Phase II and Phase III). Due to the staging of this project in three distinct phases over three years, surveys will be conducted one to two years prior to and/or after sediment disposal. In addition, plant surveys shall be initiated prior to sediment disposal and/or tilling activities. If plants are discovered in areas where they may be affected by sediment disposal, and/or tilling and construction activities, the plants shall be protected by an adequate buffer zone. The protected area shall not identify the plants to protect them from collectors, but shall be of adequate size to obscure the specific plant site.

8. No construction equipment or pipes shall be stored on the beach from May 1 through November 15.

Thank you for your cooperation with our agency in protecting Federally-listed species. Again, please note that this correspondence relates to resolution of endangered species issues and that correspondence on other environmental impacts of the proposed project may be provided. Please continue to advise us of the progress of this project, including your consideration of implementing the proposed conservation measures and an official determination of the impacts of this project on Federally-protected species. If you have any questions or comments, please contact Mr. Dale Suiter of this office at (919) 856-4520 extension 18.

Sincerely,

Tom Augspurger

Colonel James W. DeLony
District Engineer, Wilmington District
Department of the Army, Corps of Engineers
P. O. Box 1890
Wilmington, North Carolina 28402-1890

Attention: Mr. Mickey Sugg

Dear Colonel DeLony:

This responds to your September 14, 2001, request for the National Marine Fisheries Service's (NMFS) comments on the August 17, 2001, letter from Coastal Science and Engineering (CSI). CSI is the consultant for Carteret County in their plan to renourish county beaches located on Bogue Banks (**Action ID No. 200000362**). The 16.8-mile-long project would be constructed in three phases over a period of three years and up to 8 million cubic yards of material would excavated from offshore sites and placed on eroded beaches.

The CSI letter largely responds to NMFS comments, dated June 25, 2001, which addresses unresolved issues related to the project. Also involved are matters which were discussed at meetings on June 20, July 16, and August 27, 2001, that were attended by representatives from CSI, the Corps of Engineers (COE), the U.S. Fish and Wildlife Service (FWS), the North Carolina Division of Marine Fisheries (NCDMF), the NOAA Center for Coastal Fisheries and Habitat Research (CCFHR), and Dr. Charles Peterson, University of North Carolina Institute for Marine Science (IMS).

Areas of Agreement:

1. Following completion of Phase I and prior to initiation of Phases II and/or III, the COE agrees to consult with state and Federal resource agencies. This consultation will address a full range of issues including the adequacy of completed monitoring and resource management implications associated with the study results. Other points of discussion include, but are not limited to, evaluation of other sand sources, and the acceptability of the dredging and disposal techniques employed.

2. The project will include a seasonal restriction that limits dredging and discharge of dredged material on ocean beaches to the period between November 15 and April 15. This restriction applies to all phases of the project and any extension on this seasonal restriction will be limited to not more than two (2) weeks. Additionally, state and Federal resource agencies must be notified not less than two (2) weeks in advance of the desired extension.

3. Success criteria for recovery of impacted areas, as described in the August 23, 2001, monitoring plan are acceptable with the following revisions. A 90 percent recovery of the established baseline diversity level will be used. In addition, successful recovery of donax (*Donax* spp.) and mole crab (*Emerita talpoida*) abundance (population size) shall be set at 90 percent due to the importance of these species as food for surf zone fishes. If the success criteria for recovery of species diversity and abundance have not be achieved by the completion of Phase II (estimated date 2003) then additional monitoring will be required in Phase III. In the event that Phase III is not constructed and recovery has not been achieved, up to (2) additional years of monition may be required.

4. Due to limited depth of the borrow sites (2-3 feet below existing bottom elevations) excavation shall be conducted by hopper dredge. It is also agreed that two dredges may work simultaneously during the allowed dredging periods.

Unresolved issues:

1. The NMFS, in consultation with the CCFHR, the NCDMF and Dr. Charles Peterson have consistently recommended that the monitoring plan must provide sufficient statistical power to detect project related changes in the benthic infauna populations in the surf zone and in the offshore borrow sites. Following the September 10, 2001, meeting, the NCDMF agreed to conduct an independent analysis of the plan. We understand that data generated by pre-project baseline sampling were recently given to the NCDMF and that the results of their analysis will soon be provided.

2. The FWS has determinated that material to be placed on the beach (a mix of materials from two different borrow sites) is not compatible with existing beach materials and is likely result in compaction that hamper sea turtle nesting. The NMFS is also concerned over the sand compatibility issue; however, we will defer our final position on this matter until ongoing analyses, which are being conduced by the COE, are completed. In this regard, we note that the a mixture of grain sizes found in the dredged material is likely to undergo rapid sorting in the high energy surf zones and areas having suitable substrates for colonization by invertebrates are likely to develop.

3. According to COE, the applicant's Environmental Assessment may meet any Federal requirement related to the National Environmental Policy Act and related procedural requirements. While this determination rests with the COE as the lead Federal agency, the NMFS has advised that an EIS may be warranted based on the severity of possible impacts and determination by the COE's Planning and Environmental Assessment Division that an EIS would be prepared all future Civil Works projects where beach nourishment is considered.

We appreciate the opportunity to provide these comments and we hope that they are useful in efforts to resolve issues and ensure that environmental concerns and needs are adequately addressed. Please direct related comments or questions to the attention of Mr. Ron Sechler at our Beaufort Facility. He can be reached at 101 Pivers Island Rd, Beaufort, North Carolina 28516, or at (252) 728-5090.

Sincerely,

Re: Permit Application for beach nourishment project along 16.8 miles of Bogue Banks

Dear Mr. Huggett:

The Division of Marine Fisheries recommends approval of the project only if the following conditions are met:

1) For each sampling period, i.e. June and November, benthic sampling at each beach station should be conducted during the same portion of the tidal cycle. Beach benthos, especially *Donax* spp., migrate along the beach face in response to the water level. Sampling all five locations along each transect as close together, temporally, as possible will prevent sampling the same group of animals twice. We are aware that sampling in this manner was not adhered to in the June 2001 sampling, and this violation of sampling protocol cannot be allowed in future samples.

2) We have spent considerable time in reviewing the various iterations of the sampling design to monitor impacts to benthos from the beach and borrow areas and to the fish along the beach. We agree to proceed with the basic procedures described in the sampling design dated August 31, 2001, submitted by Coastal Science Associates **for Phase I only**. Our concerns with the plan are:

    a. Number 1 listed above must be adhered to.
    b. We require that a sampling design for Phase II and Phase III be developed according to the Division of Marine Fisheries' satisfaction before these phases begin.

3) The dredging/pumping window for this project shall be 16 November to 15 April.

4) Phase I dredging and pumping shall begin at the eastern end of the project to minimize impacts to the stop net fishery, unless consultations with local fishermen indicate otherwise.

P.O. Box 769, Morehead City, North Carolina 28557-0769 Telephone 252-726-7021 FAX 252-726-0254

If these conditions are not met the Division of Marine Fisheries will vigorously oppose this project.

Sincerely,

James Patrick Monaghan, Jr.

Comments dated 20 September 2001 from USF&WS

Dear Colonel DeLony:

We are in receipt of comments dated 20 September 2001 from the USF&WS on the above referenced project. This is to confirm our acceptance of all conditions (Items 1 through 8, inclusive) as outlined in the letter from Garland Pardue.

We will continue to advise the USG&WS of our progress on the project as they have requested, and will submit the required monitoring data soon after it is obtained, as applicable.

Thank you for your consideration and your support is greatly appreciated.

Yours truly,

REPLY TO
ATTENTION OF

October 1, 2001

Regulatory Division

Action ID No. 200000362

Mr. Garland Purdue
U.S. Fish and Wildlife Service
Post Office Box 33726
Raleigh, North Carolina 27636-3726

Dear Mr. Purdue:

This letter confirms the receipt of your September 20, 2001 letter, regarding Section 7 consultation, pursuant to the Endangered Species Act (ESA) of 1973, for the Bogue Banks beach nourishment project along 16.8 miles of Bogue Banks Barrier Island, in Carteret County, North Carolina.

In summary, you state that, if the applicants agree to implement the conservation measures enclosed in your letter, the Fish and Wildlife Service would concur with a determination that the proposed project is "not likely to adversely affect" any Federally-listed endangered or threatened species, designated critical habitat, or species proposed for Federal listing under ESA and would terminate formal consultation.

In a response, the applicants have confirmed, by enclosed correspondence, to accept all conservation conditions set forth in your letter. Additionally, this agreement was verified during our October 1, 2001 meeting with Messrs. Dale Suiter and David Rabon of your staff and the applicant's agent, Mr. Tim Kana of Coastal Science and Engineering. With this agreement and the implementation of the conservation measures as a permit condition, we have determined that the dredging and disposal of material associated with the beach nourishment is "not likely to adversely affect" sea beach amaranth (*Amaranthus pumilus)* and the following sea turtle species: Loggerhead (*Caretta caretta*), Leatherback (*Dermochelys coriacea*), Kemp's ridley (*Lepidochelys kempi*), Hawksbill (*Eretmochelys imbricata*), and Green (*Chelonia mydas*).

By copy of this letter, we have verified the applicant's consent to comply with the conservation measures and, at this time, concur with the discontinuation of formal consultation. If you have questions or comments, they may be addressed to Mr. Mickey Sugg, Wilmington Regulatory Field Office, at (910) 251-4811.

Sincerely,

G. Wayne Wright, Chief
Wilmington Regulatory Division

APPENDIX A-2

Permit

Permit Class
NEW

Permit Number
124-01

STATE OF NORTH CAROLINA

Department of Environment and Natural Resources
and
Coastal Resources Commission

Permit

for

X Major Development in an Area of Environmental Concern pursuant to NCGS 113A-118

X Excavation and/or filling pursuant to NCGS 113-229

Issued to **Carteret, County of, Courthouse Square, Beaufort, NC 28516**

Authorizing development in Carteret County at Atlantic Ocean, Bogue Banks Beaches

, as requested in the permittee's application dated 1/24/01, incl. drawings (19), 1,2,3a-3e, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13 & 14 of 14, all dated 1/19/01 and 3f of 14 dated 8/29/01, and 1/24/01 AEC Hazard Notice

This permit, issued on October 5, 2001, is subject to compliance with the application (where consistent with the permit), all applicable regulations, special conditions and notes set forth below. Any violation of these terms may be subject to fines, imprisonment or civil action; or may cause the permit to be null and void.

1) In addition to the permittee listed above, the Towns of Pine Knoll Shores, Indian Beach and Emerald Isle have all submitted documentation requesting that their municipalities be added as co-applicants to Carteret County's permit application. Consequently, these three Towns are hereby added to this permit as co-permittees, and as such are bound by all permit conditions contained herein.

Beach Nourishment Activities

2) Prior to the initiation of any beach nourishment activity above mean high water (MHW) within the limits of the permittee's jurisdiction (e.g. Pine Knoll Shores), easements from all property owners within that specific community must be obtained.

(See attached sheets for Additional Conditions)

This permit action may be appealed by the permittee or other qualified persons within twenty (20) days of the issuing date. An appeal requires resolution prior to work initiation or continuance as the case may be.

This permit must be accessible on-site to Department personnel when the project is inspected for compliance.

Any maintenance work or project modification not covered hereunder requires further Division approval.

All work must cease when the permit expires on

December 31, 2004

In issuing this permit, the State of North Carolina agrees that your project is consistent with the North Carolina Coastal Management Program.

Signed by the authority of the Secretary of DENR and the Chairman of the Coastal Resources Commission.

Donna D. Moffitt, Director
Division of Coastal Management

This permit and its conditions are hereby accepted.

Signature of Permittee

ADDITIONAL CONDITIONS

3) Prior to the initiation of any beach nourishment activity, the existing mean high water line and the first line of stable natural vegetation used as the reference point for measuring future oceanfront setbacks must be delineated and the line approved by representatives from the Division of Coastal Management. The approved lines must be surveyed in and the survey submitted to Division. If nourishment activity for a particular community is not initiated within sixty (60) days and/or there is a major shoreline change prior to the commencement of beach nourishment, a new survey must be conducted.

4) In order to protect threatened and endangered species and to minimize adverse impacts to offshore, nearshore, intertidal and beach resources no beach nourishment activity may occur from April 1 to November 15 of any year without prior approval from the North Carolina Division of Coastal Management in consultation with the NC Division of Marine Fisheries and the NC Wildlife Resources Commission.

NOTE: The permittee is advised that there may be additional timing restrictions placed on the authorized project by the U.S. Army Corps of Engineers as part of the Federal permit process. Nothing in this State Permit should be construed as overriding or superceding any such Federal permit requirement.

5) This permit authorizes beach nourishment activities to be carried out one (1) time along the entire reach of the requested project area. Any request to carry out additional activities within an area where nourishment activities have been completed will require a modification of this permit.

6) All excavation activities must take place within one of the three borrow areas (A, B1, and B2) as shown on the attached workplat drawings. Excavation from borrow area A shall not exceed –3' below existing contours while excavation from borrow area B1 and B2 shall not exceed –4' below existing contours.

7) Temporary dikes must be used to retain and direct flow of material parallel to the shoreline to minimize surf zone turbidities. The temporary dikes shall be removed and the beach graded in accordance with approved profiles upon completion of pumping activities within each specific area.

8) Only beach quality sand shall be used for beach nourishment purposes. Furthermore, sand of similar grain size to the existing beach will be used to reduce any changes in physical characteristics of the beach.

9) Should the dredging operations encounter any non-beach compatible sand, the dredge shall immediately cease operation and move to an approved area where suitable material does exist.

10) The seaward nourishment limit varies among the six nourishment plan reaches. However, the seaward nourishment limit for each reach must be conducted in accordance with the approved work plats labeled Nourishment Plan Reach 1 through 6, each dated January 19, 2001 except for reach six which is dated August 29, 2001.

11) In order to prevent leakage, dredge pipes shall be routinely inspected. If leakage is found and repairs cannot be made immediately, pumping of material shall stop until such leaks are fixed.

ADDITIONAL CONDITIONS

12) Once a section is complete, piping and heavy equipment shall be removed or shifted to a new section and the area graded and dressed to final approved slopes.

13) Land-based equipment necessary for beach nourishment work shall be brought to the site through existing accesses. Should the work result in any damage to existing accesses, the accesses must be restored to pre-project conditions immediately upon project completion in that specific area.

14) Where oceanfront development exists at elevations nearly equal to that of the native beach, a low protective dune will be pushed up along the backbeach to prevent slurry from draining towards the development.

15) Dune disturbance shall be kept to a minimum. Any alteration of existing dunes shall be coordinated with the Division of Coastal Management as well as the pertinent property owner. All disturbed areas must be restored and revegetated immediately following project completion in that specific area.

16) The applicant has committed to the installation of dune fencing and plantings where appropriate. Any such proposal involving sand fence installation shall be submitted to the Division of Coastal Management for approval to insure that such installation does not impede public access or emergency vehicles and does not endanger nesting sea turtles. Any derelict sand fencing shall be immediately removed from the beach.

17) Prior to any beach nourishment activity, all exposed remnants of or debris from failed erosion control structures must be removed by the permittee.

18) The permittee shall begin dredging and pumping at the eastern end of the project to minimize impacts to the stop net fishery, unless consultations with the Division of Marine Fisheries indicate otherwise.

Endangered Species Protection

19) An observer shall be present on the hopper dredge except during the colder months of January and February to document any takes of sea turtles or other endangered species. Any encounters with threatened or endangered species will be recorded and reported to the Division of Coastal Management, the Wildlife Resources Commission, the U.S. Army Corps of Engineers and the U.S. Fish and Wildlife Service. In addition, a turtle deflector draghead shall be properly used.

20) Only beach quality sand suitable for sea turtle nesting, successful incubation and hatchling emergence shall be used for beach nourishment purposes. Furthermore, sand of similar grain size to the existing beach will be used to reduce any changes in physical characteristics of the beach that may affect nest survival.

ADDITIONAL CONDITIONS

21) In accordance with commitments made in the EIS prepared for this project, immediately after completion of any phase of the beach nourishment project, and prior to the next three nesting seasons, beach compaction shall be monitored and tilling shall be conducted as necessary to reduce the likelihood of impacting sea turtle nesting and hatching activities. All tilling must be done to a depth of 36 inches and must be completed no later than May 1. An annual report on the beach compaction monitoring shall be provided to the Division of Coastal Management and the NC Wildlife Resources Commission by June 1st of each year in which monitoring takes place.

22) In accordance with commitments made in the EIS prepared for this project, immediately after completion of any phase of the beach nourishment project, and prior to the next three nesting seasons, monitoring shall be conducted to determine if escarpments are present that would affect nesting sea turtles or public access. If such escarpments are present, they should be leveled as necessary to reduce the likelihood of impacting sea turtle nesting and hatching activities.

23) Should any work take place within the sea turtle nesting period of May 1st to November 15th, sea turtle crawl and nest monitoring will take place each morning. Any necessary nest relocations will be coordinated with the NC Wildlife Resources Commission and carried out by qualified personnel prior to the construction of that project section.

Biological Monitoring Requirements

24) The sampling procedures and protocols described in the August 31, 2001 sampling design submitted by Coastal Science Associates will be carried out for the 2001-02 dredging window only. Prior to the initiation of activities any future dredging windows, a sampling design shall be developed in coordination with the N.C. Division of Marine Fisheries (DMF) that further satisfies DMF concerns. A copy of this monitoring protocol, as well as written approval of its acceptance by the DMF, must be provided to the Division of Coastal Management prior to initiation on dredging during these future dredge windows. All conditions and stipulations of this modified monitoring plan must be strictly adhered to.

25) For each sampling period (i.e. June and November), benthic sampling at each beach station shall be conducted during the same portion of the tidal cycle. Beach benthos, especially *Donax spp.*, migrate along the beach face in response to water level. Sampling all five locations along the transect as close together temporally as possible will prevent sampling the same group of animals twice.

26) Unless altered herein, the permittee shall implement the biological sampling and monitoring program outlined in Appendix C of the Environmental Impact Statement prepared for this project.

Post Nourishment Beach Sediment Monitoring

27) Beach compaction shall be monitored and tilling shall be conducted in any areas where the post-nourishment beach is harder than 500 CPU's. The monitoring and tilling shall also be done in accordance with Condition No. 21 of this Permit.

ADDITIONAL CONDITIONS

Sedimentation and Erosion Control

NOTE: An Erosion and Sedimentation Control Plan will be required for this project. This plan must be filed at least thirty (30) days prior to the beginning of any land disturbing activity. Submit this plan to the Department of Environment and Natural Resources, Land Quality Section, 127 Cardinal Drive Extension, Wilmington, NC 28405.

Cultural Resource Protection

29) The N.C. Department of Cultural Resources (NCDCR) has identified six archaeological sites along the Bogue Banks Beaches. These sites are listed as follows:

- 001BBB – Iron Steamer Pier Wreck Site
- 002BBB – Gun Emplacement Site
- 003BBB – Salter Path Site
- 004BBB – Cupulo Site
- 005BBB – Emerald Isle Pier Wreck Site
- 006BBB – Ocean Reef Site

The exact locations of these six sites may be confirmed by contacting a representative of the NCDCR at (919) 733-4763. All authorized work shall avoid these areas unless prior approval is obtained from NCDCR.

30) As referenced in the text addendum to the permit application, the western portion of Borrow Area B-2 shall be avoided due to the presence of 10 magnetic anomalies.

31) There exists the possibility that the authorized activities may unearth a beached shipwreck. Should such a finding occur, the permittee shall immediately move to another area. The NCDCR Underwater Archaeology Branch must also be contacted at (910) 458-9042 to determine appropriate response procedures.

General

32) The permittee and/or his contractor shall schedule a pre-construction conference with a Division of Coastal Management representative prior to the initiation of any dredging activities. No attempt will be made by the permittee to prevent the full and free use by the public of all navigable waters at or adjacent to the authorized work.

33) The authorized activity must not cause an unacceptable interference with navigation.

34) The permittee shall comply with all U.S. Coast Guard regulations.

ADDITIONAL CONDITIONS

35) All commitments made during the environmental review process as found in the Final Environmental Impact Statement must be adhered to, including the basic procedures described in the sampling design dated August 31, 2001 and with the associated Biological Monitoring Proposal.

36) This permit does not grant any property rights or exclusive privileges to the permittee.

37) The permittee shall obtain any necessary authorizations or approvals from the USACOE prior to initiation of permitted activity. All conditions of this Federal approval must be adhered to, including the commitment made by the permittee to provide public access consistent with Federal regulations and policies.

38) The permittee and/or his contractor shall provide for proper storage and handling of all oils, chemicals, hydraulic fluids, etc., necessary to carry out the project.

39) This permit does not authorize any permanent or long-term interference with the public's right of access and/or usage of all State lands and waters.

NOTE: This permit does not eliminate the need to obtain any additional state, federal or local permits, approvals or authorizations that may be required.

NOTE: The permittee is advised that the State of North Carolina claims title to all lands raised above the mean high water line.

NOTE: Future nourishment activities may require a modification of this permit. Contact a representative of the Division at (252) 808-2808 prior to the commencement of any such activity for this determination.

NOTE: The permittee and/or his contractor is urged to meet with a representative of the Division prior to project initiation.

NOTE: The N.C. Division of Water Quality has authorized the proposed project under General Water Quality Certification No. 3274 (DWQ Project No. 010324), which was issued on 03/23/01.

APPENDIX A-2

Permit Application

MAJOR CAMA PERMIT APPLICATION

BOGUE BANKS BEACH NOURISHMENT

January 24, 2001

Applicant:

County of Carteret
Courthouse Square
Beausfort, North Carolina
Carteret County

Submitted to:

Division of Coastal Management
Morehead City Regional Office
151-B Highway 24
Morehead City, North Carolina 28557

Form DCM-MP-1

APPLICATION

(To be completed by all applicants)

1. APPLICANT

a. Landowner: Carteret County
c/o County Manager
Name Mr. Robert Murphy

Address Courthouse Square

City Beaufort State NC

Zip 28516 Day Phone 252-728-8450

Fax 252-728-2092

b. Authorized Agent:

Name Mr. Dave Clark, PE, County Engineer

Address Carteret County Courthouse Square

City Beaufort State NC

Zip 28516 Day Phone 252-728-8452

Fax 252-728-2092

c. Project name (if any)
Bogue Banks Beach Nourishment

NOTE: Permit will be issued in name of landowner(s), and/or project name.

2. LOCATION OF PROPOSED PROJECT

a. County Carteret

b. City, town, community or landmark
Pine Knoll Shores, Salter Path, Indian Beach, Emerald Isle

c. Street address or secondary road number
Beach front from Shipwreck Lane (Emerald Isle) to Pine Knoll Shores/Atlantic Beach boundary

d. Is proposed work within city limits or planni jurisdiction? ✓ Yes ____ No
Within city above MHW; owned by state below MHW

e. Name of body of water nearest project (e.g. rive creek, sound, bay) Atlantic Ocean

3. DESCRIPTION AND PLANNED USE OF PROPOSED PROJECT

a. List all development activities you propose (e.g building a home, motel, marina, bulkhead, pier, an excavation and/or filling activities.
Excavation and filling by dredge and pipeline; beach nourishment

b. Is the proposed activity maintenance of an existin project, new work, or both? New work

c. Will the project be for public, private or commercia use? Public use

d. Give a brief description of purpose, use, methods o construction and daily operations of propose project. If more space is needed, please attacl additional pages.
See attached under Project Description, and METHODS OF CONSTRUCTION

4. LAND AND WATER CHARACTERISTICS

a. Size of entire tract 16.8 miles by 1000 feet

b. Size of individual lot(s) N/A

c. Approximate elevation of tract above MHW or NWL Berm at +7 ft NGVD (+5 ft MHW) with logistics activities on construction berm seaward of natural dunes and vegetation

d. Soil type(s) and texture(s) of tract Mixed sand (FS/MS/CS) and shell (~25%)

e. Vegetation on tract Sand placement seaward of vegetation, except where dunes are too low for storm protection

f. Man-made features now on tract Dune walkovers, seawalls, and fishing piers

g. What is the CAMA Land Use Plan land classification of the site? *(Consult the local land use plan.)*
Tables attached for each municipality

______ Conservation	______ Transitional
______ Developed	______ Community
______ Rural	______ Other

h. How is the tract zoned by local government?
Tables attached for each municipality

i. Is the proposed project consistent with the applicable zoning? ✓ Yes ______ No
(Attach zoning compliance certificate, if applicable)
Tables attached for each municipality

j. Has a professional archaeological assessment been done for the tract? ✓ Yes ______ No
If yes, by whom? Tidewater Atlantic Research Inc (Appendix B of EIS)

k. Is the project located in a National Registered Historic District or does it involve a National Register listed or eligible property?
______ Yes ✓ No

l. Are there wetlands on the site? ____ Yes ✓ No
Coastal (marsh) ______ Other ______
If yes, has a delineation been conducted? ________
(Attach documentation, if available)

m. Describe existing wastewater treatment facilities.
Wastewater on Bogue Banks by subsurface treatment and/or package plants with on-site disposal

n. Describe location and type of discharges to water of the state. (For example, surface runoff, sanitar wastewater, industrial/commercial effluent, "wasl down" and residential discharges.)
See attached under Project Description Turbidity

o. Describe existing drinking water supply source.
Potable water on Bogue Banks provided by municipal and private water utilities; source is wells

5. ADDITIONAL INFORMATION

In addition to the completed application fo the following items must be submitted:

- **A copy of the deed** (with state application only) or other instrument under which the applicant claims title to the affected properties. If the applicant is not claiming to be the owner of said property, then forward a copy of the deed or other instrument under which the owner claims title, plus written permission from the owner to carry out the project.

- **An accurate, dated work plat** (including plan view and cross-sectional drawings) drawn to scale in black ink on an 8 1/2" by 11" white paper. (Refer to Coastal Resources Commission Rule 7J.0203 for a detailed description.)

  Please note that original drawings are preferred and only high quality copies will be accepted. Blue-line prints or other larger plats are acceptable only if an adequate number of quality copies are provided by applicant. (Contact the U.S. Army Corps of Engineers regarding that agency's use of larger drawings.) A site or location map is a part of plat requirements and it must be sufficiently deta to guide agency personnel unfamiliar with the area to the site. Include highway or secondary road (SR) numbers, landmarks, and the like.

- A Stormwater Certification, if one is necessary.

- **A list of the names and complete addresses of the adjacent waterfront (riparian) landowners and signed return receipts as proof that such owners have received a copy of the application and plats by certified mail.** Such landowners must be advised that they have 30 days in which to submit comments on the proposed project to the Division of Coastal Management. Upon signing this form, the applicant further certifies that such notice has been provided.

Name Mailings from each community are proceeding
Address
Phone

Name
Address
Phone

Name
Address
Phone

- **A list of previous state or federal permits issued for work on the project tract.** Include permit numbers, permittee, and issuing dates.

None for beach nourishment

- **A check for $250** made payable to the Department of Environment, Health, and Natural Resources (DEHNR) to cover the costs of processing the application.

- A signed AEC hazard notice for projects in oceanfront and inlet areas.

- A statement of compliance with the N.C. Environmental Policy Act (N.C.G.S. 113A - 1 to 10) If the project involves the expenditure of public funds or use of public lands, attach a statement documenting compliance with the North Carolina Environmental Policy Act.
NC EPA review of EIS is underway
This application is being submitted concurrently

6. CERTIFICATION AND PERMISSIO[N] TO ENTER ON LAND

I understand that any permit issued in response to thi[s] application will allow only the development described i[n] the application. The project will be subject to condition[s] and restrictions contained in the permit.

I certify that to the best of my knowledge, the propose[d] activity complies with the State of North Carolina'[s] approved Coastal Management Program and will b[e] conducted in a manner consistent with such program.

I certify that I am authorized to grant, and do in fact grant permission to representatives of state and federa[l] review agencies to enter on the aforementioned lands in connection with evaluating information related to thi[s] permit application and follow-up monitoring of th[e] project.

I further certify that the information provided in thi[s] application is truthful to the best of my knowledge.

This is the 24th day of January, 2001.

EXCAVATION AND FILL

(Except bridges and culverts)

Attach this form to Joint Application for CAMA Major Permit, Form DCM-MP-1. Be sure to complete all other sections of the Joint Application that relate to this proposed project.

Describe below the purpose of proposed excavation or fill activities. **All values to be given in feet.**

	Length	Width	Average Existing Depth	Final Project Depth
Access channel (MLW) or (NWL)				
Canal				
Boat basin				
Boat ramp				
Rock groin				
Rock breakwater				
Other (Excluding shoreline stabilization) Fill	90,000	1,000	-2 MLW	+8 MLW and below
Excavation:				
Area A	11,000	10,000	-45 MLW	-48 MLW
Area B1	27,000	1,000	-35 MLW	-39 MLW
Area B2	27,000	1,000	-35 MLW	-39 MLW

1. EXCAVATION

a. Amount of material to be excavated from below MHW or NWL in cubic yards Up to 8,000,000

b. Type of material to be excavated See attached under Project Description Borrow Area Characteristics

c. Does the area to be excavated include coastal wetlands (marsh), submerged aquatic vegetation (SAVs) or other wetlands? ____ Yes ✓ No

d. Highground excavation in cubic yards None

2. DISPOSAL OF EXCAVATED MATERIAL

a. Location of disposal area See sheets 1 and 2 on work plats

b. Dimensions of disposal area See attached under Project Description Fill Placement on Beach

c. Do you claim title to disposal area?
____ Yes ✓ No
If no, attach a letter granting permission from the owner.
Easements for areas above MHW are being obtained

d. Will a disposal area be available for future maintenance? ✓ Yes ____ No
If yes, where? Future beach fill will be necessary for maintenance and replacement

e. Does the disposal area include any coastal wetlands (marsh), SAVs or other wetlands?
_____ Yes __✓__ No

f. Does the disposal include any area in the water?
__✓__ Yes _____ No

3. SHORELINE STABILIZATION

a. Type of shoreline stabilization
__N/A__ Bulkhead _____ Riprap

b. Length __N/A__

c. Average distance waterward of MHW or NWL
N/A

d. Maximum distance waterward of MHW or NWL
N/A

e. Shoreline erosion during preceding 12 months
N/A
(Source of information) _____

f. Type of bulkhead or riprap material _____
N/A

g. Amount of fill in cubic yards to be placed below water level
(1) Riprap __N/A__
(2) Bulkhead backfill _____

h. Type of fill material __N/A__

i. Source of fill material __N/A__

4. OTHER FILL ACTIVITIES
(Excluding Shoreline Stabilization)

a. Will fill material be brought to site?
__✓__ Yes _____ No
See attached under
Project Description Fill Placement on Beach

If yes,
(1) Amount of material to be placed in the water __See * below__
(2) Dimensions of fill area __See attached under Project Description__
(3) Purpose of fill __Beach nourishment__

b. Will fill material be placed in coastal wetland (marsh), SAVs or other wetlands?
_____ Yes __✓__ No
If yes,
(1) Dimensions of fill area _____
(2) Purpose of fill _____

*Placement above water, with slurry forming fill approximately 50% above MLW, 50% below MLW. See attached under Project Description Fill Placement on Beach

5. GENERAL

a. How will excavated or fill material be kept on site and erosion controlled? __See attached under Project Description Turbidity and METHODS OF CONSTRUCTION__

b. What type of construction equipment will be used (for example, dragline, backhoe, or hydraulic dredge)?
Hydraulic dredge

c. Will wetlands be crossed in transporting equipment to project site? _____ Yes __✓__ No
If yes, explain steps that will be taken to lessen environmental impacts. _____

3.d. DESCRIPTION AND PLANNED USE OF PROPOSED PROJECT

PURPOSE AND USE

Project Setting — Bogue Banks is a 25-mile-long barrier island along the southern margin of Carteret County (Sheet 1 of 14). It comprises about one-third of the county's ocean shoreline and is the only developed and vehicle-accessible beach in the area. The remaining 55 miles of barrier islands of the county, including Shackleford Banks and Core Banks up to Ocracoke Inlet, are inaccessible wildlife preserves that will remain undeveloped in perpetuity as part of the Cape Lookout National Seashore. The western two-thirds of Bogue Banks from Pine Knoll Shores to Emerald Isle (beach survey lines 76 to 8 on Sheet 2) has sustained severe erosion and damage to numerous structures since 1995 as a result of five landfall hurricanes. This ~16.8-mile length of Bogue Banks has a sand deficit compared to adjacent beaches which has left property unprotected and has diminished recreational use of the beach. The county and local municipalities propose a beach nourishment project to restore the sand deficit and provide improved storm protection and recreational beach area.

Project Description — The proposed project consists of excavating by hydraulic dredge up to 8 million cubic yards (cy) of beach-quality sediment from ocean borrow areas (designated A, B1, and B2 in water depths averaging 35-45 feet), situated 0.5-3.0 miles offshore of Pine Knoll Shores, Indian Beach, and Emerald Isle (Sheets 11-14). Shallow excavations (~2-3 ft deep, typical) (Sheet 10) would be made by hopper dredge or specialty suction dredge and pumped via submerged pipe to the beach. The nourishment area consists of six reaches totaling 16.8 miles and designated (1) Emerald Isle-West, (2) EI-Central, (3) EI-East, (4) Indian Beach-Salter Path, (5) Pine Knoll Shores-West, and (6) PKS-East (Sheets 3a-3f). Sediment would be spread via land-based equipment and shaped into a recreational beach between the existing toe of the foredune and low watermark. Approximately 50 percent of the excavations would be deposited between existing mean low water and the outer bar (about 500-750 ft offshore). The remaining excavations would be placed above existing mean low water and graded to match the natural beach with berm elevations at approximately +7 ft NGVD (~+5 ft above mean high water) (Sheets 4-9). The fill quantity for each reach varies according to the profile deficit, background erosion rate, and quality of the fill material (overfill factor).

<u>Coordination with Municipalities</u>. It is anticipated that individual communities would assume responsibility for project execution within a particular reach and control the timing of implementation, scale, and scope of the work (up to the maximum quantities listed herein). However, the county, on behalf of municipalities along Bogue Banks, is requesting a permit for the entire project

so that the full scope of work can be coordinated. As such, the **county requests permit(s) that will allow the municipalities of Pine Knoll Shores, Indian Beach, Emerald Isle, and the unincorporated area of Salter Path (c/o Carteret County) to implement nourishment in their respective reaches under the same permit.** An EIS for the project has been prepared and submitted for review (presently approved by NCDENR offices and in review with state "clearinghouse" agencies, January 2001).

Borrow Area Characteristics. Three offshore borrow areas (A, B1, B2) are proposed based on extensive borings in 1999 and 2000 off Bogue Banks (detailed in the EIS for the project). All areas are dominated by sandy sediments and are situated seaward of the littoral zone in water depths averaging 35-48 feet (ft). See Sheets 11-14 for detailed sediment characteristics. Borrow area A has composite overfill ratios of about 1.16. Borrow areas B1 and B2 have composite overfill ratios of about 1.97 to 2.19. Because nourishment pumping costs increase with distance, it is anticipated that borrow areas B1 and B2 will yield lower unit construction costs that borrow area A. However, because of sediment quality differences and higher overfill ratios, more volume will have to be excavated from borrow areas B1 and B2 to equal the performance of sediments from borrow area A. The nourishment plan for each reach optimizes the borrow area and cost, based on best-available information. **The applicant requests permits that allow any combination of reach and borrow areas.** Assuming the average excavation depth is 3 ft, borrow area(s) totaling a maximum of ~2.58 square miles will be required to provide up to 8 million cubic yards. If all sediment is derived from borrow A, approximately 5.1 million cubic yards will be required, encompassing an area of 1.65 square miles. Portions of the borrow area(s) will be left undisturbed so that biological recovery may be accelerated via recruitment from adjacent areas. The anticipated impacted area for excavations represents 2.1 to 3.4 percent of the ocean bottom off Bogue Banks within state territorial waters (3-mile limit).

Fill Placement on Beach. Sediment from borrow areas A, B1, and/or B2 will be pumped to the beach and distributed alongshore with the aid of land-based equipment and open-ended training dikes. The slurry mixture of sediments and seawater will be discharged parallel to shore between the toe of the existing foredune and a temporary dike pushed up about 150-200 ft seaward of the foredune. Coarsest sediments will tend to settle out near the discharge point and finer sediments will tend to wash down-profile and be discharged in the surf zone, where they will build up the underwater profile. Muddy sediments, which comprise <4 percent of the borrow deposits in total, are expected to wash seaward of the outer bar before settling. The final distribution of grain sizes across the littoral zone is expected to be similar to the natural gradation that presently exists (ie, fining in the offshore direction). The indicated fill profiles (Sheets 4-9) show the "base" fill quantity (if overfill ratios were 1.0 and the borrow and native sediment matched perfectly) and the extra volume required to account for "overfill." The overfill portion shown on the drawings represents the anticipated maximum volume required if borrow areas B1 or B2 are used. This portion of the fill volume will be reduced if borrow area A is used.

The final dimensions of the nourished beach will vary according to the site-specific deficit and particular borrow area used. The landward 100-250 ft will consist of subaerial beach (dry-sand berm and upper beach face) shaped to match a natural profile. Typical elevations will range from +7 ft NGVD at the toe of the foredune (most landward edge of nourishment) to 0 ft NGVD along the beach face. Below the mid beach face contour, waves will rework and shape the nourishment sediments into a natural profile. Nourishment sand is expected to partially fill the inner trough between the existing beach face and outer bar, a width of ~500 ft. The outer bar will provide a natural toe for the fill. Only the most landward sections of the nourishment profile above mean high water (see Sheets 3a-3f) are controllable during construction. The underwater section will be controlled by waves and will vary with the contours according to conditions at the time of placement.

Turbidity. The project will produce temporary and localized increases in turbidity, normally associated with dredging operations. Because ~96 percent of the excavated material is in the sand-size class or larger, it will settle almost immediately and not remain in suspension. Silts which constitute a major portion of the mud percentage, likewise, have settling rates measured in minutes, not hours. The clay-sized particles released with the slurry have the longest settling times and may leave localized plumes for hours. The effect of the project on turbidity levels in the surf zone is expected to fall within the natural range of turbidities associated with fair weather and storm conditions. The construction methodology provides for separation of fines either during loading of hopper dredges or during discharge along the beach. Mechanical shaping of the fill berm will preclude formation of settling basins where fines may concentrate and be buried under the nourished beach.

Purpose and Need — Carteret County and the communities on Bogue Banks recognize the ocean-front beaches and adjacent properties as a valuable public economic and ecological resource. They desire to protect these valuable resources. From an economic perspective, the need for the proposed Bogue Banks beach nourishment project is to protect and preserve the largest portion of the county's overall economy. Tourism is, by far, the largest industry in Carteret County. The industry contributes ~$208 million annually to the economy of Carteret County, with a direct payroll of more than $38 million to over 3,400 workers.

Bogue Banks represents less than 1 percent of Carteret County's land area but accounts for ~43 percent (over $2 billion of the county's $5.4 billion tax base) of Carteret County's ad valorem property tax base (1997). Approximately 61 percent of all locally generated revenues in the county derive from property taxes with the remainder from sales taxes, occupancy taxes, and fees. Nearly 80 percent of Carteret County's tax levy funds Carteret County schools. Out of 8,483 students in Carteret County schools, only 537 (6.3 percent) reside on Bogue Banks (1997-98). Thus, property owners on Bogue Banks provide almost half the funds for county schools but make up less than 10 percent of the school population. Any reduction of the effective subsidy derived from Bogue Banks property and economic activity would result in increased property taxes over the remainder of the county. Loss of the first row of oceanfront properties (which alone comprise nearly 10 percent of the county tax base) would result in a county-wide tax increase of ~$0.05/$100 (from $0.51/$100 to $0.56/$100; 2000-2001 fiscal year) to make up for the reduced tax base.

Oceanfront properties represent an inordinate share of total property tax revenues to the Bogue Banks municipalities. Emerald Isle has a total tax base of ~$1,000,000,000 with ~$300,000,000 of the tax base deriving from oceanfront property. The loss of the oceanfront row of properties in Emerald Isle would result in a property tax increase of ~$0.09/$100 from $0.195/$100 to $0.285/$100. Pine Knoll Shores has a total tax base of ~$415,000,000 with ~45 percent ($185,000,000) of the tax base deriving from oceanfront property. The loss of the oceanfront row in Pine Knoll Shores would result in a property tax increase of ~$0.13/$100 from $0.16/$100 to $0.29/$100. Indian Beach has a total tax base of ~$100,000,000 with $60,000,000 of the tax base deriving from oceanfront property. The loss of the oceanfront row of properties in Indian Beach would result in a property tax increase of ~$0.26/$100 from $0.17/$100 to $0.43/$100.

The county also recognizes the beaches of Bogue Banks as a valuable ecological resource. Of over 70 miles of barrier island shoreline located in Carteret County, Bogue Banks is the only developed portion. The remainder, made up of Shackleford Banks and Core Banks to Ocracoke Inlet, will remain undeveloped in perpetuity as part of the Cape Lookout National Seashore. Bogue Banks serves to draw human activity away from the pristine beaches and ecosystems of Shackleford and Core Banks. The health of the beach environment is essential to a positive experience for the beach visitor. The damage associated with severe storms results in the loss of high oceanfront dunes, scrub and maritime forests. Easily accessible wide dry beach areas, high dunes and maritime forests harbor a wide range of wildlife resources and, because of the effects of erosion, are becoming increasingly rare along North Carolina's shoreline.

The sportfishing industry in Carteret County is second in size only to Dare County. The health of those activities (including fishing, boat building, and outfitting and supply) is dependent on the health of the marine environment.

Project Planning Objectives – In undertaking the beach nourishment project, Carteret County has several objectives that the project must meet. Those objectives are summarized as follows:

- Preservation of the environmental, cultural and aquatic resources of the county.
- Provide an easily accessible recreational beach available to all citizens of the county.
- Provide protection of oceanfront property as a resource of tax revenues to the municipalities of Bogue Banks and the county.
- Maintain the economic viability of tourism, the county's largest industry.

PROJECT FORMULATION

Fill Profile — Beach nourishment may be performed at a continuum of scales, depending on the goals of the project, availability of borrow sediment, method of construction, and budget. Since the proposed project area has not been nourished, there are no site-specific data to use as a guide other than the existing natural profile and available erosion rate estimates. Nearby Atlantic Beach has been nourished twice, but its sediment characteristics (after nourishment) differ from those in the proposed project area.

CSE Baird-Stroud (1999) evaluated the condition of the beach and inshore zone along Bogue Banks, using the profile volume method (Kana, 1993; Kana and Mohan, 1996). This method establishes site-specific criteria by which volume deficits can be determined against an ideal or desirable profile volume (ie, one which contains sufficient dimensions to sustain daily, seasonal, and storm fluctuations of the beach without significant damage to the backshore). The profile volume method, if performed to the estimated depth of closure, integrates all cross-shore variations in profile geometry and is therefore insensitive to the timing of surveys.

Prior analyses (CSE Baird-Stroud, 1999) demonstrated that there is a profile deficit averaging ~40 cubic yards per foot (cy/ft) along the 16.8-mile reach from western Emerald Isle to Pine Knoll Shores (profiles 8-76), compared to the existing profile volume along Atlantic Beach. Considering the fact that Atlantic Beach sustained Hurricanes *Dennis* and *Floyd* (1999) as well as *Fran* (1996) with only minor damage compared to other sections of Bogue Banks, its profile volume yields a rational minimum value. During final design, the profile volume will be analyzed quantitatively to estimate the level of protection provided.

The desired fill volume is one that restores the deficit (with respect to the criteria and goals of the project) and adds "advance nourishment" to increase longevity. Advance nourishment is generally related to the anticipated average annual losses from the project area (ie, the background erosion rate). The Bogue Banks Beach Preservation Task Force evaluated projects which factored in 5-year, 10-year, and 20-year advance nourishment requirements based on best-available background erosion rates. It was the decision of the task force to formulate the project around the 10-year nourishment project (ie, initial deficit averaging 40 cy/ft plus 10-year advance nourishment averaging 10 cy/ft).

This provides a reasonable time period over which the first project can be evaluated and provides a project scale that is practical for dredging. Small-scale projects do not afford economies of scale during construction and result in more frequent nourishments and the associated disruption to normal beach use by people and animals. Bogue Banks is generally considered a good candidate site for nourishment because its background erosion rate is relatively low and it is less exposed to north-easters because of its sheltering by Cape Lookout.

METHODS OF CONSTRUCTION

The proposed fill will be placed by hydraulic dredge between the base of the foredune and the outer bar. Only the profile above high water is controllable in nourishment construction. Intertidal and underwater portions of the profile will be subject to natural adjustment by waves. Given the relatively high back-beach elevations along most of Bogue Banks and the issue of easements for construction, the majority of the fill will be placed no higher than +7 ft NGVD (the natural elevation of the berm) and seaward of the existing toe of the foredune and all development. Along portions of eastern Emerald Isle, a low dune (elevations <+12 ft NGVD) will be constructed as part of the project to prevent the dredge slurry from flowing landward across developed property (where the foredune is missing).

Equipment

- *Ocean-certified hopper dredge* – Self-propelled hopper dredges with built-in, pump-out capability are feasible for borrow areas A, B1, and B2. Ocean-certified equipment typically requires ~25 ft minimum operational depth and is efficient for excavating shallow cuts of the order 1-2 ft (Sheet 10). During excavation and loading, the slurry drains via scuppers discharging some fines in situ and leaving coarser material in the hopper compared to the excavated material. When loaded, the dredge travels to a temporary mooring and submerged pipeline near the project site. It hooks up to the pipeline and pumps the material from the hopper to the beach where it is spread mechanically by dozers.

- *Ocean-certified suction dredge equipped for shallow cuts* – This "dustpan" dredge (so nicknamed) is used primarily for beach nourishment involving thin borrow areas offshore. The dredge works most efficiently if the borrow area is close to the project area (e.g., excavations paralleling the beach less than one mile offshore). The slurry is pumped directly to the beach via submerged pipeline and distributed with the aid of dozers and other land-based equipment. In contrast to self-contained hopper dredges, the excavations are pumped only once and therefore transfer more fines to the beach according to the quality of the sediment in the borrow area. Unit costs may be substantially lower than all other methods if the pumping distances are short. This method is considered most feasible for borrow areas B1 and B2.

Construction Schedule — The proposed project involves a substantial volume of sand (>4.5 million cubic yards in-place after gradual erosion of overfill). Based on project experience elsewhere, one ocean-certified dredge can excavate and place on the order of 15,000-30,000 cy in a 24-hour period. The average production per day varies widely according to transportation distance and specifications of the project. In any case, a substantial period of time will be required to complete the project. For example, if production averages 20,000 cy/day, upward of 400 calendar days (~13 months) will be required to place the base volume plus overfill for all six reaches. It is anticipated that three reaches (#6 PKS-East, #5 PKS-West, and #4 IB/SP) will be scheduled for nourishment in 2001-2002, pending results of community funding referendums and receipt of permits. Other reaches would be completed no earlier than the 2002-2003 construction window. Reaches 4-6 comprise about 40 percent of the project length and about 45 percent of the nourishment volume requirement.

Work will progress in sections within the borrow area(s) and along the beach. The borrow area will be left to adjust naturally and to recolonize while other areas are being excavated. Fill placement along the beach will typically involve completion of 200-500 ft per day. Construction activities will involve movement of heavy equipment and pipe along ~1 mile reaches over a period of 2-3 weeks. Once a section is complete, piping and heavy equipment will be shifted to a new section and the process repeated. As soon as practicable, sections will be graded and dressed to final slopes and left to respond naturally. Other than equipment staging areas, individual lots along the oceanfront will experience disruption due to construction for one month or less, in general. Fill sections will be left to adjust naturally as soon as the required volumes are pumped into place and confirmed by surveys.

Land-based equipment will be brought to the site over public roads and will enter the beach through existing permanent accesses or temporary accesses. Any alteration of dune vegetation/topography necessary for equipment access will be performed in consultation with state regulatory agencies, local officials, and property owners. Temporary accesses will be restored to preconstruction conditions at the conclusion of work in a given reach or combination of reaches. Daily equipment staging will be on the constructed beach seaward of the dune line and any native vegetation. Construction contracts will provide for proper storage and handling of oils, chemicals, and hydraulic fluids, etc., necessary for operation in accordance with state and federal regulations.

Preliminary discussions with environmental agencies indicate construction during colder months is favored because biological productivity tends to be lowest then. Construction during winter also avoids disruption of the peak tourism season.

The following two general construction schedules were the two workable conclusions reached in the EIS. Both are requested for this permit.

Construction during limited "environmental" windows between 1 November and 15 May

- *Advantages* – Direct environmental impacts occur during periods of lowest biological productivity. Avoids prime tourist season. Yields early benefits if the project can be initiated in fall 2001.

- *Disadvantages* – A five-to-six month construction window is insufficient to complete the entire project unless more than one dredge is used. Each dredge introduces large mobilization costs, increasing the total cost of the project. The narrower the dredging window, the fewer contractors will be willing to bid the project, further raising the cost of construction. Down time for weather is more likely during winter than summer. Delays project benefits for at least one year if the winter 2001-2002 construction window is missed.

Construction during two or more seasons within limited "environmental" windows

- *Advantages* – The only viable schedule in the event only one dredge is available for the project. Generally similar environmental advantages but produces direct impacts over multiple seasons rather than one (not along the same project reaches).

- *Disadvantages* – Will require at least two mobilizations, increasing the project costs. Postpones project benefits (wider beach, improved storm protection, etc.) for the areas uncompleted during the first window. Causes disruption to habitats over multiple seasons instead of one.

Requested Construction Schedule — We request the two above schedules, namely, construction during environmental windows which may extend into the fall and spring. Specifically, we request permission to commence construction as early as 1 November and continue construction as late as 15 May, and during multiple years, if necessary.

ENVIRONMENTAL MONITORING

We expect that reviewing agencies will specify environmental monitoring. Based on our understanding to date, we propose the following:

1) Biological monitoring aboard each dredge during all hours of operation, except in January and February. Any encounters with endangered or threatened species will be recorded and reported to the appropriate agencies.

2) Sea turtle crawl and nest monitoring will take place each morning on the nourishment beach between the calendar dates specified by the agencies. Nest relocation will be performed by qualified personnel prior to construction of that project section.

3) The beach sampling, benthic sampling, and fish trawls as listed in the program outlined in Appendix C of the EIS.

4) Sampling for mud content in the placed nourishment sand.

5) Other environmental sampling specified as conditions in the permits.

4. LAND AND WATER CHARACTERISTICS

g. What is the CAMA Land Use Plan land classification of the site?
The following is provided based on query of planning staff in each municipality and the county.

Municipality (Site)	Land-Use Classification
Pine Knoll Shores	Developed
Indian Beach	Developed
Salter Path	Developed, Conservation
Emerald Isle	Developed

h. How is the tract zoned by local government?
i. Is the proposed project consistent with applicable zoning?

Municipality (Tract/Proposed Project)	(h) Zoning*	(i) Zoning Consistency
Pine Knoll Shores	R/C/I/Rec	Yes
Indian Beach	R	Yes
Salter Path	R	Yes
Emerald Isle	R/C	Yes

[*R – residential / C – commercial / Rec – recreational / I – institutional]

5. ADDITIONAL INFORMATION

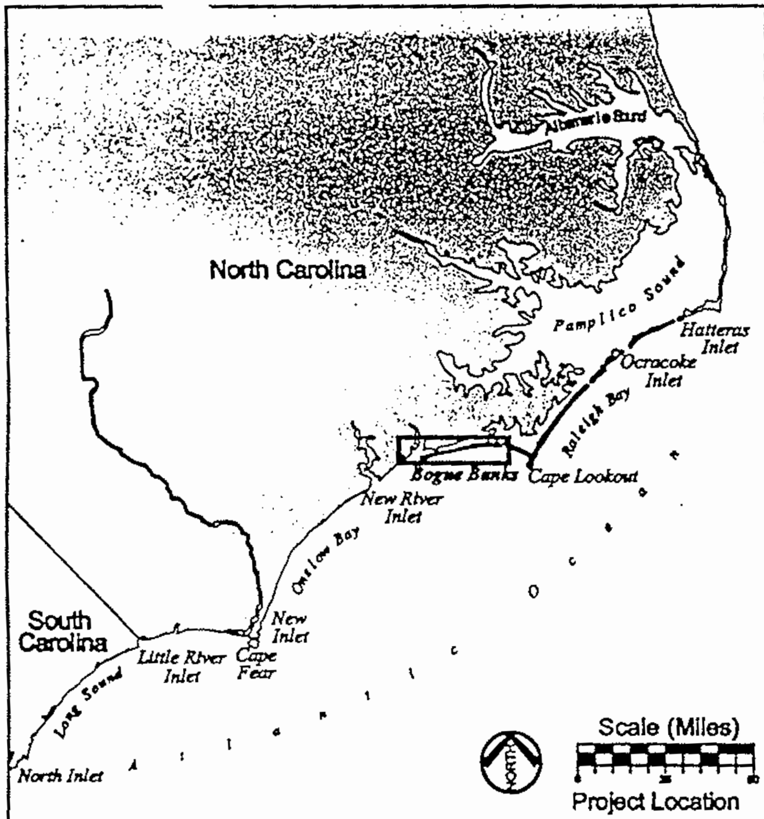
Deed — All project areas below mean high water (MHW) are within the 3-mile limit and are, therefore, owned by the State of North Carolina, not by the federal government. All project areas above MHW are within Carteret County, but are owned by individual landowners. Pine Knoll Shores and Indian Beach are now actively pursuing easements. **Applicant requests that permitting proceed for the overall project, with the condition that each community's section would be permitted once easements are complete for that community.**

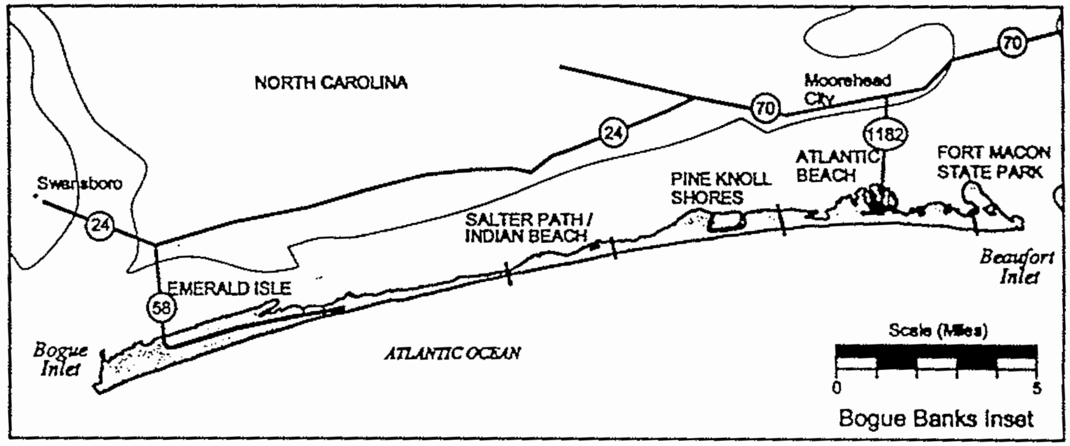
Work Plats — Drawings by the project engineer are attached to this application and are included in the packages sent to oceanfront landowners.

Names and Addresses of Adjacent Waterfront Landowners — This permit applies to four different communities, and each of those towns is assembling copies of this application for mailing to oceanfront landowners. In view of the unusually large number of mailings, which will take some time, **applicant requests that permitting proceed while registered mailings are underway.** Once each community completes and transmits the receipts to the agencies, permitting could then be completed.

AEC Hazard Notice — A hazard notice signed by the county is attached to this application.

Compliance with NC Environmental Policy Act — An Environmental Impact Statement (EIS) has been submitted for interagency review, comments have been received, the EIS has been revised, and a final EIS has been submitted for agency review. As of the date of submittal of this application, final approval of the EIS has not yet been received. Therefore, this permit application is being submitted concurrently with the final EIS review process, with the understanding that this application cannot be approved until the EIS is accepted.





Directions:

From Swansboro take Hwy 24 toward Morehead City. Turn right on Hwy 58 towards Emerald Isle. Follow signs to public beach access. (general locations below)

From Morehead City take Hwy 70 (Arendell Ave) towards Swansboro. Turn left on Hwy 1182 towards Atlantic Beach. Turn right at the first light onto Hwy 58. Follow signs to public beach access. (general locations below)

AEC HAZARD NOTICE

ɔject Is In An: _x_ Ocean Erodible Area ____ High Hazard Flood Area ____ Inlet Hazard Area

Date Lot Was Platted: N/A

This notice is intended to make you, the applicant, aware of the special risks and conditions associated with development in this area, which is subject to natural hazards such as storms, erosion and currents. The rules of the Coastal Resources Commission require that you receive an AEC Hazard Notice and acknowledge that notice in writing before a permit for development can be issued.

The Commission's rules on building standards, oceanfront setbacks and dune alteration are designed to minimize, but not eliminate, property loss from hazards. By granting permits, the Coastal Resources Commission does not guarantee the safety of the development and assumes no liability for future damage to the development.

The best available information, as accepted by the Coastal Resources Commission, indicates that the annual ocean erosion rate for the area where your property is located is 1 - 3 feet per year.

The rate was established by careful analysis of aerial photographs of the coastline taken over the past 50 years.

Studies also indicate that the shoreline could move as :h as 25 feet landward in a major storm.

The flood waters in a major storm are predicted to be about 12 feet deep in this area.

Preferred oceanfront protection measures are beach nourishment and relocation of threatened structures. Hard erosion control structures such as bulkheads, seawalls, revetments, groins, jetties and breakwaters are prohibited. Temporary devices, including sand bags, may be allowed under certain conditions.

This structure shall be relocated or dismantled within two years of becoming imminently threatened.

The applicant must acknowledge this information and requirements by signing this notice in the below space. Without the proper signature, the application will not be complete.

x Dave Clark, P.E.
Applicant's Signature

x 24 January 2001
Date

SPECIAL NOTE: This hazard notice is required for development in areas subject to sudden and massive storms and erosion. Permits issued for development in this area expire on December 31 of the third year following the year in which the permit was issued. Shortly before work begins on the project site, the Local Permit Officer will determine the vegetation line and setback distance at your site. If the property has seen little change and the proposed development can still meet the setback requirement, the LPO will inform you that you may begin work. It is important that you check with the LPO before the permit expires for official approval to continue the work after the permit has expired. Generally, if foundation pilings have been placed and substantial progress is continuing, permit renewal may not be necessary. If substantial progress has not been made, the permit must be renewed and a new setback line established. It is unlawful to continue work after permit expiration without this approval.

RE: Copy of Class II Environmental Assessment
Beach Restoration Project

Dear Mayor Musgrave:

Enclosed please find a copy of our Class II Environmental Assessment for the above mentioned project This information should be made available to other agencies contributing to the project, other interested parties, and persons that may be affected by the requirements of our assessment.

Please advise if you have questions regarding the above.

Sincerely,

EDWIN W. CAUSEY

CLASS II
ENVIRONMENTAL ASSESSMENT
TOWNS OF
INDIAN BEACH
AND
PINE KNOLL SHORES

PREFACE

USDA, Rural Development (USDA, RD) has recently received pre-applications from the towns of Indian Beach and Pine Knoll Shores in Carteret County, North Carolina for a beach nourishment project. While RD has recently become involved in the project, the towns have been considering and planning it for several years. They have worked closely with Coastal Science and Engineering, LLC of Columbia, South Carolina and Stroud Engineering, P.A. of Morehead City, North Carolina in planning the project. These consultants have prepared an Environmental Impact Statement (EIS) that meets the requirements of the State Environmental Policy Act (SEPA). USDA, RD has reviewed the EIS and considered the findings and conclusions therein and is in concurrence with same. The EIS appears to be very thorough and addresses all environmental issues which Rural Development has tentatively identified for this project. With enforcement of the mitigation measures that have been established through the review and comment phase of the EIS, RD does not believe the project as proposed will have a major impact on the human environment. Therefore RD does not believe at this time it is necessary to prepare an environmental impact statement for this project under the National Environmental Policy Act (NEPA). USDA, RD must still meet the requirements of the National Environmental Protection Act (NEPA) and must still complete an independent environmental review of the project. Therefore, RD has prepared an environmental assessment to meet the requirements of NEPA and RD Instruction 1940-G. As part of the RD review, the EIS has been reviewed in detail.

This Class II Environmental Assessment has the same findings as the EIS. Rural Development plans to issue a Finding of No Significant Impact (FONSI) for this project and to formally notify the public of this determination. The EIS is included as **Attachment 4** to this assessment and is intended to be used in conjunction with same. Rural Development's assessment contains numerous references to the EIS. Also included within **Attachment 4** to this assessment is the Supplement to the Final EIS that was prepared in connection with the federal review for the permit application for the project.

There will be several federal permit applications required for this project. An important point in RD's mitigation measures for this project is that RD will not authorize construction of the project or provide any financial assistance for the project until all applicable permits have been obtained. Therefore RD recognizes that further environmental review of the project will take place during the permit application process. Should significant issues arise during the application for federal permits that would trigger the need for an EIS under NEPA, RD does reserve the right to re-open environmental review of the project and prepare either independently or in cooperation with other federal agencies, an EIS for this project.

I. PROJECT DESCRIPTION AND NEED

Carteret County has sustained accelerated beach erosion along Bogue Banks as a result of five hurricanes passing over or in close proximity to the area. This frequency of occurrences is far greater than normal for this area since 1995. The county, the municipalities of Emerald Isle, Indian Beach, Pine Knoll Shores, and the unincorporated area of Salter Path desire to perform beach nourishment at the earliest time possible. This report addresses the specific needs of Indian Beach and Pine Knoll Shores.

The proposed nourishment project will consist of placing beach quality sediment along the coastline of both Pine Knoll Shores and Indian Beach. Figure 1 (EIS, Appendix B) shows the proposed locations at which sand is to be placed. Figure 2 (EIS, Appendix B) is a schematic diagram, which shows the general configuration of the sand to be deposited. Nourishment sand will be excavated from up to three borrow areas by hopper dredge or hydraulic dredge and placed along the three reaches that compose this project. The width of the beach will be extended approximately 100' with this project.

Three potential borrow areas have been sampled and delineated offshore of the project area. Sediment quality in each borrow area was compared with native beach sediment to determine compatibility indices. Final selection of borrow areas will be based on several factors, including sediment quality, dredging and transportation, economic/environmental impacts, and cultural resource impacts. See EIS, Appendix B, Figure 1 and Figure 2, which outline the various reaches.

II. PRIMARY BENEFICIARIES

The primary beneficiaries of the project will be the citizens of Indian Beach and Pine Knoll Shores, the citizens of Carteret County, as well as visitors from all over eastern North Carolina. (Also, see Exhibit 7, Survey Report 2000 Bogue Banks, NC and Shoreline Assessment & Preliminary Beach Restoration Plan (Sept 1999.)

The citizens of Indian Beach and Pine Knoll Shores get the direct benefit of protecting the physical integrity of their town as well as the tax base. The total Bogue Banks area represents less than one per cent of Carteret County land area but accounts for 43% of the county's tax base. Nearly 80% of Carteret County's tax base funds Carteret County Schools. Thus, the financial integrity of the entire county is closely associated with the towns of Indian Beach and Pine Knoll Shores.

The county also recognizes the beaches of Bogue Banks as a valuable ecological resource. Of the 70 miles of barrier island shoreline located in Carteret County, Bogue Banks is the only developed portion. Bogue Banks serves to draw human activity away from the pristine beaches and ecosystems of Shackleford and Core Banks.

III. DESCRIPTION OF PROJECT AREA

The towns of Indian Beach and Pine Knoll Shores are located on Bogue Banks in Carteret County, North Carolina. The 1990 census listed the permanent population of Pine Knoll Shores as 1360 and Indian Beach as 153. Tourism is the foundation of the local economy. Much of the population is made up of retired families. There are numerous second homes.

The area is an excellent candidate for nourishment because of the historically low erosion rate. Most of the Bogue Banks area is situated favorably away from tidal inlets where shoreline changes tend to be more erratic and much greater in magnitude. The major contributor to erosion along the beaches of these towns is the occurrence of large storms such as hurricanes that either skirt the coast on the east side of the towns or cross the coastline and proceed inland. This impact is magnified when several storms occur in an unusually short time frame. The benefits of nourishment can be seen in Atlantic Beach, which has received sand on two occasions from USALE projects. Atlantic Beach is located just north of Pine Knoll Shores.

IV. ENVIRONMENTAL IMPACT

AIR QUALITY:

The Air Quality Section of the North Carolina Department of Environment and Natural Resources has jurisdiction over air quality in Carteret County. According to the Wilmington District Office, ambient air quality in Carteret County is in compliance with the National Ambient Air Quality Standards.

A slight increase in total suspended particulate (TSP) is expected for a temporary period in the immediate area of construction. However, all sediment materials moved will be moist, thus minimizing the amount of suspended particulate matter escaping to surrounding air. Most of the material placed will consist of medium to large sand particles, which are less susceptible to becoming airborne. The construction period of the project should be six months or less. The resulting impact on the ambient air quality standard is considered minor.

WATER QUALITY: (EIS 3.9 and 3.10 page 3-5)

The proposed project will not affect water quality of surface or ground water.

Water quality around Bogue Banks is generally high due to large tidal flows and resultant flushing associated with Bogue Inlet and Beaufort Inlet. Waters of Bogue Sound, west of a line from the mouth of Gales Creek to Rock Point in Indian Beach, are classified as outstanding resource waters (ORW), which are waters of the state that are unique and of a special state or national recreational or ecological importance that require special protection to maintain existing uses. Waters east of Rock Point in Bogue Sound are classified SA. SA waters are suitable for shell fishing for human consumption. Ocean waters of Onslow Bay off of Bogue Banks are of high quality. This quality is due to the fact that no rivers draining large urbanized watersheds discharge directly into Onslow Bay. The White Oak River in the western end of the county and the Newport River in the east have relatively small agricultural, forested, and lightly developed watersheds.

Groundwater is plentiful throughout Bogue Banks. It is near the surface in many places, especially in the early spring and winter. The underlying limestone deposits of the Castle Hayne formation are the source of water supplies on Bogue Banks. These formations are below the surficial aquifers in the island consisting of a fresh water lens which varies in depth depending on rainfall amounts and has water that is often salty or has high concentrations of dissolved iron and hydrogen sulfide.

SOLID WASTE MANAGEMENT:

The project will not involve demolition or construction of any permanent structures. The contractor will be required to remove all supplies and equipment from the project area upon completion of sand pumping. Disposal of pipe, cable, or any expendable items will be prescribed in contract documents with penalties for violations including, at minimum, retrieval of items dumped accidentally at sea or on the project beach.

LAND USE: (EIS 3.1.1 page 3-1)

Bogue Banks is a barrier island with a southward facing ocean shoreline stretching some 25 miles between two large tidal inlets, Bogue Inlet to the west and Beaufort Inlet to the east. The Banks are surrounded by Bogue Sound on the north and Onslow Bay of the Atlantic Ocean on the south. The island is made up of the Fort Macon State Park, the Towns of Atlantic Beach, Pine Knoll Shores, Indian Beach, and Emerald Isle and the unincorporated area of Salter Path.

Over 70 miles of barrier island shoreline located in Carteret County, Bogue Banks is the only developed area. The remainder, made up of Shackleford Banks and Core Banks to Ocracoke Inlet, will remain undeveloped in perpetuity as part of the Cape Lookout National Seashore. Bogue Banks is the only ocean shoreline. Dune ridge elevations reach 40 feet (ft) above sea level at some locations.

Bogue Banks' soils vary with Newhan sandy soils in the nearshore, beach and dune zones; Duckston, Corrolla and Newhan soils in the scrub zones; Duckston, Corrolla and Fripp soils in the maritime forest zones; and Carteret soils in the salt marsh zones. Corrolla soils are fine sands, moderately to poorly drained that occur behind the frontal dune line. Fripp sands are excessively well drained and make up the interior dune ridge areas. Duckston fine sands are poorly drained and are in the troughs between dune ridges and on flats between dunes and marshes. Newhan fine sands are excessively well drained and make up the dune ridges that parallel the ocean shoreline. Carteret soils are the fine organic muck found in the salt marsh environment.

Vegetation on Bogue Banks reflects elevation and the amount of exposure to salt spray. As distance from the shoreline increases, sparse beach grasses merge with dense scrub vegetation. Maritime forests thrive in areas where the island is wide enough to provide sufficient protection from salt spray for forest growth. Maritime forests generally occur on lands that have been stable for at least 50 years. Vegetation typical of freshwater wetlands and tidal flats populate flood prone areas and natural and manmade drainage ways.

TRANSPORTATION:

All of the construction activity will occur on the ocean or beachfront. There will be no major adverse impact on transportation in the area. The borrow area from which the materials for beach nourishment will be obtained are not located in or near shipping channels. There may be some minor inconvenience to fishing boats, shrimp trawlers, etc., as they have to detour around the dredges and pipeline.

NATURAL ENVIRONMENT:

It is determined that this construction will have no major impact on important land resources.

HUMAN POPULATION:

No persons will be relocated as a direct result of the proposed project. The proposed development could accommodate a moderate amount of population increase. It is not expected that any population changes, other than those that would ordinarily occur, will occur as a result of the proposed project. Therefore, no demands will be placed on community services such as schools, health care, social services, and fire protection that have not already been planned.

CONSTRUCTION:

The location of the planned improvements is located such that minimal disruption will occur for anyone. The majority of planned improvements will occur at a time of year that will further minimize disruption. The actual construction may necessitate the actual closing of sections of the beach for a period of one-month maximum. In addition, there could be a temporary discoloration of waters around the dredge intake and a temporary decrease in aesthetic value of the beach area due to the noise impact from the machinery operating on the beach.

V. ENERGY IMPACTS

The project will not alter energy supplies and uses. Construction will require local fuel purchases to run self-contained dredging equipment and trucks. No construction will require connection to the local power grid.

VI. COASTAL ZONE MANAGEMENT ACT (EIS 2.5.1 page 2-5)

The project is located in a county covered by the Coastal Zone Management Act. Coastal Science and Engineering, LLC prepared an environmental impact statement.

CAMA representatives will submit copies of the EIS to the Army Corps of Engineers for Federal agencies' review. The Corps coordinates federal review of both the EIS and the CAMA Major Development Permit application. Federal review includes Corps review of compliance with section 10 of the Rivers and Harbors Act of 1899 for work within navigable waters. The Corps also reviews for compliance with Section 404 or the Clean Water Act, covering discharge of dredged materials into navigable waters.

The Corps distributes copies of EIS and permit applications to other federal agencies, including the Environmental Protection Agency, National Marine Fisheries Service, and U.S. Fish and Wildlife Service. These agencies review and comment on the EIS, and these comments must be received and considered by the Corps prior to the coordinated Federal response to the EIS. Likewise these agencies' responses must be received and considered prior to issuance of a Federal permit.

North Carolina's Division of Coastal Management coordinates the entire review process, both to state agencies and to the Corps. State approvals required include certification of compliance with the Coastal Area Management Act, the Dredge Fill Act, Water Quality Certification (Section 401), and Easement in Public Trust Areas.

For both the EIS review and the permit-application review, DCM distributes copies to state agencies that include the Wildlife Resources Commission, the Department of Administration, the Department of Transportation, and Divisions of Water Quality, Land Quality, Marine Fisheries, Environmental Health, Archives and History, and Community Assistance. DCM receives and reviews comments from these agencies and the coordinated Federal response prior to approval of Finding of No Significant Impact (FONSI) or a requirement for changes in this Plan.

The project requires compliance with NC EPA. This Environmental Impact Statement is the document being submitted to demonstrate such compliance. Based on the review, DCM either issues the FONSI or requires amendments to this Plan.

VII. COMPLIANCE WITH ADVISORY COUNCIL ON HISTORIC REGULATIONS

Rural Development Instructions 1901-F. 1A have been reviewed and the proposed site does not contain or affect a historic place listed in the National Register of Historic Places. The comments of the State Historical Preservation Officer (SHPO) were considered in the EIS and are included as mitigation measures. The SHPO has further requested that everyone be sensitive to the potential of unearthing a beached shipwreck and to call the Underwater Archaeology Branch at 910-458-9042 if needed.

VIII. CULTURAL RESOURCES (EIS 5.7 page 5-3)

To determine the impact of the proposed dredging and beach fill operation on potentially significant submerged cultural resources, a remote sensing survey of the proposed borrow areas was conducted by Tidewater Atlantic Research, Inc. (TAR) of Washington, North Carolina. The survey was designed to locate and identify submerged cultural resources in the study area, generate sufficient data to make an initial assessment of teach target's significance, and provide insight into the necessity for avoidance or additional investigation. The survey was carried out between 7 and 13 December 1999. No magnetic or acoustic anomalies were identified in either borrow area A or borrow area B-1. In borrow area B-2, ten magnetic anomalies were identified near the western end of survey area. Seven of those targets contained signature characteristics indicative of submerged cultural resources. Because they could be associated with an historic shipwreck, either avoidance or additional investigation to positively identify the nature and significance of the material generating the seven anomalies was recommended. To avoid the areas of the seven anomalies identified by the survey, the western portion of borrow area B-2 will be eliminated as a potential source of sand for the project (mitigation measure).

During the clearinghouse review process, the N. C. Dept. of Cultural Resources expressed concern about possible damages to unknown artifacts associated with old shipwrecks that might be uncovered during the construction process. Rural Development has considered those comments and has prepared a mitigation measure to address this concern. It is included in Section XXI of this document.

IX. COMPLIANCE WITH THE WILD AND SCENIC RIVERS ACT

Based on a review of the Wild and Scenic Rivers Inventory list for North Carolina, the proposed development will not affect a river or portion of a river included in the National Wild and Scenic Rivers System. The project area includes the approximate 10 miles of beach on which sand will be placed and the offshore borrow area from which the sand will be obtained.

X. COMPLIANCE WITH THE ENDANGERED SPECIES ACT

Attached herein are EIS Section 3.15 pages 3-9 through 3-13 (ATTACHMENT 1) which outlines species to be considered in the environmental evaluation and a description of same. The US Fish and Wildlife Service and National Marine Fisheries Service provided the list of species.

EIS Section 5.15 through 5.18 pages 5-6 through 5-11 (ATTACHMENT 2) is also attached and contains a description of potential impacts to these species as a result of the proposed beach nourishment project. These sections also outline some actions that will be taken to minimize actions. Section 5.18 of the EIS also further outlines mitigation measures that will be taken to minimize potential impacts to threatened and endangered species. Rural Development will require both towns to agree to these mitigation measures as a condition for funding.

USDA will require that concurrence of U. S. Fish and Wildlife Service is obtained for all planned mitigative requirements. The U.S. Fish and Wildlife Service concurrence will be obtained through the process of obtaining the 404 permit through the Army Corps of Engineers.

XI. COMPLIANCE WITH FARMLAND PROTECTION POLICY ACT

None of the planned improvements will occur on land protected by the Farmland Protection Policy Act. Therefore, no specific mitigation requirements will be required.

XII. COMPLIANCE WITH EXECUTIVE ORDER 11988, FLOODPLAIN MANAGEMENT AND EXECUTIVE ORDER 11990, PROTECTION OF WETLANDS

None of the project improvements are planned for areas that are considered wetlands. All of the improvements are planned for areas that are considered floodplain. Exhibits 5 and 6 contain the applicable floodplain maps.

The preliminary notification of possible impacts to floodplains was published in the Carteret County News-Times. The notice for Indian Beach was published on March 30, April 1 and 4, 2001. The notice for Pine Knoll Shores was published on April 4, 6 and 8, 2001. The Affidavits of Publication are included as Exhibit 4 for Indian Beach and Pine Knoll Shores. The primary purpose of the project is to increase the width of the current beach. However, during flood events, such as associated with a typical hurricane, there will be little if any actual change to the 100-year floodplain.

Both the Town of Indian Beach and the Town of Pine Knoll Shores are more than 90% built up. The proposed project is intended to protect existing valuable resources as opposed to significantly expanding development in the floodplain area. The beach re-nourishment project will not create any additional land on which development will take place.

XIII. COMPLIANCE WITH COASTAL BARRIERS RESOURCE ACT

None of the project area lies within areas protected by the Coastal Barriers Resource Act. The project location area is fully developed. There are areas within the COBRA system within Carteret County, however those areas are generally located along Shackleford and Core Banks.

XIV. STATE ENVIRONMENTAL POLICY ACT

An EIS has been prepared to satisfy requirements of SEPA for the project.

The project has been thoroughly reviewed by all appropriate State environmental protection agencies. No questions of inconsistencies with the SEPA have been raised. Therefore, USDA, Rural Development has determined the project to be in compliance with the State Environmental Policy Act.

XV. CONSULTATION REQUIREMENTS OF EXECUTIVE ORDER 12372, INTERGOVERNMENTAL REVIEW OF FEDERAL PROGRAMS

Comments of the State Clearinghouse Review are attached as Exhibit 2 for Indian Beach and Exhibit 3 for Pine Knoll Shores. Coastal Science and Engineering, LLC considered all comments in the final preparation of the EIS recommendations. The EIS report will be submitted to the Army Corps of Engineers for issuance of the 404 permit. The Corps will have further consultation with all State agencies to ensure that all concerns are considered.

XVI. ENVIRONMENTAL ANALYSIS OF PARTICIPATING FEDERAL AGENCY

No other Federal agency is participating in the proposed project.

XVII. REACTION TO PROJECT

Reaction to the projects has been extremely positive from both the Towns of Pine Knoll Shores and Indian Beach. Both towns have voted on bond referendums to do the project with strong support. In addition, USDA received no adverse comments regarding the project for either town during the 30-day comment period.

XVIII. CUMULATIVE IMPACTS

The project will allow the towns of Indian Beach and Pine Knoll Shores to physically improve the protection of their southeastern coastal boundaries. This protection will enhance the tax base and economic benefits for the entire county. Moreover, the responsible maintenance of the entire Bogue Banks will lessen pressure for more human utilization of other barrier islands in Carteret County.

XIX. ADVERSE IMPACTS

After analyzing the cumulative impacts of the proposed project, it is determined that the proposed project will have no permanent impact on the environment. There will be some minor temporary adverse impacts associated with construction such as increased noise levels. After analyzing the magnitude and duration of the potential impacts and mitigation measures as identified in Section XXI, these impacts are determined not to be significant.

XX. ALTERNATIVES

Section 4.0 through 4.4.4.3, pages 4-1 through 4-10 entitled "ALTERNATIVES" (ATTACHMENT 3) of the EIS that was prepared by Coastal Science & Engineering, LLC is included herein because of its detailed discussion of alternatives.

Based on the discussion presented, the project as proposed is the most environmentally sensitive proposal that can be economically developed.

XXI. MITIGATION

All mitigation measures as outlined in the EIS will be required in addition to the following:

SOLID WASTE MANAGEMENT

The disposal of all pipe, cable, and expendable items will be disposed strictly in accordance with the contract documents. Any material accidentally dumped in the ocean will be retrieved.

PERMITS

The Army Corps of Engineers will coordinate the Federal Review of the proposed project and the CAMA Major Development Permit. USDA will not authorize the project for construction until the Corps has reviewed the projects and issued a permit/certification outlined in section 10 of the Rivers and Harbors Act of 1899 for work within navigational waters as well as Section 404 of the Clean Water Act.

CULTURAL RESOURCES

To avoid areas of the seven anomalies identified by the referenced survey, the western portion of borrow area B-2 will be eliminated as a potential source of sand for the project.

During the clearinghouse review, the N. C. Department of Cultural Resources raised a concern about the possibility of previously unknown and unrecorded shiprwrecks or portions thereof being unearthed during the construction process. They further expressed the desirability of any artifacts of this type being studied, catalogued, and possibly salvaged prior to their destruction. In order to accomplish this objective Rural Development will require the Towns to adopt the following mitigation measure:

Rural Development will require the Towns to use standard construction contract documents provided by the agency. These documents already contain a provision requiring a contractor to stop work if archaeological artifacts are uncovered. A clause will also be included within the contract documents that will provide compensation for the contractor for re-mobilization if it becomes necessary for him to stop work to allow for study and possible salvage of artifacts. In addition a representative of the N. C. Dept. of Cultural Resources will be invited to the preconstruction conference to provide information and education to the contractor and his work superintendent that would alert them to the discovery of artifacts. The project construction inspector and project engineer will also be required to attend this briefing. The N. C. Dept. of Cultural Resources will be invited to observe and inspect the construction site at will to help insure that any existing artifacts are not inadvertently destroyed.

All mitigation measures identified above will be incorporated into the Letter of Conditions for any financial assistance for the project authorized by Rural Development. Rural Development will require the Towns to adopt an ordinance agreeing to the mitigation measures, thus making them binding on the Towns.

XXII. COMPLIANCE WITH ENDANGERED SPECIES ACT

The applicant has worked diligently on Section 5.15 and 5.18 to define potential impacts to endangered species and to provide appropriate mitigation. Concurrence of the U.S. Fish and Wildlife Service will be obtained on all needed mitigation through the Corps of Engineers permitting process.

XXIII. CONSISTENCY WITH RD ENVIRONMENTAL POLICIES

The proposed action is consistent with the Agency's environmental policies. The project has been planned so as to minimize the impact on the environment.

Based on an examination and review of the foregoing information and such supplemental information attached herein, I recommend that the approving official determine that this project will have

______ a significant effect on the quality of the human environment and an Environmental Impact Statement must be prepared;

or, will not have

X a significant effect on the quality of the human environment.

I recommend that the approving official make the following compliance determinations for the below listed environmental requirements.

Not In Compliance	In Compliance	
	X	Clean Air Act
	X	Federal Water Pollution Control Act
	X	Safe Drinking Water Act - Section 142(e)
	X	**Endangered Species Act**
	X	Coastal Barrier Resources Act
	X	Coastal Zone Management Act Section 307 (C)(1) & (2)
	X	Wild and Scenic Rivers Act
	X	National Historic Preservation Act
	X	Archaeological and Historic Preservation Act
	X	Executive Order 11988, Floodplain Management
	X	Executive Order 11990, Protection of Wetlands
	X	Farmland Protection Policy Act
	X	Department Regulations 9500-3, Land Use Policy
	N/A	State Office Natural Resource Management Guide

I have reviewed and considered the types and degrees of adverse environmental impacts identified by this addendum to the assessment. I have also analyzed the proposal for its consistency with RD environmental policies, particularly those related to important farmland protection, and have considered the potential benefits of the proposal. Based upon a consideration and balancing of these factors, I recommend from an environmental standpoint that the project

X be approved

______ not be approved because of the attached reasons

August 23, 2001

Introduction

The Towns of Pine Knoll Shores, Indian Beach and Emerald Isle propose to place approximately six million cubic yards of sand over approximately 16.8 miles of ocean shoreline along Bogue Banks in Carteret County, North Carolina. The sand will be dredged from three offshore borrow areas using hopper or cutter head hydraulic dredges. The work will be completed in three phases over a three year period. The first phase will include nourishment of 7.2 miles of beach in Pine Knoll Shores and Indian Beach with approximately 3 million cubic yards of sand. The first phase will be completed during the winter of years 2001 and 2002. Phase Two will include nourishment of three miles of beach in Emerald Isle with 1.7 million cubic yards of sand. Phase three, if implemented will include nourishment of 6.7 miles of beach with 1.9 million cubic yards of Sand. Phases two and three will be implemented during the winters months of 2002/2003 and 2003/2004 respectively.

The monitoring plan described herein will measure pre and post-dredging biological impacts associated with phases one and tow of the proposed project. Monitoring associated with Phase three is not proposed because funding for that phase is not being addressed at this point by the Town of Emerald Isle. If the third phase is implemented and the monitoring results from the phases one and two indicate a need for monitoring of a third phase, the plan will be modified to include an additional phase.

Purpose of Study

The purpose of this proposed ecological study is to assess the existing biological communities, and to assess impacts on benthic invertebrates and fish (to the extent feasible), at the proposed Bogue Banks Beach Nourishment Project, located in Carteret County, North Carolina. This study is based on a series of reviews and meetings with UNC Institute of Marine Sciences (IMS), the U.S. Fish & Wildlife Service, the National Marine Fisheries Service, the U.S. Army Corps of Engineers, the North Carolina Department of Environment and Natural Resources, North Carolina Coastal Federation, and others.

Based on experience of the authors and other researchers over the last 15+ years, beach nourishment projects have little or no long term environmental effects when compatible, low silt/clay materials are used and when borrow sites are properly selected and used. Following is a listing of southeast beach nourishment projects conducted by the authors which bear this out::

Daufuskie Island beach nourishment. Monitoring surficial sediments and macrobenthic infauna assemblages at the proposed offshore borrow areas. Applied Technology and Management, Mt. Pleasant, SC.

Hunting Island beach nourishment project. Environmental surveys for determination of environmental impacts of beach nourishment. SC Department of Parks, Recreation, and Tourism, Columbia, SC.

Indian River County Beach. Hardbottom surveys of fish, benthos, invertebrates, and flora for beach nourishment project. Applied Technology and Management, Gainesville, FL.

John U. Lloyd beach nourishment project. Long-term specimen identification for determining impacts of a large beach nourishment project using offshore dredging. John U. Lloyd State Park, Dania, FL.

City of Key West. Analyses of macro-invertebrate communities on Smathers and Rest Beaches for beach renourishment project. Post, Buckley, Schuh, and Jernigan, Miami, FL.

Longboat Key Beach Nourishment. Nearshore benthic and artificial reef monitoring for assessment of long_term impacts to fish and macroinvertebrates. Applied Technology and Management, Gainesville, FL.

Martin County Beach Nourishment. Nearshore benthic and artificial reef monitoring for assessment of long_term impacts to fish and macroinvertebrates. Applied Technology and Management, Gainesville, FL.

Myrtle Beach nourishment project. Long-term macroinvertebrate and turbidity studies conducted before and after major sand nourishment. Myrtle Beach, SC.

Palmetto Dunes beach nourishment project. Collection, identification and report relative to the environmental effects of shoal scraping for a beach nourishment project on Hilton Head Island. Palmetto Dunes, Hilton Head, SC.

Pawleys Island Beach Nourishment. Macroinvertebrate surveys for determination of environmental impacts. Town of Pawleys Island, SC.

Seabrook Island beach nourishment project. Environmental surveys for determination of impacts resulting from shoal dredging for beach nourishment. Seabrook Island POA, Charleston, SC.

Seabrook Island environmental study. A five_year study of the effects of a beach nourishment dredging project on the coastal vegetation, birds, and other natural resources. Seabrook Island Company, Charleston, SC.

Impacts relating to beach nourishment projects can be summarized as follows (from Lankford and Baca 1989; H=high, M=medium, L=low impacts):

Impacts	To Beach or Borrow Site	By Offshore Dredging	By Nearshore Dredging	By Shoal Scraping
Benthic macroinvertebrates	Borrow	M	H	M
Reefs and hardbottoms	Borrow	M	M	L
Fisheries	Borrow	M	M	L
Turtle nesting	Beach	L	L	L
Bird nesting	Beach	L	L	L
Species diversity/richness	Borrow	M	H	L

Commercial/recreational value	Borrow	M	H	L

Macroinvertebrate communities, species diversities, and commercial/recreational values are impacted by nearshore dredging; importantly, however, these impacts were not significant or long-lived in nearly all cases reviewed. In a recent South Carolina study comparing pre- (CSAi 1999) and post-dredging impacts (CSAi 2000) on offshore areas, although impacts were noticeable, they had virtually disappeared after one year. A long-term, comprehensive environmental study of beach nourishment conducted along the coast of New Jersey (ACOE 2001) had similar results. Beach and borrow fauna generally recovered in a few months time; borrow site taxa and biomass required longer to recover (up to 2.5 years).

Preliminary Results and Analyses

Last June 2001, a survey was conducted of beach and borrow sites as described in the methods of this plan. For the June study, organisms were identified to the lowest praticable taxon, usually species, and some preliminary analyses were performed.

A power analysis was used as a means of determining the proper sample number for this project, with the aim of insuring meaningful sampling while saving resources. The "power" of the test is the ability to reject the "no effects" null hypothesis when it is false. Although a large variety of biological parameters can be used to sample and measure populations, following are examples relating to species counts:

1. Species population changes by ±10%, with a 5% chance of error (Green 1979)
2. Subsampling to obtain 90% of the total species (Livingston et al. 1976)
3. Sampling to detect species whose abundance is a proportion of the population ((Dennison and Hay 1967)

Numbers of individuals and species for some of the first samples analyzed from the June survey are given in Appendix A. As shown, samples are relatively homogeneous and dominance is consistent. For beach samples, without lumping samples from different strata along each transect gives 9 replicate cores per site and lumping the two similar lower strata gives 18 replicate cores per site. As shown in the Appendix, any of three cores were necessary to capture 90% of the species, and the species missed on some cores were caught on others. For borrow samples, the numbers were higher but also fairly consistent. The 10 replicate cores showed low variation and many can be lumped to represent large areas of borrow site.

Looking at abundance in the preliminary survey is the preferred method of some researchers, although the patchy distribution of organisms tends to increase variability in total numbers more than in species numbers. Standard Methods (1997) recommends the following equation for determining sample number:

$$N = ((t \times s) / (D \times M))^2$$

Where N = number of samples, t = tabulated t value, s = standard deviation of samples, D = required precision, and M = mean density.

Using three subtidal cores from the attached 24th and Ocean example:

$N=((2.0 \times 26) / (0.3 \times 84.3))^2$
N= 4.2 or 5

Therefore, the 9 cores collected from each beach stratum of the three transects at each beach, should be more than adequate.

For the 10 cores of the borrow site station B2GE,

$N=((2.0 \times 18.4) / (0.3 \times 46.3))^2$
N= 7

Therefore, analysis of 7 of the 10 cores should be adequate without combining cores from each borrow site.

In summary, the preliminary survey was useful to determine variability and to establish the parameters for analysis. The proposed sampling should produce a useful number of core samples (including stations originally sampled by UNC in Fall 1999) from both the offshore borrow areas and control areas.

The following ecological study includes benthic sampling and analysis of proposed borrow and nourishment sites, and fish sampling and analysis of proposed nourishment sites, including reference sites. CSA*i* proposes to use the stations previously sampled by IMS as well as additional stations as needed.

TASK 1. Field Collection of Samples

Beach Site Sampling

Five stations will be sampled on the proposed beach to be nourished. Three stations will be sampled within the project area (Emerald I., Indian Beach, Pine Knoll Shores) and two will be sampled outside the project area to act as references/controls. Three transects will be sampled at each station, and five elevations will be sampled at each station corresponding to elevations used by Peterson et al. studies (1999, 2000). Every attempt will be made to perform the sampling at the same station location as in the Lisa Manning report (NC Sea Grant, April 2000). All stations will be located by Differential Global Positioning System (DGPS). Cores will be collected by SCUBA diving or wading using a 10.2 cm (four inch) cylindrical corer with an internal diameter of 9.9 cm (sampling an area of 77 cm^2). Benthic samples collected will be sieved in the field through a 0.5 mm stainless steel sieve bucket. All sediment and organisms retained in the bucket will be preserved in 10% buffered formalin with rose bengal stain.

Nearshore fish sampling will also be conducted at the beach sample sites. This will consist of three hauls of a 100' beach seine at the sites (one at each beach) and three at controls. Species, numbers, and life stage will be field-determined to the extent possible; fish requiring further examination will be subsampled and preserved in 10% buffered formalin. Guts of a subsample of each of the more common species will be placed on ice for gut content and volume analysis at a nearby laboratory.

Borrow Site Sampling

The proposed borrow areas have been shown in the EIS and other submittals. Sites are designated as A (offshore), B1, and B2 (both nearshore). Sample sites previously used in work by Peterson et al. (1999, 2000) will be sampled in all cases possible (see Figure A). All stations will be located by Differential Global Positioning System (DGPS). Ten cores will be taken at each site for a total of 150 cores. Cores will be collected by SCUBA diving using a 10.2 cm (four inch) cylindrical corer with an internal diameter of 9.9 cm (sampling an area of 77 cm^2). Benthic samples collected will be sieved in the field through a 0.5 mm stainless steel sieve bucket. All sediment and organisms retained in the bucket will be preserved in 10% buffered formalin with rose bengal stain.

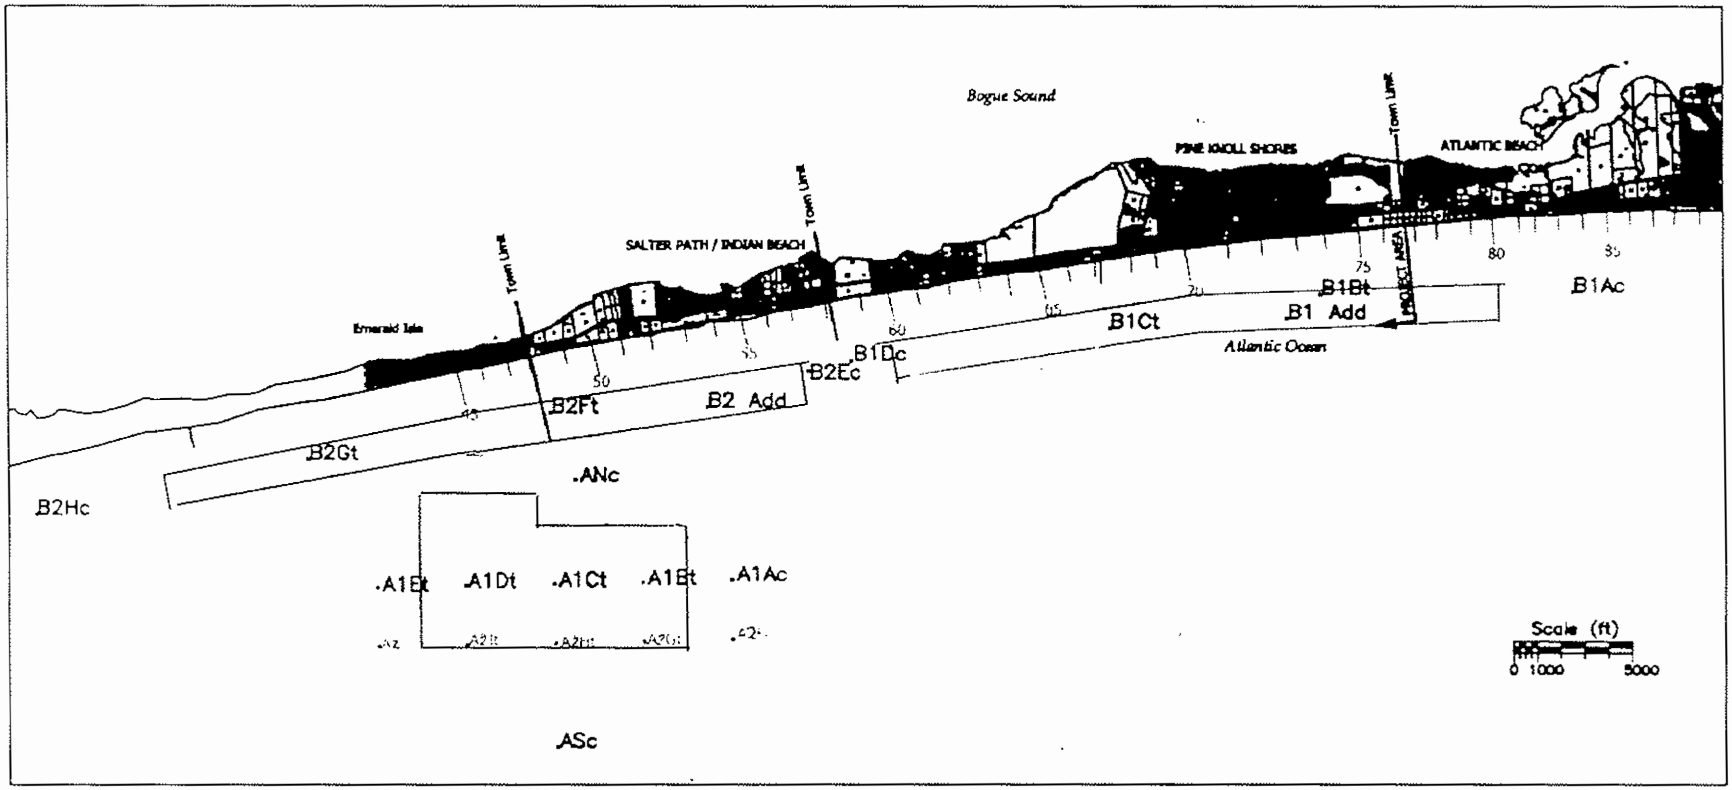

FIGURE A. Environmental monitoring stations established in November 1999 by UNC-IMS and resurveyed in June 2001 by CSA. The revised monitoring plan calls for omitting station A2 F-J because they are outside the revised area to be dredged.

A summary of proposed monitoring sampling protocols is as follows:

Beach Site invert samples	Beach Site invert replicates	Invert Device	Sieve	Beach Fish sampling	Other sampling
3 transects per each of 3 beach sites (Emerald I., Indian B., Pine Knoll) + 3 for each of 2 controls	3 cores at each of 5 elevations (strata) per transect; total 225 total cores	77 cm^2	0.5mm	100'x6'x1" beach seine, 3 hauls for sites and 3 for controls; 10% gut content analysis	Ghost crab burrows - 4m wide section on each upper transect
Borrow Site inverts	**Borrow reps**			**Borrow fish**	
15 sites - 9 inside, 6 controls: B2 and B1 (2 each), and near-shore half of A	10 cores from each; 150 total	77 cm^2	0.5mm	None	None

Schedule

The following schedule is for the proposed Phase I project (in bold); Phase II is also shown in the event the Emerald Isle component is permitted. Three sampling events (two pre- and one post-) are planned in the first year, with two additional sampling events in each of the next two years. In addition, two more years are planned as requirements of the Emerald Isle Phase II of this project, and these will be added on to the monitoring for Phase I.

DATE	SAMPLE
June 2001	**Pre-dredging; spring sample**
November 2001	**Pre-dredging, fall sample**
Nov 2001 - April 2002	***Beach nourishment, Phase 1***
June 2002	**Post-dredging, spring sample**
November 2002	**Post-dredging, fall sample**
June 2003	**Post-dredging, spring sample**
November 2003	Pre-dredging, fall sample
Nov 2002 - April 2003	***Beach nourishment, Phase 2***
June 2004	Post-dredging, spring sample
November 2004	Post-dredging, fall sample
June 2005	Post-dredging, spring sample
November 2005	Post-dredging, fall sample

Task 2. Laboratory Methods

Samples will be preserved as above, properly labeled inside and outside of the containers, and transported to the laboratory for identification using proper quality assurance/quality control procedures.

Once samples have been transported to the laboratory, core sediment samples will be carefully re-sieved through a 0.5 mm stainless steel sieve bucket and screen. This sediment reduction will expedite the sorting process. The remaining sediments and organisms will be placed in labeled, double-ziplock bags and initially preserved in 10 percent buffered formalin solution with Rose Bengal stain. Organisms will be allowed to harden in formalin for 48 hours and then transferred to 80 percent ethanol alcohol. After the hardening period, the organisms will be placed in sorting trays and submersed/diluted in de-ionized water to minimize any volatile alcohol vapor production during identification.

Organisms will then be sorted and enumerated in the laboratory and identified to a minimum of family level with the aid of a variable power dissecting microscope (Bausch & Lomb) and/or a compound microscope (Swift or Bristol). Organisms will be identified by experienced biologists using various identification keys (e.g., Abbott, 1974; Bousfield, 1965; Bynum and Fox, 1977; Dover, 1979; Fauchald, 1977; Fox and Bynum, 1975; Gosner, 1978; Heard, 1982; Kaplan, 1988; Morris, 1975; Ruppert and Fox, 1988; Uebelacker and Johnson, 1984; Williams, 1984). Taxa identified for each station will be recorded on a laboratory bench sheet (per EPA, 1989).

Task 3. Data Analysis

Organism data from the borrow area and control site will be statistically compared to evaluate changes in faunal abundance, and number of species present among sites and over time. Besides standard statistics, analyses will include variance testing (ANOVA), and equivalent parametric tests. Comparison among specific treatment groups will be completed using the Student-Newman-Keuls test (parametric design). Diversity indices will be computed for each area (all samples combined) using Shannon diversity index, Margalef's species richness and evenness. Changes in overall community composition among sites and seasons can be evaluated using a proportional similarity coefficient (e.g., Bray-Curtis) with flexible sorting strategy and a cluster intensity (ß) of -0.25.

Recovery will be assumed when 90% of the species have returned to a particular site. All other indices will be monitored to determine when, or if, taxa and numbers return to 90% or better than pre-project or reference sites status.

Task 4. Reporting

A report for each sampling event, including details of field data collection, data presentation, analysis, and conclusions/results will be submitted to NC Department marine
Fisheries within 120 days following completion of the field work portion of the work.

Termination of Monitoring

An element of this monitoring plan is that if results from data analysis from a post dredging beach or borrow area sampling event show that benthic organisms have recovered to preourishment baseline conditions within a 5 percent confidence interval, the monitoring of the area where the recovery has taken place will be stopped. Verification of the analysis indicating recovery will be indicated in the periodic reports prepared by CSAi and confirmed by the Corps of Engineers, Regulatory Branch and by the N.C. Division of Marine Fisheries.

TABLE OF CONTENTS

1.0 INTRODUCTION

On August 31, 1998, Coastal Science Associates, Inc. (CSA*i*) was contracted by Applied Technology & Management, Inc. (ATM) to monitor surficial sediments and macrobenthic infauna assemblages for the Daufuskie Island Beach Nourishment Project. The project site is located approximately 2,000 yards south of Braddock Point, Hilton Head Island, South Carolina (Fig. 1).

This report presents the results of the data taken during the pre-dredge monitoring event. Sampling for this study was conducted on September 15 and 16, 1998. All sampling and analyses for this study were performed in accordance with CSA*i*'s SCDHEC-approved Standard Operating Procedures Manual and Quality Assurance Plan (CSA*i*, 1999).

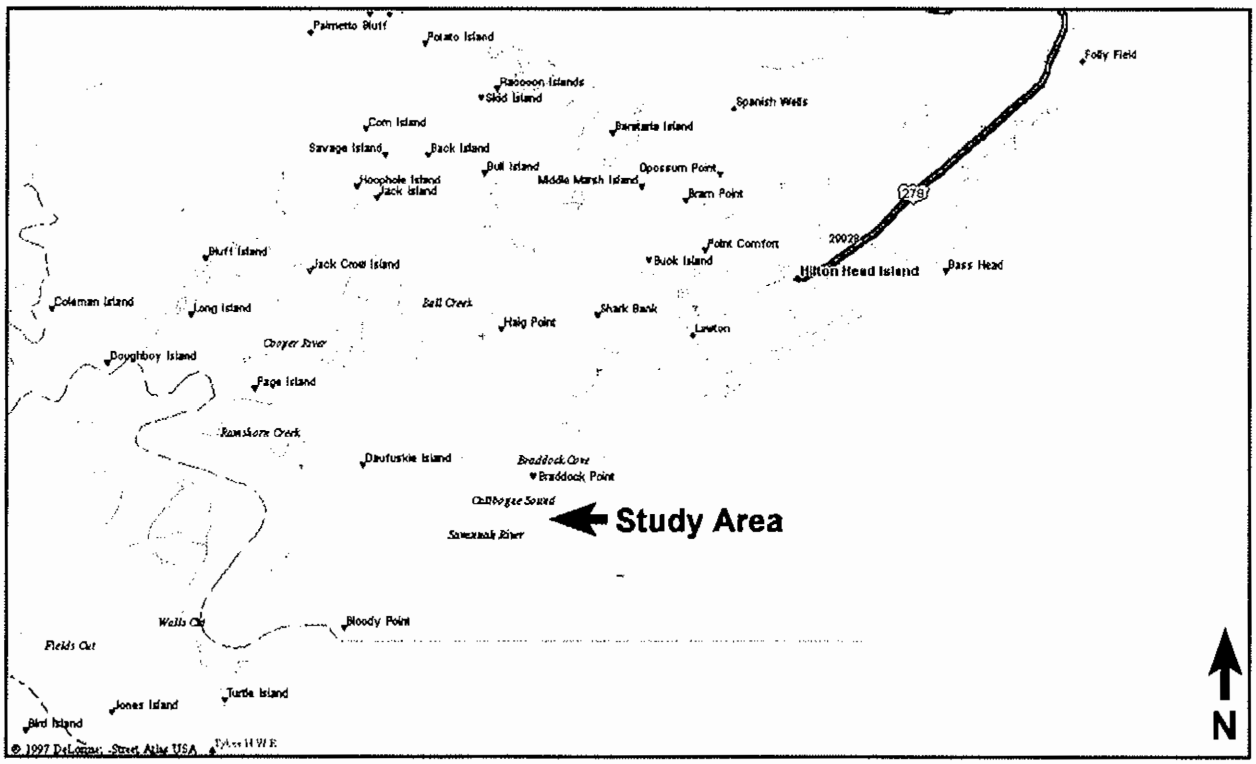

Figure 1. Daufuskie Island Beach Nourishment Pre-dredge Monitoring Study, Daufuskie Island, SC. Site location map showing the approximate location of the study area.

2.0 METHODS

2.1 Sample Areas

The Borrow Area (BA) is located approximately 1.1 miles south of Braddock Point on Hilton Head Island, South Carolina (Fig. 2). The area that was selected is just south of Braddock Point on one of the nearshore shoals in the inlet. This area was selected after several test cores from the area revealed that the sediment composition contained coarse grain sand, the type of sand desired for the proposed Beach Nourishment Project.

During storm conditions and strong longshore currents that are frequent in the area, the coarse grain sand tends to better withstand erosion compared with less coarse grain sands. Another factor in the selection of the location of BA was the proximity of the compatible sand to the area of the project site, resulting in project cost reductions. The depths in BA range from 1 to 19 feet (MLLW, 1930-1980) (Table 1).

The Control Area (CA) is located approximately 0.85 miles south of BA (Fig. 2). The CA, also a nearshore shoal, was selected for its similar bottom relief, depths, habitat, and close proximity to the BA. The depths in CA range from 4 to 17 feet (MLLW, 1930-1980) (Table 2).

Ten sample stations in each area, BA and CA, were randomly chosen. Based on similar depths, stations are paired in order to compare similar benthic community habitats (Fig. 3). The locations of all twenty stations were recorded with a Magellan 5000 DLX global positioning system with differential unit (DGPS) to ensure that all subsequent sampling events are sampled at the same locations (Tables 1 and 2). The depths of the stations were recorded using a Hummingbird Wide Eye™ electronic depth finder.

2.2 Sample Collection and Identification

2.2.1 Macrobenthic Sampling

Grab samples were collected using a 0.05 m^2 weighted ponar grab sampler. A minimum of 80% of the volume of the ponar grab sampler must be obtained for the sample to be considered viable. If less than the minimum is obtained, the sample location is moved 2 to 3 ft and re-sampled. This process is repeated until the 80% minimum is achieved. Grab samples were processed in the field by measuring the volume of each sample in a graduated 19-liter bucket and recording the data in the field logbook (Table 3). From the grab sample, a 3.5 cm (inside dia.) x 10 cm core sub-sample was taken for sediment analysis.

Table 3. Daufuskie Island Beach Nourishment Pre-dredge Monitoring Study. Ponar grab sample volumes (September 15 and 16, 1998).

Sample Station	Ponar Grab Sample Volume, BA	Ponar Grab Sample Volume, CA
1	5.0 liters	5.0 liters
2	6.0 liters	5.5 liters
3	5.0 liters	5.0 liters
4	5.0 liters	5.0 liters
5	5.0 liters	5.0 liters
6	6.0 liters	5.0 liters
7	5.0 liters	6.5 liters
8	5.0 liters	5.0 liters
9	6.0 liters	5.0 liters
10	5.0 liters	4.5 liters

The remaining sediment was then carefully sieved through a 0.5 mm stainless steel sieve bucket and screen. The remaining sediments and organisms were placed in labeled, double-ziplock bags and initially preserved in a 10 percent buffered formalin solution with

Rose Bengal stain. Organisms were allowed to harden for 48 hours and then transferred to 80 percent ethanol alcohol. After the hardening period, the organisms were placed in sorting trays and submersed/diluted in de-ionized water to minimize any volatile alcohol vapor production during identification.

Organisms were sorted and enumerated in the laboratory and identified to the lowest possible taxon (species level in most cases) with the aid of a variable power dissecting microscope (Bausch & Lomb) and/or a compound microscope (Swift or Bristol). Organisms were identified by an experienced biologists utilizing various identification keys for organisms expected to be collected (e.g., Abbott, 1974; Bousfield, 1965; Bynum and Fox, 1977; Dover, 1979; Fauchald, 1977; Fox and Bynum, 1975; Gosner, 1978; Heard, 1982; Kaplan, 1988; Morris, 1975; Ruppert and Fox, 1988; Uebelacker and Johnson, 1984; Williams, 1984). Species identified for each station were then recorded on a laboratory bench sheet (per EPA, 1989).

2.2.2 Water Quality Sampling

Water quality physical parameters were recorded at each of the sample stations. Water samples were taken at mid-depth using a Wildco Alpha water sampling bottle. Meters were calibrated prior to use according to calibration procedures outlined in CSA/'s approved Standard Operating Procedures Manual and Quality Assurance Plan (CSA/, 1999). The physical parameters and corresponding meters used for measurement are listed below:

- Water sampling bottle - Wildco Alpha
- Dissolved oxygen (DO) - YSI Meter - Model 57
- Temperature - Orion Conductivity Meter - Model 128
- Conductivity - Orion Conductivity Meter - Model 128
- pH - Orion pH Meter - Model 230A
- Turbidity - Hach 2100P Turbidimeter
- Salinity - Aquafauna refractometer

2.2.3 Sediment Sampling

The core sub-samples taken from the ponar grab samples were placed into doble-ziplock freezer bags and transported to Athena Technologies, Inc. (see Appendix B for chain-of-custody form). Athena Technologies, Inc. first cataloged the samples, and then dried them in a low heat oven. The dried samples were weighed and the shell material content was visually estimated. The dried samples were then washed through a 0.0625 mm (4.0 phi) sieve to remove silt and clay sized particles from the sample. After the wash, the samples were again dried in a low heat oven. After drying, a final weight was recorded and compared to the initial dry weight in order to determine the sand and fine particle percentages.

Grain size analysis was performed according to applicable American Society for Testing and Materials (ASTM) standards using a 0.5 phi interval sieve stack starting at -1.0 phi (2.0 mm) and ending with 4.0 phi (0.06325 mm). A 115 g composite split was taken for particle size analysis, and passed through the aforementioned sieve set. All of the samples were analyzed with shell material intact, which generally accounts for the total weight of the -1.0 phi and -0.5 phi sieves. The sieve was then Ro-tapped and the weight of material remaining in each sieve was recorded in order to calculate statistical data for each sample.

2.3 Macrobenthic Data Analyses

Six quantitative analyses were used to generate relevant statistical data based on taxonomic information gathered from the sediment samples.

1. Shannon-Wiener species diversity.
2. Species Richness - as total number of species.
3. Species Abundance - as total number of individuals.
4. Evenness.
5. T-test

The data were summarized for analysis on a data summary sheet listing the above five measures (Tables 4 - 5).

Table 4. Daufuskie Island Beach Nourishment Pre-dredge Monitoring Study. Summary of the of species diversity indices for samples taken September 15 and 16, 1998.

Taxa	BA		CA	
	Species Richness	**Abundance**	**Species Richness**	**Abundance**
Cnidaria	0	0	0	0
Rhynchocoela	2	10	0	0
Aschelminthes	1	6	0	0
Chaetognatha	1	1	1	2
Mollusca	3	12	5	28
Annelida	16	50	13	64
Arthropoda	31	802	26	938
Echinodermata	0	0	1	7
Chordata	1	1	0	0
Total Abundance/ sample area		882		1,039
Total Species Richness/ sample area	55		46	
Mean Species Richness	6.9		5.8	
Shannon-Wiener	3.761		3.677	
Evenness	0.651		0.666	

Table 5. Daufuskie Island Beach Nourishment Pre-dredge Monitoring Study. Summary of statistical analyses for samples taken September 15 and 16, 1998. Marked differences are significant at $p < 0.05$.

Sample Areas	Variable	T-Test
BA vs. CA	Species Richness	0.173
BA vs. CA	Abundance	0.667

3.0 RESULTS AND DISCUSSION

3.1 Macrobenthic Sampling

3.1.1 Macrobentic Taxa Analysis

A complete listing of the organisms collected at each station for BA and CA is given in Tables 1 and 2 of Appendix 6.1. Comparisons of the organisms sampled are shown in Table 4 with the diversity indices. As Table 4 shows, the dominant phyla found during this sampling event were Arthropoda and Annelida (see Appendix 6.1, Fig. 1). Within Arthropoda, the dominant organisms found were amphipods, mysid shrimp, and crab megalopa. Within the annelids, no one dominant organism was present; the class Polychaeta was dominant in this phylum.

3.1.2 Macrobenthic Data Analyses

The Shannon-Wiener species diversity index was calculated using the species richness, or number of taxa (Table 4). A diversity index of 2 or greater is said to be favorable (Patil and Taillie, 1982; Brower, Zar, and von Ende, 1998). As can be seen, both sample areas had a diversity index of greater than 3.5, indicating diverse macrobenthic communities. Additionally, the mean abundance was calculated for both sample areas, which is indicated graphically in Appendix 6.1, Figure 2.

The evenness or relative diversity for each area was determined (Table 4). The evenness was calculated to be 0.651 and 0.666 for BA and CA, respectively. Evenness is measured from 0 to 1. If the evenness is at or near 0, then the population's species diversity is different from the ideal community distribution (Brower, Zar, and von Ende, 1998). If the evenness is at or near 1, the population's species diversity is not different from the ideal community distribution (Brower, Zar, and von Ende, 1998).

For the T-test at the 0.05 significance level, the comparison of species richness/replicate sample and abundance/replicate sample for BA to CA resulted in a values of 0.173 and 0.667 respectively. These calculation indicate that no significant differences exist between populations.

3.2 Water Quality and Physical Data

A summary of *in-situ* water quality and other data are presented in Tables 1 and 2 of Appendix 6.2. Water quality parameter values were in the acceptable range for the time of year and weather conditions encountered during the sampling event. Turbidity levels were found to be relatively high; however, both the weather and tide may have caused this factor to be larger than normal by agitating the bottom.

3.3 Sediment Sampling

The final weight of the sediment samples were compared to the initial dry weight in order to determine the sand and fine (<0.0625 mm) particle percentages (Table 1, Appendix 6.3). The raw sediment data were input it into the U.S. Army Corps of Engineers ACES software package. Using this software cumulative frequency and histogram grain size curves were produced. Statistical data is shown on each graph outlining mean size, median size, standard deviation, skewness, and kurtosis (see Figs 1-6., Appendix 6.3). The original report from Athena Technologies, Inc. is presented in Appendix 6.4.

The sediment analysis for grain size composition indicated that all of the samples in BA had a large sand content with the average being 97.8%. The sediment analysis for grain size composition indicated that all of the samples in CA also had a large sand content with the average being 97.5%.

4.0 SUMMARY AND CONCLUSIONS

The analysis of macrobenthic populations from the Borrow Area (BA) and Control Area (CA) indicated that the populations are diverse with high numbers for species richness, Shannon-Wiener diversity, and evenness.

Comparing the populations' species richness and abundance using a t-test at the 0.05 significant level, no significant differences were seen. This can most likely be attributed to both sample areas being located on similar nearshore shoals with compatible depths, grain size, and water quality.

TABLE OF CONTENTS

1.0 INTRODUCTION

On August 31, 1998, Coastal Science Associates, Inc. (CSA/) was contracted by Applied Technology & Management, Inc. (ATM) to monitor surficial sediments and macrobenthic infauna assemblages for the Daufuskie Island Beach Nourishment Project. The project site is located approximately 2,000 yards south of Braddock Point, Hilton Head Island, South Carolina (Fig. 1).

This report presents the results of the data collected during the final post-dredge monitoring event. Sampling for this study was conducted on July 6, 7, and 11, 2000. All sampling and analyses for this study were performed in accordance with CSA/'s SCDHEC-approved Standard Operating Procedures Manual and Quality Assurance Plan (CSA/, 1999).

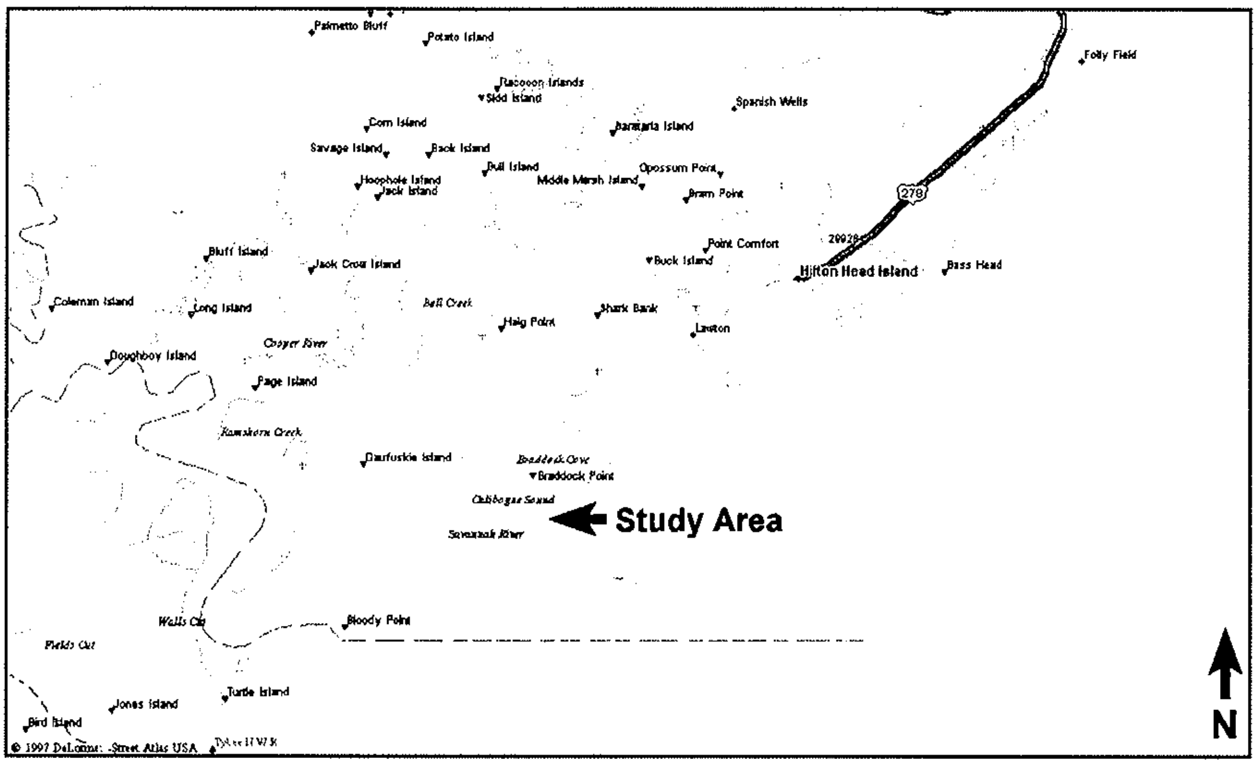

Figure 1. Daufuskie Island Beach Nourishment Final Post-dredge Monitoring Study, Daufuskie Island, SC. Site location map showing the approximate location of the study area.

2.0 METHODS

2.1 Sample Areas

The Borrow Area (BA) is located approximately 1.1 miles south of Braddock Point on Hilton Head Island, South Carolina (Fig. 2). The area that was selected is just south of Braddock Point on one of the nearshore shoals in the inlet. This area was selected after several test cores from the area revealed that the sediment composition contained coarse grain sand, the type of sand desired for the proposed beach nourishment project.

During storm conditions and strong longshore currents that are frequent in the area, the coarse grain sand tends to better withstand erosion compared with less coarse grain sands. Another factor in the selection of the location of the BA, was the proximity of the compatible sand to the area of the project site, resulting in project cost reductions. The depths range from 1 to 19 feet (MLLW 1930-1980) (Table 1).

The Control Area (CA) is located approximately 0.85 miles south of the BA (Fig. 2). The CA, also a nearshore shoal, was selected for its similar bottom relief, depths, habitat, and close proximity to the BA. The depths in CA range from 4 to 17 feet (MLLW, 1930-1980) (Table 2).

Ten sample stations in each area were randomly chosen. Based on similar depths, stations were paired in order to compare similar benthic community habitats (Fig. 3). The locations of all twenty stations were recorded with a Magellan 5000 DLX (with differential unit) differential global positioning system (DGPS) to ensure that all subsequent sampling events are sampled at the same locations (Tables 1 and 2). The depths of the stations were recorded using a Hummingbird Wide Eye™ electronic depth finder.

Table 1. Daufuskie Island Beach Nourishment Final Post-dredge Monitoring Study. Borrow area sample station coordinates and depths (July 6, 7, & 11, 2000).

Sample Station	Latitude	Longitude	Depth

2.2 Sample Collection and Identification

2.2.1 Macrobenthic Sampling

Grab samples were collected using a 0.05 m^2 weighted ponar grab sampler. A minimum of 80% of the volume of the ponar grab sampler must be obtained for the sample to be considered viable. If less than the minimum is obtained, the sample location is moved 2 to 3 ft and re-sampled. This process is repeated until the 80% minimum is achieved. Grab samples were processed in the field by measuring the volume of each sample in a graduated 19-liter bucket and recording the data in the field logbook (Table 3). From the grab sample, a 3.5 cm (inside dia.) x 10 cm core sub-sample was taken for sediment analysis.

Table 3. Daufuskie Island Beach Nourishment Final Post-dredge Monitoring Study. Ponar grab sample volumes (July 6, 7, & 11, 2000).

Sample Station	Ponar Grab Sample Volumes, BA	Ponar Grab Sample Volumes, CA
1	6.2 liters	6.0 liters
2	6.0 liters	5.5 liters
3	6.0 liters	6.0 liters
4	7.0 liters	6.0 liters
5	6.0 liters	7.0 liters
6	7.0 liters	5.5 liters
7	5.5 liters	6.0 liters
8	6.0 liters	5.0 liters
9	5.0 liters	6.0 liters
10	5.0 liters	5.0 liters

The remaining sediment was carefully sieved through a 0.5 mm stainless steel sieve bucket and screen. The remaining sediments and organisms were placed in labeled, double-ziplock bags and initially preserved in 10 percent buffered formalin solution with

Rose Bengal stain. Organisms were allowed to harden for 48 hours and then transferred to 80 percent ethanol alcohol. After the hardening period, the organisms were placed in sorting trays and submersed/diluted in de-ionized water to minimize any volatile alcohol vapor production during identification.

Organisms were sorted and enumerated in the laboratory and identified to the lowest possible taxon (species level in most cases) with the aid of a variable power dissecting microscope (Bausch & Lomb) and/or a compound microscope (Swift or Bristol). Organisms were identified by an experienced biologists utilizing various identification keys for organisms expected to be collected (e.g., Abbott, 1974; Bousfield, 1965; Bynum and Fox, 1977; Dover, 1979; Fauchald, 1977; Fox and Bynum, 1975; Gosner, 1978; Heard, 1982; Kaplan, 1988; Morris, 1975; Ruppert and Fox, 1988; Uebelacker and Johnson, 1984; Williams, 1984). Species identified for each station were then recorded on a laboratory bench sheet (per EPA, 1989).

2.2.2 Water Quality Sampling

Water quality physical parameters were recorded at each of the sampling stations. Water samples were taken at mid-depth using a Wildco Alpha water sampling bottle. Meters were calibrated prior to use according to calibration procedures outlined in CSA/'s approved Standard Operating Procedures Manual and Quality Assurance Plan (CSA/, 1999). The physical parameters and corresponding meters for measurement are listed below.

- Dissolved Oxygen (DO) - YSI DO Meter - Model 57
- Temperature - Orion Conductivity Meter - Model 128
- Conductivity - Orion Conductivity Meter - Model 128
- pH - Orion pH Meter - Model 230A
- Turbidity - Hach 2100P Turbidimeter
- Salinity - Aquafauna Refractometer

2.2.3 Sediment Sampling

The core sub-samples taken from the ponar grab samples were placed into doble-ziplock freezer bags and transported to Athena Technologies, Inc. (see Appendix B for chain-of-custody form). Athena Technologies, Inc. first cataloged the samples and then dried them in a low heat oven. The dried samples were weighed and the shell material content was visually estimated. The dried samples were then washed through a 0.0625 mm (4.0 phi) sieve to remove silt and clay sized particles from the sample. After the wash, the samples were again dried in a low heat oven. After drying, a final weight was recorded and compared to the initial dry weight in order to determine the sand and fine particle percentages.

Grain size analysis was performed according to applicable American Society for Testing and Materials (ASTM) standards using a 0.5 phi interval sieve stack starting at -1.0 phi (2.0 mm) and ending with 4.0 phi (0.06325 mm). A 115 g composite split was taken for particle size analysis and passed through the aforementioned sieve set. All of the samples were analyzed with shell material intact, which generally accounts for the total weight of the -1.0 phi and -0.5 phi sieves. The sieve was then Ro-tapped and the weight of material remaining in each sieve was recorded in order to calculate statistical data for each sample.

2.3 Macrobenthic Data Analyses

Six quantitative analyses were used to generate relevant statistical data based on taxonomic information gathered from the sediment samples.

1. Shannon-Wiener species diversity.
2. Species Richness - as total number of species.
3. Species Abundance - as total number of individuals.
4. Evenness.
5. T-test

The data were summarized for analysis on a data summary sheet listing the above five measures (Tables 4 - 5).

Table 4. Daufuskie Island Beach Nourishment Final Post-dredge Monitoring Study. Summary of the of species diversity indices for samples taken July 6, 7, & 11, 2000.

Taxa	BA		CA	
	Species Richness	Abundance	Species Richness	Abundance
Cnidaria	2	79	1	113
Rhynchocoela	2	44	2	34
Aschelminthes	1	1	0	0
Chaetognatha	1	2	1	4
Mollusca	10	284	6	198
Annelida	20	186	23	199
Arthropoda	34	1559	32	1381
Echinodermata	3	7	2	6
Chordata	0	0	1	4
Total Abundance/ sample area		2162		1939
Total Species Richness/ sample area	73		68	
Mean Species Richness	9.1		8.5	
Shannon-Wiener	3.929		4.174	
Evenness	0.635		0.686	

Table 5. Daufuskie Island Beach Nourishment Final Post-dredge Monitoring Study. Summary of statistical analyses for samples taken July 6, 7, & 11, 2000. Marked differences are significant at $p < 0.05$.

Sample Areas	Variable	T-Test
BA vs. CA	Species Richness	0.425
BA vs. CA	Abundance	0.676

3.0 RESULTS AND DISCUSSION

3.1 Macrobenthic Sampling

3.1.1 Macrobentic Taxa Analysis

A complete listing of the organisms collected at each station for BA and the CA is given in Tables 1 and 2 of Appendix 6.1. Comparisons of the organisms sampled are shown in Table 4 with the diversity indices. The dominant phyla found during this sampling event were Arthropoda, Mollusca, and Annelida (see Appendix 6.1, Fig. 1). The dominant organisms identified within the phylum Arthropoda were amphipods, copepods, mysid shrimp, and crab larva. For the phylum Annelida, the dominant organisms identified were *Magelona pettiboneae, Caulleriella* sp., *Nephtys picta*, *Lleitoscoloplos fragilis,* and *Glycera* sp. For the phylum Mollusca, the dominant organisms identified were of the species *Tellina versicolor* and, *Olivella mutica.*

3.1.2 Macrobenthic Data Analyses

The Shannon-Wiener species diversity index was calculated using the species richness and abundance (Table 4). A diversity index of 2 or greater is said to be favorable (Patil and Taillie, 1982; Brower, Zar, and von Ende, 1998). As shown in Table 4, both sample areas have a diversity index of greater than 3.75, indicating diverse macrobenthic communities. Additionally, the mean abundance was calculated for both sample areas, which is indicated graphically in Appendix 6.1, Figure 2.

The evenness or relative diversity for each area was determined (Table 4). The evenness was 0.635 and 0.686 for BA and CA, respectively. Evenness is measured from 0 to 1. If the evenness is at or near 0, then the population's species diversity is different from the ideal community distribution (Brower, Zar, and von Ende, 1998). If the evenness is at or near 1, the population's species diversity is not different from the ideal community distribution (Brower, Zar, and von Ende, 1998).

For the T-test at the 0.05 significance level, the comparison of species richness/replicate sample and abundance/replicate sample for BA to CA resulted in a values of 0.425 and 0.676 respectively. These calculation indicate that no significant differences exist between populations.

3.1.3 Final Post-dredge Study Compared to Previous dredge Studies

The macrobenthic samples collected from BA indicated that the species composition has changed slightly from the previous two studies (CSA*i*, November, 1999): as shown in Table 6 significant increases in the number of individuals from the phyla Mollusca, Annelida, and Arthropoda were observed; and species richness has increased from 55 and 61 during the previous two studies to 73 for this study. Species abundance has also increased from 882 and 1,268 during the previous two studies to 2,162 for this study. The species diversity remained relatively the same, 3.761 and 3.713 during the previous two studies as compared to 3.929 for this study. Evenness also remained relatively the same, 0.651 and 0.626 as compared to 0.635 for this study. The two previous pre and post studies are included in Appendix 6.5 for comparison purposes.

Compared to the previous two studies, the species composition from CA stayed relatively the same. The exceptions were an increase in the number of individuals from the phylum Mollusca, phylum Arthropoda, and phylum Cnidaria. The species richness has increased from 46 during the previous two studies to 68 for this study. Species abundance has also increased from 1,039 to 713 during the previous two studies to 1,939 for this study. The species diversity remained relatively the same, 3.676 and 3.702 during the previous two studies as compared to 4.174 for this study. Evenness also remained relatively the same, 0.666 and 0.670 during the previous two studies as compared to 0.686 for this study.

The rise in species richness, species diversity, and species abundance at both BA and CA may be attributed to the time frame of the sampling event. This sampling event occurred during the summer when benthic communities are at a population high because of the water temperature and higher nutrient levels.

Table 6. Daufuskie Island Beach Nourishment Final Post-dredge Monitoring Study. Summary of the of species diversity indices for the pre, post, and final post-dredge Monitoring Studies.

Taxa	BA-2000		CA-2000		BA-1999		CA-1999		BA-1998		CA-1998

Evenness	0.635		0.686		0.626		0.670		0.651		0.666	

3.2 Water Quality and Physical Data

A summary of *in-situ* water quality data for all parameters measured is presented in Tables 1 and 2 of Appendix 6.2. Water quality parameter values appeared to be in the normal range for the time of year and weather conditions encountered during the sampling event. Turbidity levels appeared to be higher than normal. The high winds and tidal action encountered during the sampling event may have caused turbidity to be greater than normal.

3.3 Sediment Sampling

The final weights of the sediment samples were compared to the initial dry weights in order to determine the sand and fine (<0.0625 mm) particle percentages (Table 1, Appendix 6.3). The raw sediment data were input it into the U.S. Army Corps of Engineers ACES software package. Using this software, cumulative frequency and histogram grain size curves were produced. Statistical data are shown on each graph outlining mean size, median size, standard deviation, skewness, and kurtosis (see Figs 1-6., Appendix 6.3). The original report from Athena Technologies, Inc. is presented in Appendix 6.4.

The sediment analysis for grain size composition indicated that all of the samples in BA had a large sand content with the average being 95.2%. The sediment analysis for grain size composition indicated that all of the sample in the CA also had a large sand content with the average being 86.7%. The sand content in the samples in both BA and CA have slightly decreased relative to the previous study.

4.0 SUMMARY AND CONCLUSIONS

The analyses of macrobenthic populations from the Borrow Area (BA) and Control Area (CA) indicated that the populations are diverse with high numbers for species richness, Shannon-Wiener diversity, and evenness.

Comparing the populations' species richness/replicate sample using a t-test at the 0.05 significance level, no significant differences were seen. A t-test was also performed on the abundance/replicate sample. The test registered no difference between the two populations at the 0.05 significance level

Compared to the two previous studies, the species composition at BA has changed slightly, with observed increases in the number of individuals from the phyla Cnidaria, Mollusca, and Arthropoda. This has lead to an increase in species richness, while species diversity and evenness remained relatively the same.

At CA, compared to the two previous studies, the species composition has changed slightly, with observed increases in the number of individuals from the phyla Cnidaria, Mollusca, and Arthropoda. This has lead to an increase in species richness and species diversity, while the evenness remained relatively the same.

Based upon numerous benthic impact studies and data gathered during this study, it appears that the environmental impacts for this project were minimal and that the impacted communities are returning to the pre-project conditions.

APPENDIX A-5

PRELIMINARY COMPILATION OF DISPOSAL/NOURISHMENT ZONES
AND
BORROW AREAS IN RECOVERY FROM 5-YEAR RUNNING TOTAL

U.S. ARMY CORPS OF ENGINEERS, WILMINGTON DISTRICT

Prepared: February 2000 — Updated: September 2000

ATTACHMENT A-5

PRELIMINARY COMPILATION OF DISPOSAL/NOURISHMENT ZONES
U.S. ARMY CORPS OF ENGINEERS, WILMINGTON DISTRICT
Prepared: February 2000, Updated: September 2000

The information contained within the preliminary compilation has been prepared using available information. The proposed projects, extending to the year 2011, are included; however, the projected information is highly speculative and should not be used as factual data.

NAVIGATION PROJECTS

The Wilmington District performs routine maintenance dredging of navigation channels along the entire 320 miles of shoreline from the Virginia line to the north and the South Carolina to the south.

The beneficial use of dredged material that meets the criteria of greater than or equal to 90% sand (retained by #200 sieve or greater than or equal to 0.074 mm) is an integral part of the navigation program. Where possible, clean, beach quality material, removed from the navigation channels, is placed in the wave uprush zone of nearby beaches or on control-of-effluent islands used by nesting colonial waterbirds. The placement of material in this manner is consistent with Section .1100 of the Coastal Management regulations (TT15A:07M.1100).

The beneficial placement of material removed from the navigation projects back into the littoral system is performed by hydraulic pipeline dredge with the pipeline extending from the area being dredged to the approved beach disposal area. The material is placed within the wave uprush zone at the proper elevation that allows the material to be under tidal influence creating a gentle slope without escarpments. The purpose of placement of material is not to build up the beachfront dune or berm system, only to return the material to the littoral system. This is the difference between what is referred to as disposal versus beach nourishment associated with a Beach Erosion Control and Hurricane Protection Project such as Wrightsville Beach.

NOURISHMENT PROJECTS

The District currently maintains active Beach Erosion Control and Hurricane Wave Protection Projects at Wrighstville Beach, Carolina Beach and Vicinity and Carolina Beach-South (Kure Beach). The Brunswick County Beaches, Ocean Isle Portion, is proposed for construction in FY 2001. Additional studies are currently underway for Beach

Erosion Control and Hurricane Wave Protection Projects at Brunswick County Beaches, Oak Island and Caswell Beach Portion and the Holden Beach Portion, and Dare County Beaches. These three projects are currently proposed for construction, contingent upon approval, for FY 2004 and FY 2005. Nourishment is generally performed by a hydraulic pipeline dredge and includes the construction/maintenance of a dune and berm system. The compatibility of the beachfront material in relationship to the borrow source is evaluated prior to placement of material. Pending studies include the Towns of Topsail Beach, North Topsail Beach, and Surf City; Bogue Banks, and the Hatteras to Ocracoke Portion of Dare County Beaches.

SUMMARY

The placement of dredged material within the 320 miles of beachfront along the North Carolina coastline is summarized below by mileage and maintenance schedule. The summary is broken down by disposal versus nourishment events. This breakdown is necessary to delineate between material placed in the wave uprush area versus on the upper beach and dune system. The computations are made based on actual mileage used during any given disposal event. For instance, an approved 5-mile of beachfront may be designated for disposal; however, during a given event only 0.4 to 1 mile of beachfront may be impacted. Calculations were made based on a 16-year period and percentage of North Carolina Shoreline (320 miles) impacted.

DISPOSAL ACTIVITIES

- Average/year – 8.0 miles or 2.5% of total NC Shoreline (320 miles)
- Minimum for any year – 3.5 miles or 1% of total NC Shoreline
- Maximum for any given year is 22.4 miles or 7.0% of total NC Shoreline

EXISTING BEACH NOURISHMENT

- Average of 2.9 miles or 1% of NC Shoreline
- Minimum of 0 (possible that no beach nourishment in any given year)
- Maximum of 9.8 (all occur at same time) which is 3.1% of NC Shoreline

PROPOSED BEACH NOURISHMENT

- Average of 16.9 miles or 5.3% of NC Shoreline
- Minimum would be 0 (possible none occurred)
- Maximum of 85.0 miles which is 26.6% of NC Shoreline

CUMULATIVE (averaging both disposal and nourishment projects existing and future)

- Average impact from existing disposal and nourishment (8.0 + 2.9) = 11.0 miles, 3.4 % of NC Shoreline
- Maximum impact (worst case) from existing beach disposal and nourishment activities (22.4 + 9.8) = 32.2 miles, 10.1% of NC Shoreline
- Average impact from existing disposal and nourishment projects and proposed projects (8.0 + 2.9 + 16.9) = 27.8 miles, 8.7% of NC Shoreline
- Maximum impact (worst case) from existing disposal and nourishment and proposed beach nourishment (22.4 + 9.8 + 85.0) = 117.2 miles, 36.6% of NC Shoreline

Submitted by:

Tidewater Atlantic Research, Inc.
P. O. Box 2494
Washington, North Carolina 27889

3 February 2000

Abstract

Carteret County is planning to conduct a nourishment project to rebuild the beaches along Bogue Banks. The proposed project will require borrowing sand from three areas south of Pine Knoll Shores, Salter Path and Indian Beach. In order to determine the proposed project's impact on potentially significant submerged cultural resources, Stroud Engineering, P.A. and CSE Baird LLC contracted with Tidewater Atlantic Research, Inc., (TAR) of Washington, North Carolina to conduct a systematic proton precession magnetometer and side scan sonar survey. The proposed remote sensing survey was designed to locate and identify submerged cultural resources in the study areas and generate sufficient data to make an initial assessment of each target's significance and provide insight into the necessity for avoidance or additional investigation. That survey was carried out between 7 and 13 December 1999. No magnetic or acoustic anomalies were identified in either Borrow Area A or Borrow Area B-1. In Borrow Area B-2, 10 magnetic anomalies were identified near the western end of the survey area. Seven of those targets contained signature characteristics indicative of significant submerged cultural resources. Because they could be associated with an historic shipwreck, either avoidance or additional investigation to positively identify the nature and significance of material generating the seven anomalies is recommended. If avoidance of the area is possible, no additional investigation should be necessary.

Introduction

Stroud Engineering, P.A., is working with Carteret County on beach renourishment projects on Bogue Banks. The source material for the project has been identified as three areas south of Pine Knoll Shores, Salter Path and Indian Beach. In order to determine the proposed project's effects on potentially significant submerged cultural resources, Stroud Engineering, P.A. and CSE Baird LLC contracted with Tidewater Atlantic Research, Inc., (TAR) of Washington, North Carolina to conduct a systematic proton precession magnetometer and side scan sonar survey to locate, identify and assess the significance of any underwater cultural material in the proposed borrow areas.

The investigation conducted by TAR was designed to provide accurate and reliable identification, assessment and remote sensing documentation of submerged cultural resources in the prospective project areas in terms of the criteria established in compliance with the National Historic Preservation Act of 1966, as amended and the Archaeological and Historic Preservation Act of 1979, as amended. The results of the investigation will provide Stroud Engineering, P.A. and CSE Baird LLC with the archaeological data essential for complying with submerged cultural resource legislation and regulations.

The methodology employed by TAR combined state of the art technology, experienced personnel and an investigative technique designed to generate appropriate historical and remote sensing data. Fieldwork activities associated with the project were carried out between 7 and 13 December 1999. Analysis of the remote sensing data identified 10 anomalies within the western part of Borrow Area B2. Seven of those targets contained signature characteristics indicative of significant submerged cultural resources and were recommended for further investigation. No magnetic or acoustic anomalies were detected in Borrow Areas A or B1.

Coordination for the survey was provided by Bill Forman, Stroud Engineering, and Phil McKee, CSE Baird. The field project staff included Dr. Gordon P. Watts, Jr., the principal investigator, archaeologists Raymond Tubby and Steve Brodie and archaeological assistants Mark Padover and Mike Phillips. Data analysis, historical research and report preparation were carried out by Gordon Watts, Raymond Tubby and Robin Arnold. All members of the project staff exceed the minimum standards for archaeological personnel identified by the Department of Interior and the North Carolina Division of Archives and History.

Project Location

The three Carteret County Borrow Areas are located south of Bogue Banks between Atlantic Beach and Emerald Isle. Borrow Area A forms an "L"-shaped polygon south-southeast of Salter Path and Indian Beach. Borrow Area B-1 is a long rectangular polygon offshore of and roughly parallel to the shoreline of the west extremity of Atlantic Beach and Pine Knoll Shores. Borrow Area B-2 is a long rectangular polygon offshore of and roughly parallel to the shoreline of Salter Path, Indian Beach and eastern Emerald Isle (Figure 1).

North Carolina State Plane Coordinates, NAD 1983 for Borrow Area A are:

Point	Northing	Easting

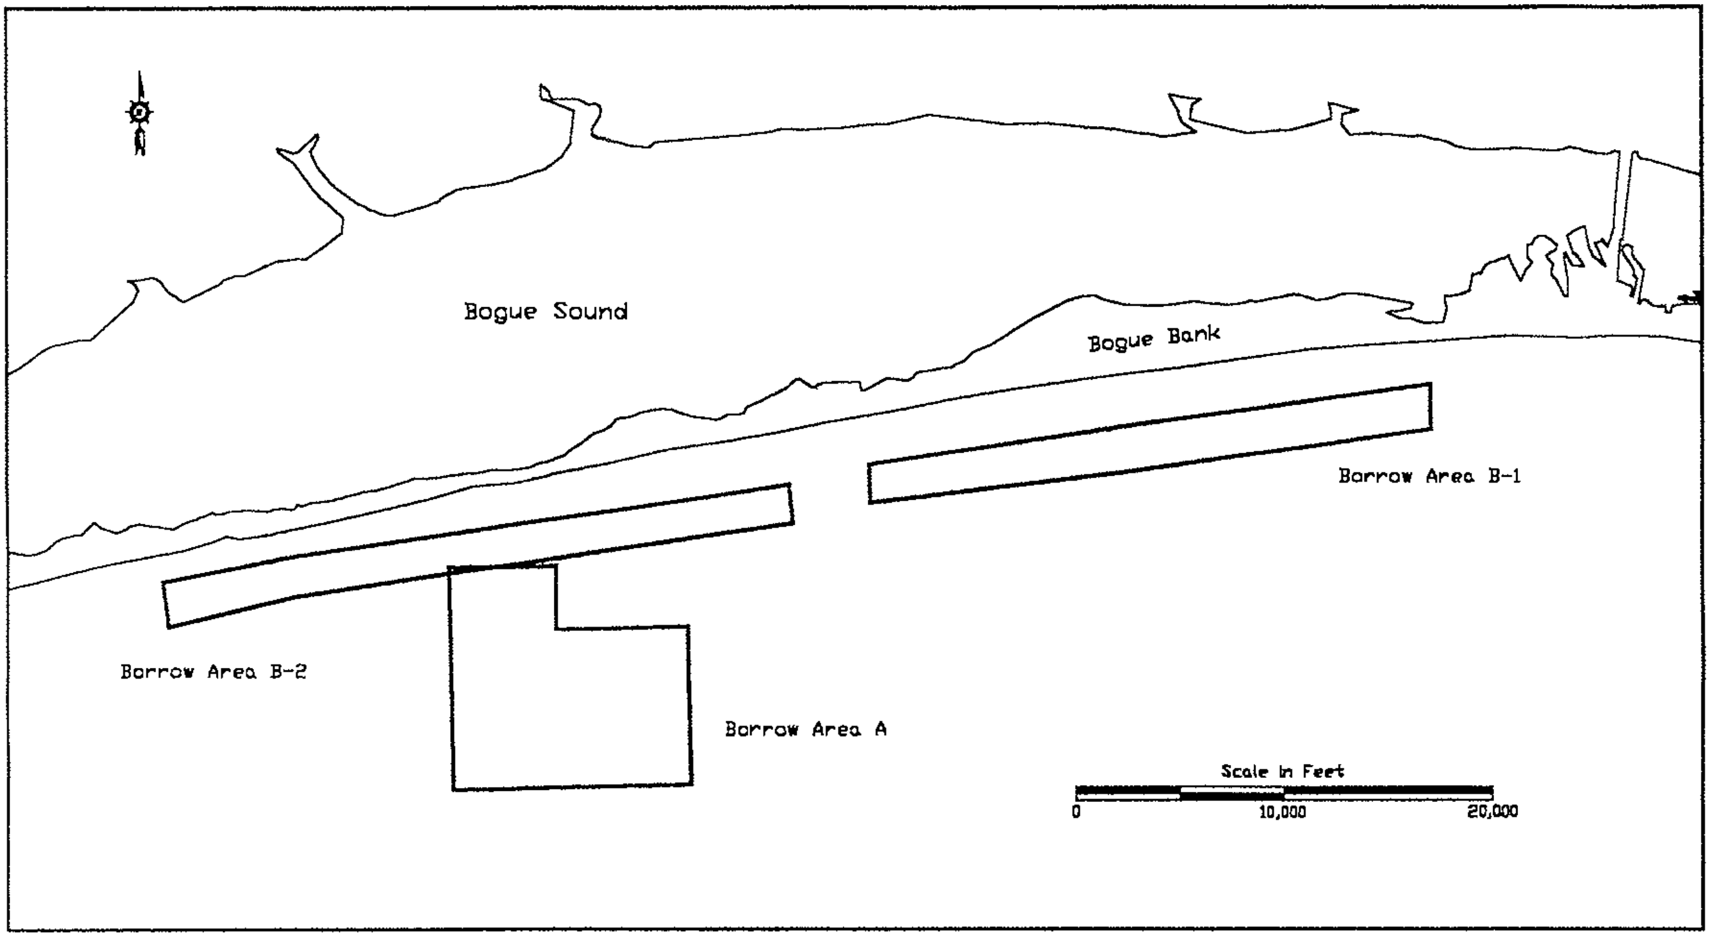

Figure 1. Project Location Map.

Project Research Objectives

The Bogue Banks Borrow Area survey was initiated in order to comply with the criteria of National Historic Preservation Act of 1966, as amended, through 1992 (36 CFR 800, Protection of Historic Properties), the Abandoned Shipwreck Act of 1987 (*Abandoned Shipwreck Act Guidelines*, National Park Service, *Federal Register*, Vol. 55, No. 3, 4, December 1990, pages 50116-50145) and the Secretary of Interior's Standards and Guidelines for Archaeology and Historic Preservation (*Federal Register* 48, No. 190, 1983). In keeping with the intent of that legislation and associated regulations Stroud Engineering and CSE Baird determined that a remote sensing survey would be necessary to assess the potential impact of proposed project activities on submerged cultural resources in the project areas. The remote sensing survey conducted by TAR was designed to identify magnetic and/or acoustic anomalies that might be generated by shipwreck resources, assess the potential significance of each one and determine the necessity for additional investigation designed to generate data to support a preliminary determination of National Register of Historic Places eligibility.

Research Methodology

Literature, Historical and Archival Research

In order to generate historical data to facilitate identification of shipwreck remains in the Beaufort/Morehead vicinity, records from a variety of repositories were examined. At the Underwater Archaeology Unit in Kure Beach, the archaeological site files were surveyed for both historic and prehistoric submerged archaeological sites in the Beaufort Inlet area. Similar surveys of site file inventories were also conducted in the Anthropology Department Research Laboratory and the Program in Maritime History and Underwater Research at East Carolina University in Greenville, North Carolina.

A literature and archival investigation was also initiated by a survey of secondary source materials associated with the historical development of eastern North Carolina. The survey focused on documentation of activities such as exploration, colonization, development, agriculture, industry, trade, shipbuilding, commerce, warfare, transportation and fishing that would have been contributing factors in the loss of vessels in the vicinity of the proposed borrow areas. In examining each of these factors special attention was devoted to activities associated with navigation in the vicinity of Beaufort Inlet.

Preliminary wreck specific information was collected from such secondary sources as: *The Encyclopedia of American Shipwrecks* (Berman 1972); *Merchant Steam Vessels of the United States 1807 - 1868* (Lytle and Holdcamper 1952); *Disasters to American Vessels, Sail and Steam, 1841-1846* (Lockhead 1954); *Shipwrecks of the Civil War, The Encyclopedia of Union and Confederate Naval Losses* (Shomette 1973); *Shipwrecks of the Western Hemisphere* (Marx 1971); *Shipwreck Encyclopedia of The Civil War: North Carolina, 1861-186* (Spence 1991) and other published materials. Additional information was also generated by a survey of selected North Carolina newspapers, the Wreck Information List of the U.S. Hydrographic Office, National Oceanic and Atmospheric Administration and maritime records associated with Beaufort and Morehead City. Select historic maps and charts preserved in the collections of the National Archives Cartographic Branch in College Park, MD and North Carolina repositories of cartographic data were also examined.

Relevant sources of shipwreck data preserved in the North Carolina Division of Archives and History in Raleigh; Underwater Archaeology Unit of the Division of Archives and History at Kure Beach; the Steamship Historical Society, Baltimore; Mystic Seaport Museum, Connecticut; the National Archives and the Mariners Museum at Newport News, Virginia were surveyed for site specific data associated with the Beaufort Inlet, Bogue Bank and Shackleford Bank areas. TAR personnel also contacted and interviewed the head of the Underwater Archaeology Unit, area archaeologists, historians and other individuals knowledgeable in maritime history and shipwreck research to solicit their assistance in generating wreck data.

Field Investigations

To reliably identify submerged cultural resources, TAR conducted a systematic remote sensing survey of the proposed borrow areas identified in the Scope of Work. TAR personnel utilized 31-foot and 25-foot vessels to conduct the survey. In order to fulfill the requirements stated in the Scope of Work, TAR employed both magnetic and acoustic remote sensing equipment. A combination of magnetic and acoustic remote sensing equipment represent the "state-of-the-art" in submerged cultural resource location technology and offers the most reliable and cost effective method of locating and identifying potentially significant targets. Data collection was controlled using a differential global positioning system (DGPS). The DGPS produces the highly accurate coordinates necessary to support a sophisticated navigation program and assure reliable target location.

Magnetic Remote Sensing

An EG&G Geometrics 866 dual channel proton precession magnetometer capable of plus or minus 0.1 gamma resolution was employed to collect magnetic data in the survey areas. To produce the most comprehensive magnetic record, data were collected on a two-second interval and the sensor was deployed and maintained in the water column at a depth of 10 to 12 feet above the bottom surface. An analog recorder provided a continuous permanent record of the magnetic background and target signatures. Because of the historical nature of the area, magnetic data were collected along transects spaced on 100-foot intervals and recorded on both an analog recorder and as a data file associated with the computer navigation system. Data from the survey were contour plotted using QuickSurf computer software to facilitate anomaly location and definition of target signature characteristics. All magnetic data were correlated with the acoustic remote sensing records.

Acoustic Remote Sensing

A 500 kHz Klein 521 high resolution side scan sonar was employed to collect acoustic data in the survey area. During the survey, the side scan sonar transducer was deployed and maintained at a 10-foot elevation above the bottom surface. Because of the historical nature of the area and the requirements for collecting magnetic data, acoustic data were also collected along transects spaced on 100-foot intervals. Sonar range scales were selected to provide a combination of 100% coverage of the survey area and high target signature definition. Acoustic data were recorded on a two channel wet-paper recorder and tied to the magnetic and positioning data by the computer navigation system event marking program.

Positioning System

A differential global positioning system (DGPS) was used to control navigation and data collection in the survey areas. The system has an accuracy of plus or minus three feet, and can be used to generate highly accurate coordinates for the computer navigation system. Differential corrections were received from the United States Coast Guard Beacon at Fort Macon, North Carolina. A Furuno GP-35 differential global positioning system was employed in conjunction with on-board IBM compatible 486-66 BSI and Pentium 233MMX ProStar computers loaded with a Coastal Oceanographics Hypack navigation and data collection software program. All magnetic and acoustic records were tied to positioning events generated by Hypack. Positioning data generated by the navigation system were tied to magnetometer records by regular annotations to facilitate target location and anomaly analysis. Annotations included lane number, date, start and end of lane, direction and target identification.

Data Analysis

To ensure reliable target identification and assessment, analysis of the magnetic and acoustic data were carried out as it was generated. Using QuickSurf contouring software, magnetic data generated during the survey were contour plotted at 10 gamma intervals for analysis and accurate location of the material generating each magnetic anomaly. Magnetic targets were isolated and analyzed in accordance with intensity, duration, areal extent and signature characteristics. Sonagram signatures associated with magnetic targets were analyzed on the basis of configuration, areal extent, target intensity and contrast with background, elevation and shadow image.

Data generated by the remote sensing equipment were developed to support an assessment of each magnetic and acoustic signature. Analysis of each target signature included consideration of magnetic and sonar signature characteristics previously demonstrated to be reliable indicators of historically significant submerged cultural resources. Assessment of each target included recommendations for additional investigation to determine the exact nature of the cultural material generating the signature and its potential National Register significance. Historical evidence was developed into a background that identified possible correlations with magnetic targets. A magnetic contour map of each survey area was produced to aid in the analysis of each target. All targets were listed and described and a map produced that showed their location within the project area.

Historical Overview of Beaufort/Morehead City Vicinity

Among the earliest residents of Shackleford Banks and Cape Lookout during the late 1600s and early 1700s were whalers, who established a series of temporary camps and shelters amid the dunes. By the 1720s, Cape Lookout and Shackleford Banks became a more permanent base of operations for New England whalers (Angley 1982:5). When Beaufort was appointed as "a port for the unloading and discharging [of] vessels," in 1722 it was clear that successful development would also depend on trade entering and clearing through Beaufort Inlet (Paul 1970:370-373; Angley 1982:8). Unlike many of the inlets along the North Carolina coast, Beaufort Inlet was relatively stable and offered a safe and deep channel for ship traffic (Stick 1958:312).

Not all of the vessels bound for Beaufort were successful in navigating the inlet. In November 1718, the pirate Blackbeard lost two vessels on or near the bar. Both the ship *Queen Anne's Revenge* and the sloop *Adventure* were run aground, perhaps deliberately. Many of the crew of the *Queen Anne's Revenge* and the *Adventure* were abandoned on Shackleford Banks while Blackbeard and a hand-picked crew sailed for Bath in the remaining sloop.

Although Beaufort remained a relatively unimportant port during the 18th century it did play a small role in Revolutionary War maritime activity. While the blockade imposed upon the American coast by the British Navy seriously impacted trade for many Colonial ports, shipping through Beaufort provided a portion of the supplies needed by the Patriots in North Carolina. In the years that followed the Revolution, North Carolina experienced an increase in the volume of maritime trade and shipbuilding. Just after the turn of the century, Beaufort Inlet was described as one of the best on the North Carolina coast, with "the channel being generally 3 1/4 to 3 1/2 fathoms" deep. Beaufort was also mentioned as having a fairly vigorous, though small, shipbuilding industry (Tatham 1806). In 1810, Jacob Henry, a former representative from Carteret County to the North Carolina House of Commons, commented upon the local shipbuilding industry at Beaufort:

> The principal trade carried on here is ship building in which they have acquired a very considerable reputation.... Live oak and Cedar are the timbers principally used but the stock is by no means so abundant as it has been. Some of the swiftest sailors and best built Vessels in the United States have been launch'd here, particularly the Ship *Minerva*, a well known Packet between Charleston and New York. There are at present five Vessels at the Stocks, two of which are ready to be launch'd (Newsome 1929:399).

The Beaufort vicinity was severely battered by a hurricane that struck the area in 1815. The storm, later described as "being one of the most violent and disastrous ever known upon the coast," brought about significant changes to the bar at Beaufort. The bar was "injured so that but 12 feet could be brought over it at low water." Fortunately, the channel eventually recovered from the storm's damage and by 1830, the depth on the bar had increased to 18 feet at mean low water. By 1854, the bar channel had decreased to a depth of 15 1/2 feet and migrated slightly to the south (United States Congress, Senate Executive Document, No. 78, 33rd Congress, pp. 3-4).

Around 1841, John Motley Morehead, governor of North Carolina, had a vision of establishing a port facility at the eastern terminus of the Atlantic and North Carolina Railroad. A decision was finally reached in 1855 to locate the proposed port and rail facility on Sheppard's Point (Konkle 1922:339-340).

The editor of the Greensboro *Patriot* described the conditions and natural advantages which he believed would benefit maritime traffic through Beaufort Inlet to the new port facility at Morehead City in September 1858:

> The inlet at Beaufort Harbor is, we understand, about three-quarters of a mile wide, extending from the point on the Shackleford banks on the east to the point at Fort Macon on the west. Ships drawing from eighteen to twenty feet can cross the bar with safety. Ships crossing the bar, enter the harbor near the Shackleford banks, then bear in a westwardly direction toward Fort Macon. From the bar at the inlet, across the Sound to Beaufort, is about three miles, this being about the widest part of the harbor. The channel is in the form of a half-moon, one horn running eastwardly along the Shackleford banks, called Core Sound, and the other westwardly by Morehead and Carolina cities, which are situated on Bogue Sound. The deepest water is along Newport river, which runs in nearly a north direction between Morehead City and Beaufort, touching the railroad wharf in the former place. The main channel is about one mile wide, so that the inside of the channel would be some two miles from Beaufort, though vessels drawing from nine to ten feet water can approach the Beaufort wharves at full tide. Running up the channel about three miles from the bar, we come to the railroad wharf at Morehead City, where vessels drawing eighteen feet can approach with ease, and unload and take in lading with the greatest safety (Konkle 1922:341-342).

Within six months, the rail and port facility at Morehead City was prospering, much to the chagrin of the people of Beaufort. Ships were continually calling at the wharfs and being loaded with cargoes directly from train cars:

> Here a steamer drawing twenty feet of water, and the locomotive weighing twenty or thirty tons, with its whole train, may be along side each other; and this, too, on each side of the wharf at the same time, while in front other vessels may be loading or discharging cargoes (Konkle 1922:360-361).

The development of Morehead City was soon disrupted by the Civil War. On 22 March 1862, Union forces occupied Morehead City. Four days later Union troops crossed the Newport River and took control of Beaufort. Fort Macon also fell into Union forces under General Ambrose E. Burnside following a fierce one-day siege (Stick 1958:148-153). Preceding the final assault on Fort Macon, a Union gunboat and one or two smaller vessels were positioned inside Beaufort Inlet, controlling the approaches and exits to Bogue and Core Sounds. On 22 April, several Union vessels anchored near Harker's Island to the east of Beaufort, including the steamer *Alice Price* that served as General Burnside's temporary headquarters. When the fall of Fort Macon was imminent, Confederate forces burned the bark *Glen* to keep it out of Union hands. On 26 April, Colonel Moses J. White, commander of Fort Macon, surrendered to Generals Parks and Burnside on Shackleford Banks (Angley 1982:34; Stick 1958:148-153).

The occupation of Fort Macon and the surrounding vicinity provided Union naval forces with access to a deep-water port and a place of rendezvous that was used to support the blockading squadron throughout the remainder of the war. During December 1864 and January 1865, fleets under Admiral David Porter massed at Beaufort Harbor in preparation for their assault on Fort Fisher in Wilmington, the last major stronghold of the Confederacy in North Carolina. During the Civil War at least five Confederate vessels were captured at sea in the Cape Lookout area: the schooners *Edwin*, *Julia*, *Revere* and *Louisa Agnes* were captured in 1861 and the steamer *Banshee* was taken on 21 November 1863 (Angley 1982:35; Price 1948). One Confederate vessel was lost in the vicinity as a result of enemy action. On 9 July 1864, the side-wheel steamer *Pevensey* was chased ashore and blown up on Bogue Banks, approximately nine miles west of Beaufort Inlet (Hill 1975:11-13). Not all of the known shipwrecks near Beaufort were a result of enemy action. On 12 June 1863, the USS *Lavender* ran aground in heavy seas near Cape Lookout Shoals while en route from the Delaware Capes to Charleston. The *Lavender* was a screw tug of 173 tons. On 20 July 1865, the 186-ton Union screw steamer *Quinnebaugh* went ashore on Beaufort bar in rough weather after her machinery failed. The *Quinnebaugh* was transporting Union troops, refugees and civilians north at the time of her loss (Shomette 1973:88-89; Berman 1972:141; Lytle and Holdcamper 1975:291).

Six years after the Civil War, the federal government began measures to reduce the severity of maritime disasters along the coast by establishing the United States Lifesaving Service. In 1874, seven stations were established along the North Carolina coast. In 1875, a similar station was authorized by Congress for Cape Lookout, though it would be another ten years before it was finally built. Over the following years three other stations were established on Core Banks, and a facility was also established near Fort Macon, just west of Beaufort Inlet (Angley 1982:35-36; Stick 1958:169-170, 310-313).

Menhaden fishing became an important source of income for the Cape Lookout-Beaufort area in the years following the Civil War. From 1865 to 1873, the state's first menhaden processing plant was in operation on Harker's Island. By the turn of the century several plants were in operation at Beaufort and at various points on Bogue and Core Sounds (Hill 1975:16-18).

Growth of Beaufort and Morehead City as ports was slow during the late-19th and early 20th centuries. In the 1880s, the federal government began work on the improvement of Beaufort Inlet in the hopes of increasing the amount of maritime trade to the port communities. The depth over the bar in the later 19th century was just over 15 feet, but it was said that "the harbor entrance was rapidly deteriorating; its width, measured from Fort Macon to Shackleford Point, having increased 500 feet between the years 1864 and 1880" (Stick 1958:312; Angley 1982:39-40). By 1880, the width of the inlet had increased an additional 900 feet. As a means to prevent further erosion, jetties were constructed from both shores into the inlet. Over the next five years, five jetties were constructed on Shackleford Point and another six on Fort Macon Point. By 1889, the deterioration of the inlet had been brought under control (Angley 1982:40; Stick 1958:312).

Between 1905 and 1907, the channel across Beaufort Inlet bar was dredged to a depth of 20 feet at mean low water. A 20-foot channel, 200 feet wide, was also provided inside the inlet to the wharves at Morehead City. A smaller channel, seven feet deep and 100 feet wide, was dredged to the wharves along the Beaufort waterfront (Angley 1982:40). The Army Corps of Engineers submitted several reports between 1907 and 1914 that indicated that both Morehead City and Beaufort were growing centers of maritime trade. The majority of vessels utilizing the two ports were fishing boats and small, shallow-draft cargo vessels (Angley 1982:41). Beaufort Inlet was described in 1907 as being limited in importance:

> The present commerce through the inlet is small, owing in a large measure to the hitherto shallow draft of not generally more than 12 feet at mean low water that could be carried across the bar.
>
> The present annual commerce of Beaufort, N. C., the principal place on the water adjacent to this harbour, amounts to about 64,000 tons annually, valued at $3,500,000, of which only about one-fourth to one-fifth passes through the inlet (United States Congress, House Document No. 1454, p. 3).

Statistics for 1912 reflect that 12 sailing and 35 gasoline powered vessels totaling 570 net tons were registered at Morehead City. For the same year, the registry at the rival port of Beaufort listed 175 sailing vessels, 240 gasoline powered vessels and 6 barges with a net registered tonnage of 6,005 (Angley 1982:42; United States Congress, House Documents No. 1022:4-11 and No. 1108:6-7).

A number of vessels travelling along the coast became victims of maritime hazards. Between 1 July 1898 and 30 June 1908, 82 vessels were reported lost off the North Carolina coast (United States Congress, House Document No. 315, pp. 5-6). Several of those shipwrecks had themselves become hazards to navigation. On 20 and 27 February 1891, notices were printed in the Wilmington *Weekly Star* that the federal government was in the process of removing wrecks that had become obstacles to other vessels:

> Masters and owners of vessels engaged in the coastwise trade will be glad to know that the commanding Officer of the USS *Yantic* has been ordered to cruise along the coast from Sandy Hook to Charleston, S. C. and to destroy, as far as practicable, all abandoned wrecks which are dangerous to navigation. There are a number of these wrecks on the coast of North Carolina and Virginia.
>
> Off the North Carolina coast the *Yantic* will find the schooner *Dudley Farlin*, twenty-four miles northwest of Bodie Island Light; the schooner *Mollie J. Saunders*, seven miles southeast of the same light; the steamer *Glenrath*, south by west of Cape Lookout Light, four or five miles further in shore, the steamer *Aberlady Bay*, and a sunken wreck eighteen miles east-northeast of Frying Pan Shoal Lightship (Wilmington *Weekly Star*, 20 and 27 February 1891).

In a 1897 Congressional report the hazards found at Cape Lookout to maritime traffic were summarized by the captain of the life-saving station at Cape Lookout:

> I ascertain that, since 1888, 19 schooners, 6 steamships, and 1 bark were disabled or ashore around Cape Lookout that would have been unharmed in all probability, if a safe harbor had been near. Two of these steamships and many of the schooners proved total losses. Unknown wrecks are occasionally discovered on or near the shoals. Nine large vessels have been anchored south of the beach at one time during northeasters. When the wind shifted they had to go to sea. Twenty-two schooners have been seen at one time laying to under the lee of Lookout Shoals during a northeast gale, and 57 vessels have been sighted passing by in one day. The locality is being frequented more and more as seafaring men learn the advantage of it. The great danger at present is being caught in the great bight with a southerly gale (United States Congress, House Document No. 25, p. 5).

To prevent vessels from wrecking near Cape Lookout a lighthouse had been in use, but mariners often complained that the light was difficult to see. As a remedy, a lightship was placed at Cape Lookout Shoals in 1904 and remained in operation until 1933 when it was removed (Holland 1968:32-35; Stick 1958:310). In addition to the lightship, a lens lantern was erected in 1900 on Cape Lookout Bight for the "large number of vessels that seek a lee under Cape Lookout" (Holland 1968:32).

During World War I, Cape Lookout Bay served as a rendezvous and staging area for convoys bound for Europe, and Morehead City was occasionally used as a distribution point for war supplies. From 1926 to 1938, the federal government made considerable improvements to the Port of Morehead City by increasing the depth of the channel through Beaufort Inlet to 30 feet (Stick 1952:237-238). In 1923, the tug *Juno* sank in the Beaufort Inlet channel causing considerable difficulty for other vessels to pass. The *Juno* was eventually dynamited to clear the entrance. This earlier event may have been a contributing factor in recognizing the need for channel improvements (*The Evening Dispatch,* 23 July 1923; Berman 1972:128).

Hostilities in the Cape Lookout vicinity were much more evident during the events of World War II. For example, on the night of 18 March 1942, German submarines sank three tankers in the Cape Lookout area: the *Papoose,* the *W. E. Hutton* and the *E. M. Clark.* Five days later another tanker, the *Naeco* was sunk in the same vicinity (Stick 1952:234). As a result of the high number of vessel losses occurring during the early stages of the war, defensive measures were put into place. Coastal communities were systematically blacked out, a more efficient convoy system was devised and additional planes and patrol vessels were put into service for the Cape Lookout area and North Carolina coast in general (Stick 1952:237-239).

In the early 1950s, improvements were once again undertaken at Morehead City. By the summer of 1954, a project to widen the 30-foot channel to 300 feet to the terminal facilities, construct a 600-foot turning basin and dredge a 12-foot channel in Bogue Sound along the city's commercial waterfront was nearly completed (Angley 1982:48). By 1954, the main shipping channel to Beaufort had also been dredged to a depth of 12 feet and a width of 100 feet. The improvements could easily accommodate sports and commercial fishing vessels and pleasure craft, but was inadequate to handle large, deep-draft cargo vessels (Angley 1982:48). Since the mid-1950s, regular maintenance dredging has been undertaken at the channels leading into the Morehead City and Beaufort harbors. Today, Morehead City continues as a major deep-water port with several large vessels arriving monthly.

Summary of Findings

Investigation of the three borrow areas off Bogue Bank identified a total of 10 magnetic anomalies. No magnetic and/or acoustic anomalies were identified during remote sensing of Borrow Area A or Borrow Area B-1 (Figures 2, 3, 4). All ten of the identified anomalies were located in the western part of Borrow Area B-2 (Figures 5, 6). Analysis of the target signatures suggest that seven of the anomalies could be associated with shipwreck remains. It is recommended that those seven targets be avoided. In the event that they cannot be avoided, additional investigation is recommended to identify the nature and assess the significance of material generating the signatures. The remaining three targets contained signature characteristics suggestive of single ferrous objects and are not recommended for additional investigation.

Borrow Area A

No magnetic and/or acoustic targets were identified in Area A.

Borrow Area B-1

No magnetic and/or acoustic targets were identified in Area B-1.

Borrow Area B-2

Target Designation: B2-01

Signature Type: Dipolar

State Plane	Northing	Easting	Intensity	Duration
	2611456	341287	262	6

Potential: Low

Target B2-01 was located in the western end of Borrow Area B-2. The magnetic signature was identified on lane 1 and the contoured signature consisted of data from the anomaly identified as 1.2 in the magnetometer records. The detectable signature had a maximum intensity of 262 gammas and a maximum duration of 6 two-second pulses (Figure 7). The contoured dipolar signature covered an area of approximately 19,800 square feet. No sonar signature was associated with the material generating the magnetic signature. The signature characteristics, intensity and duration suggest that material generating the anomaly could be a single ferrous object such as pipe, cable, anchors or other similar debris. However, as the anomaly lies on the

edge of the survey area, it may potentially be associated with a significant cultural resource adjacent the current project area. In the event that the proposed project would impact the anomaly location, consideration should be given to identifying and assessing the potential historical significance of the material associated with the target.

Target Designation: B2-02

Signature Type: Dipolar

State Plane	Northing	Easting	Intensity	Duration
	2612965	341596	59	5

Potential: Low

Target B2-02 was located in the western end of Borrow Area B-2. The magnetic signature was identified on lane 1 and the contoured signature consisted of data from the anomaly identified as 1.1 in the magnetometer records. The detectable signature had a maximum intensity of 59 gammas and a maximum duration of 5 two-second pulses (Figure 8). The contoured dipolar signature covered an area of approximately 11,220 square feet. No sonar signature was associated with the material generating the magnetic signature. The signature characteristics, intensity and duration suggest that material generating the anomaly could be a single ferrous object such as pipe, cable, anchors or other similar debris. However, because of a possible spatial association with targets B2-03, B2-04, B2-06 and B2-09 the target may represent scattered debris associated with a shipwreck. In the event that the proposed project would impact the anomaly location, consideration should be given to identifying and assessing the potential historical significance of the material associated with the target.

Target Designation: B2-03

Signature Type: Dipolar

State Plane	Northing	Easting	Intensity	Duration
	2613207	341371	27	5

Potential: Low

Target B2-03 was located in the western end of Borrow Area B-2. The magnetic signature was identified on lane 4 and the contoured signature consisted of data from the anomaly identified as 4.1 in the magnetometer records. The detectable signature had a maximum intensity of 27 gammas and a maximum duration of 5 two-second pulses (Figure 9). The contoured

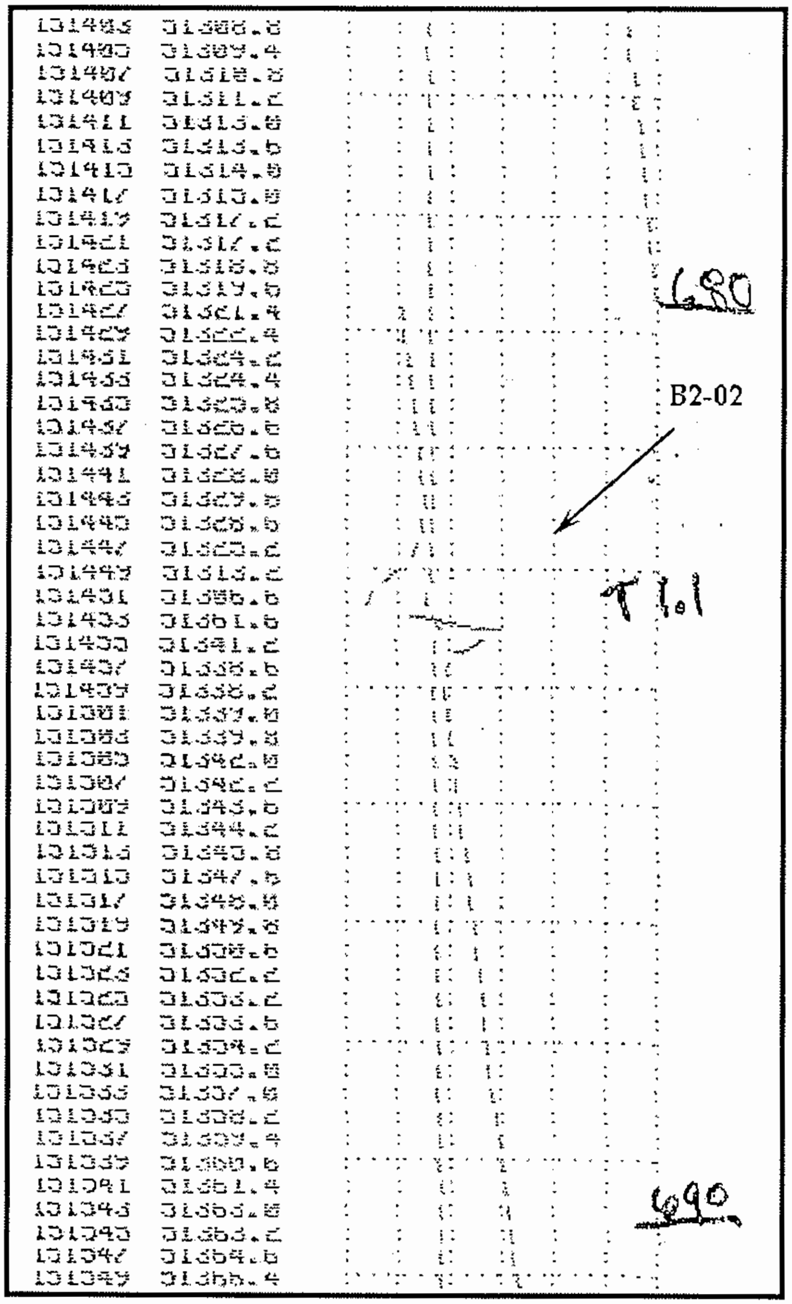

Figure 8. **Magnetic Target B2-02.**

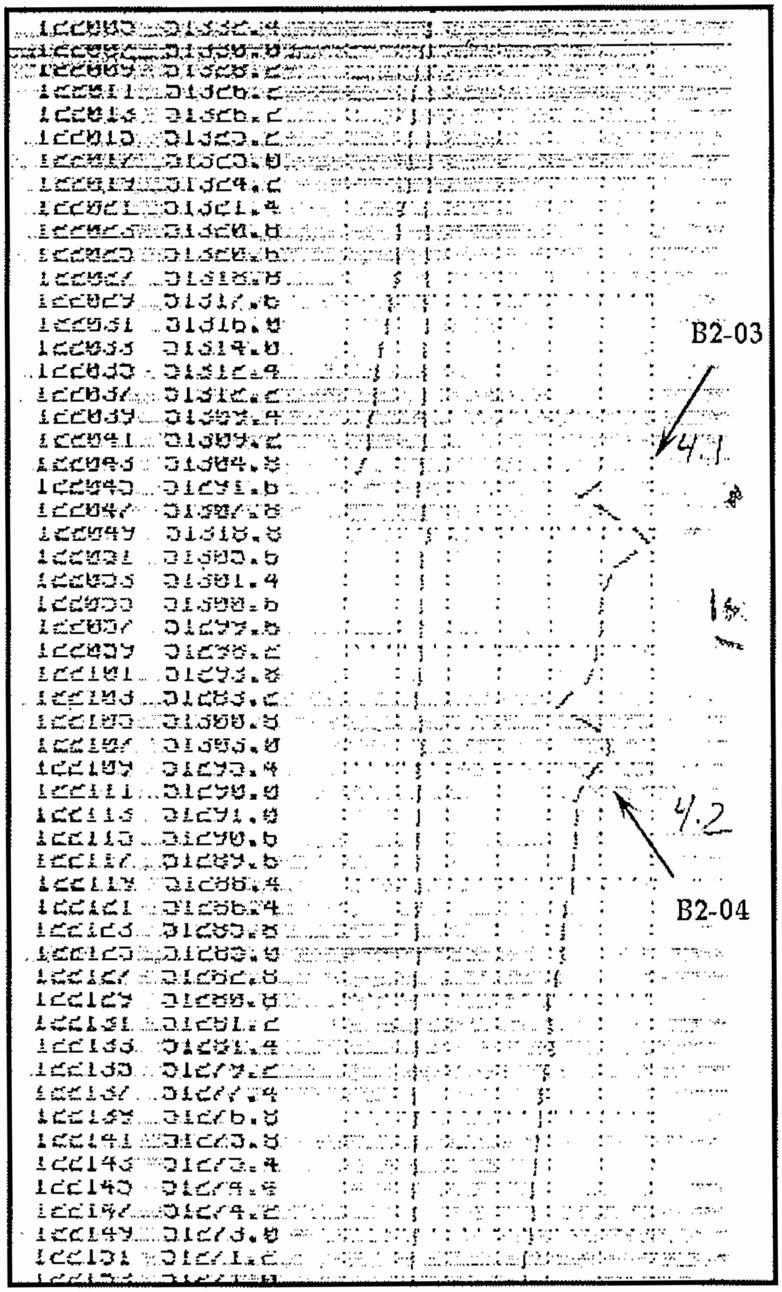

Figure 9. Magnetic Targets B2-03 and B2-04.

dipolar signature covered an area of approximately 8,800 square feet. No sonar signature was associated with the material generating the magnetic signature. The signature characteristics, intensity and duration suggest that material generating the anomaly could be a single ferrous object such as pipe, cable, anchors or other similar debris. However, because of a possible spatial association with targets B2-02, B2-04, B2-06 and B2-09 the target may represent scattered debris associated with a shipwreck. In the event that the proposed project would impact the anomaly location, consideration should be given to identifying and assessing the potential historical significance of the material associated with the target.

Target Designation: B2-04

Signature Type: Dipolar

State Plane	Northing	Easting	Intensity	Duration
	2613393	341404	20	6

Potential: Low

Target B2-04 was located in the western end of Borrow Area B-2. The magnetic signature was identified on lane 4 and the contoured signature consisted of data from the anomaly identified as 4.2 in the magnetometer records. The detectable signature had a maximum intensity of 20 gammas and a maximum duration of 6 two-second pulses (Figure 9). The contoured dipolar signature covered an area of approximately 9,500 square feet. No sonar signature was associated with the material generating the magnetic signature. The signature characteristics, intensity and duration suggest that material generating the anomaly could be a single ferrous object such as pipe, cable, anchors or other similar debris. However, because of a possible spatial association with targets B2-02, B2-03, B2-06 and B2-09 the target may represent scattered debris associated with a shipwreck. In the event that the proposed project would impact the anomaly location, consideration should be given to identifying and assessing the potential historical significance of the material associated with the target.

Target Designation: B2-05

Signature Type: Dipolar

State Plane	Northing	Easting	Intensity	Duration
	2614359	341393	50	5

Potential: Low

Target B2-05 was located in the western end of Borrow Area B-2. The magnetic signature was identified on lane 6 and the contoured signature consisted of data from the anomaly identified as 6.0 in the magnetometer records. The detectable signature had a maximum intensity of 50 gammas and a maximum duration of 5 two-second pulses (Figure 10). The contoured dipolar signature covered an area of approximately 8,000 square feet. No sonar signature was associated with the material generating the magnetic signature. The signature characteristics, intensity and duration suggest that material generating the anomaly could be a single ferrous object such as pipe, cable, anchors or other similar debris. The sharp, low intensity signature does not appear to represent the more complex types often associated with shipwreck remains. No additional investigation of the target is recommended in conjunction with the proposed project.

Target Designation: B2-06

Signature Type: Dipolar

State Plane	Northing	Easting	Intensity	Duration
	2612754	341037	49	7

Potential: Low

Target B2-06 was located in the western end of Borrow Area B-2. The magnetic signature was identified on lane 6 and the contoured signature consisted of data from the anomaly identified as 6.1 in the magnetometer records. The detectable signature had a maximum intensity of 49 gammas and a maximum duration of 7 two-second pulses (Figure 11). The contoured dipolar signature covered an area of approximately 14,025 square feet. No sonar signature was associated with the material generating the magnetic signature. The signature characteristics, intensity and duration suggest that material generating the anomaly could be a single ferrous object such as pipe, cable, anchors or other similar debris. However, because of a possible spatial association with targets B2-02, B2-03, B2-04 and B2-09 the target may represent scattered debris associated with a shipwreck. In the event that the proposed

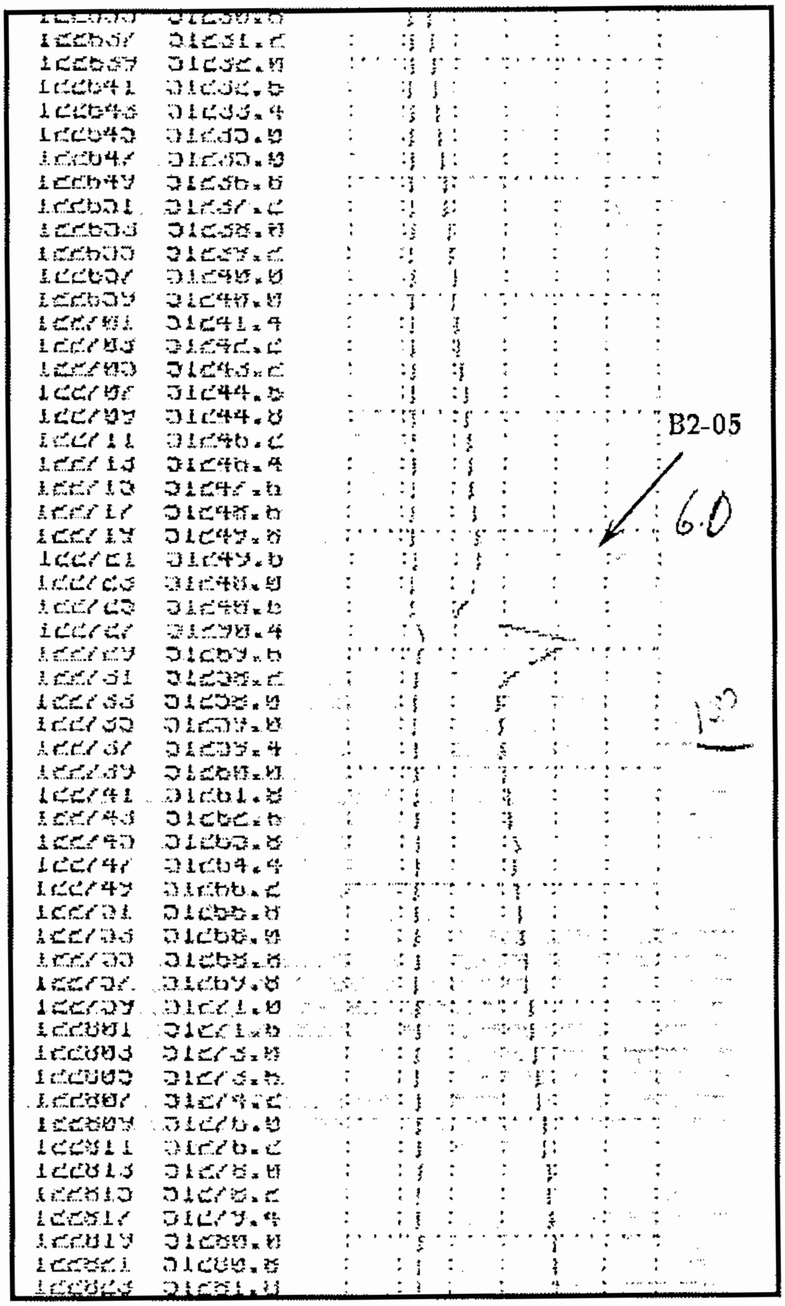

Figure 10. Magnetic Target B2-05.

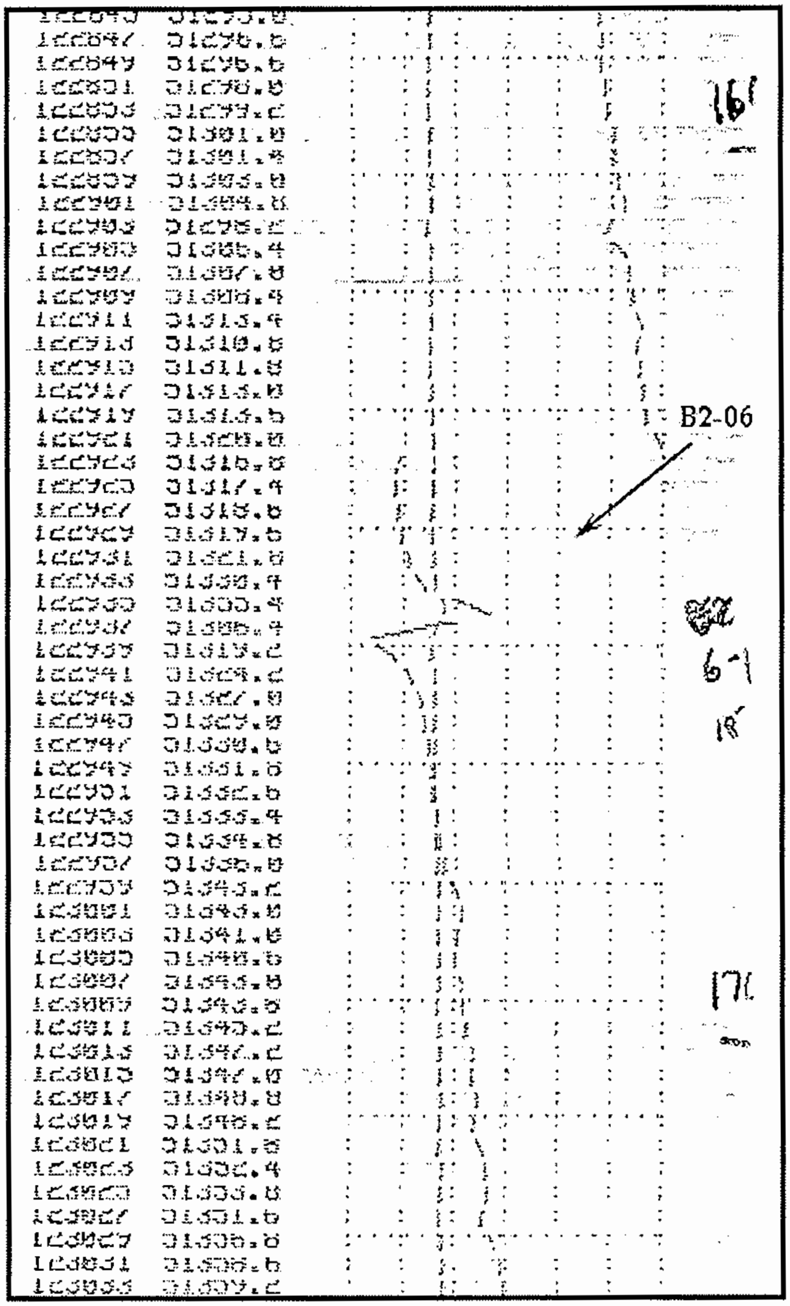

Figure 11. Magnetic Target B2-06.

project would impact the anomaly location, consideration should be given to identifying and assessing the potential historical significance of the material associated with the target.

Target Designation: B2-07

Signature Type: Positive Monopolar

State Plane	Northing	Easting	Intensity	Duration
	2611216	340557	82	5

Potential: Low

Target B2-07 was located in the western end of Borrow Area B-2. The magnetic signature was identified on lane 8 and the contoured signature consisted of data from the anomaly identified as 8.1 in the magnetometer records. The detectable signature had a maximum intensity of 82 gammas and a maximum duration of 5 two-second pulses (Figure 12). The contoured positive monopolar signature covered an area of approximately 12,000 square feet. No sonar signature was associated with the material generating the magnetic signature. The signature characteristics, intensity and duration suggest that material generating the anomaly could be a single ferrous object such as pipe, cable, anchors or other similar debris. The sharp, moderate intensity signature does not appear to represent the more complex types often associated with shipwreck remains. No additional investigation of the target is recommended in conjunction with the proposed project.

Target Designation: B2-08

Signature Type: Dipolar

State Plane	Northing	Easting	Intensity	Duration
	2610512	340108	22	7

Potential: Low

Target B2-08 was located in the western end of Borrow Area B-2. The magnetic signature was identified on lane 11 and the contoured signature consisted of data from the anomaly identified as 11.1 in the magnetometer records. The detectable signature had a maximum intensity of 22 gammas and a maximum duration of 7 two-second pulses (Figure 13). The contoured dipolar signature covered an area of approximately 11,310 square feet. No sonar signature was associated with the material generating the magnetic signature. The signature characteristics, intensity and duration suggest that

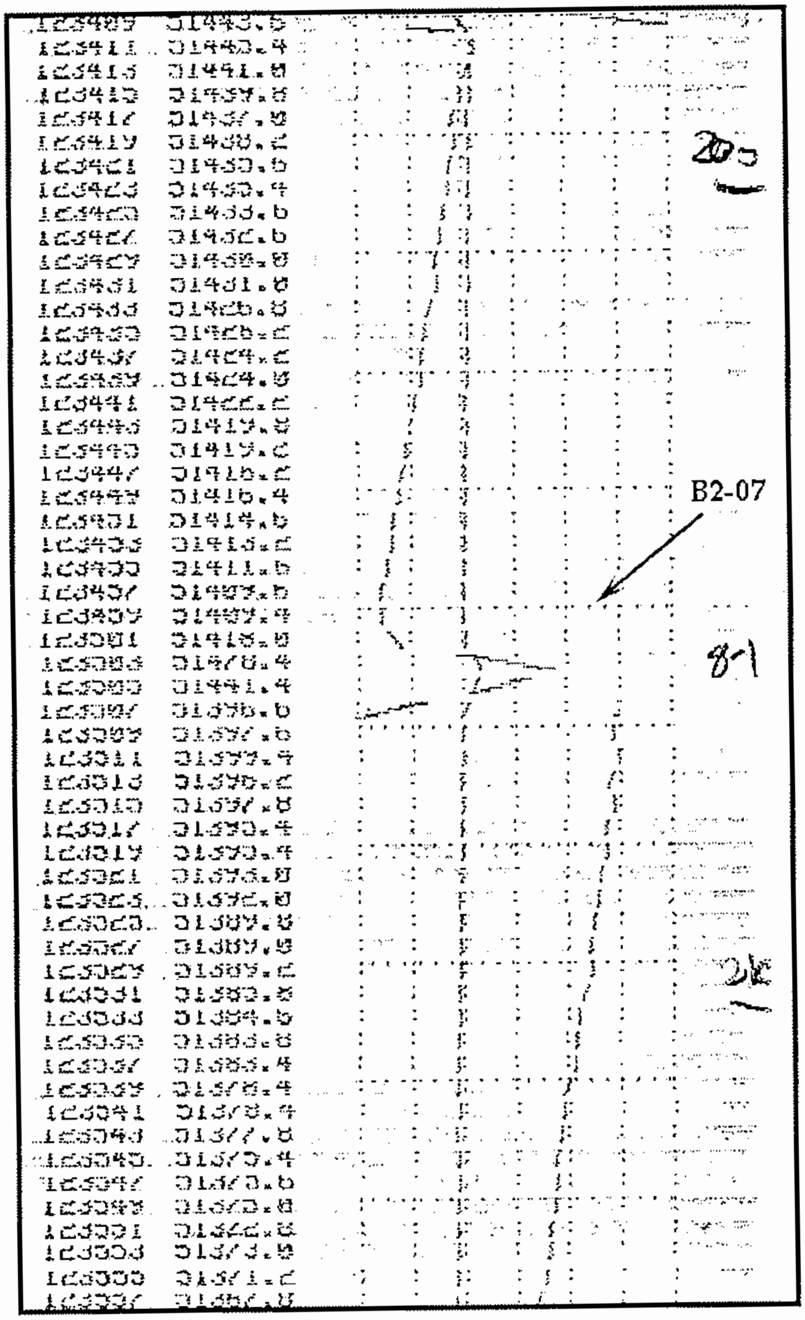

Figure 12. Magnetic Target B2-07.

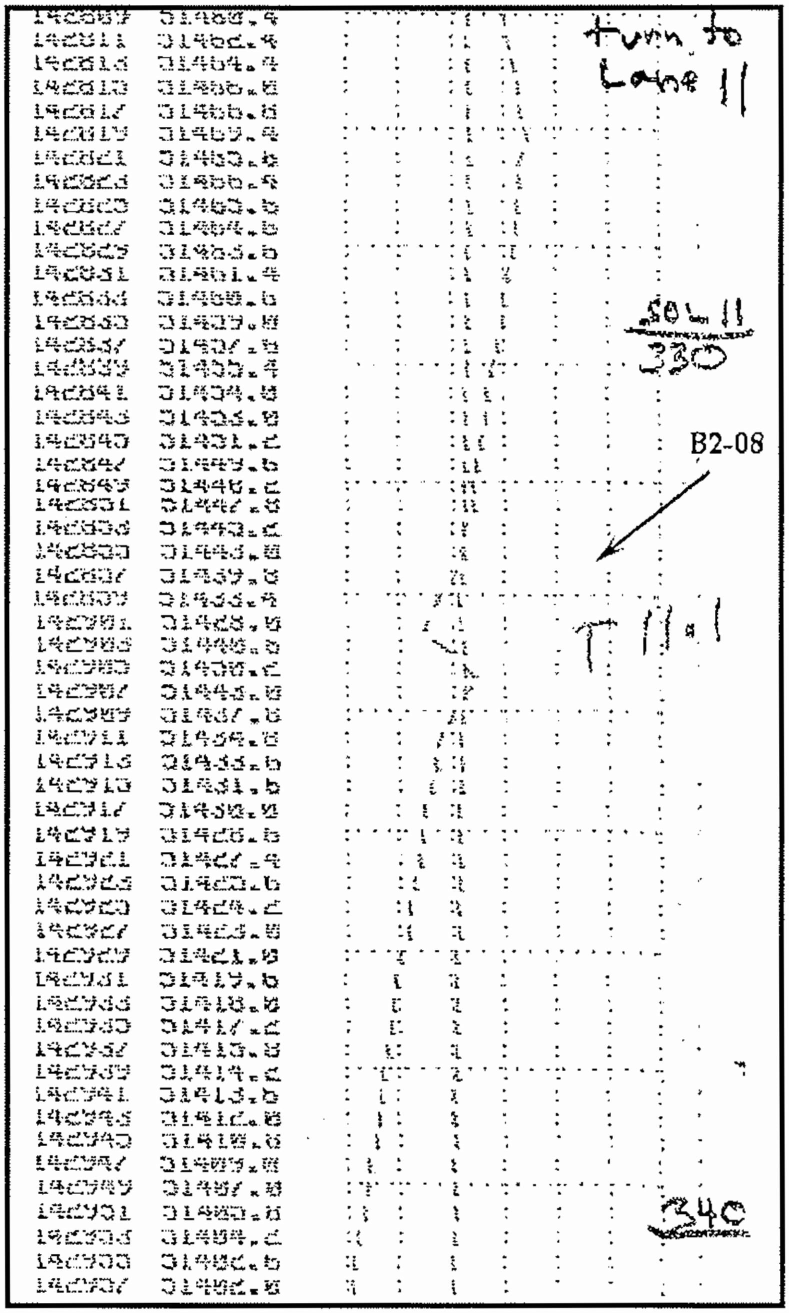

Figure 13. Magnetic Target B2-08.

material generating the anomaly could be a concentration of ferrous objects such as the fasteners of a vessel or other similar hardware. It is possible that the anomaly could be associated with the remains of a vessel as the signature characteristics are similar to those low intensity and long duration anomalies demonstrated to be associated with the remains of wooden hull vessels. In the event that the proposed project will impact the anomaly location, consideration should be given to identifying and assessing the potential historical significance of the material associated with the target.

Target Designation: B2-09

Signature Type: Negative Monopolar

State Plane	**Northing**	**Easting**	**Intensity**	**Duration**
	2613222	340888	49	5

Potential: Low

Target B2-09 was located in the western end of Borrow Area B-2. The magnetic signature was identified on lanes 8 and 9 and the contoured signature consisted of data from the anomalies identified as 8.2 and 9.1 in the magnetometer records. The detectable signature had a maximum intensity of 49 gammas and a maximum duration of 5 two-second pulses (Figure 14). The contoured negative monopolar signature covered an area of approximately 23,000 square feet. No sonar signature was associated with the material generating the magnetic signature. The signature characteristics, intensity and duration suggest that material generating the anomaly could be a single ferrous object such as pipe, cable, anchors or other similar debris. However, because of a possible spatial association with targets B2-02, B2-03, B2-04 and B2-06 the target may represent scattered debris associated with a shipwreck. In the event that the proposed project would impact the anomaly location, consideration should be given to identifying and assessing the potential historical significance of the material associated with the target.

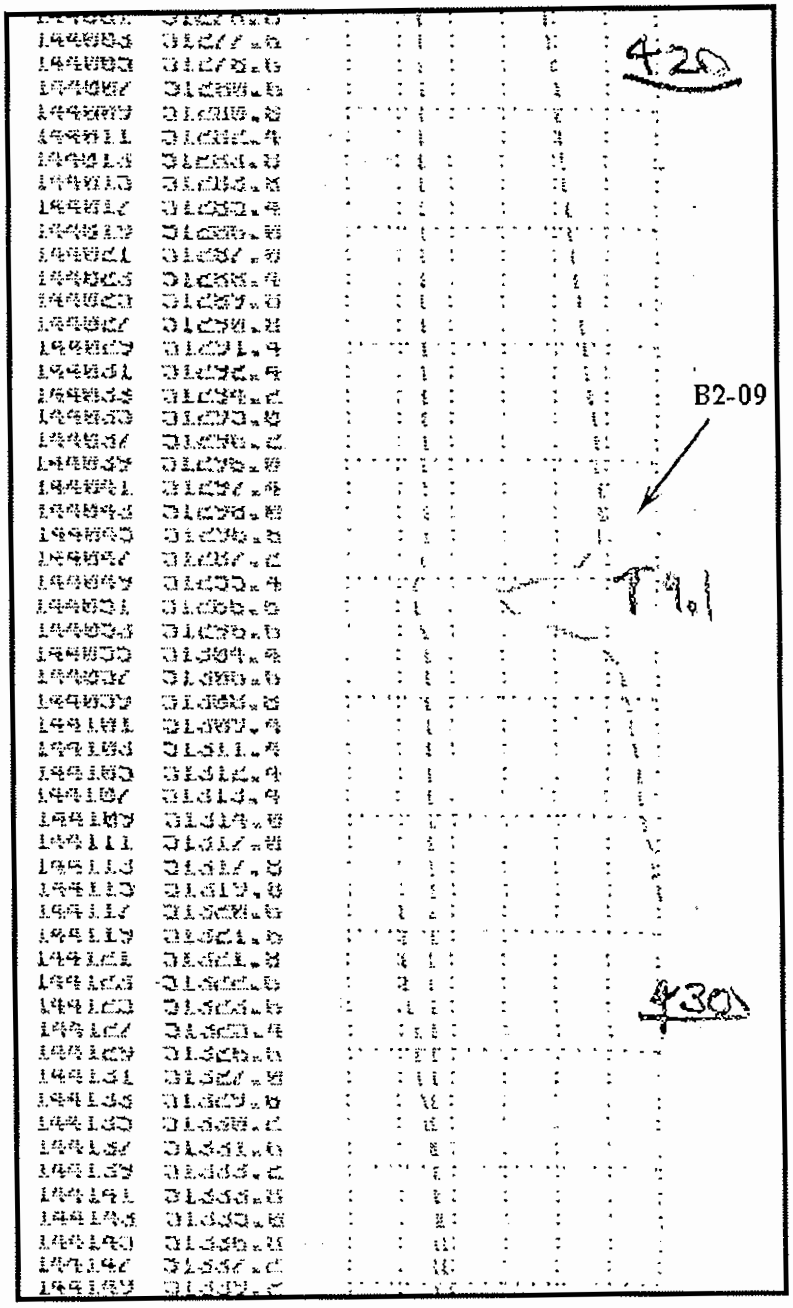

Figure 14. Magnetic Target B2-09.

Target Designation: B2-10

Signature Type: Multi-component

State Plane	Northing	Easting	Intensity	Duration
	2611288	339080	32	7

Potential: Low

Target B2-10 was located in the western end of Borrow Area B-2. The magnetic signature was identified on lane 23 and the contoured signature consisted of data from the anomaly identified as 23.1 in the magnetometer records. The detectable signature had a maximum intensity of 32 gammas and a maximum duration of 7 two-second pulses (Figure 15). The contoured multi-component signature covered an area of approximately 14,250 square feet. No sonar signature was associated with the material generating the magnetic signature. The signature characteristics, intensity and duration suggest that material generating the anomaly could be a single ferrous object such as pipe, cable, anchors or other similar debris. The sharp, low intensity signature does not appear to represent the more complex types often associated with shipwreck remains. No additional investigation of the target is recommended in conjunction with the proposed project.

Conclusions and Recommendations

A survey of historical and archaeological literature and archival background research confirmed considerable evidence of maritime activity along the southeastern North Carolina coast. That evidence suggests a high probability for submerged cultural resources in the waters around Beaufort Inlet. Discovery of what appears to be the remains of Blackbeard's *Queen Anne's Revenge* and several Civil War vessels reinforce that hypothesis. Both Beaufort and Morehead City provided early settlers with centers of transportation and trade and bases of operations to exploit the natural resources of the Carolina coast. Yet in spite of nature and the scope of maritime activity, there is only one reference to a specific vessel lost in the immediate vicinity of the proposed project. That vessel is the Civil War blockade runner *Pevensey* that was run ashore at the site of the Iron Steamer Pier. No known sites exist in the survey areas in the files of the Underwater Archaeology Unit of the Division of Archives and History.

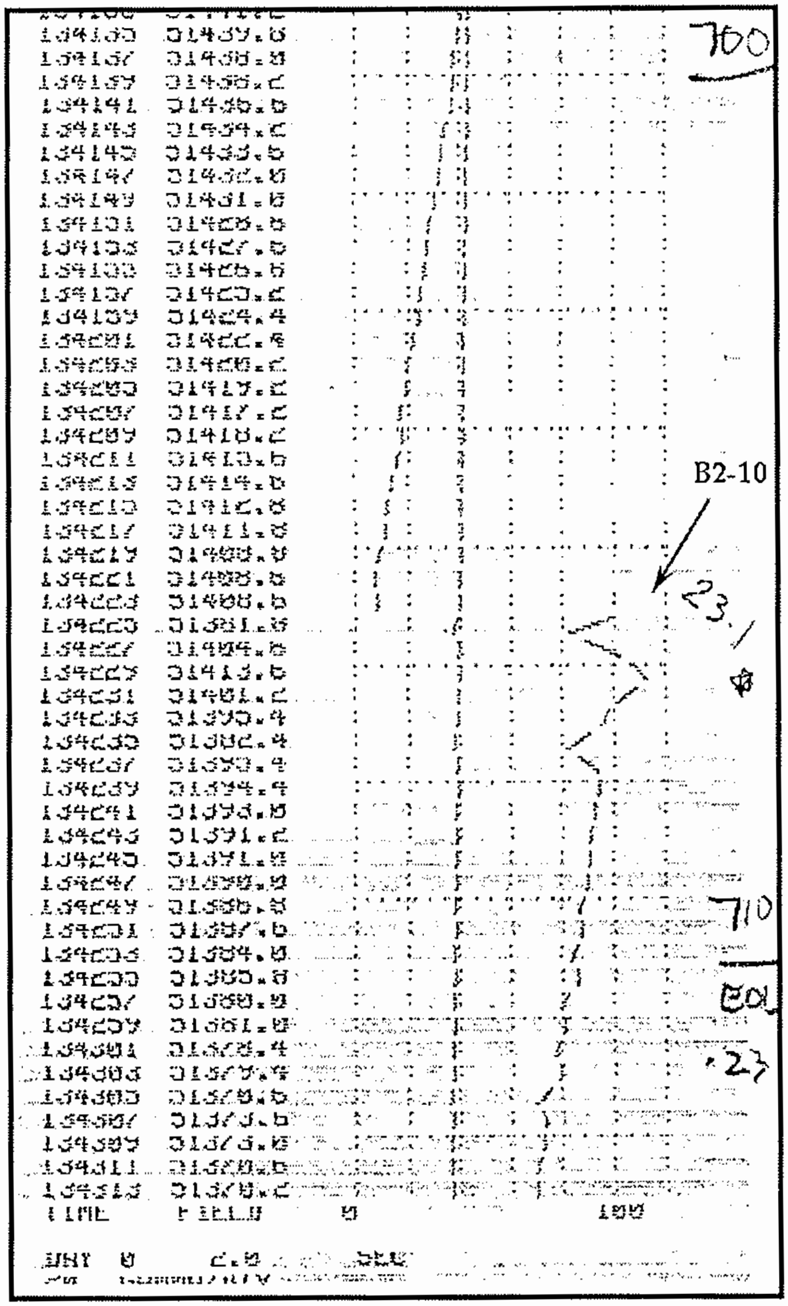

Figure 15. Magnetic Target B2-10.

Analysis of the remote sensing data revealed no magnetic and/or acoustic anomalies in either Borrow Area A or Borrow Area B-1. On the basis of that analysis, no additional investigation of the area is recommended in conjunction with the proposed project.

Analysis of the remote sensing data for Borrow Area B-2 confirmed the presence of 10 magnetic anomalies in the western part of the survey area. Seven of those targets contained signature characteristics consistent with significant submerged cultural resources. Analysis of the target signatures suggests that five of the anomalies, B2-02, B2-03, B2-04, B2-06 and B2-09, may be spatially associated and could represent scattered debris from a shipwreck. Another target, B2-08, contained signature characteristics similar to those commonly associated with wooden hull vessels. Though the final anomaly, B2-01, exhibited signature characteristics suggestive of a single ferrous object its location along the northern edge of the survey area does not rule out a possible association with a significant cultural resource lying adjacent to the project area. The remaining three targets, B2-05, B2-07 and B2-10, contained signature characteristics suggestive of single ferrous objects. With the exception of the above seven anomalies, the proposed project will have no impact on potentially significant submerged cultural resources.

In order to provide reasonable assurance that proposed dredging does not impact targets B2-01, B2-02, B2-03, B2-04, B2-06, B2-08 and B2-09, a buffer zone should be established around each anomaly location. Unfortunately, there is no concrete data regarding the establishment of an effective buffer zone around submerged cultural resource sites. In the absence of such data and due to the nature of the high energy environment off Bogue Banks, it may be appropriate to establish a buffer zone 250 feet in circumference around the center of the target coordinates. In order to assess the buffer zone effectiveness, the target environment at each site should be periodically monitored to determine what, if any, change has occurred. In the event that the target locations cannot be avoided, diver investigation of the seven anomalies is recommended to identify and assess their National Register of Historic Places eligibility.

TABLE OF CONTENTS

1. Introduction/Purpose

This benthic assessment was conducted under contract with Carteret County, North Carolina in anticipation of a beach renourishment project for Bogue Banks. The purpose of this report is to describe the results of a single fall 1999 sampling of the benthic invertebrates and surficial sediments at the offshore borrow areas and nearby controls and the results of three (late fall-winter-spring) sets of trawl samples for demersal fishes and invertebrates around the borrow areas. This information may ultimately be incorporated into a monitoring scheme and helps in the short term to describe the biological resources at risk in the offshore system. Benthic invertebrates are commonly used in environmental assessments because they are sedentary and show the imprint of any environmental perturbation and because they are important trophic links to higher levels on the food chain, demersal predatory fishes, birds, and crustaceans (Warwick 1993). Many of these consumers have value as targets of commercial and/or recreational fisheries or as attractive charismatic wildlife (McLachlan 1983).

There are several environmental issues relating to the benthic habitat and biological resources that arise in considering a beach renourishment project (e.g., Naqvi and Pullen 1982, Reilly and Bellis 1983, Nelson 1989, Van Dolah et al. 1992, Peterson et al. 2000). The most significant include: (1) impacts to and recovery of the benthic invertebrate community at the borrow areas; (2) potential impacts to commercially or recreationally important demersal fishes and crustaceans in part because of these effects on their benthic invertebrate prey; (3) impacts to and recovery of the benthic invertebrate community on the intertidal and shallow subtidal beach; and (4) potential impacts to commercially and recreationally important fishes in the surf zone and/or shorebirds in large part because of these effects on their benthic invertebrate prey and because of enhanced turbidity along the shoreline.

Each of these issues deserves consideration and typically requires some field monitoring before and after renourishment to evaluate the actual resulting impacts. Because the benthic invertebrate community at the offshore borrow sites changes across the seasons, it is appropriate to sample in multiple seasons (fall and spring, at a minimum, but during four seasons in most previous studies – see Van Dolah et al. 1994) both before and after the renourishment project to assess impacts and recovery. Because renourishment was originally planned for winter 2000-2001, an initial set of samples was collected in the late fall of 1999 to provide fall baseline data to characterize the benthic invertebrate community at the prospective offshore borrow sites and at nearby control sites, which were not planned to be mined, prior to any disturbance from the renourishment project. This report includes a description of results from an analysis of the fall1999 samples. We also include here a complete analysis of composition of surface sediment samples in each of the borrow sites and control sites so as to characterize the sedimentary habitat in which the invertebrates live. Sedimentary habitat is the prime factor that controls abundance and composition of soft-bottom invertebrate communities (Snelgrove and Butman 1994).

The test of the impacts of removing sand from any of the three "Borrow Areas" A, B1, and B2 (Fig. 1) requires the use of a BACI (Before-After-Control-Impact) experimental design (Green 1979, Stewart-Oaten et al. 1986). Such a design is required to separate spatial and temporal variation from impacts of the sand mining activity. In a BACI design, samples from impact (Borrow) areas would be compared with those from control (undisturbed) areas both before and after the sand is removed. Control areas would have no sand removed but would otherwise be affected by all other impacts, i.e. storms, shrimping, etc., that affect the impact area. These samples taken before the removal of the sand can be compared with identically conducted samplings made after sand mining to evaluate impacts. In addition, the design also calls for spring sampling both before and after the removal of sand to assess the seasonal component, for a minimum of 4 sampling periods to complete the assessment of impacts. This report describes only the first of those samplings and thus does not include any spring sampling of the Borrow Areas or any sampling of the intertidal beaches.

Assessment of the significance of the offshore mining of sands for the renourishment also involves evaluation of potential impacts on demersal fishes and crustaceans at the Borrow Area (e.g., Van Dolah et al. 1992). Impacts could occur directly during sand mining and indirectly through modification of the prey community. This effect on prey could last for some unknown time. The fish and crustacean community also changes seasonally so sampling is needed to document presence and relative abundance of demersal fish and crustaceans and to describe their utilization of benthic invertebrate prey. This report describes results of trawl sampling on three dates, late fall, winter, and spring.

No sampling has yet taken place to serve explicitly as the before-renourishment monitoring data for the intertidal invertebrates of Bogue Banks beaches or for sea turtles. The invertebrate community of the intertidal beaches is so strongly seasonal and dynamic within the warm season that sampling to provide baseline information should most appropriately occur throughout the warm season, with subsequent identically designed sampling to assess potential impacts and recovery but after the project has been completed. The complete design for such beach monitoring would include "before and after" (BACI) sampling of control beaches where no renourishment occurs (Green 1979, Stewart-Oaten 1986).

2. Description of Sampling and Analytic Methodologies

A. Benthic Invertebrate Resources

Core sampling was conducted during late fall 1999 from 20 sites, 10 of which were inside and 10 of which outside the three potential borrow areas (Fig. 1). This sampling produced a total of two hundred core samples to characterize the invertebrate macrofauna at all three prospective borrow sites and at control sites near each borrow site (Fig. 1). Ten replicate core samples were taken at each of six sites in Borrow Area A and at each of two sites from Borrow Area B-1 and Borrow Area B-2. Ten replicate cores were also taken at each of ten control sites: six around Borrow Area A and two near each Borrow Area B site. Exact locations of each site were determined using a handheld GPS with differential receiver (Table 1). Water depths ranged from 35 feet at the inshore sites to 47-49 feet at the offshore sites. Cores were taken by divers using a cylindrical corer 9.9 cm in internal diameter (each covering a surface area of 76.4 cm^2) with 500-µm mesh across the top to prevent loss of surface animals. Replicates were haphazardly positioned at each systematically distributed (see Fig. 1) sample station within a 3-m^2 area. All core samples were taken to a depth of 10 cm. After being transported to the boat, the contents were emptied from the core tubes into plastic bags, labeled, and sealed. Immediately upon returning to the lab, the material from the cores was sieved through a 500-µm mesh. Material retained on the sieve was preserved in a 5% aqueous solution of buffered formalin. Rose Bengal vital stain was added to the samples to facilitate sorting. After a week, the formalin was drained off through a 500-µm sieve and replaced with 70% ethanol. Subsequently, animals were separated from detritus by hand picking and identified to family. Several benthic impact studies including especially those by Warwick (1988) of IMER in Plymouth, England have demonstrated that analysis of response at the level of family preserves all the information about community patterns without the high costs of proceeding to species level.

At the same time that the macrofaunal cores were taken, divers collected three 2.65cm-diameter cores to a depth of 2 cm at each site to sample the meiofauna (fauna smaller than 0.5mm and greater than 0.063mm). These samples were iced onboard ship, preserved in the lab with a 5% aqueous solution of formalin, and archived for possible analysis, if required.

Benthic sled sampling was used to collect belt transect samples of larger, more sparsely distributed animals such as hermit crabs and sand dollars. The sled has matching steel blades on both the top and the bottom so that it functions properly no matter how it lands on the bottom. To produce a belt transect, the sled (25 cm tall with a 63 cm wide blade) was towed 15.8 m along the bottom by a line extending to the boat and sampled the top 6 cm of sediment. Sediment passes through the 6 mm mesh and larger organisms are retained. A taut-line buoy attached to the sled allowed for accurate positioning along the marked course. We sampled only on a flat-calm day (9 December 1999) at sea to prevent the sled from bouncing and to control its positioning. Using this sled, we took 40 belt transect samples of 10 m^2 each. This design yielded two replicate belt transect samples at each of the 20 sampling sites (Fig. 1). Animals found in the sled samples were identified, counted, and recorded. Species not immediately identifiable in the field were collected and returned to the lab for identification.

B. Demersal Fish and Crustaceans

In order to provide a semi-quantitative characterization of demersal fishes and crustaceans, including commercially or recreationally important species, that occupy the potential borrow areas and may conceivably be impacted directly by dredging operations or indirectly by loss of their benthic invertebrate prey, we sampled the demersal species of the three borrow areas. This sampling design is similar to that conducted by Van Dolah et al. (1994) in assessing impacts of sand mining on demersal fishes and invertebrates for beach renourishment at Folly Beach, South Carolina. Replicate trawl samples were taken on 29 November 1999, on 4 February 2000, and on 11 May 2000 from the R/V Capricorn using timed 20-minute otter-trawl tows at 4.02k/hr with a 12.3-m otter trawl. Thus the trawl would cover 16,492 m^2 of bottom area if there were no currents. The actual bottom area covered varied according to wind and tidal currents during any specific tow, which is why tows were standardized by time and speed rather than distance covered. These trawl samples were distributed as follows: 4 in Borrow Area A and 2 in each of Borrow Areas B-1 and B-2. The contents of each tow were identified to species, counted, and recorded. In addition, stomachs of up to 20 replicate individual fish of the most abundant species were removed, and preserved by formalin injection onboard ship. Stomach contents for up to twenty of the eight most common fish species from the November trawl survey were identified (when possible) and divided into major taxonomic group (e.g. polychaete, decapod, bivalve, etc.). Fish guts were examined from both inshore areas and offshore areas when possible. The divided categories were then weighed to the nearest 0.0001 g. Detailed inspection of some of the diet remains allowed identification to the family, genus or species level of some of the gut contents.

C. Sediments

At each site where macrofaunal cores were collected, divers also took core samples for grain-size analysis of sediments. Composite bottom samples were obtained at each of the ten Borrow Area sites and each of the ten control sites. Using PVC sampling tubes (16.5 cm [6.5 in] long and 2.5 cm [1 in] wide), divers collected 3 replicate samples of the upper 2 cm of the bottom within a 3-m^2 area at each of the twenty sites. Sample tubes were tightly capped, then brought to the surface and returned to the laboratory for analysis. Loss of fine-grained material, which can occur with conventional grab samplers, is minimized by using diver collections. Samples were assumed to be representative of the surficial material in which most of the macrofauna live.

In the laboratory, the replicate sediment samples were combined in a single container, then washed three times to remove salts and placed in a drying oven. After recording the bulk sample weight, a Calgon dispersant was added and the fine-grained (mud) component (by definition less than 0.063 mm diameter) was rinsed through a #230 mesh wet sieve. The remaining material (sand + gravel/coarse shell) was reweighed and prepared for sieve analysis. Prior to sieving the sand-sized fraction, the gravel/coarse shell fraction (by definition more than 2 mm in diameter) was removed with a #10 mesh sieve and weighed. A Tyler mechanical splitter was used to obtain a 25 g subsample of the remaining material (sand) which was then sieved at ¼ phi intervals (Carver 1971).

Each sieve stack was placed in a mechanical ro-tap for 20 minutes. Individual sieve fractions were weighed and recorded. Small amounts of fine-grained sediment that had not previously washed through the wet sieve were collected in a pan at the bottom of the sieve stack and, for computational purposes, were included with the wet-sieved material. Percentages of gravel/coarse shell, sand, and fine-grained sediment were computed from the bulk sample weights, and percentages of each size fraction in the sand range were computed from the 25 g splits that were sieved. Mean and standard deviation were computed using Excel software and mean phi values were converted to millimeters using the standard conversion, phi = $-\log_2$(mm), where mm corresponds to the intermediate diameter in mm (Folk 1974).

3. Results

A. Benthic Invertebrate Resources

Table 2 (2a for per-core results and 2b normalized to per square meter) presents the results of analyses of the 200 core samples taken to describe the benthic macrofauna at the three Borrow Areas and the surrounding Controls for each. Total macrofaunal densities were slightly greater at the offshore sites (14.1 invertebrates per core at Borrow Area A and 9.3 per core averaged over nearby Control sites) than at the inshore sites (9.7 invertebrates per core averaged over Borrow Areas B-1 and B-2 and 6.6 per core averaged over nearby Control sites). Results suggest slightly higher macrofaunal abundances in the Borrow Areas than in their respective Control Areas (Fig. 2). To test whether these possible differences are the consequence of differences in surficial sediments, we regressed average invertebrate density in cores against mean phi for each sampling site, conducting a separate analysis for the offshore and inshore sites. The inshore sites revealed no significant relationship (Fig. 3a) with a p-value of 0.28. The analogous regression for the offshore sites (Fig. 3b) was statistically significant at $p< 0.0001$, but the direction of the effect was reversed from normal expectation. Benthic infaunal abundance might normally be expected to be lower where sediments are coarser except when fine sediments are organically rich enough to create local reducing conditions and generate toxic hydrogen sulfide. However, here the two anomalous treatment sites in the offshore area with high shell content and low phi values had the highest densities of infaunal invertebrates (Fig. 3b). This relationship may be the indirect consequence of surficial shell inhibiting fish and invertebrate predation on infauna.

The higher taxonomic composition of the benthic infauna sampled in cores did not vary greatly over the sample sites. Over all sites polychaetes accounted for 65 % to 75 % of the total macrofauna in these late-fall 1999 samples. Because of the dominance by polychaetes, they exhibited the same patterns across depth and treatment (Fig. 4) as the total macrofauna (Fig. 2). Other common groups in order of abundance were bivalves (Fig. 5), nemerteans, small crustaceans, echinoderms, and gastropods (Fig. 6). The Appendix presents all the raw data.

Table 3 (3a for per-belt transect results and 3b normalized to per square meter) describes the results of analysis of all 40 belt transects for larger benthic invertebrates. The inshore sites revealed higher numbers of these larger invertebrates than the offshore sites. Borrow Area A contained 3.1 larger invertebrates per $10m^2$ belt transect and its nearby Control sites averaged 2.8, as compared to the average of Borrow Areas B-1 and B-2, which was 0.7 and their nearby control sites of 1.2 (Table 3). No consistent difference appeared between Borrow and Control Areas in this data set (Fig. 7). Gastropods were the most common taxon represented in these samples (Fig. 8), followed by echinoderms (Fig. 9).

B. Demersal Fish and Crustaceans

Trawl sampling detected relatively large numbers of demersal fishes occupying the seafloor habitat during late fall, declining by early February, and increasing again by early May (Table 4 presents the results of trawling for fishes and crustaceans on 29 November 1999; Table 5 presents the 4 February 2000 results; and Table 6 presents the 11 May 2000 results). Fish and mobile crustaceans caught in the trawls showed site averages ranging from 16,531 to 37,149 per km^2 in November, from 1,087 to 9,882 per km^2 in February, and 488 to 120,536 per km^2 in May (Tables 4-6).

In November, offshore areas were dominated by spot, which accounted for more than 50% of total catch and was sufficiently abundant there to create a pattern of slightly higher fish densities offshore than inshore. In addition to spot, pinfish, pigfish, and croaker were the most common species offshore (Table 4a). Inshore fishes were dominated by croaker, silver perch, silversides, pinfish, and sea mullet (Table 4b).

The abundance of most fish species had decreased by 4 February. This February sampling took place after a 3-week cold spell, the first prolonged cold weather of the winter of 1999-2000. The contents of these February 2000 samples (Table 5a,b) contrasted with those of November 1999 (Table 4a,b), showing an average reduction in catch by 81%. Catch in February from inshore stations was 41% and of offshore stations 3.7% of the corresponding catches in November. The abundances of two commercially and recreationally important species, spot and croaker, which made up 51% of the fall catch, dropped by 98.9% and 99.8% respectively. In February, pinfish, menhaden, and silversides made up 96.4% of the total catch. Spot, croaker, pigfish, sea mullet, and silver perch all showed large declines from November to February in both inshore and offshore areas. Pinfish catch in offshore areas was greatly reduced in February compared to November; however, inshore catches of pinfish were similar across dates. Two species of fish, menhaden and southern flounder (both found only in the inshore area), were more abundant in February than in November.

Our sampling on 11 May 2000 revealed higher total abundance of fishes in the inshore areas than we observed in either of our earlier samplings, but total fish abundance in the offshore borrow areas was intermediate between the December and February counts (Table 6a,b). Catch in May from the inshore stations was 1200% higher (Table 6a) than in February, largely due to increases in Atlantic silversides and Atlantic thread herring. In the offshore stations, catch in May was 1600% greater (Table 6b) than observed in February. Pigfish and scup largely accounted for this enhancement in total fish abundance in the offshore.

Examination of the stomach contents of the eight most abundant fish (croaker, gray trout, pinfish, pigfish, sea mullet, silver perch, silversides, and spot) taken from the November 1999 sampling demonstrated that many of the benthic invertebrates found in core samples and belt transects were major diet items of these fish (Table 7). Only about half of all stomachs examined were empty, with some variation among species. Major prey species for croaker and pinfish included polychaete worms, bivalves, and occasionally small shrimp (primarily grass shrimp, *Palaemonetes* sp.) and crabs (primarily pinnotherid crabs). Shrimp (both *Palaemonetes* sp. and penaeids) and to a lesser degree portunid crabs were the primary prey species found in the stomachs of gray trout. Sea mullet prey items were dominated by pinnotherid and portunid crabs and large polychaete worms. Small grass shrimp and other bottom-dwelling crustaceans (amphipods and isopods) were the dominant prey found in silver perch stomachs. Pigfish stomachs contained primarily polychaetes with an occasional grass shrimp present. Some polychaetes and small crustaceans (isopods, cumaceans, and amphipods) were found in the stomachs of spot, but stomachs were relatively empty compared to other species. Finally, silversides fed primarily on harpacticoid (benthic dwelling) and calanoid (planktonic) copepods.

Comparisons between stomach contents of fish collected from inshore and offshore locations were possible for six of the eight species that were caught in abundance in both areas (croaker, gray trout, pinfish, silver perch, silversides, and spot). Examination of the data revealed no consistent pattern in either the proportion of empty stomachs or major prey items between the two areas.

C. Sediments

Data are summarized in Table 8; individual size frequency curves and histograms are provided in Figure 10. With the exception of two treatment sites in Borrow Area A, sands comprised at least 90% of the bottom sediment by weight. In all cases, muds comprised less than 4% of the sediment by weight. Visual inspection of the samples revealed that the coarse fraction, typically less than 8% by weight, was comprised primarily of coarse shell fragments. Using the Wentworth size scale (Folk 1974), mean grain size in 80% of the samples was classified as fine sand and 20% as either medium or coarse sand. Values for standard deviation showed that 85% of the samples were moderately or moderately well sorted. Reed and Wells (2000) found similar sediment distribution patterns off Fort Macon, Atlantic Beach and Pine Knoll Shores, NC, in samples taken at 36 locations during each of two sampling periods, fall 1996 and spring 1997. Their samples showed muddier sediments occurring in the offshore areas but no significant seasonal variations in mean size or sorting.

Comparison of the grain size distributions taken in conjunction with the invertebrate coring and the analysis of grain sizes from the CSE Baird and Athena Technologies cores indicates finer sizes in the cores associated with the invertebrate sampling. This difference can be attributed to several factors: (1) the cores taken in association with invertebrate sampling covered only the uppermost surface layer only (2 cm), which is often covered by a thin mud drape; (2) this set of cores included Control locations outside the Borrow Areas, which were selected for their sand deposits, whereas the controls do not always match this level of coarseness; and (3) the cores associated with invertebrate sampling were collected by hand by divers in a fashion that involved minimal loss of fines during the sampling process.

4. Discussion

The benthic invertebrates occupying the bottom in both the inshore and offshore Borrow Areas represent species that are indeed being consumed by demersal fishes, such as spot, croaker, pinfish, pigfish, and sea mullets. Our gut examinations revealed that feeding was active and intense enough on the benthos in late November to yield gut contents in fishes with gut passage times of 6-12 hours. Compared to other gut data that we have taken from demersal fishes in the Neuse River and the Newport River in summer (pers. obs.), the percentages of empty stomachs in this data set are quite low. The densities of benthic invertebrates (6-16 individuals per 76.4-cm^2 core) are similar to those found occupying sandy bottoms in the Beaufort Inlet in December 1994 (Peterson et al. 1999), which were around 10 individuals per 76.4 cm^2 core (the same used in this study). The Beaufort Inlet samples were taken at a depth of 26-36 feet, similar to the inshore sites sampled in this study. Both surveys showed a general dominance by polychaetes. No other sampling of benthic invertebrates is truly comparable to these because of differences in sieve mesh size, water depth, reef proximity, geography, or sedimentology. Nevertheless, we present some benthic macrofauna data in Tables 9 (total macrofauna) and 10 (major taxa) from these other studies for contrast. Densities of benthic infauna in cores at the Borrow Areas in late November during our sampling period and in the earlier Beaufort Inlet study are lower than those observed near hard-bottom reefs off Wrightsville Beach (Posey and Ambrose 1994) and those observed by Van Dolah (1994) in finer sediments off Hilton Head, South Carolina (Table 8). For those taxa reported in Posey and Ambrose (1994), bivalves, gastropods, scaphopods, amphipods, isopods, polychaetes, and echinoderms, densities were higher than in our sampling of the Borrow Areas (Table 9).

Belt transects for larger invertebrates revealed a similar dominance by gastropod molluscs in our new data set from the Borrow Areas and in our earlier Beaufort Inlet study. These larger invertebrates were slightly more common in the Beaufort Inlet than in the study areas sampled here (Table 11). Greater echinoderm (sand dollar) densities occurred in the vicinity of the Beaufort Inlet. The only other analogous data set on larger invertebrates comes from Dahlgren et al. (1994), although they report only some taxa from belt transects near hard-bottom reefs off Wrightsville Beach. Dahlgren et al. (1994) reported belt transect data (Table 11) for several classes of echinoderms near the same reefs studies by Posey and Ambrose (1994). Dahlgren et al. (1994) observed higher densities of holothuroids (sea cucumbers) than we document in the Borrow Areas but similar densities of echinoids (sand dollars) and stelleroids (sea stars) (Table 11). The difference in sea cucumber densities is likely also a consequence of the finer sediments in the site studied by Dahlgren et al. (1994).

Our fish sampling revealed densities of many fishes as high in December as we routinely find during all the warm months in the vicinity of Beaufort Inlet immediately outside the estuary and as high as Van Dolah et al. (1994) found in the Folly River. The fish assemblage at the proposed borrow sites for the Bogue Banks project was dominated by species of substantial value to commercial and recreational fisheries of North Carolina and neighboring states. These fishes were actively feeding on the benthic macrofauna. Shrimp catches were low, although commercial shrimp trawling was being conducted in the immediate vicinity of all the Borrow Areas at the time of our sampling in late fall 1999. Many species of demersal fish of the estuaries of North Carolina and the Southeast generally are known to exit the sounds and estuaries in the fall on route to offshore sites for overwintering. The precise locations of these overwintering sites are not completely described, but our sampling indicates that this area off Bogue Banks is utilized in abundance during late fall by spot, croaker, pigfish, pinfish, silver perch, and sea mullet. Subsequent sampling during early February revealed emigration of these fishes to unknown locations as the weather became cooler. The only other conceivably comparable data on fish and crustacean abundances from trawl sampling come from Van Dolah et al. (1994). They reported average densities in the Folly River, South Carolina ranging across site and season from about 7,000 to 55,000 per km^2. These densities are similar to our average densities ranging from 500 up to 120,536 per km^2. The densities that we observed around the borrow areas in late November 1999 were judged by our boat captain, who has operated this trawl routinely for 25 years, to be similar to densities in spring, summer, and fall around Beaufort Inlet (J. Purifoy, pers. com.).

Dredging could impact the demersal fishes and crustaceans by direct removal and mortality during dredging, by causing emigration to other areas, where crowding could reduce growth and production, and by creating some unknown period of time when benthic prey abundances had not yet recovered and so growth and production were reduced. If sediment character in the borrow areas changes after sand mining, the new community of benthic invertebrates could differ dramatically from the existing community and could provide less of more food resources for demersal fishes and crustaceans. Van Dolah et al. (1994) demonstrated an effect of sand mining at the borrow area on species richness of demersal fishes and crustaceans that persisted through the first spring and fall after the cessation of the winter project; however, no effect was detected on total fish abundance.

Our sampling was designed to serve as the fall baseline data set for the Borrow Areas in contemplation of a monitoring scheme to assess impacts of and recovery from the sand mining for beach renourishment. This includes not only the benthic macrofauna and demersal fishes but also the sediments on the sea floor. Unfortunately, two sites in the offshore borrow area (A) possesses sediments that are much coarser with much higher shell content than any of the controls (Fig. 3b), so that we have no adequate control for this portion of the borrow area. Unless one of these sites is mined and one is not, any subsequent assessment of impacts of sand mining will be compromised by this sedimentological anomaly. Because the macrofauna is so closely tied to sediment character, the evaluation of any changes in surface sediment character after mining is critical to interpreting the impacts on and recovery of benthic invertebrates and probably also fishes. The limited amount of past literature on impacts of sand mining at borrow sites on the nearshore shelf gives mixed indications of whether recovery of benthic invertebrates will occur rapidly or slowly. Borrow areas in which sedimentation has not dramatically reduced the average size of surficial sediments have tended to show recovery of total benthic abundances in about a year, whereas borrow areas that experienced deposition of fine sediments exhibited recolonization by dramatically different benthic organisms and did not converge to reference or pre-dredge composition even after multiple (3 or more) years (Saloman 1974, Taylor Biological Company 1978, Van Dolah et al. 1992, 1994). There has been no definitive analysis of the conditions that lead to mud deposition in some but not other borrow areas, so no confident predictions can be generated for this specific Bogue Banks project. Presumably, rate of supply of suspended fine sediments and bottom shear stress help determine the degree of deposition of fine sediments.

Baseline sampling of the nourishment sites and control sites on the beach itself would also need to be conducted prior to sand mining, but during the warm months when the intertidal beach is used by macrofauna. We already possess a substantial amount of data on abundances of intertidal beach invertebrates from all along Bogue Banks from 1997-1999 from studies conducted by L. Manning (unpubl.: see Table 11 for an example data set). This information could conceivably be incorporated into an assessment design to evaluate the potential consequences of the renourishment on the beach system, allowing contrasts between the multiple summers before renourishment and the summer or summers afterwards as one means of assessing impact and rate of recovery. This previous sampling was not conducted in a design intended for evaluation of the Bogue Banks renourishment project, so it is unclear whether sufficient sites were sampled throughout the biologically active (warm) seasons in sufficient places to provide a set of replicated reference and treatment (renourished) sites sufficient to achieve adequately powerful tests of impacts on intertidal invertebrates. A review of past studies of the response of beach invertebrates to renourishment projects (Nelson 1989, 1993, Peterson et al. 2000) suggests that return of macroinvertebrates will be rapid if renourishment is restricted to months when invertebrates are largely absent from the intertidal beach and if a good match exists between grain size distributions of the natural beach and the new sands that are added. Finer particles are detrimental to suspension feeders, especially mole crabs (Bowman and Dolan 1985), and slow their recovery. In analyzing short-term effects of renourishment in Pine Knoll Shores on Bogue Banks, North Carolina, Peterson et al. (2000) documented virtual failure to initiate the recovery process by mole crabs and coquina clams, the biomass dominants of the Bogue Banks intertidal beaches, by mid July, 5-10 weeks after termination of the project. This renourishment grossly modified the beach sedimentology, changing average phi from 2.33 to 3.67 (Peterson et al. 2000). A previous renourishment project on Bogue Banks at Fort Macon studied by Reilly and Bellis (1983) documented a similar failure of coquina clams to return to the beach by the first July after project completion, but mole crabs did return with only a one-month time lag relative to the seasonal cycle at control beaches. No information on quantitative sedimentology is provided in that report, although there is a claim of a good match in grain size, which could explain why mole crabs were able to initiate recovery sooner than in the Pine Knoll Shores project studied by Peterson et al. (2000). Manning (unpub. data) also has shown that enhancing shell content on the intertidal beach has a strong negative effect on coquina clams by inhibiting normal rates of burrowing, thereby exposing them to transport off the beach into unfavorable and potentially inhospitable environments.

5. Conclusions and Recommendations

(1) Based on our benthic invertebrate sampling, fish trawling, and observations of fish guts, we conclude that demersal fishes of commercial and recreational value are using the invertebrates on the seafloor at the Borrow Areas as food during the late fall (and presumably also winter and spring). We recommend a targeted evaluation of the degree to which these fishes are food-limited during late fall through spring and the degree to which they rely in all seasons on the prospective Borrow Areas for feeding as compared to nearby bottom habitats and sites, so as to evaluate the significance of reduced abundances of benthic invertebrates in Borrow Areas. It is presently unclear in the absence of sampling other shelf habitats and sites whether the sand bodies proposed for dredging are preferred feeding grounds, relatively low-use feeding grounds, or used in proportion to the bottom area that they occupy.

(2) We conclude that demersal fishes are sufficiently abundant at the Borrow Areas to justify additional sampling at other seasons and in other habitats offshore so as to be able to quantify the importance of the Borrow Areas to the total fish populations.

(3) We conclude that benthic invertebrates are common enough during late fall in the Borrow Areas and important enough as food for demersal fishes as to justify benthic monitoring in other seasons of the year prior to and after mining activities to assess impact and recovery.

(4) We conclude that sampling of intertidal beach invertebrates is necessary to provide the baseline for impact assessment after the renourishment. Such baseline information could conceivably come from historical data, but only if a sufficiently powerful design can be created, based on knowledge of spatial and temporal fluctuations and the project plan.

(5) A review of limited information on recovery rates of sediments and benthic invertebrate resources in offshore borrow areas from other studies suggests that recovery rate is unpredictable, requiring times ranging from a year to indefinite (undetermined) numbers of years.

(6) Results of the most applicable and recent study of impacts of renourishment on beach invertebrates imply effects that could last throughout the warm season if sediments used in renourishment do not match those of the natural beach. We recommend that renourishment occur in winter (the period of low intertidal abundances of beach invertebrates, which is December through March) and that sands used in renourishment be treated to remove shell that exceeds the average on the untreated beach and be selected to avoid deposition of mud balls and silts and clays to minimize duration of negative impacts. It seems that enhancement of the phi size to 3.67 was inadequate to allow rapid recolonization in a previous renourishment of Bogue Banks, but what phi increase is possible without impact on recovery rates of beach invertebrates is unclear.

(7) We conclude that inadequate information exists to recommend one proposed Borrow Area over any other for this project. Sampling of benthic invertebrate resources on only a single date does not provide sufficient seasonal coverage to rank the proposed Borrow Areas by importance as prey for demersal fishes and crustaceans.

(8) We conclude that the Bogue Banks renourishment project could be conducted with minimal adverse ecological damage (a) if the borrow sites were dredged in a way that avoided complete excavation of the sand body and avoided changes in sedimentation processes, thus preventing their transformation into depositional muddy areas, (b) if the dredging were confined to periods of low abundance of demersal fishes and shrimps at the borrow areas (as determined by in situ monitoring prior to dredging), and (c) if the sands deposited on the intertidal beach matched the size distribution of natural sands on the beach with minimal muds and minimal shell and were deposited during the winter (December through March) when these invertebrates are largely absent. These requirements present technical uncertainties because (a) it is not clear that we understand the potential sources of fine sediments and the processes of deposition of fine sediments at the Borrow Areas well enough to have confidence in designing the sand mining in a way that will avoid transformation into muddy bottoms; (b) the costs of placing the dredge on hold while awaiting departure of demersal fishes in late fall may preclude using monitoring to determine exactly when fish impacts will be minimized; and (c) costs of providing a sand resource that matches the sedimentology of the natural beach may be high.

Table 2b. Mean (SD = standard deviation) abundance expressed as number m^{-2} of individuals by taxonomic family found in $76.4cm^2$ core samples taken within (Treatment) and adjacent (Control) to inshore and offshore proposed sand borrow areas for the Bogue Banks beach renourshment. Statistics are calculated from the average of 10 cores taken from each of 6 sites sampled both within and around the offshore area and 4 sites sampled both within and around the inshore areas.

Silver Perch	Offshore	10%	0.005	0%	0%	0%	61%	0%	38%	0%
Silversides	Nearshore	nd	nd	0%	0%	0%	0%	0%	100%	0%
Silversides	Offshore	nd	nd	0%	0%	0%	0%	0%	100%	0%
Spot	Nearshore	56%	0.007	55%	20%	0%	0%	0%	20%	5%
Spot	Offshore	50%	0.010	5%	10%	0%	0%	65%	10%	0%

* Percentage calculated by dividing the number of fish examined whose stomach contents weighed 0.000 g by the number of fish examined.

** Percent of total diet made up by each group was calculated by summing the total stomach contents weights in that category of all fish examined and dividing that weight by the total wet weight of identifiable stomach contents off all fish within that species.

nd = not determined, stomach contents do not weigh enough to make a reasonable evaluation.

Table 9. Mean (SD = standard deviation) abundance m^{-2} of total infauna from this study compared with infauna abundances found in other studies from nearby locations.

Study			TOTAL INFAUNA m^{-2} mean SD
This study	Inshore Nov. 1999	Treatment	1266 (510.73)
	Inshore Nov. 1999	Control	867 (221.99)
	Offshore Nov. 1999	Treatment	1850 (1150)
	Offshore Nov. 1999	Control	1215 (187.96)
Day et al. (1971)[a]	Apr. 1965 - Jan. 1966	10m site	1005
	Apr. 1965 - Jan. 1966	20m site	936
Peterson et al. (1999)[b]	Dec. 1994	East Site	1597 (959)
		West Site	1170 (592)
Posey & Ambrose (1994)[c]	Jul.1990		3680 (900)
	Apr. 1991(1)		11030 (1281)
	Apr. 1991(2)		6880 (917)
Van Dolah et al. (1994)[d]	Winter 1990	Control site	2755
	Fall 1990	Control site	3527

[a] Day et al. (1971) took samples with a $0.2m^2$ van Veen grab and sieved them through a 1mm sieve. Infaunal abundances from samples taken from sites along a transect off Cape Lookout NC, were averaged over 5 sampling dates from Apr 1965 to Jan 1966. The two sites with depths closest to those of this study are presented.

[b] Peterson et al. (1999) present abundances of infauna (> 0.5mm) from 9.9cm diameter cores taken at sites about 1km SE (East Site) and SW (West Site) of Beaufort Inlet, Beaufort NC prior to any experimental disturbance. Replicate cores were taken from each of 9 stations on each side of the inlet.

[c] Posey and Ambrose (1994) present abundances of infauna (> 0.5mm) from 12cm diameter cores taken 12cm deep from stations along transects (1 & 2) perpendicular to "23 Mile Reef" 43.5km from Wilmington, NC. The 32m deep stations presented here are the stations 75m from the reef and least affected by the presence of the reef and associated fauna.

[d] Abundances of infauna (> 0.5mm) from 7.6cm diameter core samples 15cm deep taken by Van Dolah et al. (1994) are from an undisturbed control site 3km from Hilton Head I.

Table 10. Mean (SD = standard deviation) abundance expressed as number m^{-2} of infauna from major taxanomic groups from this study compared with abundances found in studies from nearby locations.

[a] Dahlgren et al. (1994) present abundances of benthic fauna (> 1.5cm) from $10m^2$ belt transects taken by divers from 32m deep stations along a transect perpendicular to "23 Mile Reef" 43.5km from Wilmington, NC. The means presented here average samples from 1, 10, 25, 50, and 75 m from the reef. Tests among the transect stations showed no statistical difference in abundances relative to reef proximity.

[b] Peterson et al. (1999) present abundances of benthic fauna from (> 1.5cm) from $10m^2$ belt transects taken at sites about 1km SE (East Site) and SW (West Site) of Beaufort Inlet, Beaufort NC prior to any experimental disturbance. At the West Site transect were sampled by divers using visual and manual examination. Visibility was insufficient at the East Site for diver counts thus samples were taken using a benthic sled.

Table 12. Mean counts (standard error) of major taxa per transect for sampling conducted at six sites along Bogue Banks, NC. Sampling at each site was conducted along three transects oriented perpendicular to shore and spaced 50 m apart. Organisms were collected using a hand-operated aluminum corer with an internal diameter of 10.2 cm taken to a depth of 20 cm. Two cores were taken, seived on 1 mm mesh and pooled to form a single sample. Cores were collected every three meters along each transect and extended from just landward of mean high water to approximately 1 m deep in the surf zone. All sampling was conducted in the Spring and does not reflect relative abundances that may occur in other seasons.

APPENDICES

Appendix 1. Number of individuals by taxonomic family found in 76.4cm2 core samples taken at sites in (Treatment) and adjacent (Control) to inshore and offshore proposed sand borrow areas for the Bogue Banks beach renourishment. Ten cores were taken from each of 6 sites sampled both within and around the offshore area and 4 sites sampled both within and around the inshore areas.

Appendix 2. Number of individuals by taxonomic family captured in a 10m² tow of a benthic sled at sites in (Treatment) and adjacent (Control) to inshore and offshore proposed sand borrow areas for the Bogue Banks beach renourishment. Two tows were taken from each of 6 sites sampled both within and around the offshore area and 4 sites sampled both within and around the inshore areas.

EFH Assessment

Bogue Banks Beach Restoration Plan

Draft Essential Fish Habitat Assessment

May 10, 2001

1.1 Introduction

The Fishery Management Plan amendments of the South Atlantic Fishery Management Council identify a number of Essential Fish Habitat (EFH) and Habitat Areas of Particular Concern (HAPC), which are listed in Table 1.1. While all of the habitat categories occur in the southeastern United States, many are absent from the potential impact areas of the Bogue Banks beach nourishment project. Those absent include estuarine scrub/shrub mangroves, which require a much more tropical environment; and several areas that are much removed from the impact areas associated with the project including Hoyt Hills, located in the Blake Plateau in water depths of 300 to 600 meters, the sandy shoals of Capes Hatteras and Fear and New River. There are no Council Designated Artificial Reef Special Management Zones, Intertidal Flats, Oyster Reefs and Shell Banks, Aquatic Beds, Wetlands or Seagrass Beds or estuarine EFH's in or adjacent to the potential impact areas of the project. Impacts on habitat categories potentially present in the project area are addressed in Section 2.0 of this report.

Table 1.2 list by life stages 81 fish species which may occur in the vicinity of Bogue Banks Beaches, and which are managed under MSFCMA. These fish species and habitats require special consideration to promote their viability and sustainability.

1.2 Project Description

The proposed beach nourishment project will consist of placing the equivalent of ~4.5 million cubic yards of beach-quality sediment along ~16.8 miles of Bogue Banks from the Atlantic Beach/Pine Knoll Shores town line to ~Shipwreck Lane along western Emerald Isle (Fig. 1.1). Nourishment sand will be excavated from three borrow areas by hopper dredge or hydraulic dredge and placed along as many as six contiguous reaches. (CSE Baird-Stroud, 1999, Shoreline assessment and preliminary beach restoration plan, Bogue Banks, NC. Executive Summary Report, 38 pp.)

Three potential borrow areas (A, B1, and B2) have been identified, sampled and delineated offshore of the project area. Sediment quality in each borrow area was compared with native beach sediment quality to determine compatibility indices (R_A, after the method of James, 1975). Twenty samples from the dune, berm, beach face, and low-tide terrace were used to determine the "native" sediment characteristics. The mean grain size computed from 20 samples was ~0.30 mm [versus 0.17 mm used by USACE (1976) for planning along Atlantic Beach].

Borrow area A (revised) had the lowest R_A value (1.16), meaning that ~85 percent of the deposit would be stable as beach fill. Borrow area B1 yielded an R_A value of 2.19; B2 yielded an R_A value of 1.97; and C yielded an R_A value of 1.57. The R_A factors predict how many cubic yards of nourishment material will be required to perform as 1.0 cy of native beach sediment. Variations in R_A factors were used to adjust the required (base) nourishment volume for a particular borrow area. Borrow areas with higher R_A will require proportionately higher excavation volumes to achieve the same performance as native beach sand.

Final selection of borrow area(s) will be based on several factors, including sediment quality, dredging and transportation economics/environmental impacts, and cultural resource impacts. Borrow area A is tentatively identified as the optimal sand source. It extends from ~0.5 to 2.5 miles offshore, centered near the Emerald Isle/Indian Beach town line. Sediments have been confirmed over an ~4.5 square-mile area to a section thickness averaging ~2.25 ft. This yields potentially 10 million cubic yards of beach quality sediment. Only a portion of borrow area A will be required to satisfy the nourishment volume requirements of the project (~5.1 million cubic yards after factoring in the overfill ratio). The average water depth in borrow area A is ~46 ft. The anticipated optimal equipment for excavations will be ocean-certified, self-contained hopper dredges. Such equipment typically excavates shallow trenches (~2 ft of section) in each pass (leaving narrow undisturbed areas at the margin of each cut), then travels to a buoyed pipeline anchored close to shore. Discharge to the beach is via submerged pipeline across the surf zone, then by way of shore-based pipe positioned along the dry beach.

The project will be built in ~1-2 mile sections, optimizing the disposition of pipeline. Sections will be pumped into place with the aid of temporary dikes pushed up by bulldozer in the surf zone. Daily operations will directly impact ~ 500-1000 ft of shoreline as work progresses in either direction from the submerged pipeline. Upon completion of a section, the submerged pipe and beach-building equipment will be shifted to the next section.

The project will add an average of ~50 cy per linear foot along the recreational beach between the base of the foredune and the outer bar. It will displace the shoreline ~75-100 ft seaward after fill adjustment. The backbeach grade for the project will be set close to the existing grade of the dry beach (~+7 ft NGVD). The fill will be sloped in the seaward direction to maintain proper drainage. Where oceanfront development exists at elevations nearly equaling the native dry beach, a low protective dune will be pushed up along the backbeach to prevent the slurry from draining toward buildings.

Under normal circumstances, using a single dredge, the project will require 180-300 days to construct (at 15,000-25,000 cy per day average production). The applicant desires to perform construction during winter months to avoid the tourist season, turtle-nesting season, and periods of highest biological productivity. Alternatives involving use of more than one dredge (to shorten the construction period) or splitting construction over two winter seasons are being investigated.

As construction progresses, sections will be graded to final contours, dressed to eliminate low areas, and opened for use by the community. Support equipment will be shifted out of completed sections as soon as practicable, such that construction activities in a given reach will disrupt normal beach use for only a month or so at any locality.

Table 1.1 Catagories of Essential Fish Habitat and Habitiat Areas of Particular Concern in Southeast States 1

Essential Fish Habitat	Geographically Defined Habitat Areas of Particular Concern
Estuarine Areas	**South Atlantic**
Aquatic Beds	Council Designated Artficial Reef
Estuarine Emergent Wetlands	Special Habitat Management Zones
Estuarine Scrub / Shrub Mangroves	Hermatypic (reef-forming) Coral Habitat & Reefs
Submerged Aquatic Vegetation	Hard Bottoms
Oyster Reefs & Shell Banks	Hoyt Hills
Intertidal Flats	*Sargassum* Habitat
Palustrine Emergent & Forested Wetlands	State Designated Areas of Importance to Managed Species
Estuarine Water Column	Submerged Aquatic Vegetation
Marine Areas	**North Carolina**
Artificial / Manmade Reefs	Big Rock
Coral & Coral Reefs	Bogue Sound
Live / Live Hardbottoms	Pamlico Sound at Hatteras/Ocracoke Inlets
Sargassum	Capes Fear, Lookout, & Hatteras (sandy shoals)
Water Column	New River
	The Ten Fathom Ledge
	The Point

1 Areas shown are identified in Fishery Management Plan amendments of South Atlantic Fishery Management Council and are included in Essential Fish Habitat: New Marine Fish Habitat Mandate for Federal Agencies, February 1999 (rev. 10/00, Appendices 6 and 7)

2.0 Impacts to Essential Fish Habitat Areas and Habitat Areas of Particular Concern.

2.1 Impacts to Cape Lookout Shoals, Big Rock and Ten Fathom Ledge off of Cape Lookout.

A North Carolina HAPC is the sandy Shoals of Cape Lookout and the Big Rock off of Cape Lookout. These sites are over 15 miles from the borrow and disposal areas and will not be impacted by the project.

2.2 Impacts on *Sargassum*

Sargassum is a pelagic brown algae which occurs in large floating mats in the waters of the continental shelf, in the Sargasso Sea and in the Gulf Stream. It is a major source of biological productivity in nutrient-poor regions of the ocean. Masses of *Sargassum* provide extremely valuable habitat for a diverse assemblage of marine life including juvenile sea turtles, sea birds, and over 100 species of fish. Unregulated commercial harvest of *Sargassum* for fertilizer and livestock feed has prompted concerns over the potential loss of this important resource. There have been instances of relatively small masses of Sargassum washing ashore or into the project area under certain wind conditions. Since Sargassum occurs in the upper few feet of the water column and is not commonly found in the project area, it is not subject to impacts from dredging or disposal associated with the project.

2.3 Impacts to Artificial Reefs

The North Carolina Division of Marine Fisheries lists three artificial reef sites in the vicinity of offshore of Bogue Banks. The closest sites are AR-315, AR-320 and AR-342 and are shown on Figure 2.1. All of the sites are located 1.7 to 6.7 miles from the borrow areas and 2.4 to 2.2 miles from the closest beach deposition areas of the project.

No adverse impacts would be expected to the artificial reef areas since dredging conducted as part of the project will not be done in close proximity to the reefs. Disposal of the sand on the beaches of Bogue Banks will involve discharge of high quality sand material (sand content greater than 95 percent) onto the upper beach and will have no affect on the reefs.

Temporary increases in turbidity are associated with both dredging operations and the washing of fine sediments by waves on the nourished beach. The applicable standard required for Section 401 Water Quality Certification quoted here from WQC#2949 issued for a Corps dredging and disposal operation for the nearshore berm off of Atlantic Beach is "that the activity be conducted in such a manner as to prevent significant increase in turbidity outside the area of construction or construction related discharge . . . 25 NTUs in all saltwater classes . . ." .

Published measurements of turbidity during beach nourishments are rare. Reference (USACE, 1993, p. 6) is made to turbidity measurements for pipeline discharge of nourishment sediment on Atlantic Beach. Turbidity was a function of distance from the discharge pipe. Measurements ranged up to 250 NTUs in the vicinity of the pipe, but decreased rapidly with distance. That sediment pumped from Brandt Island had a much higher overfill ratio and mud percentage than the borrow areas proposed for this project, so turbidity must necessarily be lower for this project. A fairly comprehensive set of measurements was made for another project with mud percentages more similar to the one proposed here by Hanes (1994). Table 5 in that publication lists measured turbidities for times during and after nourishment and for both the project area and a control site uninfluenced by the nourishment. Turbidities were not measured in the immediate vicinity of the discharge pipe, but rather seaward of the breakers along the nourished stretch of beach. Values are listed for surface, mid-depth, and near bottom in the water column. The control site must have had slightly different conditions, because the after-nourishment numbers showed an average ratio of 0.6 of nourishment site to control site. (The nourished area had less turbidity than the control site well after construction.) But the numerical values were low for this post-construction period: 2.8 to 4.4 NTUs for the nourished area and 4.4 to 9.2 for the control site.

The artificial reef sites located within close proximity to the project borrow or deposition areas will be identified on the project plan sheets as sensitive areas to be avoided during dredging operations. The proposed project will not significantly impact any artificial NCDMF artificial reef sites.

2.4 Impacts on Hard Bottom

Figure E1 taken from the Final EIS, Appendix E shows Tertiary (hard bottom) outcrops and estimated Quaternary layer thickness (of unconsolidated sediments) based on Hine and Snider (1985, Figure 6). Infilled paleochannels comprise the thickest deposits but have limited extent. Additionally, in the process of sampling bottom sediments in the offshore of Bogue Banks by CSE (Final EIS, Appendix E1, Figure E5, reproduced in this assessment as figure 2.2) live hard bottom was observed in the sample locations C18a1and C18a2. These sample locations occurred in water depths of 45 feet. Project borrow areas A, B1 and B2 are superimposed on the figure to illustrate proximity of the borrow and deposition areas to the known hardbottom areas.

The closest outcropping of hard bottom is ~6500 ft from borrow areas A and B2. This distance is ~four times greater than from the expected maximum radius of sediment plumes around the dredge or around the discharge point. The nearest outcrop of hard bottom off the project area occurs about 1600 ft seaward of the bar near transect 11 (Emerald Isle, west reach) and transect 25 (Emerald Isle, central reach). There are no inlets or channelized discharges between the preferred borrow area and adjacent hard bottom areas that could direct a concentrated plume of fine-grained sediments into these habitats.

Hine and Snider (1985) documented no hard bottoms near the outer bar along Bogue Banks. The documented hard bottom areas are beyond the closure depths for the project as estimated by CSE Stroud (Final EIS, 2001 Appendix G). It is estimated that sediment located below a depth of 30 feet MLW will not receive fine sediments deposited on the beach.

The locations of exposed hard bottoms will be shown on the project construction drawings so that the areas will be avoided and protected from physical impacts due to anchoring or pipe and equipment mobilization.

2.5 Impacts on State-Designated Areas Important for Managed Species

Primary nursery areas (PNA's) are designated by the North Carolina Division of Marine Fisheries and are identified by the State as tidal saltwater which provide essential habitat for the early development of commercially important fish and shellfish. The locations of PNA's are identified in 15 NC Administrative Code 3R. 0100. There are no primary nursery areas designated by the Division of Marine Fisheries in the Atlantic Ocean. The designated areas are in Bogue Sound and the adjacent creeks and tributaries. The project will not impact primary nursery areas.

2.6 Impacts to the Marine Water Column

Dredging and disposal activities conducted during project construction may cause impacts in the marine water column in the immediate areas of the borrow and deposition sites that could potentially impact nearshore and intertidal resources. These impacts may include minor and short term suspended solids sediment plumes and related turbidity as well as the release of trace constituents from the sediment. During dredging turbidity increases outside the immediate area of dredging should be less than the N. C. Division of Water Quality standard of 25 NTU's and are considered insignificant. In case of overflowing hopper, dredges sediment from the overflow will be from sediment with more than 95 percent sand and is not likely to produce significant turbidity or other water quality impacts. Living marine and estuarine resources dependent upon good water quality are not expected to experience significant impacts.

Scientific data are limited with regard to the effects of beach disposal on fishery resources. The impacts associated with this project may be similar, on a smaller scale, to the effects of storms. Storm effects may include increased turbidity and suspended sediment load in the water column and, in some cases, changes in fish community structure (Hackney et. al.,1996). Severe storms have been documented to create conditions of fish kills, but such situations are not associated with beach disposal of dredged sand.

In a 1999 Environmental Report on the use of Federal offshore sand resources for beach and coastal restoration, U. S. Department of Interior, Minerals Management Service provide the following assessment:

In order to assess if turbidity causes an impact to the ecosystem, it is essential that the predicted turbidity levels be evaluated in light of conditions such as during storms. Storms on the Mid-Atlantic shelf may generate suspended matter concentrations of several hundred mg/L (E.G. Styles and Glenn, 1999). Concentrations of plums decrease rapidly during dispersion. Neff (1981, 1985) reported that solids concentrations of 1000 ppm two minutes after discharge decreased to 10 ppm within one hour. Poopetch (1982) showed that the initial concentration in the hopper overflow of 3,500 mg/l decreased rapidly to 500 mg/l with in 50 meters. For this reason, the impact of settling particles from the turbidity plume is expected to be minimal beyond the immediate zone of dredging.

Beach disposal of dredged sediments can affect fishery resources and EFH through increases in turbidity and burial of beach resources. These impacts may create localized stressful habitat conditions and may result in the temporary displacement of fish and other biota. However, the sand proposed for disposal on the Bogue Banks beaches will average 95 percent or more sand (4 percent or less mud). Because of the low mud content in the sediment, turbidity induced water column impacts are expected to be localized, short term, and minor.

There are several environmental issues relating to the benthic habitat and resources that arise in considering a beach renourishment project. The most significant include: (1) impacts to and recovery of the benthic invertebrate community at the borrow sites; (2) potential impacts to commercially or recreationally important demersal fishes and crustaceans in part because of these effects on their benthic invertebrate prey; (3) impacts to and recovery of the benthic invertebrate community on the intertidal and shallow subtidal beach; and (4) potential impacts to commercially and recreationally important fishes in the surf zone and/or shorebirds in large part because of these effects on their benthic invertebrate prey and because of enhanced turbidity along the shoreline. The biological monitoring program outlined in The Draft Environmental Monitoring Plan for Phase 1 – Towns of Pine knoll Shores and Indian Beach, dated April 25, 2001 is intended to address these issues. That monitoring plan is provided in appendix A of this Assessment..

2.6.1 Impacts to Offshore Resources

Monitoring studies of post-construction borrow areas in the southeast indicate that borrow areas fill in and return to near predredging conditions when there is adequate transport of sediment under the influence of strong currents in the area (Bowen and Marsh, 1988). This project's offshore borrow areas are in depths between 30 and 40 ft MLW (borrow area B) and 40 and 50 ft (borrow area A). Divers at these sites have not observed currents of sufficient magnitude to move sediment. However, most coastal areas in these depths have some rare events (e.g., hurricanes) that generate sufficient flows to move sediment. Thus the conclusion is that sediment levels in borrow areas will return to predredging conditions only during such rare events.

2.6.1.1 Impacts to Offshore Vertebrates - Fish, plankton, and other mobile animals in the vicinity of the borrow area during dredging are least likely to be affected during dredging, because of their ability to avoid the disturbed areas. Fish species have been observed to leave the area temporarily during dredging operations and return when dredging ceases (Pullen and Naqvi, 1983). A study of nearshore borrow areas after dredging offshore of South Carolina revealed no long-term impacts to fisheries, both fish and planktonic organisms, as a result of the dredging (Van Dolah et al., 1992). Creation of new habitat and the uncovering and suspension of food that attract fish during dredging have been attributed to dredging offshore borrow areas (Naqvi and Pullen, 1982). Dredging of the bottom sediments in the borrow areas can be expected to attract fish (after the dredge leaves) as a result of suspension of bottom material

2.6.1.2 Impacts to Offshore Invertebrates - Benthic organisms in the immediate area being dredged will be largely eliminated during dredging. However, initial recolonization of the dredged areas by opportunistic species is expected to occur soon after cessation of any dredging activities. Further recovery is expected from recolonization from migration of benthic organisms from adjacent areas and by larval transport. Monitoring studies of post-dredging effects and recovery rates of borrow areas indicate that most borrow sites show significant recovery by benthic organisms approximately one year after dredging (Naqvi and Pullen, 1982; Bowen and Marsh, 1988; Van Dolah et al., 1992). To encourage recolonization by organisms from undisturbed substrates, the borrow areas will not be "swept clean." Furrows of undredged materials will remain.

The monitoring plan will include collection and evaluation of bottom sediment samples from impact (borrow) areas. Benthic populations in the samples will be compared with those from control (undisturbed) areas both before and after the sand is removed. [Control areas would have no sand removed, but would otherwise be affected by all other impacts (i.e., storms, shrimping, etc., that affect the impact area).] These samples taken before the removal of the sand will be compared with identical samplings made after the nourishment to evaluate impacts. In addition, the design also calls for spring sampling both before and after the removal of sand to assess the seasonal component, for a total of four sampling periods to complete the assessment of impacts.

2.6.2 Impacts to Nearshore Resources

Nourishment sediment will be placed on the upper part of the beach, but flow down into the surf-zone region. The placed sediments are a close match in size to the sandy beach sediments, but with higher carbonate content, and a few percent mud (Appendix E, Final EIS).

There are three direct impacts from nourishment projects:

- Very short-lived substantial increases in turbidity during the placement operation (a few days at each location) alter the water column conditions sufficiently that it causes mobile species to leave the area. Return is rapid. Studies have found that speed of return of mobile species is more dependent on the return rate of their prey than on the rapid return of normal turbidity levels.

- Burial of bottom-dwelling organisms essentially destroys the community present, but Reilly and Bellis (1983) found that larval recruitment is rapid, and recovery occurs in one or two seasons.

- Alteration of sediment type necessarily results in changes in type and densities of species. Numerous monitoring studies recommend that the key to minimizing impact is to match the sediment types as closely as possible.

2.6.3 Impacts to Intertidal Resources

During project construction there will be an increase in the turbidity of the surf zone in the immediate area of sand deposition. Most of the fine material in the beach fill is expected to be washed seaward into the surf during construction. This increase in fine material may cause the temporary displacement of various species of sport fish, causing a negative impact to surf and pier fishing in the area of deposition. A study done by the National Marine Fisheries Service on the effects of beach nourishment on nearshore macroinfauna concluded that beach nourishment projects using offshore dredged material have no harmful effects, provided that the sediments are similar to those where they are placed (Saloman and Naughton, 1984).

2.6.3.1 Impacts to Intertidal Vertebrates - In view of the high mobility of fish, it is expected that fish will leave the areas under active construction. Impact on fishing resources in the intertidal zone will be minimized simply by the fact that sand-placement operations will take place at any one location for only a few days and then move further along the beach. Quantitative impacts on fish will be judged from offshore tow counts.

2.6.3.1 Impacts to Intertidal Invertebrates - Impacts on intertidal microfauna in the immediate vicinity of the nourishment project are expected as a result of discharges of nourishment sediment on the beach. A study by Reilly and Bellis (1983) was conducted on Bogue Banks and is used as a seminal study on beach projects throughout the Southeast U.S. "The Ecological Impact of Beach Nourishment with Dredged Materials on the Intertidal Zone at Bogue Banks, North Carolina" concluded that beach nourishment virtually destroys existing intertidal macrofauna, but that recovery is rapid once the pumping operation ceases. In most cases, recovery occurs within one or two seasons following the sediment placement. "...a speedy recovery largely depended on recruitment from pelagic larval stocks." Most species fell into this category. The few that did not, and recruited instead from neighboring beaches, were slower to recover.

2.6.4 Impacts to Beach and Terrestrial Resources

After construction the beach sediment will be sampled and analyzed. The primary purpose will be to determine how much of the mud in the nourishment sediment still remains and did not decant off during the construction process.

Since the project is being constructed with offshore sediments, there will be little impact on the upper (dune) portion of the beach. Project construction will result in disturbance and removal of some of the existing vegetation along the seaward side of the existing dune. Dune stabilization with vegetative planting will take place only in the isolated sections of the project where new dunes are built. Most of the project has vegetated dunes. The project is intended to widen the base of the dunes and the beach face, not build up the dune itself. Thus replanting makes sense only for those areas where new dune will be built. The Reilly and Bellis (1983) study that focused on the intertidal zone also encompassed dry-beach sampling. Most species, including all of the larger organisms such as crabs, recruited from pelagic larvae and thus recovered rapidly (one or two seasons). The Environmental Monitoring Plan for Phase 1 will address effects of the nourishment on beach species. The pre-project sampling is scheduled for summer 2001. The standard deviations in previous infauna samplings suggest that there will be sufficient statistical power to detect about a 20 percent change in total infaunal density. Analyses of densities of individual families will be less powerful, but an ordination analysis on the entire community data set will have power similar to that of the test of total infaunal density.

In a 1999 Environmental report on the use of federal offshore sand resources for beach and coastal restoration, U. S. Department of the Interior, Minerals Management Service provided the following assessment of the potential impacts to beach fauna from beach disposal;

As with benthic organisms living in borrow areas, benthic organisms are significantly impacted by beach nourishment activities (Nelson 1985; Van Dolah et. Al. 1992). These impacts, however, are considered shorter in duration than the impacts observed in offshore borrow areas. Because benthic organisms living in the beach habitats are adapted to high energy environments, they are able to quickly recover to orginal levels following beach nourishment events; sometimes in as little as three months (Van Dolah et al. 1994; Levison and Van Dolah, 1996). This is again attributed to the fact that intertidal organisms are living in high energy habitats where disturbances are more common. Because of lower diversity of species compared to other intertidal and shallow subtidal habitats (Hackney et al., 1996), the vast majority of beach habitats are recolonized by the same species that existed before nourishment (Van Dolah et al., 1992, Nelson, 1985; Levision and Van Dolah, 1996; Hackney et al., 1998)

Geotechnical Data

APPENDIX E. PROPOSED BORROW AREAS

This section summarizes results of field sampling of offshore sediments.

E-1. SURVEY DESIGN

Despite a limited supply of beach-quality sand offshore of Bogue Banks as inferred from the literature (see Section 2), more detailed confirmation was required before ruling out alternative borrow areas. The applicants initiated a reconnaissance-level survey during initial planning of the Bogue Banks restoration project based on the following desirable criteria:

- Viable sand deposits closer to the project areas than Beaufort or Bogue Inlets could potentially yield very large cost savings for the project.
- Sediments that are somewhat coarser (on average) than the native beach and coarser than the material typically available from channel maintenance would improve the durability of the nourishment projects.
- Deposits with lower mud/fine-sand content than previously used in Corps disposal projects would reduce the rate of fill losses and minimize turbidity in nearshore waters.
- If broad, shallow areas (at least 1-2 ft thick) could be confirmed, hopper dredges or alternate equipment could be used for excavations, and the rate of environmental recovery might be more rapid based on experience elsewhere (Jutte et al 1999a,b).

The sediment survey encompassed the following field sampling over three phases between June 1999 and November 2001:

- **Beach sampling and textural analysis** (June 1999) to quantify native material — 20 samples divided among dune (2), berm (6), beach face (6), and low-tide terrace (6) at CSE-Stroud transect 10 (west Emerald Isle), transect 30 (central Emerald Isle), transect 50 (Indian Beach), transect 70 (Pine Knoll Shores east), transect 90 (Atlantic Beach), transect 110 (Coast Guard Station); spacing of transects was approximately 20,000 ft. These were supplemented by 64 additional beach samples (32 analyzed pairs) between transects 48 and 78 in May 2001 following a request for more data from the USFWS (interagency meeting of 11 May 2001–detailed results submitted 24 May 2001 with letter to Garland Pardue, USFWS, Raleigh, NC).
- **Phase I borrow source sampling** (June 1999) — *offshore reconnaissance* — 53 short cores by divers in a regional grid pattern encompassing a 16-mile length of coast

from central Atlantic Beach to central Emerald Isle and extending between ~0.25 and 3 miles offshore. Generally consisted of shore-perpendicular transects of 3-5 boring locations at approximate two-mile intervals in the longshore direction. Additional, more closely spaced cores were collected 0.5-1 mile from the most promising sites. Cores average about 2 ft long. Other potential sources were sampled but rejected for various reasons as detailed in the EIS for the project. Three offshore borrow areas (A, B1, and B2) were tentatively identified for further sampling (CSE Baird-Stroud 1999).

- **Phase II confirmation sampling** (November 1999)
  - *Borrow area A (western half)* — 46 borings (averaging ~2.3 ft) at ~1200-1500 ft spacing; eight vibracores (3-9 ft) at ~3000 ft spacing.
  - *Borrow area B1* — four diver borings (~2.8 ft); three vibracores (7.5-11 ft).
  - *Borrow area B2* — seven diver borings (~2.9 ft); three vibracores (~9-10 ft).
  - Phase II sampling formed the basis of proposed borrow areas A, B1, and B2 as shown on the permit application for the project (P/N ID #200000362).

- **Phase III borrow area refinement sampling** (November 2000-March 2001)
  - *Borrow area A)* — 13 additional borings (averaging ~2 ft)
  - *Borrow area B1* — 32 additional borings (averaging ~3.4 ft)
  - *Borrow area B2* — 25 additional borings (averaging ~3.0 ft)

  Phase III sampling serves as the basis for further refining the borrow areas proposed for the project as detailed herein. (Note: The refined areas are fully within the boundaries specified in the permit application for the project.)

CSE Baird (now Coastal Science & Engineering) performed all Phase I and Phase III sampling and the diver sampling for Phase II. Athena Technologies, Inc. (Columbia, SC) performed the vibracore sampling under subcontract to CSE.

E-2. LABORATORY ANALYSIS

Sediment samples were collected and stored as follows.

Diver cores — two-inch aluminum barrels driven by hammer to refusal, cut, and temporarily capped in situ; then decanted, cut to sediment level, and recapped in the field noting penetration depth and recovery thickness; stored vertically for transport to the lab.

Vibracores — 2½-inch steel barrels driven remotely via large-scale vibrator to the depth of refusal; removed, cut, capped, and measured for penetration depth and recovery thickness.

Grab samples (beach) — hand samples from the upper three inches placed in sample bags.

Samples were logged, split, and analyzed as follows.

1) **Diver and vibracore cores** — split by saw, logged, and one-half sampled as a single or multiple composite; the remaining core half was sealed in plastic in its half barrel and archived.

   Phase I samples — visual estimates of mud percentages; then washed, dried, and dry-sieved using 0.25 phi (ϕ) intervals from -1ϕ to 4ϕ – that is, granule (2 mm) to very fine sand (0.0625 mm); fractions retained >2 mm and <0.0625 mm were noted.

   Phase II and Phase III samples — same handling and grain-size analysis procedures as Phase I samples except nearly all tested for percent mud and percent carbonate via subsampling.

   - *Percent mud* was determined by drying an undisturbed sample (composite from the length of the core), weighing it, rewetting and disagregating the sample, decanting the mud fraction until the water ran clear, redrying the sample, then reweighing it. Percent mud is computed from the difference in dry weight of the unwashed and washed samples.

   - *Percent calcium carbonate* was determined from a 20-gram subsample that had been washed and dried, then treated with repeated quantities of 10 percent dilute HCL for several hours until all reactions stopped. Samples were redried and reweighed for comparison with the untreated sample weight, and the percentage of carbonate material is computed.

2) **Native beach samples** — representative splits were obtained, washed, dried, and dry-sieved at 0.25ϕ intervals. No mud analyses were performed because the grab samples were void of mud. Percent calcium carbonate was determined via the same procedure for Phase II cores and groupings of native beach samples (ie, physical composites of multiple berm, beach face, etc, samples).

Raw data were entered into spreadsheets and analyzed via custom software (CSE's BPAS system) which automates computation of standard statistical parameters [including moment measures and the graphic parameters of Inman (1952) and Folk and Ward (1957)]. Grain-size distributions (GSDs) were graphed as frequency and cumulative frequency distributions using phi (ϕ) and millimeter (mm) axes for cross-reference. To facilitate evaluation and comparison with other engineering sieve sizes, Figure 3.24 (main text) shows the general relationships of grain size (mm), phi value, sediment classification, and ASTM sieve mesh sizes.

Sediment quality and compatibility for beach nourishment were based on the technique of James (1975) (CERC 1984), whereby a population of potential borrow area samples is compared statistically with the native beach size distribution. James (1975) presents methodology for computing the "overfill ratio" (R_A), which represents how similar a particular size distribution of sediments is compared to the native population of sediments. R_A's of nearly 1.0 suggest the sample will perform more or less equal to the native population. Higher R_A's represent the ratio of non-native "borrow" material required to perform as 1.0 unit of native material. Thus, an R_A equal to 2.0 suggests it will take twice as much material to equal 1.0 unit of native sediment.

The concept of overfill ratios is not a perfect predictor of nourishment performance, but it remains perhaps the most useful and proven technique for comparing nourishment sediments (NAS 1995). The primary factors considered are mean grain size and sorting (standard deviation measure of the size distribution). Experience has shown that borrow sources at least as coarse as the native beach (Dean 1991, CERC 1984) or having significant coarse fractions (Kana and Mohan 1998) perform equal to or better than native sediments (as measured by durability of the dry beach). Borrow sediments that are finer than native or that contain high percentages of fine material perform worse (NAS 1995). This response is related to profile adjustment (function of wave energy and wave steepness) as well as the background erosion rate. Obviously, the concept of R_A as a predictor of performance assumes that the scale of the nourishment is relatively large and covers a reasonable length of shoreline. Short projects do not perform as well for another reason–because end losses cause spreading away from the nourishment "bulge" (NAS 1995).

For purposes of the present study, we determined R_A's following standard practice, using the James (1975) nomogram in CERC (1984). Sediment quality and borrow area suitability was based on the R_A's, mean grain size and sorting parameters, percent mud, percent carbonate, percent coarser than 2 mm (ie, granule, or larger), and proximity to the project area. Isopach maps of various sediment size and quality parameters are appended after this section.

E-3. SEDIMENT RESULTS

This section provides a summary of results and refers to data sets contained in the EIS (CSE-Stroud 2001) and various supplements (eg, 24 May 2001 letter and data set to Garland Pardue, USFWS; 19 June 2001 letter to Col. J. DeLony, USACE). These previously submitted data sets include core locations, beach sample locations, and offshore core sediment characteristics (grain-size distribution curves and statistics).

E-3.1 Beach Composites

Native-beach size distributions were established using statistical composites of physical composite results of individual samples. Table 3.3 (main text) contains the individual sample results (primary statistics) from 21 dune/beach/low-tide terrace samples distributed in six transects along Bogue Banks collected in 1999 and 64 (32 pairs) supplementary samples collected in May 2001. Of the three dune samples from 1999, only two were considered representative of natural dunes, which tend to have finer sediment than beach-face samples. At stations CSE-Stroud 30, CSE-Stroud 50, and CSE-Stroud 70, repeated dune scraping has introduced anomalously coarse sands from the berm. Therefore, these stations were not sampled at the dune. At station 110 (Coast Guard station), nourishment via Corps spoil projects has introduced a coarse sediment which similarly does not reflect native dune sands; therefore, it was eliminated from the 1999 composites (top half of Table 3.3). The supplementary samples in 2001 yielded nearly identical composite statistics based on 28 or 32 samples depending on how many dune samples are included in the analysis (bottom of Table 3.3).

Review of the results confirmed coarsest sediments tend to reside on the berm and beach face (medium sand, moderately sorted, coarse-skewed) with finer sediments occurring along undisturbed dunes and low-tide terrace (typically fine sand, well sorted). Composite "12" (from the initial 1999 samples) yielded a mean grain size of 0.362 mm (1999 samples) along the beach face and berm, whereas composite "20" yielded a mean size of 0.302 mm. Considering that the proposed nourishment is designed to widen the recreational beach including part of the underwater profile, we elected to use the composite "20" as a "native" beach (1999 samples). This weights the composite toward the coarse sizes common along the beach face, berm. and low-tide terrace where the majority of the nourishment sand will be placed.

We also elected not to include samples over the outer bar or further offshore (even if these areas are part of the littoral zone), because they tend to be much finer than the beach face and would weight the "result" toward less stable sediment sizes. Similarly, we elected to only include two dune samples in composite "20" because a relatively small percentage of nourishment sediments will be subject to aeolian processes or contribute to dune building after construction. In updating these results with additional samples in 2001, we found virtually the same mean grain size and sorting for the 28 or 32 sample composites (bottom of Table 3.3). Combining the 1999 samples and 2001 samples yielded a composite of 48 beach samples as follows: mean = 0.300 mm, standard deviation = 0.601 mm. These latter values were adopted as the revised **native beach** composite.

The "native" composite selected for a baseline in the 1999 study is considerably coarser than the native sediment distribution used by the USACE (1976) in planning for potential disposal projects along Atlantic Beach. The Corps sampled at 2-ft intervals from the berm to -30 ft mean low water (MLW) along four transects at the eastern end of Bogue Banks. Their statistical composites yielded a mean grain size of 0.17 mm (2.52ϕ) and standard deviation of 0.77ϕ. The Corps results confirm the fining of sediments offshore but tend to weight the result toward less stable material. The native composite we chose is much more conservative for beach nourishment planning because it eliminates from consideration certain fine deposits that characterize the area seaward of the bar. Use of a coarser "native" size distribution lowers the amount of potentially beach-compatible material in our search areas. At the same time, it better distinguishes beach-compatible sediment from marginally acceptable sediment.

E-3.2 Phases I-III Offshore Core Samples

The Phases I-III sediment test results are presented in Table 3.4 (main text) and in Figures 3.25 and 3.26 (overfill ratios only). Detailed isopach maps of mean grain size, percent mud, percent calcium carbonate material, and percent coarser than 2 mm are given in this Appendix.

E-3.3 Proposed Borrow Areas

Offshore borings were used to delineate three potential borrow areas: A, B1, and B2 offshore of Pine Knoll Shores, Indian Beach, and Emerald Isle as described in the permit application (ID 200000362). As a result of additional sampling in January-March 2001, we have further refined the potential borrow areas as shown by shading on Figures 3.25 and 3.26 (main text) based on the following general criteria:

- R_A's should be as low as possible, approaching 1.0.
- Mud percent should be as low as possible and generally less than 5 percent.
- Calcium carbonate percentage should be at least 20 percent to match the native beach.
- Borrow sediments should be coarse-skewed, with a significant portion of granular-sized sediments to improve stability and match the coarse sediments in the lower beach face/step along Bogue Banks.

Based on this review, the preferred borrow sediment is a combination of sediments from portions of borrow areas A, B1, and B2 as shown by shading and as given by specific coordinates in Figures 3.25 and 3.26.

The revised borrow areas total 2,810 acres and are represented by 133 borings. Table 3.5 (main text) summarizes key sediment parameters (averages of individual sample results). The mean grain size in borrow area:

- A ranges from 0.51 mm to 0.54 mm (coarse sand).
- B1 averages 0.28 mm (medium sand).
- B2 averages 0.313 mm (medium sand).

Note that the native beach averages 0.30 mm. Percent mud in each borrow area averages 3.1 to 4.0 (state standard is 10 percent). The percentage of shell material (calcium carbonate) averages 27-45 percent. Approximately 7-20 percent of each deposit considered for use as borrow sediment consists of granular-shelly material with grain diameters of >2 mm.

Figures 3.27 to 3.29 (main text) show three typical cross-sections along borrow areas A, B1, and B2 – illustrating the sediments in the profile. Based on available borings, sediments are confirmed to approximately 10 ft in borrow areas B1 and B2 with more detailed confirmation in the upper 3-4 ft. Borrow area A is confirmed to ~5.5 ft with more detailed confirmation in the upper 2-2.5 ft. Based on these data and the project goal of limiting the depth of excavations to shallow cuts of the order 2-3 ft following best-management practices, **we have set a limit of ~3 ft for excavations in borrow areas B1 and B2 and ~2 ft for excavations in borrow area A**.

Applying the respective cut limits for each borrow area yields a total of ~8.7 million cubic yards. As noted in Table E.1, these estimates assume that at least 15 percent of revised borrow areas B1 and B2 will not be dredged and at least 33 percent of revised borrow areas A1 and A2 will not be dredged. The purpose of leaving some undredged corridors running through each borrow area is twofold:

1) Undredged corridors leave undisturbed areas in close proximity to each cut such that natural recruitment of biota is accelerated after construction (Jutte et al 1999a,b).

2) The anticipated type of dredging equipment (hopper dredges) reportedly works more efficiently if gaps are left between each cut (E. Elefson, Weeks Marine, August 1999, pers. comm.).

The effect of these undredged corridors will be to reduce the total acreage impacted in the offshore area. A further reduction in impacted area will result if a lesser fill quantity is needed for the project than requested in the permit. Following standard practice, we have identified and confirmed approximately 25 percent more borrow area sediment than required (Figs 3.25 to 3.29 and Table E.1). It is also prudent to have extra borrow-area sediment available for emergency nourishments after catastrophic storms. These factors are anticipated to reduce **the total acreage impacted directly by excavations to ~731 acres in borrow area A, 330 acres in borrow area B1, and 530 acres in borrow area B2 (total ~1,591 acres or ~2.5 square miles)**.

TABLE E.1. Summary R_A's and representative statistics for revised borrow areas A, B1, and B2, based on Phases I-III samples. See Figures Section 2 for revised borrow area delineations and coordinates.

Borrow Area	# Samples	Mean Grain Size (mm)	Mean Grain Size (ϕ)	% Mud	R_A's Revised
A1	22	0.509	0.974	3.2	**1.14**
A2	35	0.539	2.105	3.9	**1.15**
B1	36	0.276	1.729	3.1	**1.58**
B2	40	0.313	1.255	4.0	**1.50**
Native Beach	48	0.300	1.736	<1	**1**

Borrow Area	Area Acres	% Calcium Carbonate	% >2mm (granular)	Average Core Length (ft)	Confirmed Borrow Volume (cubic yards)
A1	653	45	17	2.3	*1.4 million
A2	807	45	20	2.2	*1.7 million
B1	520	27	7	3.2	**2.2 million
B2	830	30	8	2.9	**3.4 million
Native Beach		~15-20	~5		* @ 2 ft cut ** @ 3 ft cut

The confirmed borrow volumes represent the potential maximum volume of material that could be obtained from the indicated borrow areas. In keeping with best management practice, more source sediment must be confirmed so that some undisturbed areas can be left around each dredge cut to promote rapid recruitment of species after the project is complete. The above volumes assume 33 percent of the indicated Areas in A1 and A2 will not be dredged for purposes of wildlife recruitment, and 15 percent of the B1 and B2 will not be dredged for purposes of wildlife recruitment. Details of the Phase I excavation plan and anticipated Phase II plan are given in a later section.

E-3.4 Sediment Compatibility

Groups of samples for each potential borrow area were compared with the native beach. Using the method of James (1975), borrow composites were compared with native beach composites to yield an overfill (R_A) factor for each borrow area (see Table 3.4). The results, using beach composites of 48 samples, show that the majority of samples have R_A's under 2.0. R_A's for revised borrow area A were 1.15. Revised borrow areas B1 and B2 had slightly finer sands on average, yielding R_A's of 1.58 and 1.50 (respectively).

Upon further review of the sediment quality data and specific requirements of the project, we determined that the optimal borrow sediment will be a mixture of sands from borrow areas A and B1 or A and B2. Borrow areas B1 and B2 contain more fine sand and are slightly less stable for nourishment than borrow area A (ie, approximately 33 percent of the B1 and B2 deposits will serve as overfill). The finer sands in these areas will migrate to the outer bar after placement and will build up the underwater profile (a desired outcome). Sediments in borrow area A are slightly coarser than the native beach (lower end of the coarse sand range). These sediments will be more stable in the berm and beach face and will serve to improve the longevity of the dry beach.

As shown in Table E.1, approximately 65 percent of the borrow sediment is anticipated to be derived from revised borrow areas B1 and B2. The remaining 35 percent would be excavated from borrow area A. Using these approximate proportions, we have developed composite grain-size distributions for representative combinations of borrow areas A and B1 or A and B2 as detailed in previous correspondence to USACE (letter and attachments dated 19 June 2001 in response to 1 June 2001 comments from USFWS). Table E.2 and Figure 3.30 (main text) provide example results. Using 62 representative cores from borrow areas B1, B2, and A, we computed composite grain-size distributions for mixtures of borrow areas A and B2 and A and B2. This simulates the effect of mixing sediments during placement. The composite size distributions resulting from each mixture yield overfill ratios of 1.25 to 1.3 (Table E.2). Grain-size distribution curves for the composites are given in Figure 3.31(main text). Only 25-30 percent more borrow sand would be required in these cases to match the performance of the native beach. As NAS (1995) and experience suggest, borrow areas with R_A's under 1.5 are generally considered to be good matches with the native beach.

The selected borrow areas have several advantages:

1) They are in close proximity to the project site and will result in lower transportation costs and more rapid construction.
2) They contain a broad range of sediment sizes that fully encompass the natural variation that presently exists on the beach.
3) They have relatively low mud content (<4 percent on average).
4) They contain a sizable portion of granular material which will be more stable on the beach.

5) They are relatively free of large shell clasts. Most of the shell material consists of *Donax* sp., which is thinner walled and more friable than heavy shell such as *Crassostrea* sp.
6) They are situated in water depths of 30-50 ft, beyond the limit of normal sediment exchange with the beach.

The result of the above-listed refinements of the proposed borrow areas for the proposed project is to yield a beach-compatible sediment. Final plans and specifications for contractors will direct hopper dredges (the anticipated equipment) to alternate between borrow areas A and B1, or A and B2 in proportion to the volumes prescribed for each area. Construction will be monitored closely by the applicants' engineer with frequent sand sampling for quality control.

TABLE E.2. Example composite overfill ratios for borrow areas B1 and A and borrow areas B2 and A, assuming mixture of sediment to yield a more compatible fill. (Example to simulate mixture of ~65 percent B1 and 35 percent of A or 65 percent of B2 and 35 percent of A.) See CSE response letter dated 19 June 2001 to USACE for more details. [*See Table 3.3 for definitions.]

Summary

1) As Reported In SEPA Final EIS dated 4 April 2001

Native Composite (20 Samples @ Dune Face, Berm, Beach Face, Low tide terrace)
Mean=1.725 phi (Mn) ***Std dev=0.773 phi (SDn)*** ***Skewness=-0.648***
Mean=0.302 mm ***Std dev=.585 mm*** ***Skewness=-0.648***

Native Composite (12 Samples @ Berm, Beach Face)
Mean=1.466 phi (Mn) *Std dev=0.* *Skewness=-0.542*
Mean=0.362 mm *Std dev=.5* *Skewness=-0.542*

2) Based On May 2001 Supplementary Beach Sampling For Beach Transects 48 - 78

Native Composite (28 Samples @ Dune Face, Berm, Beach Face, Low tide terrace)
Mean=1.747 phi (Mn) ***Std dev=0.696 phi (SDn)*** ***Skewness=-0.714***
Mean=0.298 mm ***Std dev=.617 mm*** ***Skewness=-0.714***

3) Average of June 1999 and May 2001 Results

Native Composite (48 Samples @ Dune Face, Berm, Beach Face, Low tide terrace)
Mean=1.736 phi (Mn) ***Std dev=0.735 phi (SDn)*** ***Skewness=-0.681***
Mean=0.300 mm ***Std dev=.601 mm*** ***Skewness=-0.681***

Table E5. Potential Borrow Area Sediment Quality and Compatibility Factors (RA). Revised May 2001

***CS-Coarse Sand; MS-Medium Sand; FS-fine sand*
ms-moderately sorted; mws-moderately well sorted; ws-well sorted; ps-poorly sorted
c-s coarse skewed; sc-s strongly coarse skewed; f-s fine skewed; sym - symmetrical size distribution
** These samples have a limiting acceptable depth for excavation based on recovered cores*
(ie. Underlying material is considered less suitable for nourishment).

RE: Carteret County – Bogue Banks Beach Restoration Project – Federal Action ID# 200000362]
Supplementary Information Requested by USFWS on 11 May 2001 (interagency meeting)

Dear Mr. Pardue:

I am writing on behalf of Carteret County and the Towns of Pine Knoll Shores, Indian Beach, and Emerald Isle in regard to the permit application for the above-referenced project. Representatives from your agency, Ms. Tracy Rice and Mr. John Ellis, attended an interagency meeting in Morehead City on 11 May 2001 and provided comments and requests for additional information. This letter and its attachments provide the information requested. These data are intended to supplement the information contained in the permit application and final EIS approved under the SEPA review process.

Work Accomplished

At the request of your agency, the Towns of Pine Knoll Shores and Indian Beach funded additional beach sediment collection and analyses as follows:

- 64 surficial sediment samples from Bogue Banks transect 48 (Emerald Isle) through transect 78 (Atlantic Beach). Sixteen, even-numbered transects were sampled along the dune face, top of berm, beach face, and low-tide terrace at low tide on 15 May 2001.

- 32 samples were analyzed in the laboratory by combining physical pairs from adjacent transects (eg, dune samples from transects 48 and 50 were combined physically, mixed completely, and a representative ~100-gram sample was tested for sediment properties). Samples were labeled B4850a for dune samples at transects 48 and 50, B4850b for berm samples, etc.

- Laboratory analysis of each sample consisted of:
  - Mechanical sieving at 0.25ϕ intervals.
  - Computation of grain-size distribution (GSD) parameters (mean, standard deviation, skewness, percent coarser than 2 mm, etc.).
  - Chemical analysis of the calcium carbonate fraction via acid reduction (dilute HCl) using a representative 20-gram sample.
  - Physical separation of the mud fraction (sizes passing the 230 ASTM sieve; ie, <0.0625 mm diameter) to determine the mud percent.
  - Size parameters were calculated by the Method of Moments and via graphic techniques of Inman (1952) and Folk and Ward (1957).

- Groups of samples were combined statistically using the raw weight percentages of each size fraction to calculate "composite" GSDs. Composites included:
  - CDUNE8 – composite of the eight dune tests (representing 16 physical samples).
  - CDUNE4 – composite of four of the dune tests (representing transects less altered by scraping).
  - CBERM8 – composite of the eight berm tests (representing 16 berm samples).
  - CBF8 – composite of the eight beach face tests, etc.
  - CLTT8 – composite of the eight low-tide terrace tests, etc.

- Overall beach composites were computed for all 32 tests ("COMP32") and 28 tests ("Comp28" which omits four of the dune samples).

- The composites from the 15 May 2001 sampling were compared with the June 1999 results. All new beach sediment data have been added to Table E3-Revised (EIS) and are attached to this letter. The 1999 "Native Beach" composite is compared with the 2001 composites at the bottom of Table E3.

- The "Native Beach" GSD was revised by averaging the results from the June 1999 and the May 2001 survey as follows (see Table E3 for additional details):
  - 1999 beach composite (20 samples) – mean = 0.302 mm
  - 2001 beach composite (28 samples) – mean = 0.298 mm
  - Revised native composite – mean = 0.300 mm

CSE

- Overfill ratios (RAs) for individual samples in three offshore borrow areas were recomputed using the revised native composite GSDs. These are given in Table E5-Revised. The typical change in RAs after this revision was ~0.01, or about 1 percent.

- Sediment characteristic maps of various textural parameters were updated for the three borrow areas. These include data from additional borings obtained between November 2000 and March 2001, which were in processing at the time of the interagency meeting.
    - Area A – ~76 cores
    - Area B1 – ~46 cores
    - Area B2 – ~42 cores

  Additional core data are given in Annex E1-Table E1-F (Appendix E to EIS).

- Results of the supplementary individual and composite GSDs (sample split weights, frequency, cumulative frequency, and statistics) are enclosed with this letter.

Borrow Area Delineation

As part of the final design for the Pine Knoll Shores and Indian Beach projects, we will optimize borrow areas A, B1, and B2 to effect a close match between the borrow sediments and the revised native beach sediments. This is an iterative process because of the number of variables involved and the natural variability of Bogue Banks' beach and offshore area. However, final decisions regarding exactly which portions of the borrow areas will be used cannot be made until all variables are known. These include the capabilities of each dredge of the winning construction bidder and the unit-volume bid price. (For example, if bid prices are lower than expected, more sand may be dredged, up to the maximum permitted volume.)

The final design will identify the optimal areas for excavations and will provide statistical composites for applicable groups of samples from borrow areas A, B1, and B2.

We anticipate collecting additional borings prior to any nourishment along Emerald Isle. The present data are focused in anticipation of construction along Pine Knoll Shores and Indian Beach reaches between November 2001 and April 2002. We request that your agency review these data in the context of the Pine Knoll Shores and Indian Beach reaches.

CSE

Supplement to the Biological Assessment

Also enclosed herein is a supplement to the biological assessment given in the EIS. Additional site visits and surveys have been performed since the EIS was prepared. The most recent survey was 14-15 May. The majority of Pine Knoll Shores and Indian Beach lacks any dry beach. Property owners are continuing to scrape the beach and rebuild the foredune. There are escarpments up to 8 feet high in some newly scraped dunes (see photo 1.4) and continued undercutting and mass wasting of vegetated dunes. In addition to the reduction of viable turtle nesting and seabeach amaranth habitat (see photos), even more habitable structures are imminently threatened than was reported in the EIS. We encourage you and your staff to visit the site and see the continued loss of dune and dry beach habitat. This is particularly noticeable upon leaving Pine Knoll Shores and traveling east along the beach into the Town of Atlantic Beach (which was nourished in 1986 and 1994 prior to five landfall hurricanes, see photo 1.6).

We appreciate the comments from your agency and hope you find the enclosed information responsive. Time is of the essence, and it is critical that we obtain your review of the project at the earliest time. Our project team and representatives of the county and towns would like to meet with you any time in the next two weeks and discuss these results in detail. Thank you for your consideration.

Yours truly,

Tim Kana

APPENDIX F

ECONOMIC STUDIES

LIST OF TABLES

APPENDIX F

Supporting Computations for Section 4.3 "Retreat/Relocate Alternative"

The first three tables in this Appendix are the calculations for the summarized numbers in Section 4.3. Table F-1 breaks down the costs for relocating a house on the same lot, Table F-2 the same computations but for moving to a different lot (insufficient room remains on the same lot), and Table F-3 shows the cost breakdown by municipality.

In the analyses of the retreat/relocate alternative it is assumed that costs occur equally in each year of the 10 year study period; that construction costs escalate at 3 percent per year; that real estate costs escalate at 4.8 percent per year. Final costs for comparison with project costs are normalized to present value based on the discount factor for 30 year Treasury bonds as of February 24, 2000 as published in the Wall Street Journal.

The relocation costs used in the previous tables are supported in detail in Table F-9, showing the different relocation costs by community. The accumulation of these costs by year and type of relocation are further broken down in Table F-10. Thus F-10 feeds the supporting data into F-9, which then provides supporting data for the first three Tables F-1 through F-3.

Finally, the net present worth of all these relocation costs are summed in Table F-11 over the ten years.

Supporting Computations for Section 4.2 "Do-Nothing Alternative"

Impacts on Property Values

The number of oceanfront properties that will be lost under the 10-year project life are totaled in Table F-4 and the values totaled. The appropriate tax rates are then applied to determine the total property tax losses, broken down by community in each section of Table F-4. This is a government loss.

Table F-5 shows the lost property values by year and by community. These are losses to those in the special tax districts.

The present worth of the property tax losses are computed in Table F-6. **This value of $6.3 million is reported in the summary table in Section 4.2.**

In addition to the actual loss of property, there is a loss to the appreciated values, had the structures remained. The present worth of all lost properties, taking into account appreciation, are totaled by community in Table F-7. The listed property losses are losses in the Special Tax Districts, and the listed property tax losses are government losses.

All types of property loss are summarized in Table F-8. These include lost property, lost taxes, beach scraping, property repairs, and debris removal.

The relocation costs used in the previous tables are supported in detail in Table F-9, showing the different relocation costs by community.

Impacts to the Community (Carteret County) Economy

Tourist Expenditures – Total revenues generated from domestic tourism in Carteret County has been estimated by Carteret County Economic Development Council to be $208.55 million (1998) in "Facts on Carteret County Tourism" based on statistics provided by NC Department of Commerce. The proportion of tourist revenues in Carteret County that are generated on Bogue Banks has been estimated by the same sources as 84 percent. The proportion of recreational beaches on Bogue Banks that this beach-nourishment project is planned to improve is the ratio of this project length to the total beach length or 78 percent. Thus the maximum tourist expenditures that are in jeopardy if there is no recreational beach over the proposed project length is 0.84 x 0.78 x $208.55 million = $136.64 million annually or $1,366.4 million over the ten-year lifetime of the project. The prime tourist attraction in Bogue Banks is the beach. It is difficult to estimate the percent of tourists who would not come to Bogue Banks if the proposed project beach has little or no beach above high tide. Some tourists who come to the area do not use the beach. Those who do use the beach will increasingly crowd onto remaining healthy beach areas such as Atlantic Beach. However, a range of possibilities can be considered. For inclusion in the high and low estimates in Section 4.2, we propose a low limit of 10 percent and a high limit of 25 percent proportion of tourist population that will elect to go elsewhere. Thus the total lost tourist revenues over ten years would range between $136.64 million and $341.61 million. For the purpose of ascertaining who will experience these losses, lost tourism is broken down into the following categories.

Occupancy Tax – There is a 3 percent occupancy tax on all short-term (visitor) rentals. In fiscal year 1998-99 this generated $1,706,788 in Carteret County. Using the numbers in Tourist Expenditures above, losses of occupancy tax for one year would be 10-25 percent of 0.84 x 0.78 x $1,706,788. So the loss range over ten years is $1,118,287 to $2,795,718. This is a governmental loss.

Sales Tax – There is a 6 percent sales tax on non-housing expenditures. The Economic Development Council (reference publication listed above under Tourism Expenditures) estimates $20.05 million of these annual revenues are generated by tourists in Carteret County. Using the numbers in Tourist Expenditures above, losses of sales tax for one year would be 10-25 percent of 0.84 x 0.78 x $20,050,000. So the loss range over ten years is $13,136,000 to $32,840,000. This is a governmental loss.

Payroll – The tourism industry is Carteret County's largest industry. The Economic Development Council estimates this annual payroll at $48.99 million. Using the numbers in Tourist Expenditures above, losses of payroll in one year would be 10-25 percent of 0.84 x 0.78 x $48,990,000. So the loss range over ten years is $32,098,000 to $80,245,000. This is a private loss.

Other Tourist Expenditures – The remaining tourist expenditures (total minus tax and payroll) over the project portion of Bogue Banks are annually 0.84 x 0.78 x ($208.55 - $1.71 - $20.05 - $48.99). So the range of possible losses (10-25 percent of this value multiplied over ten years) is $90.287 million to $225.718 million. This is a private loss.

Recreational Losses – Losses to the environment are more difficult to quantify than economic losses. However, the Corps of Engineers has established procedures for estimating the value of a recreational beach to the general public. Procedures outlined in Engineering Regulation 1105-2-100 were followed. Some choice of methods is allowed under the regulation, but most nourishment projects designed by the Corps use example surveys of the beach-going public that have resulted in "use curves" based on surveys conducted in Florida that were later updated in the Myrtle Beach, SC, project (USACE, 1993). These studies compute the number of beach visits annually by each person (P) as $P = A \exp(B x)$ where A and B are empirical coefficients determined by surveys, and x is the travel distance between a community and the beach. The Florida study generated values of $A = 6.8$ and $B = -0.03$, and Myrtle Beach updated these to $A = 8$ and $B = -0.04$. The A value represents the annual number of beach visits made by a resident who is within walking distance of the beach. Using these values the annual number of beach visits made by residents of Carteret County was computed in Table F-12.

The annual visits total 310,181. To translate this into a dollar value, procedures are available for assigning "point" values to various recreational experiences associated with the amenities at a particular beach. Rather than follow these complex procedures which tends to result in variation in the final number of only 10-20 percent, we simply used the value computed in another study for Folly Beach, SC (USACE, 1991) which produced a value per visit of $3.44. Multiplying the number of annual visits by this value results in an annual recreational value to County residents of $1,067,022. The portion of Bogue Banks represented by this project is 78 percent, so the annual recreational value to residents is 0.78 x $1,067,022 or $832,277. Following the same logic outlined above for Tourist Expenditures, we propose that 10-25 percent of these visits will not occur because of the degraded beach. Ten to 25 percent of the above value multiplied over the ten-year project results in value of $832,277 to $2,080,693. This is an environmental/quality-of-life impact to the county.

Impacts to Owners in Special Tax Districts

Beach Scraping – Since Hurricane *Floyd* (September 1999), an estimated 80 percent of oceanfront properties in the proposed project area have scraped the beach and restored the foredune. Scraping was continuing on 1 March 2000, nearly six months after *Floyd*. Typical dimensions of scraping are 10-15 cubic yards per linear foot. Scraping is performed by skimming the upper 2–4 ft of dry beach by bulldozer and pushing it into a steep sloping dune (typically 1 on 4 seaward slope). Elevation of the top of the scraped dune generally coincides with the backshore escarpment elevation (typically 15-20 ft NGVD). Typical range of expenditures per 100-ft oceanfront lot have been $500–3000 per incident. Some owners have scraped nearly every year since 1995. While the crest elevation of the scraped dune is well above the 10-year or 25-year surge elevation, the protection is not equivalent because the remaining beach after scraping is narrower and less able to absorb wave energy. As a result, the scraped dune is exposed at the toe and vulnerable to scarping. This, in turn, leads to mass wasting of the scraped dune and the need to rescrape. As erosion continues under the no action alternative, the frequency of erosion and undermining of the artificial dunes will increase. For purposes of cost estimating, we assume that 50 percent of the beach will require scraping in any given year. Scraping 50 percent each year results in an annual cost of $250,000. Escalating and normalizing to present value is $ 2.2 million over ten (10) years: (Table F-8).

Reconstruction of Dune Walkovers – An estimated 80 percent of existing dune walkovers in the project area have been rebuilt since Hurricane *Floyd*. Many of these same property owners had to replace their walkovers after *Fran* and the other hurricanes of the late 1990s. The nature of repairs ranges from replacement of just a few steps at the base to entire reconstruction of support piles, observation decks and handicapped ramps. A majority of walkovers extend from relatively high backshore elevations (typically 15–20 ft NGVD), thus the support systems are elaborate in many cases. With increasing frequency of runup to the base of structures, repaired walkovers are usually improved and more expensive compared to the destroyed walkover. We estimate a range of expenditures per property is ~$200 to $10,000 after *Floyd*, with a typical cost around $3000, or approximately $2.2 million. Thus, the ten-year cost of walkover replacement due to storm erosion has a present value of $19.1 million (Table F-8). This is an impact to oceanfront property owners.

APPENDIX G

APPENDIX G

Littoral Processes

APPENDIX G — LITTORAL PROCESSES

APPENDIX G1. PREVIOUS STUDIES

A substantial amount of literature exists on Outer Banks beaches, some of it specific to Bogue Banks. Generally there are two types of data that are fairly plentiful: monitoring studies of Beaufort Inlet by the Corps of Engineers and geological studies of the Outer Banks as student theses at various universities.

The Corps of Engineers studies on Beaufort Inlet are so numerous that Beaufort is used as the Corps' example of how to evaluate inlets in their Engineering Manual "Coastal Inlet Hydraulics and Sedimentation" (USACE, 1995). There is a substantial amount of bathymetric profile data for the inlet, and more recently, beach profiles for Atlantic Beach. What is generally missing are "coastal process" measurements, that is, waves, currents, tides, and sediment transport.

The student theses from Duke University, North Carolina State University, and University of North Carolina are rich in information about the geology of the islands themselves (hundreds of core samples taken on various barrier islands and sometimes profiles of the beach), but they are quite sparse in information for the underwater portion of the beach. Core samples and beach profiles generally end at the water line.

Many of the findings in the literature relevant to a Bogue Banks beach-nourishment project are listed in Table G1.

TABLE G1. Literature Summary — Historical Documents

Thesis on relict inlet locations — 1962. UNC. Fisher, J.J., Geomorphic expression of former inlets along the Outer Banks of North Carolina, 120 pp.

- Summary of former inlets in NC, as detected by geomorphology
- Distribution of relict inlets for entire outer banks shown in Figure 4
- Aerial photo of 3 Atlantic Beach relict inlets in Figure 5
- 1860 map of Atlantic Beach relict channels, Figure 6
- Opening history of Beaufort Inlet, p. 88
- Opening history of Bogue Inlet, pp. 88-89
- Opening history of Bogue relict inlet #1, pp. 89-90
- Opening history of Bogue relict inlet #2, p. 90

Study on hurricane impacts on Bogue Banks — 1966. USACE. Beaufort Inlet to Bogue Inlet, North Carolina. US House Document No. 479, 89th Congress.

- Survey of hurricane damages
- Recommends flood dike for west side of New River. Other protections not economically feasible
- 8 hurricanes listed, 1953-60, p. 16
- Hurricane surges, 1953-60, p. 17
- Hurricane tracks, 1953-60, p. 18
- Hurricane damages, 1953-60, p. 19

Dissertation on geologic history of Bogue Banks (UNC Chapel Hill) — 1967. UNC. Fisher, J.J. Development pattern of relict beach ridges, Outer Banks barrier chain, North Carolina, 247 pp.

- Maps of 300+ relict beach ridges on Bogue Banks, with 7 sequences (Fig. 53)
- Sequential development of Bogue Banks, Fig. 57
- Soil map for Bogue Banks, Fig. 58

NCSU study on North Carolina beach erosion — 1973. NCSU. Knowles, C.E., J. Langfelder, and R. McDonald. A preliminary study of storm-induced beach erosion for North Carolina. NCSU Rept. No. 73-5, 14 pp. + figs.

- Topographic surveys along each fishing pier
- Storm surge levels recorded and plotted as function of return frequency
- Design surge levels and breaking-wave depths, Table 1
- Estimated beach recession for 25 yr storm (21 ft), 50 yr (162 ft), 100 yr (220 ft) at Bogue Banks, Table 2
- Plot of storm surge versus return period (Fig. 1)

Thesis on Shackleford Banks geology and subsurface sediments — 1975. Duke. Susman, K.R. Post-Miocene subsurface stratigraphy of Shackleford Banks, Carteret County, North Carolina, 70 pp + app.

- Sediment-size statistics, radiocarbon dates, and fauna count for core samples within Shackleford Banks (Tables 1-3)
- Schematic cross-section of Shackleford, Fig. 4

Morehead City harbor general design memorandum — 1976. USACE. Morehead City Harbor, North Carolina, General Design Memorandum, USACE-Wilmington, 41 pp. + app A-F.

- Recommended increasing navigation channel depth to 40 ft in harbor and inlet and 42 ft in ocean approach.
- Proposed disposing of sediment along 4000 ft of Shackleford by hopper, initial disposal via pipeline dredge on the eastern 5000 ft of Atlantic Beach, and later disposal via pipeline for additional 25,000 ft west of the 5000 ft
- Inlet migration and throat width, pp. B2-3
- Table of dredging volumes through 1974, pp. B5-6
- Hurricane surge and winds for *Donna*, 1960, table, p. B8
- Table of tidal currents, p. B10
- Cumulative dune-line location for entire island, p. B17
- Hydrographic surveys since 1839 showing channel, plate B1
- 8 beach profile transect taken well offshore in 1958 and 1972, plates B6-B9
- Appendix C: longshore transport analysis from ship-based winds
- Attachment D1: boring logs
- D6-D7: grain-size information. **Reaches shown on Plate D-3. Reach P (inner harbor) has retention of 60% (Ra of 1.67); Outermost (ocean) Reach Hc has retention of 68% (Ra of 1.47); composite retention for all of H(a-c) is 80% (Ra of 1.25). Thus 1.25 is best estimate of beach-fill material Ra. Native material is rather fine, with mean of 2.52 phi (0.17 mm) and standard deviation of 0.77 phi.**
- Sediment transport conclusions: (1) transport is to the east (75%), (2) shoaling occurs more on the west side of the channel (68% of the channel shoaling), (3) bypassing efficiency of the inlet dropped from 52% to 28% after dredging, (4) net transport is about 14% of the gross

Thesis study of sediments and geology of Bogue Banks — 1977. UNC, Goff, W.T. Sedimentation in a modern tidal inlet: Bogue Inlet, North Carolina, 117 pp + app.

- Analysis of 244 bottom samples, 20 can cores, 9 trenches in Bogue Inlet
- Sketch of inlet geomorphics compared to Hayes' model, Fig. 2 and 3
- Mean tide range at Bogue (71 cm) and Beaufort (96 cm), p. 11
- Bathymetric map, Fig. 5
- Inlet migration maps, Fig. 7
- Sediment size-distribution map, Fig. 8
- Percentage shell content, Fig. 13
- Transport paths inferred from ripple/sand-wave geometry, Fig. 18
- Sediment environment map, Fig. 26
- Sediment environment vertical cross-section Fig. 28 (cross-shore)
- Fig. 29 (longshore)

Thesis on geology and sediments of Outer Banks — 1977. Duke. Moslow, T.F. Quaternary evolution of Core Banks, North Carolina, from Cape Lookout to New Drum Inlet, 171 pp.

- Analysis of many core samples from within Core Banks, nothing south of Cape Lookout
- Radiocarbon dating, macrofauna counts, and analysis of each depositional environment

- Comparison of relict and modern inlets, p. 108
- Rates of landward migration of Core Banks, 50-100 m/century, p. 102

Thesis on coastal process measurements in Beaufort Inlet — 1977. Duke. Sarle, L.L. Processes and resulting morphology of sand deposits within Beaufort Inlet, Carteret County, North Carolina, 152 pp.

- Storm frequencies, p. 14, 1.64 hurricanes per year for Bogue Banks
- Monthly wind roses, p. 19
- Data collected: surveys, fathometer, tidal currents, and grab samples
- Fathometer traverses all in Sound, locations p. 27, results, p. 98
- Tide measurement locations, p. 29
- Sediment sample locations, p. 31
- Tidal velocity data summary, p. 34
- Average curves for spring, neap, mean tides, p. 36
- Sedimentary structure flow-indicator classification, p. 40
- Tidal velocity curves for each station, p. 45-54
- Sketch of pre-dredging model of Beaufort Inlet, p. 57
- Western growth rate of Shackleford Spit, p. 66
- Morphological classifications of underwater topography: map p. 74, sketch p. 84
- Aerial photo with tidal current directions superimposed, p. 135
- Conclusion: tidal current velocities increased because of narrowing of inlet by stabilizing Fort Macon State Park and western growth of Shackleford, p. 139
- Conclusion: dredging causes sediment to be transported seaward and deposited in deeper water, where it is not available for beaches, p. 139

Thesis on geology and sediments for Core Banks — 1978. Duke. Herbert, J.R. Post-Miocene stratigraphy and evolution of northern Core Banks, North Carolina, 140 pp.

- Sediment size analysis, geological history, and inlet cross-sections, all north of New Drum Inlet

Thesis on sedimentation of Shackleford Banks — 1979. Duke. Berelson, W.M. Barrier island evolution and its effect on lagoonal sedimentation; Shackleford Banks, Back Sound, and Harkers Island: Cape Lookout National Seashore, 220 pp.

- Textural and size analysis of core samples throughout and landward of Shackleford, but no data offshore

Thesis on sediments in Bogue Banks — 1980. Duke. Steele, G.A. Stratigraphy and depositional history of Bogue Banks, North Carolina, 220 pp.

- 42 bore-hole locations on Bogue, p. 10 (none offshore)
- No prevailing longshore transport direction, except at eastern end, where sand accumulates on west side of jetty (p. 13)
- Monthly wind roses, p. 15
- Tide discussion, p. 16; maximum ebb in Beaufort 116 cm/s, flood 106 cm/s; tidal prism of Bogue Sound 80 million cubic meters
- Dune-line change along entire island, 1964-71, p. 18
- Sediment analyses: faunal counts, lithology, radiocarbon dating, size
- Detailed discussion of geologic history, by community, pp. 91-142
- Summary of Bogue Banks forming, pp. 165-167

Planning brochure on options for stabilizing Bogue Inlet — 1980. USACE. Planning Brochure for Bogue Banks Stage II Study, 21 pp.

- Summarizes Phase II study for inlet stabilization
- p. 20 summarizes plans; bottom line is that only channel deepening (by only 2 ft from 6 ft to 8 ft) is economically justified; all structural alternatives examined were not economical

North Carolina erosion task force report — 1984. NCDNRCD. Coastal Resources Commission's Outer Banks Erosion Task Force Report, 29 pp.

- Evaluated the following alternatives for responding to coastal erosion: (1) hardening (seawalls), (2) trapping (groins), (3) nourishment, (4) dune building, (5) beach pushing (scraping), and (6) relocating threatened buildings. General cost comparisons were made:

Sandbags	$125-250/ft/yr
Bulkheads	$25-50/ft/yr
Revetments	$5-15/ft/yr
Groins	$12-25/ft/yr
Breakwaters	$60+/ft/yr
Beach pushing	$200/ft/yr
Nourishment	$240/ft/yr

- Determined that federal nourishment projects have taken 15-18 years to authorize, with a minimum of eight years.
- Conclusions: an unobstructed public beach is essential to the continued vitality of the tourism industry.
- Beach nourishment is the preferred response to erosion.

Sedimentation study of Shackleford Banks/Cape Lookout — 1984. Marine Geology. Heron, S.D., T.F. Moslow, W.M. Berelson, J.R. Herbert, G.A. Steele, and K.R. Susman. Holocene sedimentation of a wave-dominated barrier-island shoreline: Cape Lookout, North Carolina, Vol. 60, pp. 413-434.
- Process/response model of wave-dominated barrier islands in sand-rich environments with 5 parts of model in Fig. 8
- Per Nummedal et al. (1977) classification, area has relative to the rest of the southeastern United States: high waves, small tidal range, little ebb-tidal delta, and large inner shoal area
- Waves average 1.7 m height with 2 m exceeded 30% of the year, more than anywhere else in southeastern United States (Nummedal, Fig. 2)
- Bogue summarized in section lower-energy depositional limb with vertical sequence of sediments in Fig. 15

Vibracore data and interpretation for Bogue Banks — 1985. Marine Geology. Hine, A.C. and S.W. Snyder. Coastal lithosome preservation: evidence from the shoreface and inner continental shelf off Bogue Banks, North Carolina, Vol. 63, pp. 307-330.
- Analysis of Bogue shelf based on drill holes on Bogue Banks, 125 vibracores on shelf, and seismic data
- Much of sand deposits removed from shelf, but paleochannels with sand identified (fig. 2)
- Isopach map of Quaternary deposit thicknesses, fig 6, shows sands confined very close to shore and within the paleochannels
- Shoreface is narrow, generally 12 m deep and 500-800 m wide

Morehead City harbor improvement feasibility report and environmental assessment — 1990. USACE. Feasibility report and environmental assessment: Morehead City harbor improvement, Morehead City, North Carolina, App. A-F.
- Coastal engineering information in Appendix C contains:
  - Tides (IIB)
  - Changes in shoreline volumes (IID), including historical rates (Table 20) and recent (since dredging) rates (Table 21); Fort Macon recent erosion is explained as erosion of the large (1.2 million cy) nourishment placed in 1978
  - Longshore transport calculations in Section IIE and later are all based on wind hindcasts and are thus suspect
- Channel boring logs are in Appendix D

Morehead City general design memorandum (updated) — 1992. USACE. Design memorandum and environmental assessment: Harbor improvement, Morehead City, North Carolina, 50 pp. + App. A-M.
- Project encompasses deepening of outer harbor, extending ocean approach dredging, and enlarging harbor
- Proposed disposal for inner harbor is via pipeline to Brand Island, with pumpout to Atlantic Beach every 8-10 years; deposit outer harbor material on nearshore berm at 20 ft contour
- Disposal alternatives and their unit costs in Table 15, p. 37
- Analyzed potential for nearshore berm to move using Hands/Allison figure and WIS hindcast data to determine currents (p. C12); results suggest active motion; also applied LTD program, which also suggested active motion of berm (p. C13).
- Appendix D contains bore logs and sieve analyses, but no computation of composite size and overfill ratios

Shoreline erosion methods and maps — 1997. NCDEHNR. Benton, S.B., C.J. Bellis, M.F. Overton, J.S. Fisher, J.L. Hench, and R. Dolan. North Carolina long term average annual rates of shoreline change: methods report 1992 update, 20 pp. + app A-F.

- Uses both wet/dry line and vegetation line to estimate shoreline changes; latest update is 1992; previous updates in 1986 and 1980
- Bogue USGS maps are Q19-Q22 and SNC54-65; SNC photogrammetry available for Bogue in 1943, 1959, 1980, 1986, and 1992

Preliminary 111 evaluation on causes of erosion at Pine Knoll Shores — 1998. USACE. Preliminary Section 111 evaluation, Morehead City Harbor/Pine Knoll Shores, North Carolina, 15 pp. + figs.

- Lists dredging history in Tables 1 and 2
- Beach disposal volumes and locations, p. 3
- Pine Knoll Shores interests claim disruption of westerly LST by navigation channel and also increased flow (and thus sediment) into harbor because of increased tidal prism
- The results of the two previous LST studies are summarized below:
  1) The Corps of Engineers 1976 study compared two time periods relative to navigation-channel maintenance, before (1854-1936) and after (1960-1974) and concluded: (a) sediment transport is to the east (75%), (b) shoaling occurs more on the west side of the channel (68% of the channel shoaling), (c) bypassing efficiency of the inlet dropped from 52% to 28% after dredging, and (d) the net transport is about 14% of the gross.
  2) The Corps of Engineers 1990 study concluded that (a) the gross transport rate was about 600,000 cy/yr greater than shown in the 1976 study, but (b) the net transport proportion was about the same as in the previous study, in this case 78% of the total.
- The current study uses updated 1993 WIS hindcasts that show sufficiently changed wave-direction predictions from the past studies, that the transport direction may be from west to east. The use of the updated hindcasts in LST equations was not performed in this preliminary phase of the study, but postponed till the next phase.
- Tidal ranges increased 0.1-0.4 ft in the Sound after the 40 ft project deepening, thus increasing the tidal prism and flow rates.
- Analysis of Corps profiles uses both wet/dry line and vegetation line demarcations to examine shoreline erosion rates
- Conclusions: (1) Pine Knoll Shores has higher erosion rates than areas further west along Bogue. (2) WIS hindcast updates suggest the possibility of westward LST. (3) Tidal prism has increased, suggesting the possibility of increased sediment trapping in the inlet. These three factors plus annual removal of 325,500 cy by the harbor project suggest a possible impact on the beach. Further study was recommended.

Wave hindcast study on erosion impacts of Morehead City navigation channel maintenance — 1998. UNC. Roessler, T.S. Effects of offshore geology and the Morehead City Harbor project on Eastern Bogue Banks, North Carolina, 112 pp.

- General conclusion: dredging has increased the tidal prism, thereby increasing tidal velocities and ebb-tidal delta to move seaward. This increases gradients in longshore currents during storms and thus increases erosion.
- Maps of Beaufort Inlet channel since 1850, Fig. 2
- Inlet location now stable, since western side is jettied
- Dredging has occurred since 1911; inner harbor now dredged every two years, outer channel every year
- Dredging location and disposal sites, Fig. 4; volumes, Table 1
- Beach profiles collected monthly over two years on 13 transects in AB and PKS
- Longshore currents computed from offshore winds, RCPWAVE wave model, and Komar's longshore current equation
- Erosion for AB 1958-1972, Fig. 7
- Beach nourishment volumes changes, 1986 and 1994, Fig. 9
- Measured erosion rates of nourishment sand, 1996-1998, Fig. 10
- Volumetric and linear erosion rates from this study and NCDCM, Fig. 14
- Hurricane-induced erosion, Fig. 23
- Recent bathymetric map, Fig. 31; maps from 1854, 1925, and recent, Fig. 34

- Summary of effects of dredging, p. 860
- Conclusions:
  - Net longshore sediment transport is to the west
  - During hurricanes disposal area decreased longshore currents on beach
  - Progradation of ebb-tidal delta caused by dredging increases erosion at PKS
  - Dredging alters longshore currents from large storms and may increase erosion

Historical beach profile data set
- 1998. UNC. Bogue Banks historical beach profile data set; digital files provided by T.S. Roessler.
- 1978. USACE (Wilmington). Bogue Banks historical beach profile data set provided by Tom Jarrett

USACE/Pine Knoll Shores (PKS) — series of correspondence (various dates) — USACE. Correspondence between USACE-Wilmington, Pine Knoll Shores, Carteret County, and NCDEHNR contain the following relevant information.
- Cost-sharing documents provided by County show annual estimated cost of harbor-depth maintenance of $5,000,000 federal and $50,000 state. Sand is piped to Brandt Island, and is periodically pumped to nourish Atlantic Beach.
- Federal feasibility study is underway to determine whether federal navigation maintenance is eroding Bogue Banks (specifically Pine Knoll Shores). Expenditures on study to date total $54,000. Completion of study to cost $400,000 more, 50/50 federal/state cost split. Nourishment project estimated at $1,678,000 federal and $904,000 state costs.
- Proposed plastic pipeline plan for nourishing Bogue submitted by Bill Price to Carteret County. Feasibility of using small-diameter plastic pipe was evaluated by a rental company that has not performed beach nourishment. Phone check with a company specializing in beach nourishment confirms that the material and diameter would not withstand required pressure and stresses imposed by sand slurry.
- Series of correspondence between USACE-Wilmington, Pine Knoll Shores, and Sen. Helms provides the following information regarding possible use by PKS of sand dredged from the harbor and navigation channel:
  1) Option 1 is for direct pumping from Beaufort Inlet via ocean-certified dredge. Additional cost for 1 million cubic yards is estimated at $2.75-$4 million
  2) Option 2 is hoppers with direct pumpout capability with additional cost for 1 millon cubic yards at $4 million
  3) Option 3 is transport by pumpout hopper and later redistribution by dredge and pipeline, additional cost at $5-6 million
  4) Total available sand in harbor and range A (approach channel) is typically 1.6 millon cubic yards
  5) Corps says their surveys show stable or accretionary beaches for 6.5 miles west of Beaufort Inlet, since beach has been nourished
  6) PKS does not have full public beach access and is thus not currently eligible for 50/50 cost sharing of the additional costs under WRDA 1986
  7) Brandt Island disposal reaches capacity every 8-10 years and is not expected to be used as nourishment source again until 2002-4.
- State DEHNR cost-sharing with local governments for areas allowing public access can be up to 75% of non-federal costs for construction and 50% for preliminary studies and engineering. Typical state contributions in other NC beach nourishment projects ranged from $105,000 to $6,000,000. Detailed cost-sharing breakdowns with these other local governments are enclosed in the gathered materials.

APPENDIX G2. DIMENSIONS OF LITTORAL ZONE (Depth of Closure)

The dimensions of the active area of the littoral zone are of interest, since nourishment projects are supposed to move sediment from regions where it is not part of the beach system to locations where it will help build the active beach. If the nourishment sand were to simply be moved from one location to another within the beach system, then it is questionable whether such a project has a significant net value. To answer this question, standard coastal engineering practice is to determine the "depth of closure" where sequential beach profiles at the same location "close" to the same offshore location, indicating very infrequent motion.

Closure depth is sometimes erroneously referred to as the "depth of no motion" in some publications. The standard definition (Hallermeier, 1978) is the depth beyond which there is active seabed motion for an average of only 12 hours per year. This standard definition has been incorporated into the standard texts, such as the Shore Protection Manual (CERC, 1984).

To be confident of the results, we used several different methods of determining depth of closure. Described below are six methods, three of them computational methods using different wave databases, and three of them empirical geological evidence specific to this site.

1. From Nearshore Hindcast Wave Data

Closure depth is supposed to be computed from wave databases **nearshore**, that is in the general vicinity or depth at which closure is often found, typically in the 30 to 50 ft range. A de facto standard that has arisen is the 10-meter depth, for two reasons. The Corps of Engineers has its Phase III Wave Information Study stations at 10m depth. Also, the national field testing center for coastal engineering, the USACE Field Research Facility in Duck, North Carolina, has its permanent wave-measuring array at 10m depth. That station makes measurements of both waves and the resulting changes in beach topography, so tests of depth-of-closure methods are made with those data.

The data used in these computations were the Phase III 10m-depth hindcast waves at Stations 96 and 97 (USACE, 1983). Stations 95-97 are along Bogue Banks, with Station 97 for the western third, 96 the middle third, and 95 the eastern. Our project does not encompass nourishment for the eastern third. The 12-hour-per-year data were selected as the 80 highest readings out of the 58,440 predictions each year. This database averages all years during 1956-75, but does not include hurricanes. The 80th highest wave height was selected by interpolation between the tabulated bands and was determined to be 2.63m for Station 96 (mid-Bogue) and 2.47m for Station 97 (western Bogue). Wave periods were computed by weighting the periods in each height band by the number of occurrences in each band and produced 8.82 sec for #96 and 8.74 sec for #97.

There are two accepted equations for computing depth-of-closure:

(Hallermeier, 1978) $d_l = 2.28\ H_e - 68.5\ (H_e^2 / g\ T_e^2)$

(Birkemeier, 1985) $d_l = 1.75\ H_e - 57.9\ (H_e^2 / g\ T_e^2)$

where d_l is closure depth, H_e the extreme wave height (12 hrs/yr), T_e the associated wave period, and g the acceleration of gravity.

The latter method was determined from a study correlating measured waves with depth of observed motion at the North Carolina FRF site. Considering the proximity of that site to Bogue Banks suggests it is more appropriate for this project. Furthermore, the measurement methods were cruder and less accurate in the earlier study. The results from both equations in feet below MLW are:

Mid-Bogue:	Hallermeier 17.6 ft (5.38m)	Birkemeier 13.4 ft (4.08m)
Western Bogue:	Hallermeier 16.6 ft (5.07m)	Birkemeier 12.6 ft (3.85m)

2. From UNC Measured and Modeled Storm Waves

A University of North Carolina study (Roessler, 1998) shoaled the deep-water WIS database (Station 46, 1975-93) over bathymetry with the model RefDif. That work examined the resulting currents and potential sediment transport for the **average** wave conditions in that database. In addition to that main part of the study, certain storm wave conditions were modeled using brief visual measurements of the waves. The storm-wave input data were H = 3.0 m, D = 158 TN, and T = 15 sec. These storm waves were generated by the simultaneous combined distant departure of Hurricane *Bonnie* and approach of Hurricane *Fran*. Inserting these numbers in the two equations yields depth of closure of 21.5 ft (6.56m) (Hallermeier) and 16.4 ft (5.01 m) (Birkemeier).

3. From UNC Modeled Hurricane Waves

The same UNC study (Roessler, 1998) modeled the direct effects of Hurricanes *Bertha* and *Fran* for the conditions when they were in the immediate vicinity of Bogue Banks. These very brief extreme conditions produced results that varied somewhat along the study area, but which were fairly unvarying for the study area west of Atlantic Beach, with wave heights of about 7 m and period of 15 sec. (This result of 7m wave height is expected for the most extreme condition possible, because it is the highest wave that can possibly exist in the depths modeled, referred to as "depth limited".) The results from the two equations are 47 ft (14.44m) (Hallermeier) and 36 ft (10.96m) (Birkemeier).

4. Measured Closure Depths at Duck

The results presented thus far are predictions from equations, whereas measurements of both waves and resulting seabed motion were made at the reasonably close site of Duck, North Carolina (on the exposed open-coast Outer Banks close to the Virginia border). The results are reproduced here as Table G2-1 and Figure G2-1. Equation (1) in the table is Hallermeier and (2) is Birkemeier. Equation (3) is a simpler less accurate version of the Birkemeier equation. The results indicate a range of depths between 3.9 and 6.4m. These "ground truth" measurements appear to validate use of the Birkemeier equation results computed in Section 1 above for Bogue of 3.8 to 4.1m. It is expected that results for Bogue would be on the low end of the measured values at Duck, since Bogue is a south-facing beach protected from more of the wave climate than the east-facing Outer Banks site at Duck.

TABLE G2-1. Wave and limit depth data (from Birkemeier, 1985). [Note: 1 m = 3.281 ft]

Closure Estimate (1)	Wave Data: Date (2)	Wave Data: H (m) (3)	Wave Data: T (sec) (4)	Limit Depth (d_l) in Meters Below MLW: Measured (5)	Predicted (Eq. 1) (6)	Best Fit (Eq. 2) (7)	Best Fit (Eq. 3) (8)
1	08/20/81	3.3	10.2	4.0	6.8	5.2	5.2
2	10/12/81	2.7	6.8	3.9	5.1	3.8	4.2
3	10/31/81	2.3	9.3	4.3	4.8	3.7	3.6
4	11/14/81	3.9	12.9	6.4	8.3	6.3	6.1
5	11/25/81	3.0	8.4	5.0	6.0	4.5	4.7
6	01/01/82	2.9	10.9	4.8	6.1	4.7	4.5
7	10/12/82	2.4	12.0	4.2	5.2	4.0	3.8
8	10/24/82	3.8	10.8	5.2	7.8	5.9	6.0
9	11/23/82	2.5	14.0	4.3	5.5	4.2	3.9
10	12/13/82	3.7	10.0	6.1	7.5	5.7	5.8

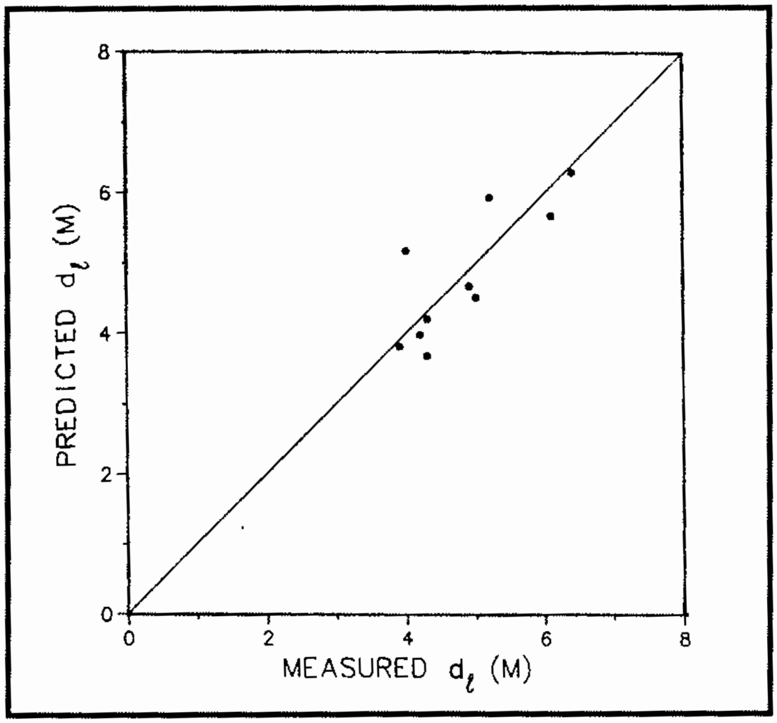

FIGURE G2-1. Best-fit comparison between predicted (Eq. 2) and measured d_l (from Birkemeier, 1985).

5. UNC Sediment Texture Study (Reed, 1997)

For this thesis, measurements were made of the color, texture, and size distribution of beach sand, shelf sand, and nourishment sand from Pine Knoll Shores to Shackleford Banks. The nourishment sand was from navigation-channel and harbor dredging projects by the Corps of Engineers. The excavation and delivery methods of the nourishment sand were similar to those proposed for this project, although the sand in the Corps project was significantly finer than that proposed in this project. Numerous surface grab samples enabled classification of sand type on the bed, and the results are reproduced here as Figure G2-2. The important point for this project is the solid line separating the native or replenishment sands from the shelf sands. The fact that the shelf sands are staying in place and not moving onto the beach in any quantifiable amounts suggests that the bounding line is one measure of the depth of closure.

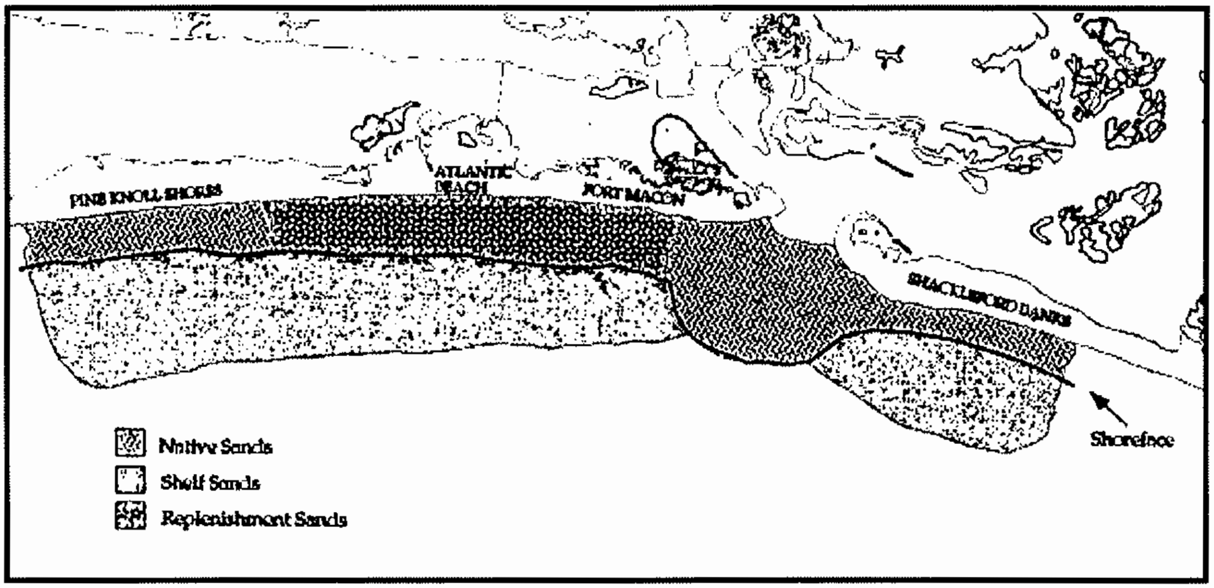

FIGURE G2-2. Interpretive map of offshore sediment distribution during the spring 1997 sampling period.

The figures in the thesis do not show bathymetric contours, so to estimate the bounding depths from the figures, we computed a scale conversion factor between the thesis figures and NOAA Chart #11543. Each 1.4 unit of distance on the NOAA chart equals 1 in the thesis figures, and this enabled us to determine depths of the solid bounding line at the following locations alongshore:

At the western end of the study area, d_l = 33 ft.
At the Pine Knoll Shores/Atlantic Beach border, d_l = 33 ft.
Along the line formed by the causeway to the mainland, d_l = 32 ft.
At the Atlantic Beach/Fort Macon border, d_l = 24 ft.

The latter two sites are east of and outside of the proposed project area.

The appropriateness of the contour data presented in Figure G2-2 for use in determining depth of closure is addressed in the thesis. Our professional opinion is that the data presented in the thesis are valid and useful and that the following opinions regarding their usefulness are incorrect and the result of misinterpretation of valid data (Reed, 1997, p. 66):

"The interpretive maps of offshore sediment distribution (Figures 17 A and B) may appear to indicate a closure depth, however this is only a result of the limitations of contour maps. . . . the stratigraphy of the cores (Cores #1-6), are better able to represent the history of sediment transport. Also, most sediment is transported offshore, past the designated "closure depth" during brief, but significant, storm events that are best recorded in the shallow stratigraphy and rippled scour depressions features."

In rebuttal to the three sentences above:

1) No evidence is presented in the thesis invalidating the results in the contour maps. Great care was taken in classifying the sediment types, and large numbers of grab samples allowed detailed delineation of sediment boundaries.

2) In three of the very small number of six cores taken, there are coarse shelly layers that are properly classified as to type of sediment, but their source is identified as "storm event" with no evidence to support that cause. Similar deposits were found in many of our core samples, which previous studies (Hine and Snyder, 1985) correctly identify as lag deposits from relict inlets and times of lowered sea level. No mechanism is identified in the thesis (e.g., computation of threshold velocities) for producing these deposits with current conditions.

3) The final sentence refers to sidescan sonar images collected by Thieler (1997), which identify linear ridges of coarser deposits. Those images of sand waves are consistent with the relict flows and conditions identified by Hine and Snyder (1985). Again, no mechanism is proposed in the thesis for causing these features under current conditions.

6. Non-motion of Nearshore Berm

The most conclusive hard evidence of the depth at which significant seabed motion occurs is the lack of motion of the Corps of Engineers' nearshore berm, a mound of dredged sediment disposed offshore of Atlantic Beach. The intended concept was to use the Beaufort Inlet navigation channel's dredged sediments for a beneficial purpose of feeding the beaches, rather than dumping the materials offshore in much deeper water where they would not move. Unfortunately, the originally intended placement depth of 18ft MLW was changed to 25-30 ft (USACE, 1994, p. 11), and the result from the monitoring survey is little motion, "little" meaning less than the error in survey methods. This confirms that **sediment deeper than 30 ft will not contribute to the beach** system.

Conclusions

1) Hindcast data of extreme (12hr/yr) conditions produce depths of closure between 13 and 18 ft MLW.

2) Measured storm conditions produce closure depths between 16 and 22 ft.

3) During the few hours that hurricanes are present in the immediate vicinity, closure depth has been computed as 36 ft.

4) The limit of sediment activity was measured at a nearby but more open-coast site at between 3.9 m and 6.4 m (13-21 ft).

5) Mapping sediment types by color, texture, and size result in a boundary between beach and shelf sands between 32 and 33 ft depths.

6) The Corps of Engineers nearshore berm off of Atlantic Beach in 25-30 ft depths has not exhibited significant motion and has not contributed sediment to the beach.

APPENDIX G3. WAVES

Databases of wave climate were utilized for the purposes of (1) characterizing the site, (2) use in final design of beach fill sections and berm heights, (3) use in computing potential longshore sediment transport (summarized in the next Appendix G4), and (4) changes in waves on the beach caused by dredging the borrow sites. Only the last item will be detailed here.

Several different estimates of the wave climate have been computed by the US Army Corps of Engineers over the years. All of these data have come from models relating offshore winds to the waves that they create. There is no wave database for the Bogue Banks area. As a measure of how inaccurate this method of computing waves from winds is, note that the resulting annual average sum of wave energy flux along the beach has changed direction, as the Corps uses different methods over the years for estimating the winds. Thus the current methods are incapable of resolving the question of total longshore wave-energy flux. Nevertheless, this database is thought to be somewhat more reliable for relative changes. That is, comparisons of percent changes in the same database under different scenarios are likely to be more accurate than the actual values of wave-energy flux.

The Corps' Wave Information Study data of waves computed from wind models is divided into separate data sets by: (1) location or "Station," (2) depth or "Phase," and (3) time period.

1) For the computations below, we used Station 45, which is the station directly south of Bogue (at 34° 15' latitude, 77° 00' longitude and 27 m depth). The next closest station, #46, is offshore of Atlantic Beach.

2) WIS data appear in three Phases. Phase I is in deep water. These waves are then refracted in to form the databases at the Phase II stations, typically in 20-30 m depths. Along some coasts data are refracted into Phase III stations at 10m depth. Up-to-date Phase III data for the Atlantic Coast do not exist. (The only Phase III data are in old reports using hindcast methods that are no longer used.) Thus we used the Phase II data for wave-energy computations.

3) Data have been hindcast for two time periods: 1956-75 and 1976-95. The two databases are not directly comparable, since different methods for estimating the winds and shoaling the waves were used. Furthermore, a statistical average of hurricane-generated waves were included in the 1976-95 database, but not in the earlier one. The wave-energy comparisons we made used the more recent 1976-95 database. We used this database to compare before-and-after dredging scenarios for the **relative** change in wave heights and energies. However, caution should be used in accepting the longshore energy fluxes computed from this database, since independent analyses (Reed, 1997; CERC, 1984, Table 4-7) suggest the longshore fluxes are unrealistically high.

The Automated Coastal Engineering System (ACES) program was used to shoal the waves from the offshore Phase II station 45 into the borrow areas. The subroutine "Linear Wave Theory with Snell's Law" was used. The main limitation of this program is that it assumes depth contours are straight and parallel. For the depths offshore of borrow area A this is a reasonable assumption, but is less so the closer to shore one approaches. The other main assumption is that wave data of different periods (or wavelengths) and direction can be shoaled separately and then recombined ("linear superposition"). Compared to the other assumption of parallel contours, this assumption is quite good for the depths we used in the model, since we did not shoal waves inshore of the innermost borrow area B. A graphical representation of the shoaling process is illustrated in Figure G3-1. Note that as the waves cross various depth contours as they approach the coast, the wave crests turn to become more parallel with the coast. As this happens, the wave heights (and energies), wave angles, and energy fluxes change.

Borrow area A is between depths 50 ft and 40 ft, and B is between 40 ft and 30 ft. Thus the first step was to shoal the WIS wave data from 27m (88.6 ft) to 50 ft. From CERC's website, the WIS datafile "au2percnt.045" was used as input. Only the directional bands from which it is possible for waves to approach Bogue Banks were used. WIS uses numbered bands to identify directions. Bands 6 through 12 produce waves that are within the half of the compass facing the beach. The angle of the shoreline for this application was measured as 171d for "shore normal" for the section of Bogue at borrow areas A and B-1 (approximately at the Salter Path/Emerald Isle border). Inputs into the shoaling model were the WIS statistics of mean wave height and period (Hmo and Tp), depth, wave directions, shoreline angle, and bottom slope from NOAA charts. Outputs for the wave conditions at the seaward side of borrow area A (depth of 50 ft) are shown in Table G3-1. As expected in these still relatively deep depths, wave heights decrease slightly, and energy flux remains constant.

The next step was to shoal waves over the existing topography in borrow area A. The results in Table G3-2 still show little change in total wave heights and energy flux.

The change in conditions if 6 ft of borrow area A is dredged is shown in Table G3-3. The results show a wave height increase of 0.2 ft, an increase in height of 2%, an increase in energy of 4%, and an increase in longshore energy flux of 9%.

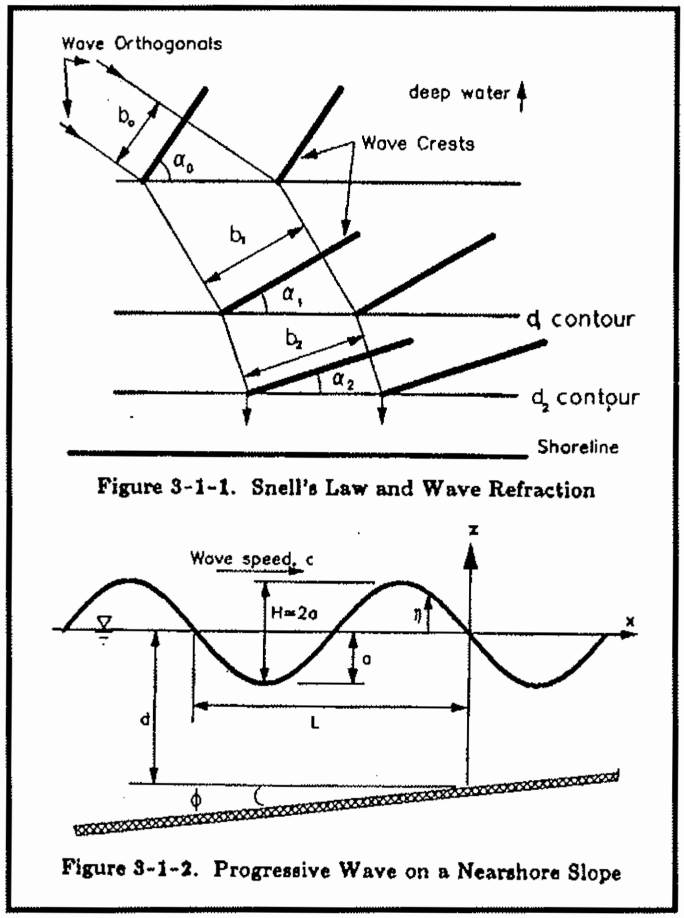

FIGURE G3-1.

The maximum dredging of borrow area A is not expected to be as large as 6 ft. That case was computed to show an extreme condition. The maximum anticipated dredging of the borrow area is 4 ft. The results for that scenario are listed in Table G3-4 and show a 1% increase in wave height of 0.1 ft, an energy increase of 2.5%, and an energy flux increase of 6%. Like the 6 ft scenario, this one should be viewed as unrealistically extreme, since the entire borrow area will not be dredged to this depth. Only localized areas within the delineated borrow area limits would experience this extreme of sediment removal.

The most realistic scenario for dredging is a 2 ft cut in borrow area A. The results in Table G3-5 show a 0.6% increase in wave height of 0.1 ft, a 1% increase in energy, and a 3% increase in energy flux.

To examine the effects of dredging the nearshore borrow areas B, the existing conditions in borrow area B1 were first computed and are listed in Table G3-6. Since the waves are now shoaling over shallower water, energy is being used in the shoaling process, and there are decreases in all relevant quantities of height, energy, and flux.

The maximum expected cut in borrow area B is 4 feet. The scenario of dredging B but not dredging A is investigated in Table G3-7. Results show less than 1% increase in wave height of less than 0.1 ft, a 1.5% increase in energy, and a 9% increase in energy flux.

The combined effect of dredging both borrow areas A and B is investigated in Table G3-8. The most likely scenario of dredging 2 ft in A and 4 ft in B was computed, and results show only 0.7% increase in wave height of less than 0.1 ft, a 1.5% increase in energy, and an 8% to 9% increase in energy flux. Note that the combined effect of dredging both borrow areas is **less** than the effect of dredging B alone. The reason for this is that the changes in topography caused by the dredging are spread out over a longer distance. The less abrupt change felt by the waves results in less change to the waves.

The final conclusions to this investigation are that:

1) Maximum anticipated dredging of the borrow areas will result in a **temporary** increase in wave heights at the landward edge of the borrow areas of somewhat less than 1% or less than 0.1 ft. The potential for longshore transport of sediment will also temporarily increase by several percent. The reason that these changes are temporary is that currents will smooth out the changes in topography by moving sand in the longshore direction to "even out" the changes.

2) Conclusions regarding the several percent increase in longshore sediment transport are suspect, because of the poor quality of the model wave data, illustrated by enormous changes in the wave database for different time periods and methods used by the Corps of Engineers in producing the Wave Information Study hindcast databases.

TABLE G3-1. Waves at the seaward edge of borrow area A (depth = 50 ft). Statistics for each directional band are listed, with the angle of wave approach shown as an azimuth (degrees clockwise of north). Statistics include wave height H, wave energy E, longshore energy flux P, the percent energy %E that each direction represents compared to the total energy, and the wave angle alpha (α). At the bottom right, the height H, energy E, and energy flux P are summed for the total values within the spectrum.

Shoaling from 88.6 ft to 50 ft depth. 1976-1995 (with hurricanes). Station 45. Shore normal = 171°. Filename SEA45U.OUT

TABLE G3-8. 4 ft cut in borrow area B, with 2 ft cut in A. "In" statistics are the waves at the seaward edge of borrow area A (depth = 50 ft), and "Out" are the waves at the shoreward edge of borrow area B (depth = 34 ft). Statistics for each directional band are listed, with the angle of wave approach shown as an azimuth (degrees clockwise of north). Statistics include wave height H, wave energy E, longshore energy flux P, the percent energy %E that each direction represents compared to the total energy, and the wave angle alpha (α). At the bottom right, the height H, energy E, and energy flux P are summed for the total values within the spectrum.

Shoaling from 42 ft to 34 ft depth (2 ft cut in A and 4 ft cut in B). 1976-1995 (with hurricanes). Station 45. Shore normal = 171°. Filename 34AB45U.OUT (uses borrow area A's 2-ft-cut output as input)

APPENDIX G4. LITTORAL TRANSPORT

Previous Transport Studies

Several studies have been performed by both the Corps of Engineers and the University of North Carolina to estimate the potential for longshore sediment-transport:

1) The Corps of Engineers 1976 study compared two time periods relative to Beaufort Inlet navigation-channel maintenance, before (1854-1936) and after (1960-1974). The results vary considerably over time, as shown in Table G4-1. But the overall results from the study concluded: (a) sediment transport is to the east (75%), (b) shoaling occurs more on the west side of the channel (68% of the channel shoaling), (c) bypassing efficiency of the inlet dropped from 52% to 28% after dredging, and (d) the net transport is about 14% of the gross. These results suggest that the dredged channel at Beaufort Inlet is blocking some (about half) of the longshore transport and that this impact should be felt more on Shackleford than Bogue, since net transport is to the east. The dataset used for these computations was a series of shipboard observations of winds, which in turn were used in models to predict the waves they create. The fact that this dataset was abandoned by the Corps several years later is an indication of its quality.

2) In 1990, the Corps of Engineers updated its previous study with a different set of wind data, but from the same time period of 1956-1975. That study concluded that (a) the gross transport rate was about 600,000 cy/yr greater than shown in the 1976 study, but (b) the net transport proportion was about the same as in the previous study, in this case 78% of the total or gross transport, and still to the east. Results are summarized below in Table G4-2.

TABLE G4-1. Results of the 1976 sediment budget analysis. [*Negative transport quantities indicate drift moving in opposite direction from assumed in the analysis. **Negative bypassing quantities indicate transport into the inlet by tidal currents. [From USACE, 1999]

1980-1988	1,130,000	328,000	898,000	−113,000

3) The Corps is currently performing an updated hindcast study, and results are not yet available.

4) Roessler (1998) performed a very similar study as the Corps, but used a very different set of wind data (the 1976-1993 Station 46 WIS dataset), a different wave-shoaling model (REF/DIF), and a slightly different set of digitized topographic data (UNC, 1998). He reached the following conclusions:

- **"Net longshore current velocity (and hence transport) in the study area is to the west.** Modeled fairweather and storm wave conditions based on USACE Hindcast Wave data indicated that the net longshore transport at eastern Bogue Banks is to the west."

- **"Although approximately 17 million cubic meters of sediment were removed from the active littoral system by offshore disposal, the offshore disposal area appeared to actually decrease both velocities and gradients in longshore current velocity during simulations of Hurricanes *Bertha* and *Fran* and potentially decrease erosion rates.** The offshore disposal area actually decreased longshore current velocities in some locations by up to 50 percent during Hurricane *Bertha* and up to 65 percent during Hurricane *Fran*."

- **"According to model results, the nearshore berm had a minimal effect on the refraction and diffraction of fairweather waves; however, during storm events the potential for cross-shore transport (perpendicular to the shoreline) was much greater.** REF/DIF results agree with USACE predictions that the nearshore berm will have a very limited effect on fairweather waves."

- **"Inlet orientation had only minor effects on wave refraction/diffraction processes during fair weather and storm conditions."**

- **"Although the offshore disposal area decreased gradients in longshore current velocity, the overall effect of dredging Beaufort Inlet, which caused the ebb tidal delta to prograde seaward, was to increase gradients in longshore current velocity during simulations of Hurricanes *Bertha* and *Fran*.** REF/DIF results suggested that the progradation of the ebb tidal delta of Beaufort Inlet caused by dredging likely increases erosion rates in certain locations of the study area including Pine Knoll Shores. During storm conditions, steeper gradients in longshore current velocity were predicted for the recent bathymetry when compared to model runs for bathymetry from 1854 and 1925. These steep gradients in longshore current velocities were reflected in the erosion and accretion patterns following Hurricanes *Bertha* and *Fran*."

- **"Eastern Bogue Banks is susceptible to high erosion from storm waves approaching from the south, and longshore current velocities are altered by the progradation of the ebb tidal delta of Beaufort Inlet when simulated storm waves approach from the southeast.** When large storm waves (greater than 4.5 m) approach Bogue Banks from a direction less than 137 degrees, calculated longshore current velocities are altered throughout most of the study area which can potentially lead to higher erosion rates. When storms waves approach Bogue Banks from between 140 and 179 degrees, calculated longshore current velocities are changed in the vicinity of Atlantic Beach and Fort Macon State Park which can also potentially increase erosion rates especially at eastern Atlantic Beach and Fort Macon State Park."

Transport Computations for This EIS

We performed a similar type of analysis of potential longshore sediment transport along Bogue Banks to:

1) Investigate the variation of the transport along the entire island. (The Corps and UNC studies were for Atlantic Beach, Beaufort Inlet, and Shackleford Banks, since those were the areas being considered for Corps dredging and nourishment projects.)

2) Determine the sensitivity of the results to data source. We compared the variation in transport results for the different WIS time periods (1956-75 and 1976-95) and for different stations (45 and 46), by using exactly the same procedures for both time periods and both stations.

3) Determine the sensitivity of the results to wave shoaling method (i.e., simple linear shoaling vs. models such as RCPWave that account for the effects of nonparallel seabed contours).

We calculated potential for longshore sediment transport for both time periods and both wind-data stations. In addition, computations were performed at several different stations along the island listed in Table G4-3. The angle of "shore normal" was measured from NOAA charts for each location. "Shore normal" is the azimuth angle perpendicular to the beach, as illustrated in Figure G4-1. We did not perform wave-shoaling computations as a part of these longshore transport computations, since the Corps had already done so, and our intention was to determine how much the results depended on whether the waves were shoaled. Longshore sediment-transport theory says that if the seabed contours are straight and parallel, then no shoaling is necessary, because the longshore energy flux will remain the same. The transports were computed using the Longshore Sediment Transport module in the Automated Coastal Engineering System (ACES). The wave data inputs were in "CEDRS" format as obtained from the WIS datasets on the US Army Corps of Engineers' Coastal Engineering Research Center's website.

TABLE G4-3 Shore normal from NOAA chart 11543.

	Longitude	Normal Azimuth
West end of Emerald Isle west	77°04.5'	162°
Mid Emerald Isle west	77°02.0'	165°
Mid Emerald Isle central	76°59.0'	169°
Mid Emerald Isle east	76°56.0'	169°
Salter Path/Emerald Isle boundary	76°54.0'	169°
Mid Salter Path/Indian Beach	76°53.0'	171°
Salter Path/Indian Beach/Pine Knoll Shores boundary	76°52.0'	170°
Mid Pine Knoll Shores West	76°51.0'	172°
Mid Pine Knoll Shores East	76°49.0'	172°
Pine Knoll Shores/Atlantic Beach boundary	76°47.0'	173°
Mid Atlantic Beach	76°45.0'	180°
Atlantic Beach/Fort Macon boundary	76°42.0'	187°

The results for each combination of ten locations along the island, two time periods, and two WIS stations are listed as the 40 longshore transport rates in Table G4-4. Using the standard sign convention for transport, for an observer standing on the beach, transport to his right is positive, to his left negative. For Bogue Banks, this means positive transport is to the west. The **results** can be summarized as follows:

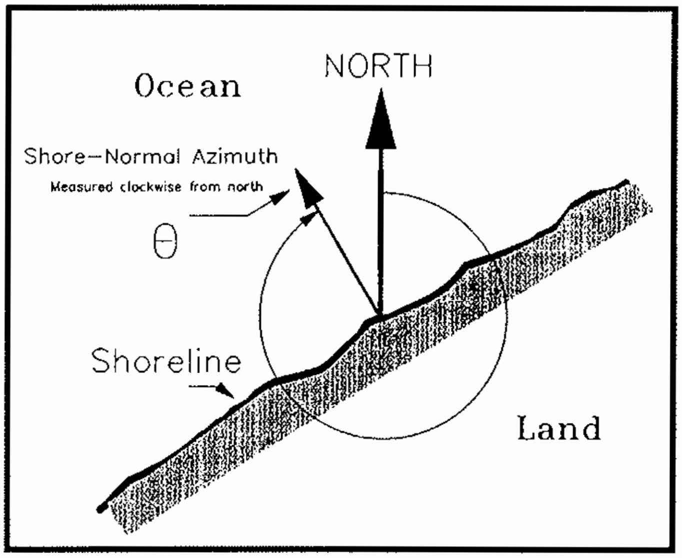

FIGURE G4-1. Definition diagram for shore-normal azimuth.

1) The results for the 1956-75 time period are directly comparable to the second Corps of Engineers study, which used the same input data. As found in the Corps study, the Station 45 data (directly south of Bogue Banks) generate longshore sediment transport **toward the east at every station** along the island. Numerical values decrease from a maximum 560,000 cy/yr at the west end of the island to 260,000 cy/yr at the eastern border of Atlantic Beach (next to Fort Macon).

TABLE G4-4. Longshore sediment transport rates from WIS hindcast data. Positive transport is to the west, negative to the east. Longitudes are in Table G4-3. [*No hurricanes. **Includes hurricanes.]

	Station 46		Station 45	
Location along Bogue Banks	**1956-1975***	**1976-1995****	**1956-1975***	**1976-1995****

Pine Knoll Shores/Atlantic Beach boundary	285,997	1,186,473	-258,183	938,429

2) For the same 1956-75 time period Station 46 data (southeast of Bogue Banks) generate transport which has **somewhat smaller transport values (about 20% less)** until a point in the middle of Atlantic Beach is reached. At that point the transport is essentially zero. East of that point the data generate results that are geologically impossible: transport is to the west. This would require sediment to be piling up in the middle of Atlantic Beach, which it is not. Most likely, the model is generating unrealistic results for eastern Atlantic Beach and Fort Macon, because of the nonlinear bathymetric topography in that area, which violates the basic assumption of the shoaling model. For

this station, the values range from a high of 450,000 cy/yr at the west end of Bogue Banks to zero in the middle of Atlantic Beach. [For the record, the results that we do not believe show: to the east of that point, transport is back to the west, increasing from the mid-Atlantic Beach nodal point of zero transport to 286,000 cy/yr westward transport at the border with Fort Macon.]

3) The computations for the time period 1975-95 are directly comparable to the University of North Carolina study, which used essentially the same database. (Since that study, the WIS data were changed only slightly by adding two more years of data during 1994-95.) As found in the UNC study, transport is **to the west everywhere** along the island (although the UNC study was only for the eastern half of Bogue). Our values of longshore transport for Station 46 (the same as used by UNC) ranged from a minimum of 551,000 cy/yr at the western end of Bogue to a maximum of 1,186,000 cy/yr at the Fort Macon border.

4) The results for the 1975-95 time using Station 45, directly south of Bogue, were qualitatively similar to the Station 46 runs, but the values **(all transport to the west)** ranged from a minimum of 350,000 cy/yr at the west end of the island to 938,000 cy/yr at the Fort Macon border.

Conclusions which can be made from these results include:

1) Error in the wave data results in inability to predict even the direction of longshore transport, since opposite directions are predicted for all locations, depending on which datasets are used.

2) Because of change in beach orientation, transport necessarily becomes more and more westward-directed as one progresses to the east end of Bogue.

3) Results are far more dependent on input wave data than on what wave-shoaling model is used, or even if a shoaling model is used at all.

4) Although different methods were used to determine the WIS wave data for the two time periods, the only significant difference in which winds were "counted" in modeling the waves was the presence of hurricanes. The 1956-75 datasets do not include hurricanes, whereas the 1976-95 datasets do. This may account for the change in predicted net transport direction for most of the island from eastward (1956-75, no hurricanes) to westward (1976-95, with hurricanes).

5) Other independent methods of determining longshore sediment transport, such as measuring dispersal of nourishment sand (Reed, 1997) show small values of net transport in the Atlantic Beach area. This places doubt on all the WIS hindcast results, which tend to show high transports.

APPENDIX G5. EROSION RATES

Erosion rates are important in determining environmental impacts for the following reasons:

- Nourishment volumes are computed so as to counteract the natural erosion for a specified number of years. Erosion rates are used in computing the needed nourishment volumes.

- The severity of erosion is the most important indicator of how fast detrimental impacts will occur to the economy and infrastructure, if the "no action" option continues.

- The rate of erosion will determine how long beneficial impacts will last for both humans and plant/animals (e.g., increased dry beach width for turtle nesting).

Estimates of erosion rates have been obtained from two types of data analysis: linear retreat of shorelines seen in aerial photographs, and comparisons of profile surveys of the beach. The latter method is far more accurate, but also far more expensive. The available data from both methods on Bogue Banks will be described below, but the best method of determining erosion (a comparison of two comprehensive surveys) is not possible, since there have not been multiple surveys of most of the island.

Most of the studies described below are comparisons of "lines" on aerial photographs. Typically, there are two such lines that are identifiable: a high-tide or "wet/dry" line and a dune or "vegetation" line. Regardless of which line is identified and compared between successive photograph dates, this linear shoreline change (ft/yr) must then be translated into a volumetric erosion/accretion rate in cubic yards per year (cy/yr). There are various rules of thumb for doing so, but site-specific determination of the conversion factor is more accurate than rules of thumb. The site-specific conversions are computed by comparing the two types of rates (linear and volumetric) for that site and then dividing the results to determine the conversion factor. This exercise was performed by the Corps of Engineers (USACE, 1976, p. C-10), and for Bogue Banks 1 ft/yr equates to 1.3 cy/yr.

Long-Term Linear Erosion Rates (COE & NCSU)

Several recent studies of aerial photography have been performed to determine recent erosion rates, but for long-term erosion there are two important studies, one conducted by an agency of the Corps of Engineers called the Beach Erosion Board in 1948, and a study conducted by North Carolina State University. The BEB study determined erosion along the entire island between the dates 1854 and 1933. Of course, this study did not use aerial photography, but instead relied on surveys by the National Ocean Survey of certain topographic contour lines. Starting from the eastern end of Bogue at Beaufort Inlet, the BEB measured erosion averaging 0.14 ft/yr for the first mile, 0.90 ft/yr of accretion for the next two miles, and 1.14 ft/yr erosion for the remaining 7 miles. The Corps of Engineers uses different rates from the BEB study, depending on the location of the proposed project. But clearly the most appropriate number for this EIS is the 1.14 ft/yr erosion for the island west of Atlantic Beach. Using the USACOE conversion factor of 1.3 over our project length of 88,760 feet results in an **erosion rate of 132,000 cy/yr during 1854-1933.**

NCSU measured locations of vegetation lines and wet/dry lines on aerial photographs from 1939, 1953, 1958, 1964, and 1971. The vegetation or dune-line results (USACE, 1976, p. B-15) for the long-term period of 1939-71 were 4.2 ft/yr erosion for the easternmost 32,000 feet of Bogue and 2.9 ft/yr for the remainder. Multiplying the latter rate by 1.3 and our project length of 88,760 feet produces an **erosion rate of 335,000 cy/yr during 1939-1971.**

Beach Erosion from Aerial Photos (COE & NCDCM)

North Carolina's Division of Coastal Management updates shoreline erosion rates from aerial photographs about every 6 years. Erosion maps for Bogue Banks are available for 1980, 1986, and 1992. The resulting erosion rates are computed as changes from the baseline set of photos from 1938. So the results are averages from 1938 until the update. We tabulated the 1980 and 1992 erosion rates for each of our beach-profile stations along the island for comparison. The plotted erosion/accretion values for the two time periods (1938-80 and 1938-92) are shown in the upper half of Figure G5-1.

The Corps of Engineers performed similar analyses in a study of effects of their dredging projects (USACE, 1999). They measured the changes in both types of linear indicators: the wet/dry line and the vegetation line. We tabulated these results alongside our survey results for use in computing nourishment volumes. The Corps' rates are plotted in the lower half of Figure G5-1.

Beach Erosion from Comparison of Surveys (COE & CSE)

Repetitive beach surveys, encompassing the entire littoral zone, are the best means of determining how much sand is lost or gained along the beach (NAS, 1995). Bogue Banks, unfortunately, does not have an extensive data base of historical surveys. One island-wide survey by the USACE in 1978 allowed comparisons to low-tide wading depth (~−4 ft NGVD) with 60 of our profile lines. USACE profiles were superimposed on our present surveys and analyzed for changes. By extrapolating profile cross-sections over one foot of shoreline ("unit width") or from one profile to the next, a measure of the sand volume change can be obtained. The two sets of profiles, plotted for the entire island, are presented at the end of this appendix.

Figure G5-2 presents our summary of **estimated volumetric rates**, based on best-available data (bold-faced values in Table G5-1).

All five of the methods described above were tabulated for each profile line (1-111) shown in Figures G5-1 and G5-2. Starting with profile line 1 at the western end of Bogue Banks and working east, we tabulate below the results for each of the island "reaches" (separated by solid vertical lines on both figures). Since volumetric methods are considered more accurate, the numbers from that method were generally selected as most appropriate. When those values differed drastically from the other methods, the method which most closely matched the volumetric method, namely the Corps wet/dry line, was selected. The selected value for each reach is in boldface in Table G5-1.

Clearly there are large discrepancies between individual methods and reaches. However, there are some trends. Generally, the Volume Change method and the COE Wet/Dry Line methods were consistent. The two methods that used vegetation lines over roughly the same time period were also consistent: the NCDCM 1992 and COE vegetation lines. Some choice had to be made as to the most reliable estimates for each reach.

The computed **volumes on each of the 111 profile lines are in Table G5-2**. The volumes are all relative to the Stroud survey baseline. Each profile volume computation was started at the listed "offset" distance from the baseline and ended at the listed "cutoff" distance from the baseline.

Plots of each profile are included at the end of this appendix in Annex G1.

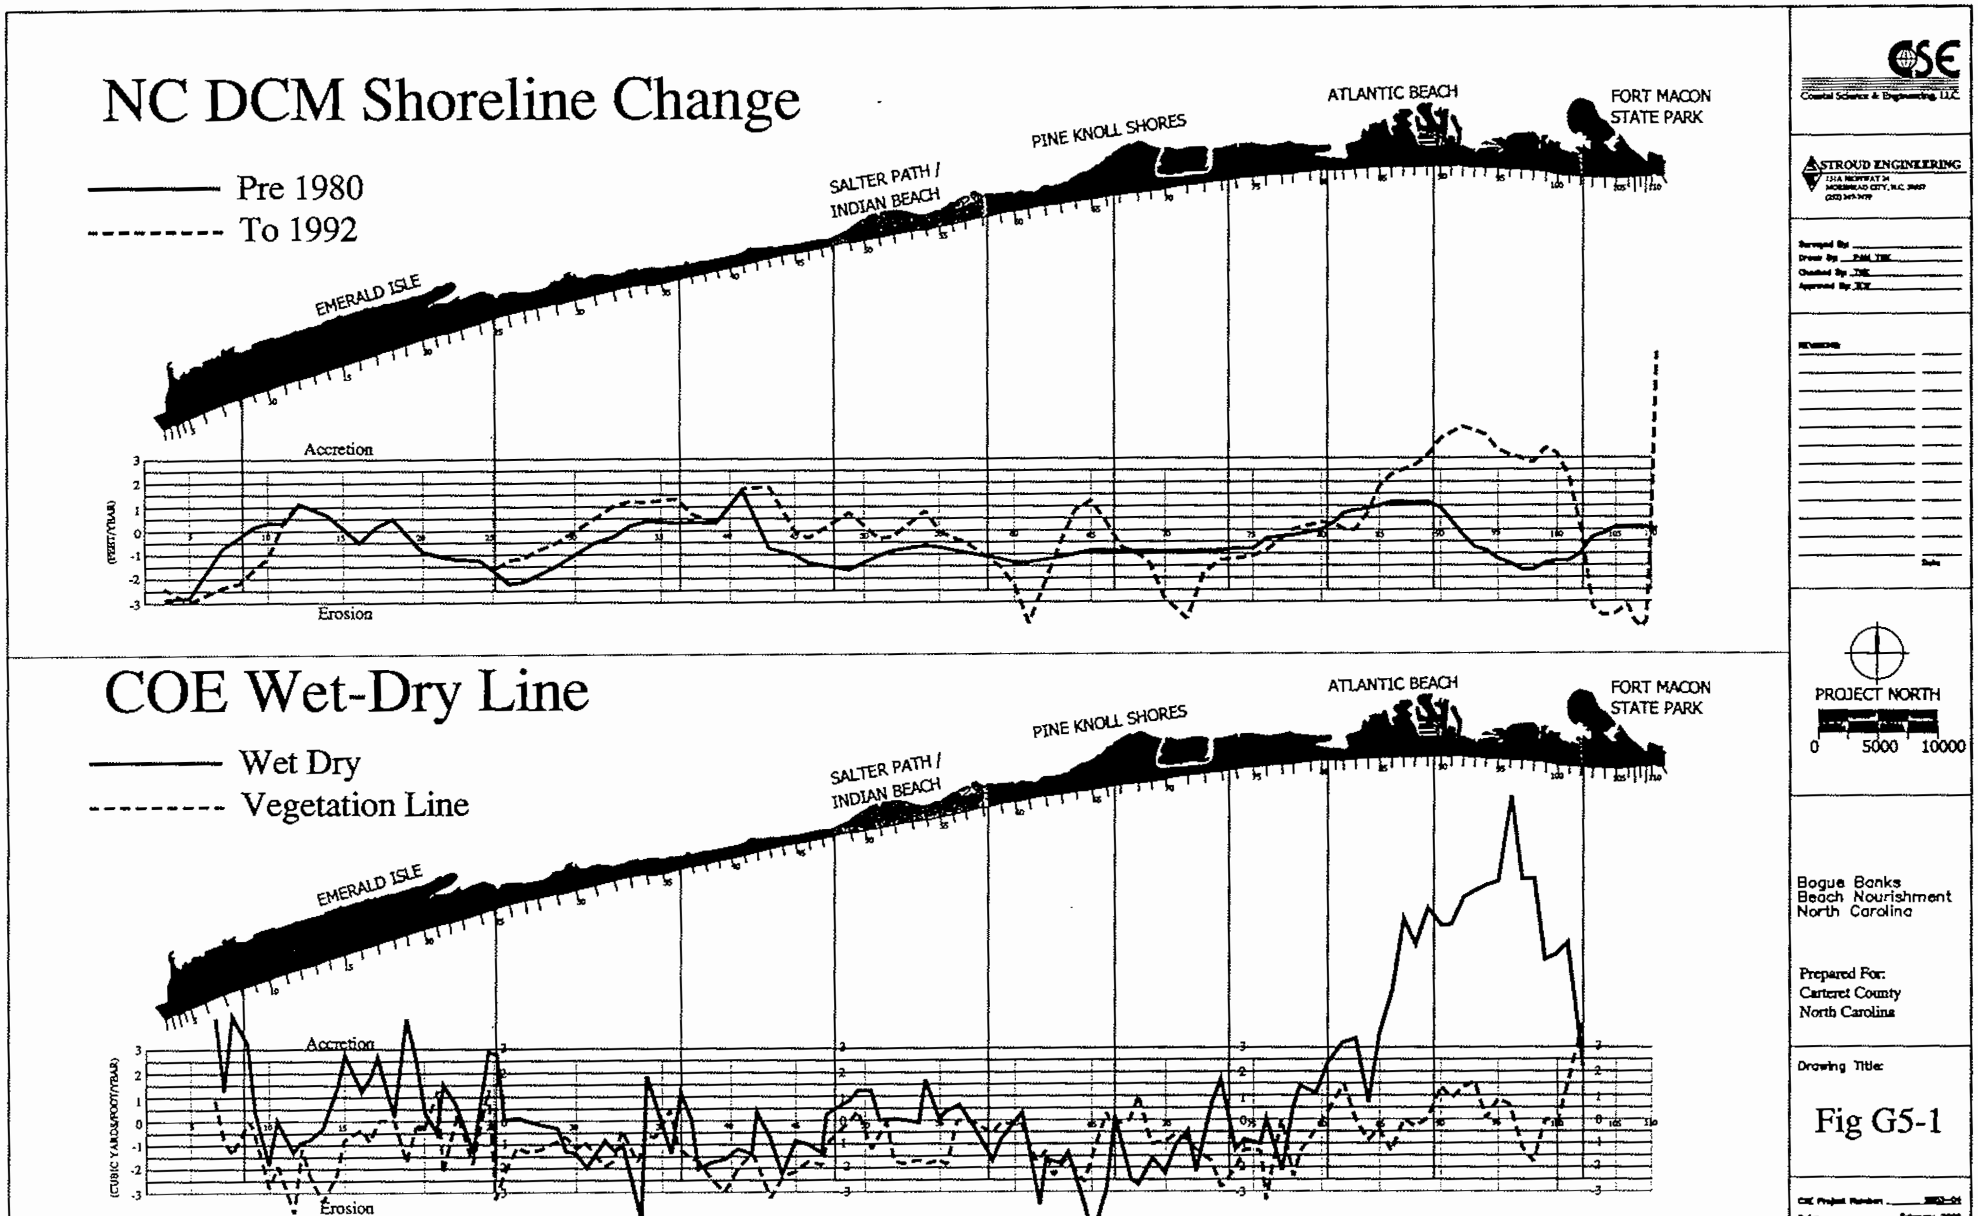

FIGURE G5-1. Linear shoreline change rates for Bogue Banks compiled by the State of North Carolina (upper) and the USACE (lower), based on analysis of aerial photography.

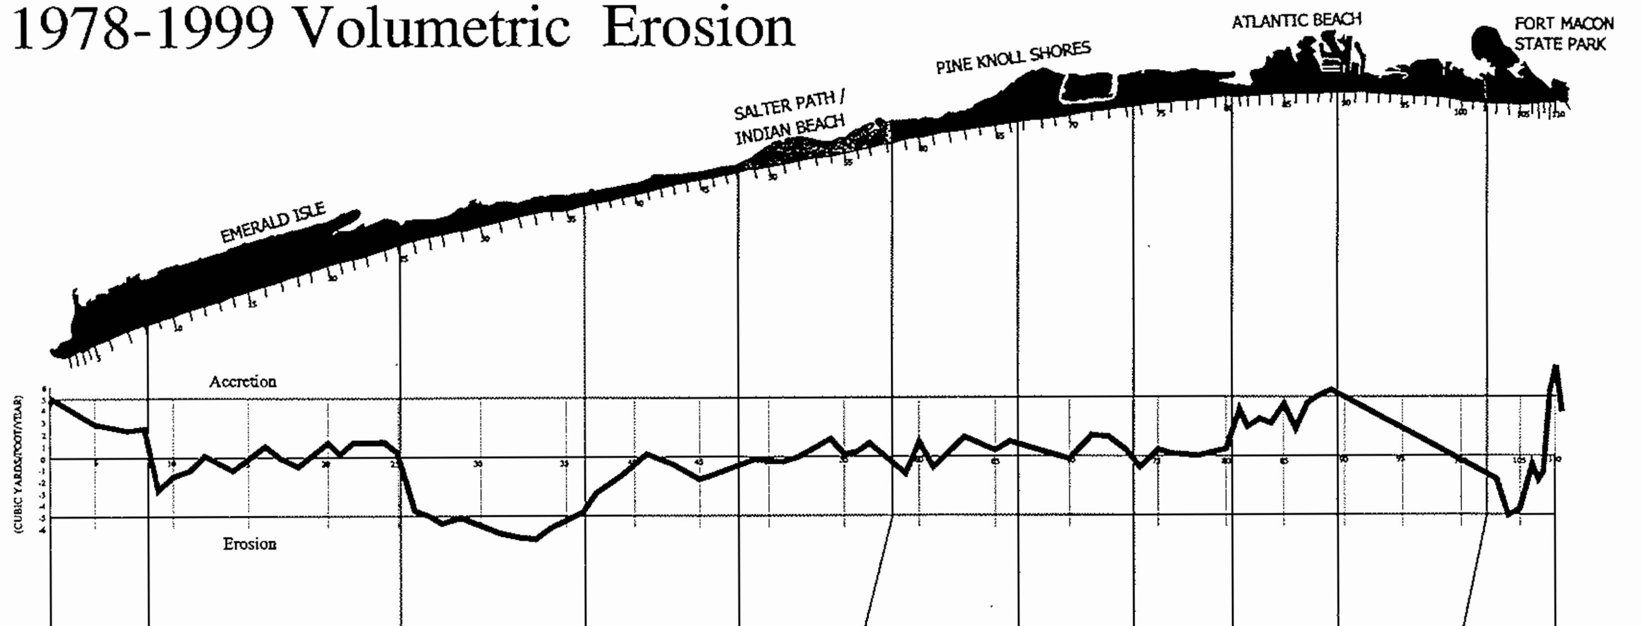
1978-1999 Volumetric Erosion



Accreting 3.15 cy/ft/yr	Very Slow Erosion 0.11 cy/ft/yr	Slow Erosion 0.78 cy/ft/yr	Moderate Erosion 1.62 cy/ft/yr	Stable	Slow Erosion 0.34 cy/ft/yr Note: Used NCDENR pre 1992 rates.	Stable	Moderate Erosion 1.87 ct/ft/yr	Very Slow Erosion 0.40 cy/ft/yr	Stable	Slow Erosion 0.88 cy/ft/yr Note: Used NCDENR pre 1980 rates.	Rapid Erosion 2.62 cy/ft/yr	Accretion
		Note: Difference in Corps baseline in this reach gives high erosion rates (above). Corps Wet/Dry line analysis used instead.						With Continuing Corps Nourishment: Stable	Accreting 3.79 cy/ft/yr	Accreting 3 to 9 cy/ft/yr

Beach Erosion Analysis used to determine Nourishment Requirement

Significantly, up to four data sources confirm relatively low rates of shoreline change over the past 5-20 years. Highest erosion rates were found for the following areas: Fort Macon State Park, Pine Knoll Shores, and Emerald Isle-East. Some reaches were found to be stable, meaning only minor erosion or accretion (e.g., Emerald Isle-West, Salter Path/Indian Beach), and some were accreting (e.g., Emerald Isle-Inlet and Atlantic Beach due to nourishment).

Similarly, where no comparative data are available, the "profile volume" can be calculated between reference contours by extrapolating a two-dimensional cross-section over a particular length of beach. Figure G5-3 illustrates the concept and shows how some sections may have less than or more than the normal volume of a viable healthy beach in a particular area.

Profile volumes were computed for several representative portions of the active beach:

- *"Dry beach"* from the base of the foredune/seawall to approximately mean high water (+9 ft to +2.5 ft NGVD).
- *"Wet beach"* to wading depth (from +2.5 ft to -5.0 ft NGVD).
- *"Underwater"* to the outer bar (from -5.0 ft to -10 ft NGVD).

These standard boundaries allowed comparisons of beach condition from place to place and helped identify specific reaches where there was less sand than desirable for a "healthy" beach.

Figure G5-4 shows the variation in sand volumes to low-tide wading depth in relation to the average for the entire island. Thus, 1.0 represents the average volume, 0.5 means there is only half as much sand in that beach area, and 1.5 means there is one and one-half times as much sand as average. While Figure G5-4 reflects considerable variation from place to place along the shoreline, it is obvious that most of Emerald Isle, Indian Beach, Salter Path, and Pine Knoll Shores have less than the average beach sand volume. These differences are easier to visualize when groups of profile lines are averaged as in Figure G5-5.

For purposes of preliminary planning, we used historical erosion rate data, profile volumes, and political boundaries to delineate nine shoreline reaches, varying from about one mile in length (state park) to about five miles in length (Emerald Isle-West and Atlantic Beach). Figure G5-5 shows the average profile volume by reach between the foredune and -10 ft contour (to the outer bar). The dry beach volume is reflected in the upper portion of each bar, and the wading zone is reflected in the middle portion.

The island-wide trend is apparent with two reaches standing out as the "healthiest" at present--Emerald Isle-Inlet and Atlantic Beach. The western end of Emerald Isle (profiles 1-8) generally has a wide dry-sand beach, broad low-tide terrace, and shallow water nearshore associated with the ebb-tidal delta of Bogue Inlet. Its typical volume to -10 ft is at least twice the average for the island. Atlantic Beach has considerably more sand in the profile at all contour intervals, reflecting the effect of repeated beach fills by the USACE in recent years. The state park and Pine Knoll Shores-West contained the lowest sand volumes along the project shoreline.

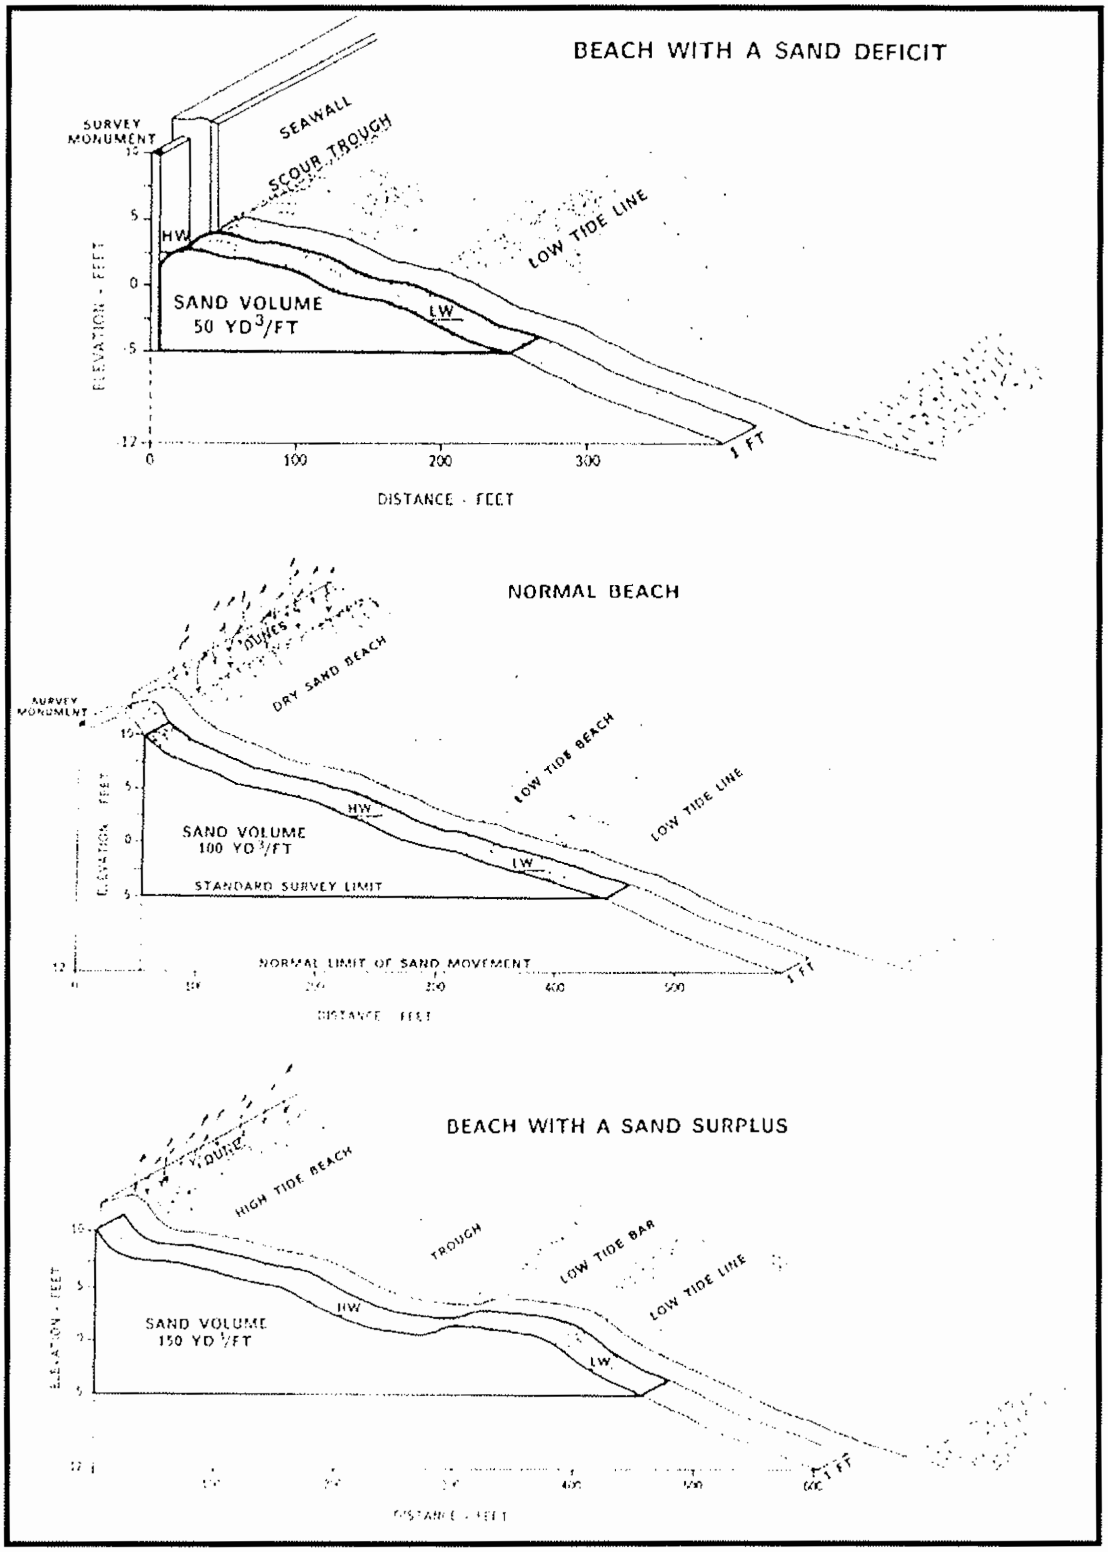

FIGURE G5-3. The concept of profile volumes (i.e., the sand volume contained in a unit length of shoreline between the dunes/seawall and representative underwater contours). In the absence of comparative data, profile volumes provide an objective measure of the beach condition from one place to another. [From Kana, 1990]

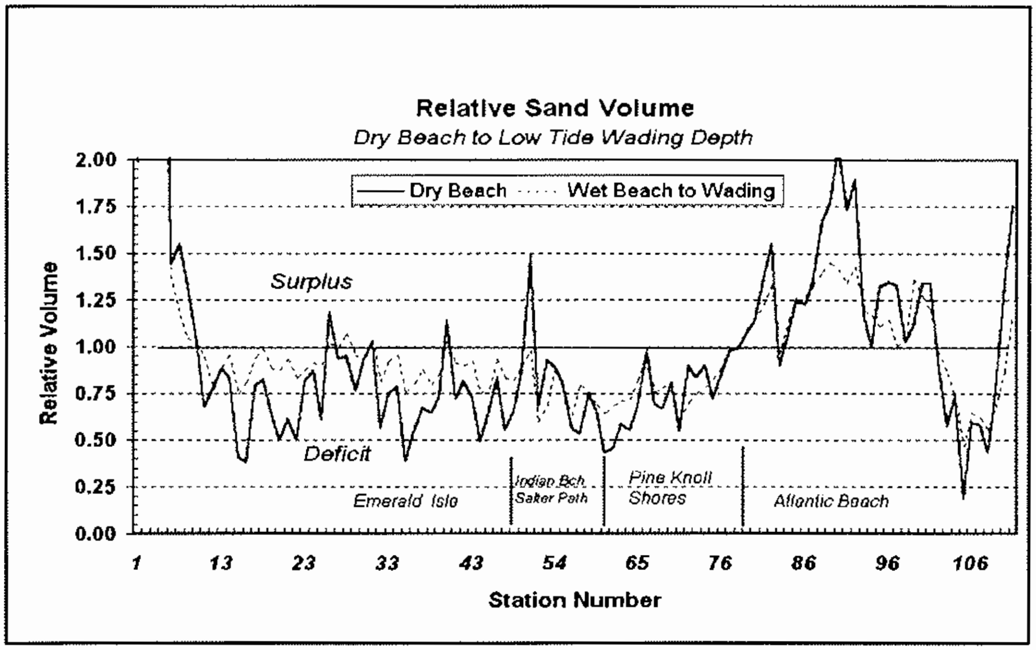

FIGURE G5-4. Relative sand volume on the beach between the foredune and low-tide wading depth from Bogue Inlet (profile 1) to Beaufort Inlet (profile 111). The average for all profiles is 1.0. A value of 0.5 means that point along the shoreline contains half as much sand as the average. A value of 1.5 means the area contains 1.5 times the average. Numerous factors produce variations in beach volumes, including rhythmic shoreline topography, dune scraping, encroachment of shore-protection structures, etc.

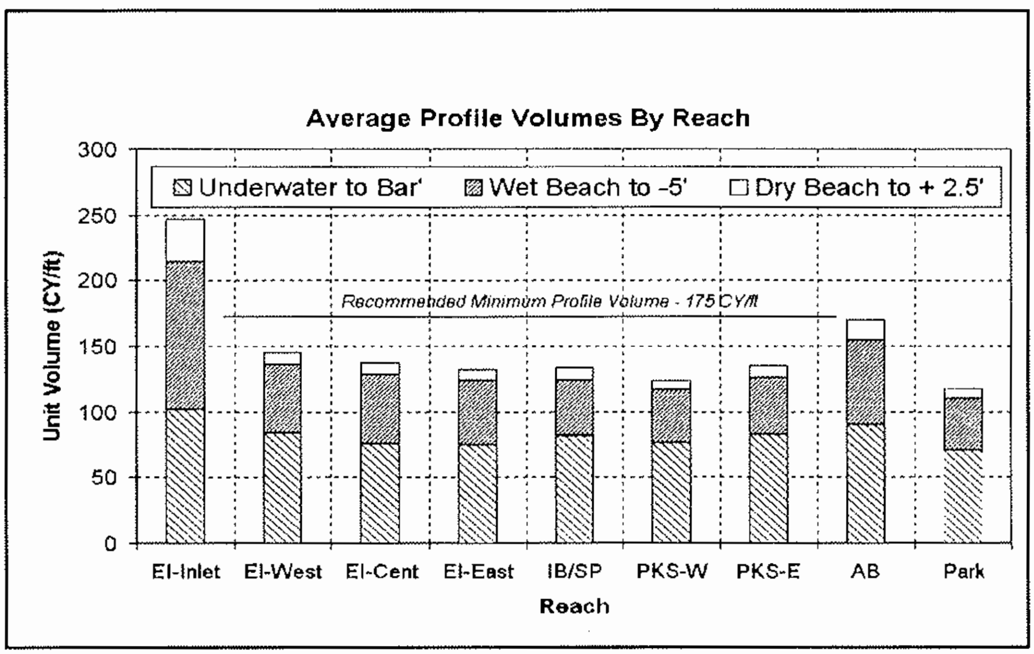

FIGURE G5-5. Average profile volumes by reach along Bogue Banks in June 1999.

If profile volumes reflect the condition of the beach from place to place (assuming similar sediments and exposures to waves and currents), they can be used to quantify sand deficits with respect to some ideal beach condition. A number of analytical and numerical techniques are generally used to define a healthy beach/dune profile for a particular level of storm protection. Erosion models, such as S-BEACH used by the USACE, allow prediction of the expected sand volume losses or dune recession during storms of a particular size. While these models are important design tools and should be a part of any final analysis, they are limited by the availability of coastal process data which are needed to "drive" the models.

For this preliminary study, which was budget-limited, we used an empirical approach for estimating an ideal "minimum" profile volume. We located Bogue Banks profiles where there was more-than-average sand volume and reviewed the beach and backshore conditions for evidence of long-term stability, wide berms for recreation, and extra sand nearshore. We also obtained hurricane erosion data for *Bertha* (June 1996) and *Fran* (September 1996) which showed short-term sand losses to low-tide averaging ~8-15 cubic yards per foot (cy/ft). [Note: This range was also confirmed by re-surveys of 18 of our profile lines after Hurricane *Floyd* during the week of September 20, 1999.] Based on these criteria, we established a threshold minimum profile volume of 175 cy/ft (Fig. G5-5). While this is not a value based on determination of a particular level of storm protection, it is one that reflects the site-specific conditions of Bogue Banks. Based on experience elsewhere, it reflects a level which we believe will provide adequate protection for ~10-year return-period events.

Once a minimum profile volume is established, it is a straightforward procedure to compute the volume deficit at each point along the shoreline. Figure G5-5 shows that, on average, six reaches fall below the minimum volume--Emerald Isle-West, Emerald Isle-Central, Emerald Isle-East, Indian Beach/Salter Path, Pine Knoll Shores-West, and Pine Knoll Shores-East. Atlantic Beach, on average, presently contains nearly the minimum sand volume and can be used as a practical guide to what other reaches would look like if they were nourished as proposed in the present plan. By extrapolating the volume deficit over representative shore lengths, a measure of **initial** fill-volume requirement is obtained.

The actual amount of nourishment recommended consists of **three components**. It begins with the **volume deficit** and then takes into account the long-term **erosion** rate and the **quality of borrow area** sediment. For the present study, our team provided estimates of the additional sand needed over a 5-year, 10-year, and 20-year period to accommodate background erosion. These amounts were calculated by applying the site-specific erosion rates shown in Table G5-1 over the representative time periods. A final adjustment was made to account for variations in the quality of borrow material. For example, a borrow area with a fill ratio of 1.1 will require about 10 percent more nourishment than the volume requirement; a borrow area with a fill ratio of 2.0 will require twice as much nourishment. While these adjustments may seem confusing at first, they are important because of the wide differences in performance of various borrow areas. This last adjustment puts projects using alternate borrow areas on an equal basis and allows fairer comparisons of cost. For example, one million cubic yards of sand that have a fill ratio of 1.1 will perform much better than two million cubic yards that have a fill ratio of 4.0. Unfortunately, differences in borrow material quality are often ignored, leading to widely varying opinions regarding project performances.

In short, we developed a detailed beach condition survey, historical erosion rate data, and borrow area sediment quality data to establish:

- Initial profile volume deficit for six reaches.

- 5-year, 10-year, and 20-year volume requirements to accommodate the long-term background erosion.

- Additional nourishment volume for each borrow area to provide the equivalent performance of native beach sediments.

Implications of the Analysis

The present study confirms a moderately large sand deficit along much of Bogue Banks compared to an "ideal" minimum healthy beach. It also confirms relatively low average erosion rates during the past ~20 years, although the quality of historical data is only fair. We did not locate any data which could be used to quantify changes in erosion rates over time or demonstrate accelerated erosion as a result of recent hurricanes. Nevertheless, empirical evidence suggests that the beach has not recovered from erosion produced by *Bertha*, *Bonnie*, and *Fran* and that it remains in a deteriorated state. (The dry beach and foredune were further eroded during *Floyd* as this report was being finalized.) Although there are insufficient data to prove a cause-and-effect relationship between Corps dredging projects and erosion, some evidence from academic studies (Roessler, 1998) does show the following effects:

- Increased flow through the inlet and thus increased transport of sediment into the harbor.
- Alteration of currents at Atlantic Beach and Pine Knoll Shores.
- Periodic removal of sediments from the littoral system by dredging (sand that would otherwise eventually end up on the beach).

To determine any erosion caused by dredging requires wave-and-current data for computing longshore sediment transport.

The shoreline data that we have examined do support several conclusions:

1) Net longshore transport rates are low along Bogue Banks, otherwise there would be large-scale variations in the erosion rates from one place to another and larger accumulations of sand near Bogue Inlet.

2) Net transport is to the west along Emerald Isle, producing accumulation at Bogue Inlet.

3) Net transport rates and directions along Atlantic Beach remain uncertain.

4) Pine Knoll Shores is eroding at a higher rate than adjacent reaches and may be supplying sand to Salter Path as well as to Atlantic Beach, acting as a zone over which net transport approaches zero.

FINDING OF NO SIGNIFICANT IMPACT

MOREHEAD CITY HARBOR
SECTION 933

CARTERET COUNTY, NORTH CAROLINA

August 2003

SYLLABUS

The removal of 6,300,000 cubic yards of maintenance material from Brandt Island Upland Disposal Area as well as the maintenance dredging at Morehead City Harbor has created an opportunity for beneficial use of sand for the Carteret County beaches. The beach communities of Pine Knoll Shores, Indian Beach, and Salter Path are experiencing severe storm damage and erosion problems, particularly as a result of Hurricane Fran in September 1996 and Hurricane Floyd in September 1999. During the period from 1996 through 1999, Hurricanes Bertha, Bonnie, Dennis, and Irene have also affected the area. The storm damage and associated erosion from six named storms has resulted in considerable damage to homes and loss of the natural protective berm and dune system since 1996. The erosion of the berm and dune system has also increased and continues to increase the storm damage susceptibility of existing structures and infrastructure. The placement of sand from Brandt Island and Morehead City Harbor on these beaches would reduce the potential for erosion and storm damages.

This report presents two areas of beach placement to take place in conjunction with the Winter 2003/2004 Morehead City Harbor maintenance dredging and Brandt Island pumpout activities. The base disposal area is 100% fully funded by the Federal government and covers approximately 32,000 feet of Atlantic Beach and Fort Macon. If the Section 933 Project is implemented, the Base Disposal Plan will be modified from its 150-ft berm width to a 30-ft berm width; this is referred to as the Base Disposal Plan under the Section 933 project. This base disposal area under the Section 933 project will receive 1,834,000 cubic yards of sand. The area nourished with Federal/Sponsor cost sharing under the authority of Section 933 includes approximately 38,000 feet of shoreline along Pine Knoll Shores, Indian Beach, and Salter Path. The Section 933 project area will receive approximately 4,466,000 cubic yards of sand to construct a 30-ft berm width to an elevation of 7 feet above NGVD.

For the 38,000 feet of Pine Knoll Shores, Indian Beach, and Salter Path, where evaluation is required under Section 933, potential storm damage reduction benefits were analyzed. Expected annual hurricane and storm damages are reduced by 62 percent with the Section 933 project. Evaluating the Section 933 project over a twenty-year period of analysis, the total expected annual benefits (including incidental recreation) are estimated to be $10,655,000, whereas the equivalent expected annual increase in cost for placement of material along the Section 933 project area is $2,178,000. Thus, the net benefits would be $8,477,000 and benefit-cost ratio for the Section 933 project area is 4.9.

Based on the findings in this report, Carteret County is eligible for 65% Federal and 35% non-Federal sponsor cost sharing for the added cost of depositing dredged navigation material on the beaches of Pine Knoll Shores, Indian Beach, and Salter Path, under authority of Section 933 of PL 99-662.

The added cost of placing this quantity of material on the beach rather than in the base disposal plan area is estimated to be $16,354,000, of which $10,630,000 would be paid by the Federal Government and $5,724,000 contributed by non-Federal interest.

EVALUATION REPORT
AND FINDING OF NO SIGNIFICANT IMPACT

MOREHEAD CITY HARBOR SECTION 933
CARTERET COUNTY, NORTH CAROLINA

SECTION I - INTRODUCTION

The purpose of this study is to investigate the beneficial placement of dredged maintenance material from the authorized pump out of Brandt Island confined dike disposal area, and the maintenance dredging of the Morehead City Harbor navigation project, both of which are scheduled for the Winter of 2003-2004. This study analyzes the deposition of this dredged material along a portion of Bogue Banks beaches beyond the Corps' Base Disposal Plan, referred to as the "Section 933 Study Area" (Figure 1).

The Section 933 Study Area must be assessed for hurricane and storm damage reduction needs. This study also develops a plan of protection for this area based on the economic, engineering, and environmental feasibility, as well as the requests of the local sponsor.

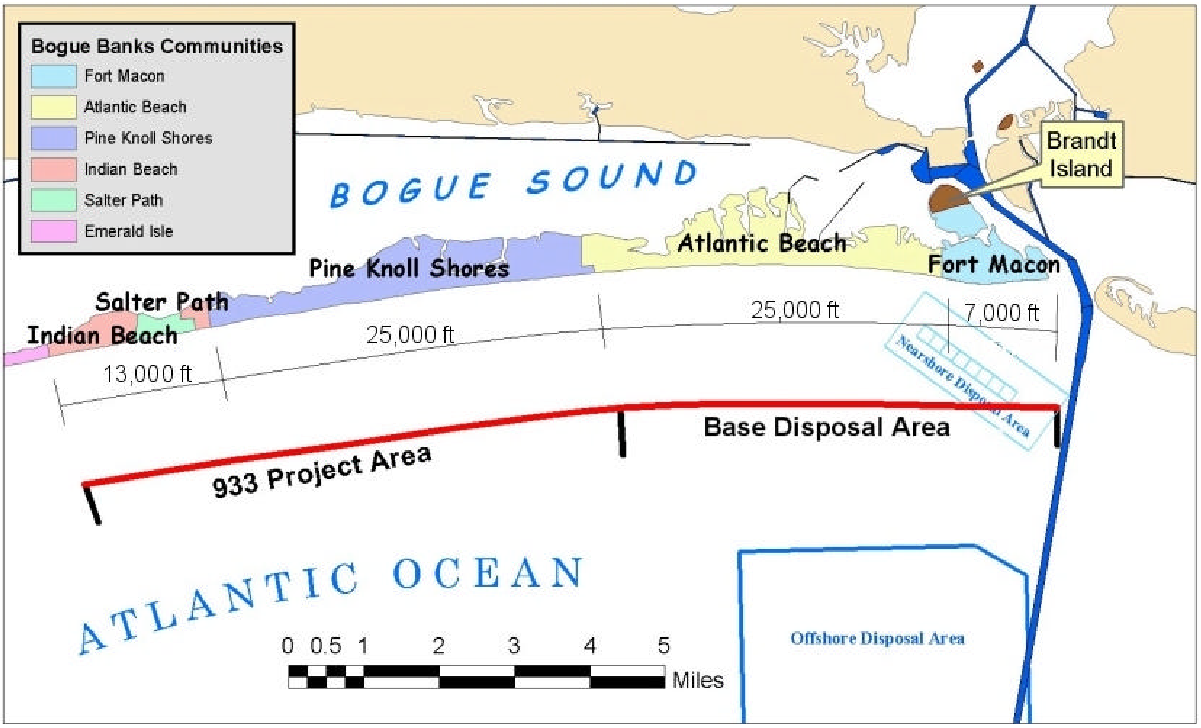

Figure 1. Morehead City Harbor Section 933 Study Area and Base Disposal Plan Area

Carteret County beaches are located on the central North Carolina Coast (Figure 2). The section of beachfront requested to be investigated for the beneficial placement of dredged material for hurricane and storm damage reduction needs includes the resort communities of Pine Knoll Shores, Indian Beach, and Salter Path. This 7.2-mile-long shoreline reach is eroding due to hurricane and storm action. A minimal berm exists along most of the Study Area, resulting in the dune system being frequently inundated during moderate energy events. Numerous structures in this area are highly vulnerable to damage by storm action due to the eroded dune system and loss of natural protection.

Based on analyses conducted during this study, the beneficial placement of dredged material for hurricane and storm damage reduction along the 7.2 miles of Pine Knoll Shores, Indian Beach and Salter Path was determined to be economically justified using a uniform 30-ft berm design width. The sponsor had requested the distribution of the dredged material to be placed in a uniform 30-ft berm design width stretching from Fort Macon to the Indian Beach/Emerald Isle border. Only those areas beyond the Base Disposal Plan are required to be studied and justified as part of the Section 933 project.

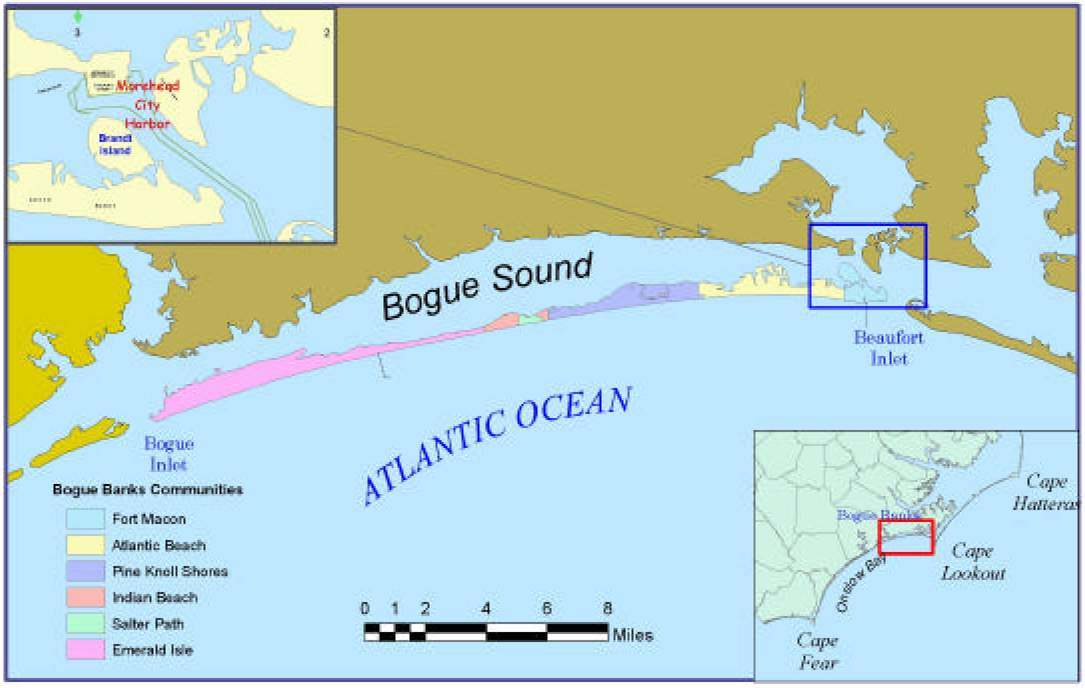

Figure 2. Morehead City Harbor Section 933 Location Map

NON-FEDERAL SPONSOR

In a letter dated February 22, 2001, (see Appendix A, Exhibit 1) the State of North Carolina stated that they supported the interest of Carteret County in a study for a potential Section 933 Project for use of dredge maintenance material from the authorized pump out of the Brandt Island disposal area and dredging of Morehead City Harbor navigation channels, scheduled for 2003-2004, onto Bogue Banks beaches. This letter was produced on behalf of Carteret County that had passed a resolution on January 22, 2001 requesting a Section 933 Project to place this material onto the beaches of the Towns of Pine Knoll Shores and Indian Beach, and the Village of Salter Path (see Appendix A, Exhibit 2).

In their January 6, 2003, letter to the Wilmington District, Carteret County stated their commitment to acting as the cost-sharing sponsor for this Section 933 project (see Appendix A, Exhibit 3).

STUDY AUTHORITY

This study was conducted under the authority of Section 145 of the Water Resources Development Act of 1976, P.L. 94-587, as amended by Section 933 of the Water Resources Development Act of 1986, P.L. 99-662, and other laws, 33 U.S.C. § 426j. Projects carried out under this authority are commonly referred to as "Section 933 projects." The primary study emphasis was directed toward hurricane and storm damage reduction measures at Pine Knoll Shores, Indian Beach and Salter Path. The guidance for this study authority is:

ER1105-2-100, Section II, E-14(h), 22 April 2000:

> "Placement of Dredged Material on Beaches for Hurricane and Storm Damage Reduction. When placement of dredged material (beach quality sand) on a beach is the least costly acceptable means for disposal, then such placement is considered integral to the navigation project and cost shared accordingly. In cases where placement of dredged material on a beach is more costly than the least costly alternative, the Corps may participate in the additional placement costs when: (1) requested by the State; (2) the Secretary of the Army considers it in the public interest; and (3) the added cost of disposal is justified by hurricane and storm damage reduction benefits.
>
> When all local cooperation requirements are met the Corps may cost share the additional 65 percent (Section 933, WRDA 1986, as amended). In cases where the additional costs for placement of the dredged material is not justified, the Corps may still perform the work if the State requests it, and the State or other sponsor contributes 100 percent of the added cost. If the State requests, the Corps may enter into an agreement with a political subdivision of the State to place the sand on its beaches, with the subdivision responsible for the additional costs. The Corps should consider and accommodate to the degree reasonable and practicable a State's or subdivision's schedule for providing its cost share. Each placement event should be supported by a separate decision document. Subsequent decision reports may be supplements to the original Section 933 decision document."

SCOPE OF STUDY

This report presents the results of studies conducted to address the needs for the placement of dredged material for hurricane and storm damage reduction for Carteret County beaches. The study area is shown on Figure 1. Study emphasis was placed on hurricane and storm damage reduction measures for the 7.2-mile-long Study Area as requested by the local sponsor. This area includes the communities of Pine Knoll Shores, Indian Beach and Salter Path. This report is submitted in compliance with Section 933 of WRDA 1986, as amended and Engineer Regulation 1105-2-100 quoted in the "Study Authority" section of this document.

The congressionally authorized Feasibility Study of Bogue Banks (Atlantic Beach, Pine Knoll Shores, Indian Beach, Salter Path and Emerald Isle) will investigate the long term shore protection needs for those beach communities and will be conducted as a separate study and reported later. Carteret County is the non-federal sponsor for this study.

PRIOR STUDIES

There have been several prior studies in the study area and adjacent waters by the Wilmington District. These studies, listed below, include three shoreline studies, two navigation studies and a shoreline mitigation study.

House Document No.555, 87th Congress, "Fort Macon - Atlantic Beach and Vicinity, North Carolina," dated 1961. This report presents the results of an investigation of beach erosion along the Fort Macon - Atlantic Beach shoreline by the Wilmington District.

House Document No. 93-121, "National Shoreline Study," dated 1970. This report, approved by Congress in 1970, presents the results of an investigation of the nations' shorelines as part of a comprehensive study to address shoreline conditions including shoreline ownership, property values, and shoreline changes (eroding, stable, or accreting).

Wilmington District report, "Beaufort Inlet to Bogue Inlet, North Carolina," dated 1965. This report presents the results of an investigation of beach erosion along the Bogue Banks shoreline by the Wilmington District.

House Document No. 92-170/92/1, "Morehead City Harbor, North Carolina," dated 1970. This report presents the results of an investigation to deepen the project to 40-feet Mean Low Water (MLW).

Report of the Chief of Engineers, "Morehead City Harbor, North Carolina," dated 1991. This report presents the results of an investigation to deepen the project to 45-feet MLW.

Wilmington District Section 111 Feasibility Report, "Morehead City Harbor (Pine Knoll Shores), North Carolina," dated 2001. This report presents the results of an investigation of shoreline mitigation for the Morehead City Harbor Navigation Project.

EXISTING FEDERAL PROJECTS

There are no active Federal hurricane and storm damage reduction projects in the study area. There is an active navigation project. The Morehead City Harbor navigation project presently consists of a 47-foot deep (MLW) by 450-foot wide ocean entrance channel through the ocean bar of Beaufort Inlet, which connects with channels and inner harbor which is generally 45 feet deep at MLW (East Leg) and 35 feet deep (West Leg and Northwest Leg). The current project is generally referred to as the 45-foot draft navigation project. A map of the Morehead City Harbor project is shown on Figure 3 and Figure 1 in the EA. Note that the entrance channel is composed of three reaches; namely, Range B (inner channel), the Cutoff, and Range A (ocean bar channel). The primary commodities passing through Morehead City Harbor are fertilizer products, rubber, and wood chips, which are handled by facilities provided by the North Carolina State Port Authority. Lesser amounts of petroleum products, machinery, and paper also pass through the State Port.

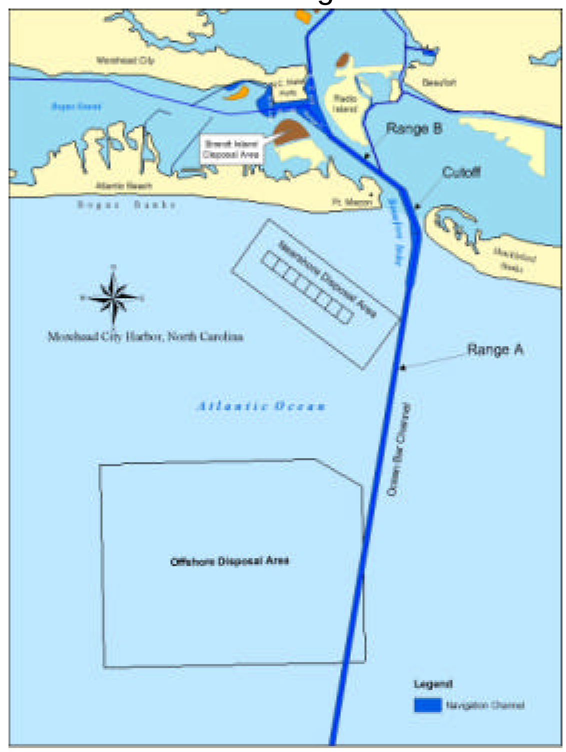

Figure 3. Morehead City Harbor

Historically, the Cutoff and Range A have been maintained by hopper dredge with the dredged material deposited in an offshore dredged material disposal site (ODMDS) located west of the seaward end of the bar channel. During the 1996 maintenance cycle for the bar channel, the disposal location was modified to include an option for near shore placement west of the bar channel in an area centered on the 30-foot MLW depth contour. Subsequent maintenance operations conducted in 1997 and 1999 required that all ocean bar channel material be placed in a near shore disposal site centered on the 25-foot MLW contour west of the channel.

However, operational constraints associated with the operation of hopper dredges has not allowed all of the maintenance material to be placed in the near shore site. The constraints associated with a hopper dredge operation include the inability of the dredge to deposit the material in shallow depths during unfavorable weather and wave conditions and the restricted dredging window (i.e. the time period in which hopper dredges are allowed to operate) imposed on hopper dredge operations due to their propensity to interfere with sea turtles. The dredging window for hopper dredges extends from January through March.

Maintenance of Range B and inner harbor has been performed by pipeline dredge with disposal on Brandt Island, a confined dredged material disposal site located immediately across the harbor from the State Port facility. Due to the limited capacity of this site, and the absence of other suitable upland disposal site in the area, Brandt Island was identified as a temporary holding area for the inner harbor dredged material during the formulation of the 40-foot project in 1976 and the 45-foot project in 1994. In this capacity, maintenance material is to be temporarily stored on Brandt Island for a period of 8 to 10 years after which the material is transferred to a beach disposal site located along the eastern end of Bogue Banks. Previous beach disposal sites have covered sections of both Fort Macon State Park and the Town of Atlantic Beach. Transfer of material from Brandt Island to the beach was accomplished in 1986 and 1994.

FEDERAL STANDARD - BASE DISPOSAL PLAN

Should present plans for sharing sand by Bogue Banks beaches not materialize due to funding problems or other unforeseen reasons, up to 6.3 million cubic yards dredged maintenance material from the inner and outer harbor, as well as the pump out of Brandt Island would be distributed according to the base disposal plan as determined by the Federal Standard (see Appendix B). The base disposal plan represents the least cost alternative for the government, which is engineeringly feasible and environmentally acceptable.

Under the base disposal plan, the outer harbor would be maintained by hopper dredge and the resultant 1.5 million cubic yards of dredged material would be placed in the previously approved near-shore disposal area or the offshore dredged material disposal site (ODMDS) if inclement weather will not allow nearshore placement. The pumpout of Brandt Island and the maintenance dredging of the inner harbor by pipeline dredge would be placed using a design berm width of 150-feet. Up to 4.8 million cubic yards (about 4.0 million from Brandt Island and about 0.8 million from the inner harbor) of beach quality sand may be placed along approximately 32,000 feet of shoreline from Fort Macon State Park to the Atlantic Beach/Pine Knoll Shores border (Figure 1). If the North Carolina State Port Authority does not fund its share of approximately 1.2 million cubic yards of the Brandt Island material, this amount could be reduced to 3.6 million cubic yards.

HISTORICAL BEACH DISPOSAL OF MOREHEAD CITY HARBOR DREDGED MATERIALS

Generally, routine maintenance dredging occurs every two years for Morehead City Inner Harbor and every year for the Outer Harbor. Pump outs of Brandt Island are scheduled every 8-10 years, depending on disposal capacity within the existing confined disposal area. Material removed from the Morehead

City Harbor project, from either Brandt Island or direct transfer onto beaches from maintenance activities, has been deposited on the shoreline of Bogue Banks on four separate occasions (Figure 4).

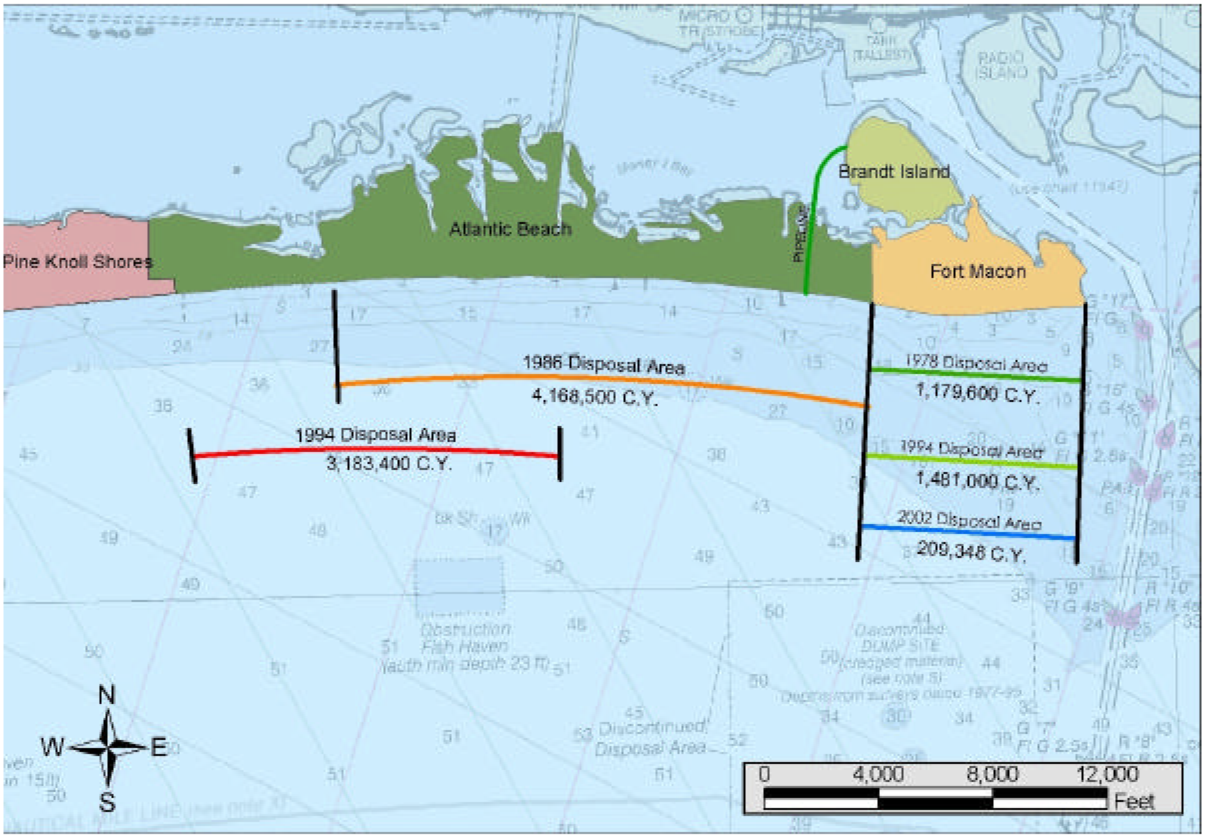

Figure 4. Historic Beach Disposal Operations

In 1978, a total of 1,179,600 CY of material removed for the deepening of the inner harbor and Range B was deposited along the Fort Macon State Park shoreline. In 1986, a total of 4,168,600 CY of dredged material was placed on Atlantic Beach between Corps of Engineers baseline stations 100+00 and 290+00. Of this total, 3,912,900 CY were from Brandt Island, and 255,700 CY of channel and basin maintenance material was transferred directly to the beach disposal site. In 1994 a total of 4,664,400 CY of material was placed on Fort Macon and Atlantic Beach with 3,183,400 CY being deposited between baseline stations 210+00 and 318+00 and the remaining 1,481,000 placed on the shoreline of Fort Macon State Park. Of the total 4,664,000 placed on the beach, 465,700 CY was maintenance material from the inner harbor, 1,725,000 CY was from new work construction, and 2,473,700 CY was from the Brandt Island disposal area. And finally, during the Spring of 2002, a direct transfer of 209,348 CY of maintenance material from the inner harbor was placed on the shoreline of Fort Macon between Corps of Engineers baseline stations 0+00 and 39+00 while the dike on Brandt Island was being reworked and was unavailable for accepting disposal material. The total amount of material available during any given pump out varies depending on the amount of material in Brandt Island and the annual maintenance needs of the inner harbor. There is no foreseeable new work dredging in the immediate future.

LOCALLY FUNDED RENOURISHMENT

This project proposes to place approximately 4.57 million cubic yards of sand over 16.8 miles of Pine Knoll Shores, Indian Beach, Salter Path, and Emerald Isle shoreline. The source of the sand is an ocean borrow site. The project will be completed in three phases over a three-year period. The first phase has been completed with the nourishment of 6.8 miles of beach in Pine Knoll Shores and Indian Beach with approximately 1.7 million cubic yards of sand, which has been taken into account for the pre-Section 933 project conditions. The second phase is expected to place 1.8 million cubic yards of sand on 5.9 miles of Emerald Isle beginning January 13, 2003. And the final phase, if implemented would place 1.0 million cubic yards of sand on 3.5 miles of Emerald Isle in the winter of 2003/2004.

STUDY PARTICIPANTS AND COORDINATION

This Section 933 study will be coordinated with various Federal, State, and local agencies and the public having concerns about the beneficial placement of dredged material for hurricane and storm damage reduction and the environmental impacts of proposed improvements. The Environmental Assessment (EA) was circulated for review and comment along with this Evaluation Report. Comments received during the public review of the EA are addressed in the Finding of No Significant Impact. Required coordination was conducted with all appropriate agencies.

SECTION 933 PROJECT REQUIREMENTS

A Section 933 Project, as described under " Study Authority", allows for the placement of navigation maintenance dredged materials onto beaches other than those that are determined to be part of the Base Disposal Plan. However, a Section 933 Project is subject to the availability of adequate Federal funding as well as the following conditions being met (ER 1165-2-130, *Federal Participation in Shore Protection,* and ER 1105-2-100, *Planning Guidance Notebook*).

a) The State must request that the dredged material be placed on the beach (this may be on the behalf of a political subdivision of the State);

b) The added cost of placing the material on the Section 933 project beaches over the Base Disposal Plan must be justified by the benefits it produces;
c) At least 50 percent of the additional costs must be covered by storm damage reduction benefits;
d) The beach must be open to the public and provide reasonable public access that has been defined as access points approximately every **one-half mile or less**. In addition, sufficient public parking, located within a reasonable walking distance of the access points should be provided. Parking should be sufficient to accommodate the lesser of peak hour demand or the beach capacity for the project area.
e) The placement of the dredged material must satisfy all applicable environmental statutes and regulations;
f) The non-Federal sponsor must pay **35 percent** of the added cost of disposal above the cost of the Base Disposal Plan; and
g) The non-Federal sponsor must provide, without cost to the Federal Government, all lands, easements, rights-of-way, and relocations needed to accomplish the work.

If all of these conditions are not met, the material could still be placed on the proposed beach areas outside of the Base Disposal Plan providing:

a) The State requests that the dredged material be placed on the beach (this may be on behalf of a political subdivision of the State);
b) Protection of the beach is in the public interest, regardless of benefits produced;
c) The placement satisfies all applicable environmental statutes and regulations;
d) The non-Federal-sponsor pays 100 percent of the added cost of disposal above the Base Disposal Plan; and
e) The non-Federal-sponsor provides without cost to the Federal Government, all lands, easements, rights-of-way, and relocation.

AREAS OF CONCERN

The following issues are considered areas of particular concern regarding the proposed project.

- In response to the January 15, 2002, scoping letter, the public and review agencies expressed the following major concerns: fishery resources and habitats, rare butterfly habitat, short- and long-term impacts of the proposed activity, endangered/threatened species, cultural resources, sediment contamination, and other natural resources.

PUBLIC BEACH ACCESS AND PARKING

The Army Corps of Engineers has several requirements that must be met in order to fully cost share in a Section 933 project (see "Section 933 Project Requirements" section on the preceding pages). The Corps' Wilmington District, additionally, has developed more specific public access and parking requirements for participation in Section 933 projects within the District's boundaries of North Carolina (see Appendix E).

The Wilmington District, using aerial photography and traffic surveys from the July 4th holiday, conducted an analysis to determine the peak hour demand for the area. The data was used to determine that the communities currently have adequate parking to meet the Corps' requirements for peak hour demand (see Appendix E).

The additional Section 933 requirements have been addressed by the local sponsor and documented in their Public Transportation and Parking/Access Plan for the proposed project area (see Appendix E – Exhibit 1). The document identifies the number of (8) and location of current public beach access sites and parking spaces (301) available, and outlines the sponsor's plans for future public beach access sites and parking. Additionally, the document addresses the installation of a public transportation system to assist visitors in accessing areas of the beach that have public access, but no public parking.

The sponsor's plan as currently proposed is acceptable to the Corps. Any changes to this plan or any new issues that arise will need to be resolved prior to the signing of the Project Cooperation Agreement.

When the plan is implemented, the sponsor will be eligible for full Federal cost sharing for the majority of the project area. The only exception currently identified includes the westernmost 1900 feet of Indian Beach (between Station 700+00 and Station 681+00) that does not meet the Corps' criteria, and would require 100% non-Federal funding to nourish. The local Sponsor has indicated that they do not intend to pursue this option at this time.

The sponsor will be eligible for cost sharing of 65.0% Federal and 35.0% non-Federal sponsor for the Section 933 project. These values are based on the sponsor's beach access and transportation plan and will be subject to change if more, less, or different access sites are decided upon prior to signing of the Project Cooperation Agreement. Once all access and/or parking sites are obtained, and prior to signing the PCA, the Corps will obtain specific measurements using GIS and or survey data of these sites to make a final determination on project cost sharing.

The local sponsor has developed the Public Transportation and Parking/Access Plan to identify how they will fulfill their commitment to meet the Corps' Section 933 requirements. The adequacy of public access will be revisited before the signing of a Project Cooperation Agreement. At that time, the Corps will verify that all plans have been implemented and that they meet all Section 933 requirements as outlined in this report.

If additional access points and parking are deemed necessary, the Wilmington District and local sponsor will work together on the local sponsor's plan to provide these. Should the local sponsor be required to obtain additional public access areas, these areas should be acquired as easements for the term of years identified in the Project Cooperation Agreement for which the local sponsor is responsible for providing public access for the project. The sponsor will be responsible for ensuring that the Section 933 requirements are met throughout the life of the project. Beach access and parking requirements are presented in Appendix E.

SECTION II - PROBLEM IDENTIFICATION

The purpose of this report section is to identify problems, needs and opportunities in the study area in accordance with the study authority. This report section includes the following: (1) description of the study area; (2) an analysis of public concerns, which presents the concerns of local interests, Federal agencies, and others having interests in the study; (3) a statement of the National Objective, which outlines the criteria for Federal participation in water resources developments; (4) an assessment of Federal interest, which identifies concerns in the study area which the Federal government can address under this objective; and (5) specification of Problems, Needs, and Opportunities.

STUDY AREA

Carteret County is located on the central North Carolina coast. Bogue Banks is a 25.4 miles long south-facing barrier island located on the low-energy limb of the Cape Lookout foreland within Carteret County. It is oriented in an approximate east to west direction between Beaufort and Bogue Inlets, located on the east and west terminuses of the island, respectively. The island is bound to the north by Bogue Sound, a relatively shallow water body through which the Atlantic Intracoastal Waterway passes (Figure 2).

Fort Macon State Park occupies the eastern end of the island. Political subdivisions on the rest of the island include, from east to west: the Town of Atlantic Beach, the Town of Pine Knoll Shores, an unincorporated area known as Salter Path, Town of Indian Beach, and the Town of Emerald Isle. The width of the upland portions of the island (the landmass above mean high water) varies from a minimum of approximately 800 feet to a maximum of over 4,000 feet. The narrowest part of the island, which ranges in width from 800 feet to 1,000 feet, is located along the easternmost 2.8 miles of Emerald Isle. The widest part of the island, which measures over 4,000 feet, is located on the westernmost 5.1 miles of the island, also within the corporate limits of Emerald Isle.

A maritime forest area is located on the sound side of Bogue Banks between the east portion of Indian Beach through Pine Knoll Shores. This reach of the island includes the Theodore Roosevelt Natural Area, which is the only portion of Bogue Banks included in the Coastal Barrier Resources System. In general, the island has been developed in such a manner as to preserve as much of the natural vegetation from the ocean to the sound as possible.

Hurricanes, extratropical events and progressive erosion have always occurred in the study area. Increasing development in Carteret County over the last several years has raised the potential for damages considerably. Development in the study area consists of single family houses, multi-unit apartment and condominium buildings, hotels, motels, and commercial buildings of various sorts, all covering a wide range of values and susceptibility to storm damages. Long-term erosion rates and elevations also vary over the study area.

Because of substantial variations in every factor that will affect storm damages, it is impossible to select any small areas or reaches that could be considered representative of the study area as a whole.

From 1990 to 2000, the population of Carteret County grew about 13% (i.e., 1990 population was 52,407 and 2000 population was 59,383). About 40 percent of the residents live in one of the county's municipalities. With its overwhelming economic emphasis on tourism, retail sales in Carteret County comprise the most important source of jobs and income for the county's economy. In 1993, total farm income for Carteret County was over 18 million dollars, with corn, soybeans, and tobacco the leading commodities. In 1995, the manufacturing sector employed about 10 percent of Carteret County workers.

The North Carolina Office of State Budget and Management estimates Carteret County's 1994 employment at 25,000, with about 35 percent in trade and 21 percent in Government employment. In 1997, per capita income in Carteret County was estimated at $21,624, somewhat higher than the North Carolina per capita income of $20,217.

The 1990's were a decade of rapid growth for the Carteret County beaches. The populations of the towns and Carteret County since 1990 are shown below. The total permanent population for the three principal towns in 2000 is estimated at 3,400. However, peak daily population in the summer can swell to more than 160,000 for the entire county.

TABLE 1

POPULATION STATISTICS
CARTERET COUNTY, NORTH CAROLINA

Town/County	1990 Population	2000 Population
Atlantic Beach	720	789
Pine Knoll Shores	1,360	1,524
Indian Beach	153	95
Morehead City	6,046	7,691
Carteret County	52,407	59,383

Carteret County population projections for 2000 – 2020 are shown below.

TABLE 2

**POPULATION PROJECTIONS
CARTERET COUNTY, NORTH CAROLINA**

County	2005 Population	2010 Population	2020 Population
Carteret	65,633	69,358	76,341

Source: Office of State Planning, State of North Carolina.

In the summer months, a large portion of the homes along Bogue Banks are available as summer rentals to vacationers. Almost 2 million people, including those residing in the Research Triangle area of North Carolina, live within a two-hour drive of these beaches. During the summer months, the population of Carteret County is estimated to exceed 160,000 people. In the off-season months, it drops to 59,000, which includes about 789 permanent residents in Atlantic Beach (2000), 1,524 in Pine Knoll Shores, 95 in Indian Beach and 7,691 in Morehead City.

PUBLIC CONCERNS

Local interests have expressed a need for hurricane and storm damage reduction measures for the 7.2-mile-long shoreline reach, which includes the communities of Pine Knoll Shores, Indian Beach, and Salter Path. In addition, agencies and individuals with interests related to environmental quality have expressed concerns that any plan of improvement be implemented in a manner, which avoids or minimizes environmental impacts. Public concerns are summarized below; detailed discussion of these concerns will be presented in subsequent report sections.

HURRICANE AND STORM DAMAGE REDUCTION

The concerns of local interests, as expressed by their elected representatives, are reflected in the Carteret County resolution and the State's request for a Section 933 evaluation, which is the basis for this study (see Appendix A, Exhibit 2). Hurricane and storm damage have been persistent public concerns in the communities of Pine Knoll Shores, Indian Beach and Salter Path. All three of these areas of Bogue Banks are faced with moderate erosion problems and there is a high potential for hurricane and storm damage to structures in these areas where the protective berm and dune system has been weakened or lost due to recent storm action and long term erosion.

ENVIRONMENTAL QUALITY CONCERNS

In response to the January 15, 2002 scoping letter, the public and review agencies expressed the following major concerns: fishery resources and habitats, rare butterfly habitat, short-and long-term impacts of the proposed activity, endangered/threatened species, cultural resources, sediment contamination, and other natural resources. Specific concerns will be addressed in the Final Report.

CONSISTENCY WITH STATE COASTAL MANAGEMENT PROGRAM

As will be discussed in subsequent report sections, the plan of improvement recommended is considered to be consistent with the State's Coastal Management Program.

THE FEDERAL OBJECTIVE

The Federal Objective in water resources planning is to contribute to the National Economic Development in a manner consistent with protection of the nation's environment. If hurricane and storm damage reduction measures at Pine Knoll Shores, Indian Beach, and Salter Path are economically feasible (benefits exceed costs) and environmentally acceptable, construction of a Federal project for this purpose utilizing the beneficial use of dredged material from the Morehead City Harbor navigation project would contribute to this objective.

FEDERAL INTEREST

In accord with the Federal Objective any plan of improvement to be recommended for Federal implementation must produce benefits that exceed costs. The area must also be open and accessible to the general public on an equal basis. Therefore, detailed studies were directed toward those areas within the 7.2-mile-long reach of shoreline that includes the communities of Pine Knoll Shores, Indian Beach and Salter Path, which will be referred to as the "Section 933 Project Area" (Figure 1). The technically feasible solutions identified in this study consisted of beach berm construction utilizing maintenance dredged material from the Morehead City Harbor navigation project to reduce hurricane and storm damage along the Section 933 project area. These measures will be discussed in detail in the subsequent report section on "Plan Formulation".

PROBLEMS, NEEDS, AND OPPORTUNITIES

The primary public concerns identified in the study area are the loss of land and potential loss of structures due to progressive beach erosion and potential damages to structures due to hurricane and storm action. These concerns are discussed below, and protective solutions are identified. These solutions will be discussed in detail in subsequent report sections.

LONG-TERM EROSION

"Long-term erosion" as used in this report section refers to long-term shore processes. These processes can be documented based on shoreline history, and projected to estimate future conditions. Erosion in this sense differs from erosion during storms, which, although devastating to development, is generally of a temporary nature. Following storms, the coastline tends to reshape itself into its former configuration, as sand displaced from the beach is returned by wave action. The beach shape then conforms to the prevailing wave climate and littoral processes.

However, land losses due to progressive erosion are essentially permanent, as documented by the shoreline history along the Section 933 project area. Analyses of coastal processes conducted during this study indicate that historical erosion trends along the Section 933 project area can be expected to continue if no action is taken to stabilize erosion-prone areas. Past and projected future shoreline positions for the Section 933 project area are discussed below.

Past Shoreline Positions, Section 933 Project Area. Shoreline changes for beach segments from Fort Macon through Indian Beach are shown in Table 3. Figure 5 displays the “representative” reaches identified in Table 3. As shown, the peak erosion has occurred along the Pine Knoll Shores shorelines. Erosion has resulted in the loss of much of the protective berm and results in the dune system and structures located just upland of the shoreline being frequently threatened. Many of the seaward most buildings are highly vulnerable to damages by storm wave action due to the loss of the natural protective berm and dune system. Also, the width and quality of the beach available for recreation have diminished.

Table 3

Shoreline Changes – Project Base Year 2004

		Erosion Rates Change (+ Accretion - Erosion)	Future Shoreline Positions Linear Distance (ft) (+ Accretion - Erosion)	
REPRESENTATIVE REACH	LENGTH (ft)	RATE (ft/yr)	10-yrs 2014	20-yrs 2024

IB-R2	6011	+0.3	+3	+7

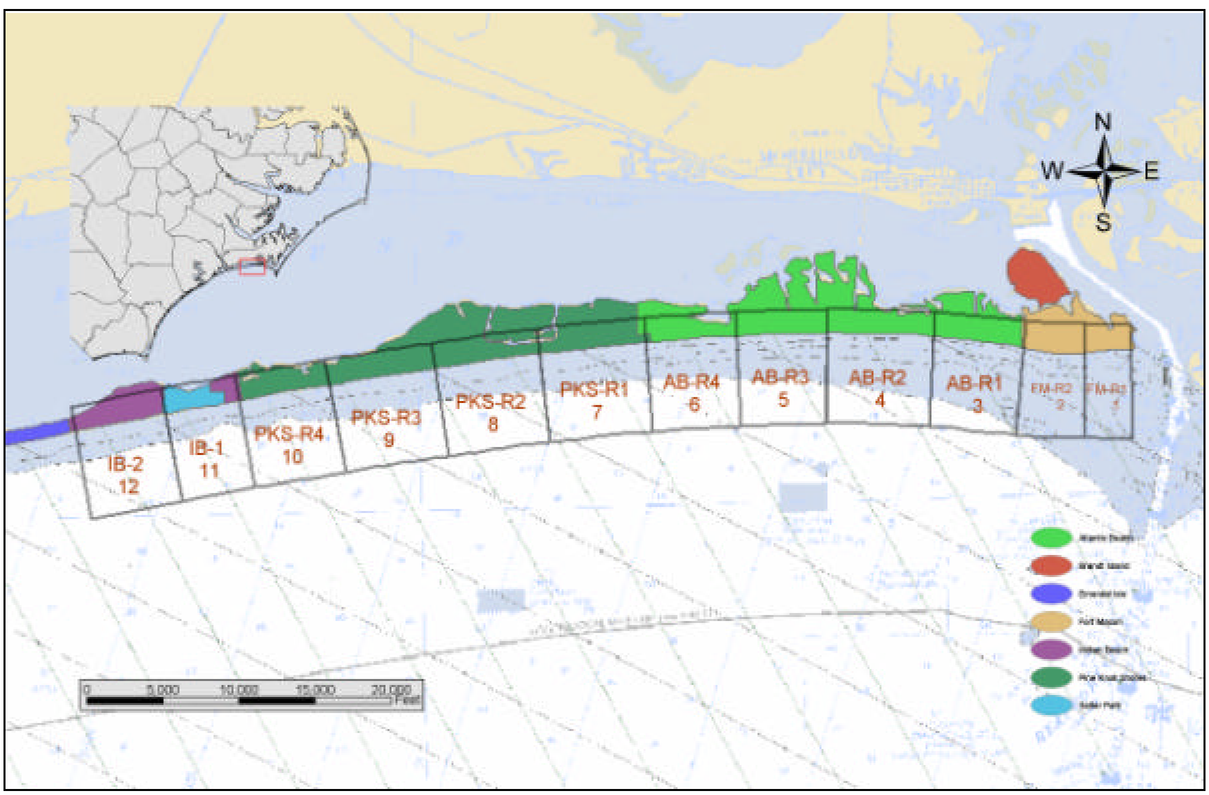

Figure 5. Representative Reach Layout

Estimated Future Shoreline Conditions, Section 933 Project Area. The discussion below presents an estimate of the future shoreline. Again, emphasis is placed on the 7.2-mile-long reach along the shorelines of Pine Knoll Shores, Indian Beach and Salter Path, which is the Section 933 Project Area. This estimated future without-project condition will form the basis for evaluating potential economic benefits for hurricane and storm damage reduction and developing dredged material placement plans to address these needs. For purposes of this discussion, it is assumed that no Federal project will be constructed before 2004. The year 2004 is referred to as the "base year" in subsequent report sections. (It should be noted that a Federal project could be implemented before or after 2004; however, this base year is assumed for purposes of economic analysis.)

Table 3 shows the estimated shoreline positions 10 and 20 years from the base year (2004). These projections were developed based on historic rates of erosion and shoreline adjustments, and do not take into account any erosion-control measures that might be undertaken during the periods of analysis.

By the year 2024, progressive long-term erosion is expected to threaten many structures along the Section 933 project area. The period of analysis for the Section 933 project has been selected to be 20 years. This is based on a 10-year physical life for the Section 933 project and doubling this time period for the period of analysis of the project.

The future shoreline positions discussed above are based on continuation of uniform historic rates of shoreline change. However, considering the value of property along the Section 933 project area (Pine Knoll Shores, Indian Beach, and Salter Path) relative to the cost of erosion control measures, it is likely that local interests will undertake temporary measures to protect against progressive erosion.

At present, the three towns bulldoze the beaches to create artificial dunes in the areas where erosion is most acute. Also, property owners have placed a small beachfill project along their property and have sandbagged for temporary protection. These projects have to be approved by the NC Division of Coastal Management. For beach communities that are actively pursuing a beach nourishment project, these local projects provide temporary protection until the long-term project is constructed. At the present level of activity, these measures are not sufficient to prevent erosion from proceeding landward, as shown in table 3. Therefore, unless more effective beach erosion control measures are undertaken, erosion is expected to progress landward.

Thus, the "most likely future" scenario along the Section 933 project area is that erosion control measures by local and state interests are not expected to provide significant protection against the erosion and flooding associated with hurricane and storm events.

HISTORICAL HURRICANE AND STORM DAMAGE

"Hurricane and storm damages," as used in this report, refer to flooding by wave overwash during hurricanes and extratropical events, as well as short-term erosion, which occurs during these events. When the island is under hurricane and storm attack, the full force of the waves is felt along the immediate ocean shoreline; as the waves break and spill over the ocean edge of the island, development in upland areas is subject to the force of the waves. As noted in the discussion of "beach erosion" problems above, erosion is threatening much of the dune system along the shoreline within the Section 933 project area. These segments of the island could be overtopped by a category 2-storm event. With the smaller storms, such as a category 1-storm event, the principal damages would be associated with the battering and loosening of the pilings, which support beachfront structures, and the loss of decks and other structures. With the larger storms, such as Hurricane Donna in 1960, entire structures can be swept away. Past hurricanes and extratropical events and their damage potential are discussed below.

Past Hurricanes and Extratropical events. Devastating hurricanes and extratropical events periodically strike the study area. Storms occur in cycles with the recent years being fairly active. The following list is intended to present some of the worst storms that have been experienced in the study area. Hurricane season runs from 1 June through 30 November; while the northeaster season extends from 15 October to 10 April. Dollar estimates of the extent of the damages were not available for every storm and sometimes the available estimate covered a wider area than the scope of this study. Where any damage figures are given for storms in previous decades, it should be kept in mind that the damages would of course be far worse if a similar storm occurred today due to the surge in development during recent years.

During the years 1954 and 1955, three extremely severe and devastating storms struck the North Carolina coast. These hurricanes are important because similar storms do have the potential to occur in the study area. Hurricane Hazel, which pounded the coast from 5 to 18 October 1954, was the most destructive storm to strike North Carolina in 50 years. Every fishing pier along 170 miles of coast was destroyed. Between the North Carolina-South Carolina State line and Cape Fear, grass covered dunes, some 20 feet high, and a line of beach houses behind the dunes simply disappeared. Nineteen people were killed and 200 were injured. Damages throughout the State were estimated at $125,309,000, of which $31,190,300 occurred in the coastal and tidal areas. Hurricane Connie caused tremendous beach erosion between 3 and 14 August 1955. The damage throughout the State was thought to be about $50,000,000, but before damages could be fully assessed, Hurricane Diane followed, and between 7 and 21 August, caused about $40,000,000 more in damages.

Recent Hurricane History - Bertha, Fran, Bonnie, Dennis, Floyd, Irene

12 July 1996 - Hurricane Bertha. The center moved over the North Carolina coast near Wilmington on 12 July with sustained winds of approximately 105 mph and gusts reported as high as 144 mph at Topsail Beach. The category 2 hurricane was an early season Cape Verde Hurricane. Damages were estimated to exceed $60 million for homes and structures and over $10 million for agriculture. Corn, tobacco, and other crops received severe damage from the storm. Rainfall totals of over 5 inches were common in eastern North Carolina.

6 September 1996 - Hurricane Fran. The center moved over the Cape Fear area around 0030 on 6 September and was moving northward near 15 knots. When it made landfall, Hurricane Fran was a category three hurricane resulting in significant storm surge flooding on the North Carolina coast and widespread wind damage over North Carolina. At landfall, the minimum central pressure was estimated at 954 mb and the maximum sustained surface winds were estimated at 100 knots. Twenty-one died in North Carolina alone. Rainfall totals exceeding six inches were common near the path of Fran. Extensive flooding spread well inland from the Carolinas. Storm surge on the North Carolina coast destroyed or seriously damaged numerous beachfront houses. Widespread wind damage to trees and roofs, as well as downed power lines, occurred as Fran moved inland over North Carolina. Extensive flooding was responsible for additional damage in the Carolinas. Nearly a half-million tourists and residents were ordered to evacuate the coast in North and South Carolina. Press reports from Reuters News Service stated that 4.5 million people in the Carolinas and Virginia were left without power. The Property Claim Services Division of the American Insurance Services Group reported that Fran caused an estimated $1.6 billion dollars in insured property damage to the United States. This estimate includes $1.275 billion in North Carolina, $20 million in South Carolina, $175 million in Virginia, $50 million in Maryland, $20 million in West Virginia, $40 million in Pennsylvania and $20 million in Ohio. A conservative ratio between total damage and insured property damage, compared to past landfalling hurricanes, is two to one. Therefore, the total U.S. damage estimate is $3.2 billion.

26 August 1998 - Hurricane Bonnie. The center drifted along the coast, with the western part of the eye moving across extreme southeast Brunswick County and over eastern New Hanover County. The center officially came onshore a short distance northeast of Wilmington during the late evening of the 26th and early morning of the 27th. Bonnie then moved slowly over extreme eastern North Carolina, emerging off the Outer Banks near Kitty Hawk early on the 28th. After being downgraded to a tropical storm while over land, Bonnie re-strengthened into a hurricane with 75-mph winds as it moved back into the Atlantic. Early estimates of storm tides are as follows. Brunswick coast: 7 to 9 feet above normal, 2 feet of overwash at Bald Head and eastern end of other islands. New Hanover and Pender County coasts: 9 to 10 feet above normal, 2 to 3 feet overwash at the north end of Carolina Beach. There was less overwash on the south end of Topsail Island.

30 August 1999 - Hurricane Dennis. The hurricane lashed the Carolina coast on the 30th and part of the 31st with sustained tropical storm force winds, gusts to hurricane force, large waves, and high surf. The hurricane turned northeast away from the coast on the morning of the 30th and began to accelerate later that day while moving to the east-northeast. Dennis stalled about 150 miles east of Cape Hatteras on the morning of the 31st and then began to drift westward and weaken. During the first couple of days of September, Dennis continued to weaken and was downgraded to a tropical storm as it drifted slowly to the southwest along the lower Outer Banks. The storm turned to the northwest on the 4th and made landfall over the Outer Banks between Cape Lookout and Ocracoke as a tropical storm. NC 12 was washed out north of Buxton.

16 September 1999 - Hurricane Floyd. The center made landfall near Cape Fear North Carolina as a category two hurricane around 0230 EDT September 16. The hurricane moved over the eastern part of the state and accelerated north-northeast up the coast, weakening to a tropical storm before moving into New England and losing its tropical characteristics early on the 17th. Floyd is responsible for massive inland flooding over portions of the eastern United States, particularly in North Carolina. The death toll from Floyd was 51 and makes this the deadliest United States tropical cyclone since Agnes of 1972. Many ocean front homes were heavily damaged.

18 October 1999 - Hurricane Irene. The center passed just east of the Outer Banks early on the 18th. After passing the Outer Banks, Irene rapidly intensified and reached a peak intensity of 105 mph on the 18th. Irene continued northeast and was absorbed by an extra-tropical low on the 19th.

Hurricane and Storm Damage Potential. The Section 933 project area is heavily developed and the potential for hurricane-wave damage is more likely given the weakened dune system in this area. Unlike long-term erosion, which can be predicted, to some extent, based on past trends and observed shore processes, damages from hurricane-wave attack can occur in any year, and can be predicted only as a mathematical probability. Based on these probabilities, average annual damages were computed for hurricane and storm events, and will be discussed in Section III of this report, "Economic Benefits".

CONDITIONS IF NO FEDERAL ACTION IS TAKEN

Development at Pine Knoll Shores, Indian Beach, and Salter Path is expected to continue, with or without any Federal projects. However, if no Federal action is taken this development will continue to be threatened by hurricanes and storm damage and long-term erosion. Basic assumptions are as follows:

(1) Most development is expected to still be in place by year 2004, the year in which it is assumed that a Section 933 project could be implemented along the Section 933 project area. Local interests are expected to take

short-term actions (bulldozing and sandbagging) to protect their property, however erosion will eventually threaten their structures.

(2) Local measures are not considered likely to provide significant protection against hurricane and storm damage, including wave overwash and flooding.

(3) The Corps of Engineers will continue to pursue the Federal Standard in navigation maintenance dredged material disposal for Morehead City Harbor, which is the most cost effective disposal plan that is environmentally acceptable and consistent with sound engineering practices.

SUMMARY OF PROBLEMS, NEEDS, AND OPPORTUNITIES

The principal water-resources problems identified along the Section 933 project area are progressive beach erosion, due to long-term shore processes, and the threat of hurricane and storm overwash. The need for action to address these problems is particularly acute along the Section 933 project area including the resort communities of Pine Knoll Shores, Indian Beach, and Salter Path.

SECTION III - ECONOMIC BENEFITS

The purpose of this analysis is to estimate the potential economic benefits that could be realized with the reduction of preventable damages due to beach erosion and hurricane and storm action in the Section 933 project area. As discussed previously, the Section 933 project area includes the 7.2-mile-long reach of shoreline, which includes the communities of Pine Knoll Shores, Indian Beach, and Salter Path. This is the area along Bogue Banks beaches where potential benefits are of significant magnitude to merit detailed study of a Section 933 project. Reduction of these damages, along with benefits for enhanced recreational use of the area, constitutes the economic justification for the plans of improvement that will be discussed in subsequent report sections.

METHODOLOGY AND ASSUMPTIONS

The analysis of potential economic benefits, which follows is based on the assumption that no effective action will be taken to reduce hurricane and storm damages along the Section 933 project area. However, efforts by local and state interests will include bulldozing and sandbagging.

The interest rate for the analysis is 5-7/8 percent and a 20-year Period of analysis is used. October 2002 price levels are applied. The "base year" used for the economic analysis is 2004.

The structural database used for this analysis was compiled by field surveying every structure on the oceanfront and second-row in the Study Area, which includes the communities of Fort Macon, Atlantic Beach, Pine Knoll Shores, Indian Beach and Salter Path. Each structure was assigned a reasonable estimate of its depreciated replacement value. Factors such as age, condition, quality of materials, and type and quality of construction enter into this value determination. Tax values were used for the sake of comparison, since the Carteret County tax appraisers also strive to measure replacement value less depreciation.

Estimates of values of contents of commercial structures in the Study Area are based on interviews with business owners and insurance agents familiar with the Carteret County oceanfront, as well as empirical data collected for past studies. Each type of business has a unique content factor applied to its structural value. Motels comprise most of the commercial base and 50 percent of the structural value was used for their content value. For estimating the value of household contents of residential structures in the area, 40 percent of the structural value is used. This is based on site-specific responses from Carteret County officials, insurance agents, realtors, and homeowners familiar with the residential development along this section of oceanfront.

This analysis includes 842 structures that occupy the Study Area and Base Disposal Plan Area. Of this total, there are 470 structures in Atlantic Beach, 258 structures in Pine Knoll Shores, 69 structures in Indian Beach, 44 structures in Salter Path, and 1 structure in Fort Macon State Park. Altogether, they represent a total structural value of about $377 million as shown in table 4.

TABLE 4
Structural Inventory by Town

Town	**Number**	**Oceanfront Structure Value**	**Second Row Structure Value**	**Total Structure Value**
Fort Macon	1	$160,000	$0	$160,000
Atlantic Beach	470	$105,959,000	$31,768,000	$137,727,000
Pine Knoll Shores	258	$119,791,000	$27,688,000	$147,479,000
Indian Beach (Salter Path)	113	$77,258,000	$14,039,000	$91,297,000
TOTAL	842	$303,168,000	$73,495,000	$376,663,000

BENEFITS FOR
HURRICANE AND STORM DAMAGE REDUCTION

Expected annual hurricane and storm damages for these areas were computed using Wilmington District computer programs (see Appendix D). The level of storm damage reduction for this beach fill configuration is determined by simulating hundreds of 20-year life cycles. This is accomplished through the use of the model, GRANDUC, which incorporates risk and uncertainty principles into the analysis. Through a random selection process, a particular 20-year simulation may include several severe storms or perhaps none. All of the 20-year life cycle simulations are run for the existing conditions, then again for a particular plan. Then, the average storm damage reduction potential afforded by a particular design configuration is computed. These damages are then estimated at an expected annual amount. Expected annual hurricane and storm damages for the Section 933 Project Study Area were estimated at $14,543,000 as shown in table 5. The expected annual damage figure includes damages to structures and contents associated with inundation, wave impacts, and storm induced erosion.

TABLE 5
Expected Annual Hurricane and Storm
Benefits for the Section 933 Study Area

TOWN	Expected Annual H&S Damages Existing	 BD Plan	 933 Plan	Expected Annual H&S Benefits 933 Plan
Pine Knoll Shores	$12,008,057	$12,008,057	$4,750,681	$7,257,376
Indian Beach	$2,534,965	$2,534,965	$842,311	$1,692,654
TOTAL	$14,543,022	$14,543,022	$5,592,991	$8,950,031

BENEFITS FOR EMERGENCY COSTS AND OTHER DAMAGE REDUCTION

Emergency costs prevented refer to expected annual expenditures that residents and local and state governments are experiencing under the without project condition that a Federal project would preclude. Other damages prevented include storm damages that are not covered under the National Flood Insurance Program, but represent financial impacts on public and private storm victims that a Federal project could prevent. The categories for this benefit include: (1) bulldozing; (2) sandbagging; (3) emergency costs incurred by the North Carolina Department of Transportation (NCDOT); (4) damages to public property (water and electric utility distribution systems and access walkways); (5) damages to private property such as walkways, driveways, and cleanup costs; and post-storm recovery expenses and storm related expenses such as police patrolling, inspections, and permits. Expected annual emergency costs and other damages for the towns of Pine Knoll Shores, Indian Beach, and Salter Path are estimated at $140,000. The Section 933 Project would reduce this amount to an estimated $18,000. Therefore, the expected annual emergency costs reduction benefits for the Study Area amount to $122,000.

BENEFITS FOR RECREATION

As discussed previously, local interests are expected to bulldoze sand after storm events and place sandbags along the shoreline fronting their structures in an attempt to protect their structures for as long as possible. The local beach nourishment project has provided some additional relief to the beach area. However, the recreational beach that remains by 2004 is expected to be narrow at high tides. Potential recreation benefits for the Study Area were computed by estimating the unit day value of the recreational experience available with and without a Federal project. The term "unit day value" represents the economic value that is assigned to a day of recreational experience (see Appendix D).

A unit day value of $3.96 was assigned for the "without project" condition (see Appendix D). The unit day value will be higher if a Section 933 project is implemented to restore and stabilize the beach strand. With the improved beach width and public access that would accompany a Section 933 project, a unit day value increase of $5.32 for Pine Knoll Shores and $5.11 for Indian Beach and Salter Path is considered more appropriate. This increase of $1.36 for Pine Knoll Shores and $1.15 for Indian Beach and Salter Path per unit day multiplied by estimated annual visitation represents the potential economic benefits for a restored and stabilized beach along the Study Area. Estimated visitation is discussed as follows.

Beach use along the Section 933 project area is estimated at a daily peak of 17,200 persons, based on data from the Towns of Pine Knoll Shores, Indian

Beach, and the Village of Salter Path and the Carteret County Tourist Bureau. This total represents an annual visitation of 776,000 for the Section 933 project area. Therefore, recreational benefits for the Section 933 project area are estimated at an expected annual amount of $1,009,000 (555,000 visitor days x $1.36 increase in unit day value for Pine Knoll Shores plus 221,000 visitor days X $1.15 increase in unit day value for Indian Beach and Salter Path).

SUMMARY OF ECONOMIC BENEFITS

The total expected annual benefits for shore protection along the 7.2-mile-long Section 933 project area that includes the resort towns of Pine Knoll Shores, Indian Beach, and Salter Path, are summarized in table 6. As shown, economic benefits include three categories: (1) Hurricane and Storm Damage Reduction Benefits - Potential benefits in this category are based on damages due to long-term beach erosion and short-term storm erosion and wave overwash during hurricanes and northeasters; (2) Emergency Costs and Other Damage Reduction - Potential benefits in this category are based on storm related expenditures that are not covered by the National Flood Insurance Program; (3) Recreation - Potential benefits in this category are based on increases in the value of the recreation experience for beachgoers with implementation of a Federal project within the Study Area; (4) Benefits During Construction – Those benefits that accrue to the project as it is being constructed.

TABLE 6

EXPECTED ANNUAL BENEFITS
FOR THE SECTION 933 PROJECT AREA
(Pine Knoll Shores, Indian Beach, and Salter Path)

Benefit Category	
Hurricane and Storm Damage Reduction	$8,950,000
Emergency Costs and Other Damages Reduction	122,000
Recreation	1,009,000
Benefits During Construction	574,000
TOTAL	$10,655,000

As shown in Table 6, total expected annual benefits for the Section 933 project area are estimated at $10,655,000. In accord with the National Objective stated previously, the expected annual cost of any Federal improvement recommended must be less than the expected annual benefits. In addition, any plan of improvement to be recommended must be shown to be environmentally acceptable. Environmental resources in the Study Area are discussed in the following report sections.

SECTION IV - ENVIRONMENTAL CONSIDERATIONS IN PROJECT PLANNING

The purposes of this report section are (1) to identify significant environmental resources which might be affected by a Section 933 project along the Section 933 project area; and (2) to identify criteria which should be followed in planning and designing a project to minimize impacts on those resources. Significant, or potentially significant, resources are discussed as follows.

SIGNIFICANT RESOURCES

Generally, the upland areas in the Section 933 project area (i.e., Towns of Pine Knoll Shores and Indian Beach (including Salter Path)) have limited natural values, due to the intensity of development. However, the estuaries, inlets, beaches, and shallow ocean bottom surrounding the Section 933 project area has significant values, as discussed below.

BIOLOGICAL RESOURCES

Marine waters in the vicinity of the beach disposal sites and maintenance dredging of the Morehead City Harbor outer navigation channels, provide habitat for a variety of ocean fish and are important commercial and recreational fishing grounds. Kingfish, spot, bluefish, weakfish, spotted sea trout, flounder, red drum, king mackerel, and Spanish mackerel are actively fished for from boats, the surf, and local piers. Off shore marine waters serve as habitat for the spawning of many estuarine dependent species. These species, according to the National Marine Fisheries Service, "compose approximately 75 percent of commercially and recreationally important catch of fish and invertebrates in North Carolina". The surf zone serves as a nursery area for Florida pompano and juvenile gulf kingfish during the summer. Nearshore waters also accumulate juvenile, ocean spawning, and estuarine dependent fish and invertebrates in the late winter and early spring prior to their transport through Beaufort Inlet and Bogue Inlet to the Bogue Sound estuary.

Although developed areas in the Study Area have limited habitat value, portions of the barrier island beaches (i.e., the inlet shorelines) within the Study Area are important nesting areas. During Migratory periods, piping plover, Wilson's plover, semipalmated plover (*Charadrius semipalmatus*), red knot (*Calidris canutus*), sandwich tern (*Sterna sandvicensis)* Foster's tern (*Sterna forsteri*), Royal tern (*Sterna maxima*), least tern, gull-billed tern (*Sterna nilotica*), common tern, black tern (*Chlidonias niger*), Caspian tern (*Sterna caspia*), herons, egrets, marbled godwit (*Limosa fedoa*), laughing gull (*Larus atricilla*) and cormorant are commonly found in and around the inlets. Overwintering bird species include piping plover, brown pelican, cormorants, Foster's tern, Royal tern, dunlin, and various gull species. Potential project areas were surveyed during this study to determine potential use of these areas by the species mentioned above and the results are presented in the attached Finding of No Significant Impact (FONSI).

A natural dune system is present along the Study Area, however, this dune system is being severely eroded. These dunes are vegetated primarily with grasses, sea oats, and salt meadow hay, which provide habitat for some wildlife species including birds and small mammals. Dunes serve an important function as a barrier to storm tides, protecting barrier island development. Dune vegetation such as sea oats is important as a dune builder and helps to protect against erosion. It is expected that the recommended plan will result in reestablishing and protecting the dune system along the project area.

More detailed descriptions of the landforms and fish and wildlife resources of the study area are presented in the attached FONSI.

ENDANGERED AND THREATENED SPECIES

Coordination with the U.S. Fish and Wildlife Service and the National Marine Fisheries Service has been conducted to identify endangered and threatened species (as well as Federal Species of Concern) that might be present in the vicinity of the Study Area. Species that are currently Federally listed as endangered or threatened (as well as Federal Species of Concern), which may or do occur in the Study Area, and which may be subject to impacts from beach disposal are listed in Table 7.

TABLE 7

THREATENED AND ENDANGERED SPECIES (INCLUDING FEDERAL SPECIES OF CONCERN) POTENTIALLY PRESENT IN CARTERET COUNTY, NORTH CAROLINA

Species Common Names	Scientific Name	Federal Status
Vertebrates		
American alligator	*Alligator mississippiensis*	T(S/A)
Eastern cougar	*Felis concolor couguar*	Endangered*
Green sea turtle	*Chelonia mydas*	Threatened 1
Hawksbill turtle	*Eretmochelys imbricata*	Endangered
Right whale	*Eubaleana glacialis*	Endangered
Sei whale	*Balaenoptera borealis*	Endangered
Sperm whale	*Physeter macrocephalus*	Endangered
Finback whale	*Balaenoptera physalus*	Endangered
Humpback whale	*Megaptera novaeangliae*	Endangered
Kemp's ridley sea turtle	*Lepidochelys kempii*	Endangered
Leatherback sea turtle	*Dermochelys coriacea*	Endangered
Loggerhead sea turtle	*Caretta caretta*	Threatened
West Indian Manatee	*Trichechus manatus*	Endangered

Piping Plover	*Charadrius melodus*	Threatened
Roseate tern	*Sterna dougallii*	Endangered
Shortnose sturgeon	*Acipenser brevirostrum*	Endangered
Smalltooth sawfish	*Pristis pectinata*	Endangered
Invertebrates		
a skipper (butterfly)	*Atrytonopsis sp1*	FSC
Arogos skipper	*Atrytone arogos*	FSC

Species Common Names	**Scientific Name**	**Federal Status**
Vascular Plants		
Rough-leaved loosestrife	*Lysimachia asperulaefolia*	Endangered
Seabeach amaranth	*Amaranthus pumilus*	Threatened

[1]Green turtles are listed as threatened, except for breeding populations in Florida and on the Pacific Coast of Mexico, which are listed as endangered.

KEY:

Status	Definition

Endangered - A taxon "in danger of extinction throughout all or a significant portion of its range."

Threatened - A taxon "likely to become endangered within the foreseeable future throughout all or a significant portion of its range."

T(S/A) - Threatened due to similarity of appearance (e.g., American alligator)--a species that is threatened due to similarity of appearance with other rare species and is listed for its protection. These species are not biologically endangered or threatened and are not subject to Section 7 consultation.

FSC - A Federal species of concern--a species that may or may not be listed in the future (formerly C2 candidate species or species under consideration for listing for which there is insufficient information to support listing).

Species with 1 asterisk behind them indicate historic record:

* Historic record - the species was last observed in the county more than 50 years ago.

Potential project-related impacts have been addressed for each of these species and are presented in the attached FONSI. It has been determined that the project, as currently proposed, may affect the, piping plover, green sea turtle, hawksbill sea turtle, Kemp's ridley sea turtle, leatherback sea turtle, loggerhead sea turtle, shortnose sturgeon, and sea-beach amaranth. Methods to minimize impacts to these species are found in the attached EA.

WATER QUALITY

Morehead City Harbor is located at the confluence of the Newport River and Bogue Sound. All tidal waters within Morehead City Harbor are classified as SC and SA. Coastal waters offshore of the project area are classified SB by the State of North Carolina (NCDEM 1989). Class SA waters are defined as suitable

for shellfishing for market purposes and any other usage specified by the "SB" and "SC" classification. Best usage of class SB waters includes swimming, primary recreation, and all Class SC uses including fishing, secondary recreation, fish and wildlife propagation, and other uses requiring lower water quality (NCDEM 1991). The waters in the vicinity of Morehead City Harbor are prohibited shellfish areas.

CULTURAL RESOURCES

The Morehead City Harbor Section 933 study has been reviewed pursuant to Section 106 of the National Historic Preservation Act (16 USC 470 et seq.) and the Abandoned Shipwreck Act (43 USC 2101 et seq.). This review has included consultation with the North Carolina State Historic Preservation Officer and staff of the NC Division of Archives and History Underwater Archaeology Unit and indicates that six archaeological sites have been recorded along the Bogue Banks beaches. Some of these sites consist of transient wreckage that has washed ashore from ships lost nearby in offshore waters.

0001BBB Iron Steamer Pier Wreck Site
Believed to be the Civil War blockade-runner *Pevensey*, an iron-hull side-wheel steamer, lost June 9, 1864. The wreck is located approximately 100 yards offshore on the east side of the pier lying almost parallel to the beach. Portions of a paddle wheel are visible during low tide.

0002BBB Gun Emplacement Site
Granite stones located in the surf zone adjacent to the 6200 block of Ocean Drive at Emerald Isle, believed to be from a World War II coastal shore battery exposed by beach erosion.

0003BBB Salter Path Site
Ship timbers 14" square, approximately 42 feet and 18 feet long with 1.25" diameter iron fasteners located roughly 1200 feet east of the beach access road near Squatters Campground.

0004BBB Cupola Site
Portions of a ship hull approximately 30' long and 14' wide fastened with iron pins, yellow pine planking on oak frames. This site is located in the surf zone near 18th Street, Emerald Isle. (Tag Numbers 134, 135)

0005BBB Emerald Isle Pier Wreck

Ship timber 40' long, 12" x 18" square, iron fasteners and one attached frame. This site is located near Emerald Isle Fishing Pier. (Tag Numbers 155, 156)

0006BBB Ocean Reef Site
Ship wreckage covering an area of approximately 100' by 35' near the Ocean Reef Condos (marked by a warning sign on the beach). This site consists of extensive debris with iron fasteners.

AESTHETIC RESOURCES

The Carteret County beach communities of Pine Knoll Shores, Indian Beach, and Salter Path that are located in the Section 933 project area, provide a vacation area for millions of visitors each year. The beaches within the Section 933 project area are used extensively for recreation. This includes sunbathing, swimming, surf fishing, jogging, bird watching and sightseeing. Public access with parking or public transportation will be available along the Section 933 project area as outlined in Appendix E – Exhibit 1.

ENVIRONMENTAL CRITERIA AND CONSTRAINTS

No environmental constraints were identified which would preclude implementation of a Section 933 project at Pine Knoll Shores, Indian Beach, and Salter Path. However, any plan of improvement should be designed and implemented, to the extent practicable, to avoid impacts on the threatened species known to occur along the Section 933 project area (see Table 7).

Generally, any plan of improvement should be designed to avoid adverse impacts on water quality and biological resources. Also, the timing of project construction should be adjusted as practicable to avoid periods of high biological productivity. Methods to minimize impacts to these periods of high biological productivity are found in the attached EA.

As noted above, the aesthetic qualities of the beach strand at Pine Knoll Shores, Indian Beach, and Salter Path will probably continue to be degraded as erosion encroaches on development. Therefore, there is an opportunity to enhance this aspect of the island's aesthetic quality by restoration of the beachfront.

SECTION V - PLAN FORMULATION

This report section describes the procedures by which the Recommended Plan of improvement was developed and ultimately selected. The Recommended Plan, which may also be referred to as the Section 933 Project, includes approximately 7.2 miles of beachfront, and is the maximum project area that has been identified within the Study Area. The non-Federal sponsor prefers a project that covers the maximum project area.

PLAN FORMULATION RATIONALE

A Section 933 project would consist of a beach berm project to control erosion and reduce wave overwash during storms. Beneficial use of dredged material for a Section 933 project for hurricane and storm damage reduction is limited to the volume of dredge maintenance material required to be removed from the navigation project due to channel shoaling and is also limited to operation and maintenance funds available for maintaining the project. Furthermore since dredged volumes are tied to the navigation project, the typical plan optimization (identification of the NED Plan based on maximum net average annual benefits) is not required. Therefore only one plan need be evaluated to determine economic feasibility.

ALTERNATIVE PLANS

As explained above, only one plan need be evaluated in determining economic feasibility. The Recommended Plan, therefore, was the only plan considered in great detail. Although the Recommended Plan was the only plan analyzed in detail, there were several plans initially assessed which would have provided protection for a number of different combinations of areas within the Study Area and the Base Disposal Plan Area. These plans were used as tools to assist in the initial determination of the one plan to evaluate in more detail. The recommended project area was evaluated since: (1) this area has had consistent development and erosion has weakened the protective dune; (2) there are no significant environmental constraints associated with these reaches; and (3) The non-Federal sponsor prefers a project that covers the maximum project area.

SECTION 933 RECOMMENDED PLAN

The Recommended Plan would consist of constructing a sand berm along the oceanfront at an elevation of 7 feet above NGVD, which mimics the natural berm elevation in the Study Area. The design berm ties into the existing dune system at + 7 ft NGVD, extends 30-ft seaward, and transitions at a 1V:25H slope to the Mean Tide Level (MTL). The offshore portion of the profile then parallels the preplacement profile slope out to closure depth.

The construction profile will greatly differ from the design profile. Since it is not economically feasible to groom the offshore portion of the profile to mimic design profile conditions, it is common construction practice to place an equivalent volume of material in the upper part of the profile as shown in Figure 6. Natural wave conditions will restore the profile shape to equilibrium conditions, resulting in the design profile berm width. The increase in berm width during construction varies according to profile conditions. The average construction berm width for the project increased to 107 ft as compared to the 30-ft design berm width. Average volumetric requirements for the recommended plan were approximately 90 cubic yards per foot.

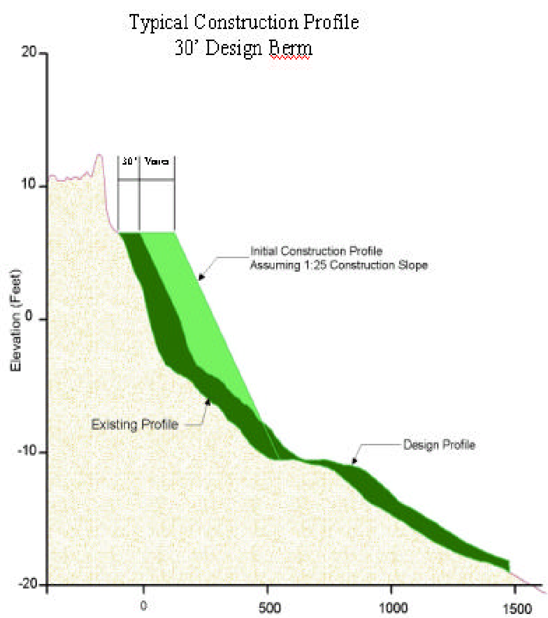

Figure 6. Design and Construction Profile Conditions.

It should be noted that existing dune conditions in the Project Area typically exceeded 15 ft NGVD. Such conditions exceed typical dune systems commonly incorporated into storm damage reduction projects. Therefore, dunes were not considered as an alternative. The 30-foot design berm width along the entire study area (7.2 miles) is expected to provide increased protection against long-term erosion.

The Recommended Plan includes a transition zone at the west end of the main fill. Since the fill will cause the shoreline to protrude seaward, the west end of the fill will erode rapidly unless measures are taken to terminate the fill with a gradual transition. The transition zone at the west end of the fill is 1,000 feet long. The transition fill will taper into the existing system. The east end of the main fill will tie into the base disposal main fill.

The Recommended Plan would be constructed by hydraulic dredges (pipeline and hopper with pump out capability) using the navigation project areas shown on Figure 3. The material would be pumped from the navigation project areas to the beach and shaped by earth moving equipment. The beachfill would be constructed at an elevation of +7-feet NGVD, the elevation of the existing beach berm along the project reaches. A benefits and costs discussions for the Recommended Plan follows.

BENEFITS AND COSTS FOR THE RECOMMENDED PLAN

Benefits for the Recommended Plan as well as the Base Disposal Plan, the disposal plan that would be used in the without project condition as determined by the Federal Standard, are shown below in Table 8.

TABLE 8

EXPECTED ANNUAL BENEFITS FOR RECOMMENDED PLAN
(Based on 5-7/8 percent interest rate, 20-year Period of analysis)
(October 2002 price levels)

Benefit Category	
Hurricane and Storm Damage Reduction	$8,950,000
Emergency	$ 122,000
Recreation	$ 1,009,000
Benefits During Construction	$ 574,000
Expected Annual Total Benefits	$10,655,000

BENEFITS FOREGONE

Benefits foregone were evaluated for those reaches that are located within the Base Disposal Plan (Atlantic Beach and Fort Macon) that would not receive the entire dredge disposal due to the proposed Section 933 project. There are no benefits foregone related to emergency costs or recreation, only hurricane and storm damage reduction. The total expected annual benefits forgone are estimated at $705,000. This amount is added to the cost side of the Section 933 Project to account for the lower level of protection that the Base Disposal Plan would have offered Atlantic Beach and Fort Macon.

COSTS FOR RECOMMENDED PLAN

First costs for the Recommended Plan and the Base Disposal Plan are shown in Table 9. The costs between the two plans vary proportionately to the volume of the fill and the distance the fill is located from the navigation project areas. Expected annual costs of the recommended Section 933 Project are shown in table 10 and presented in Appendix H.

TABLE 9
FIRST COST SUMMARY

Description	Sand Placement Location	Costs
TOTAL SECTION 933 PROJECT + MODIFIED DISPOSAL PLAN:		
Mobilization & Demobilization		$2,850,000
Pumpout Brandt Island & Inner Harbor	Fort Macon & Atlantic Beach	$3,706,654
Pumpout Brandt Island, Inner Harbor, & Entrance Channel	AB, PKS, & IB	$24,654,870
Embankment Replacement		$500,000
Beach Tilling		$137,600
Planning Engineering & Design		$375,000
Construction Management		$100,000
SUBTOTAL before Contingencies		**$32,324,124**
Contingencies (10%)		$3,211,876
TOTAL Section 933 Project + Modified Disposal Plan		**$35,536,000**
BASE DISPOSAL PLAN:		
Mobilization & Demobilization		$1,750,000
Pumpout Brandt Island & Inner Harbor	Atlantic Beach and Fort Macon	$10,737,600
Mobilization & Demobilization		$250,000
Dredge Entrance Channel	Near Shore Disposal Area	$3,900,000
Embankment Replacement		$500,000
Beach Tilling		$130,400
Planning Engineering & Design		$120,000
Construction Management		$50,000
SUBTOTAL before Contingencies		**$17,438,000**
Contingencies (10%)		$1,744,000
TOTAL Base Disposal Plan		**$19,182,000**
SECTION 933 PROJECT COSTS		**$16,354,000**

Note: The percentage of the Section 933 Project costs ($16,354,000) to the total Section 933 Project plus the Modified Disposal Plan ($35,536,000) is 46.0 percent.

TABLE 10

EXPECTED ANNUAL COSTS FOR RECOMMENDED PLAN
(Based on 5-7/8 percent interest rate, 20-year Period of analysis)
(October 2002 price levels)

Total Project Summary	**Total 933 Project**	**Base Disposal Plan**	**Difference to be Justified**
Total Initial Construction:	$36,927,000	$20,573,000	$16,354,000
Interest During Construction	$708,000	$0	$708,000
Total Investment Cost	$37,644,000	$20,573,000	$17,062,000
Expected Annual Cost:			
I&A-20 years			$1,473,000
Annual Benefits Forgone			$705,000
Total Expected Annual Cost			$2,178,000

SUMMARY OF BENEFITS AND COSTS, SECTION 933 PLANS

Table 11 summarizes benefits and costs for the Recommended Plan. As shown in this table, the Recommended Plan would produce benefits greater than costs. This plan would provide effective protection for long-term shore erosion.

TABLE 11

EXPECTED ANNUAL BENEFITS AND COSTS OF THE RECOMMENDED PLAN

Expected Annual Total Benefits	$10,655,000
Expected Annual Total Costs	$2,178,000
Benefit-to-Cost Ratio	4.9

RATIONALE FOR DESIGNATION OF RECOMMENDED PLAN AND PLAN SELECTION

The Recommended Plan would control progressive erosion and minimize permanent land losses. The plan would reduce damages to structures caused by short-term, storm-induced erosion. The plan is considered to be environmentally acceptable. As discussed previously, the National Objective for Federal water resources projects is to contribute to the National Economic Development.

SECTION VI - RECOMMENDED PLAN OF IMPROVEMENT

The purpose of this report section is to centralize information concerning the Recommended Plan of Improvement for the Section 933 Project. The Recommended Plan is discussed in terms of (1) Plan Features, (2) Construction, (3) Plan Accomplishments, (4) Plan Impacts, (5) Public Views and (6) Plan Implementation.

PLAN FEATURES

The Recommended Plan of Improvement includes a 30-ft wide berm placed at 7-ft NGVD. Project dimensions are shown on Figure 7. The project will extend along the reaches shown on Figure 1. The total length of the main fill will be approximately 38,000 feet, which includes the 1,000-foot transition zone on the west end of the main fill.

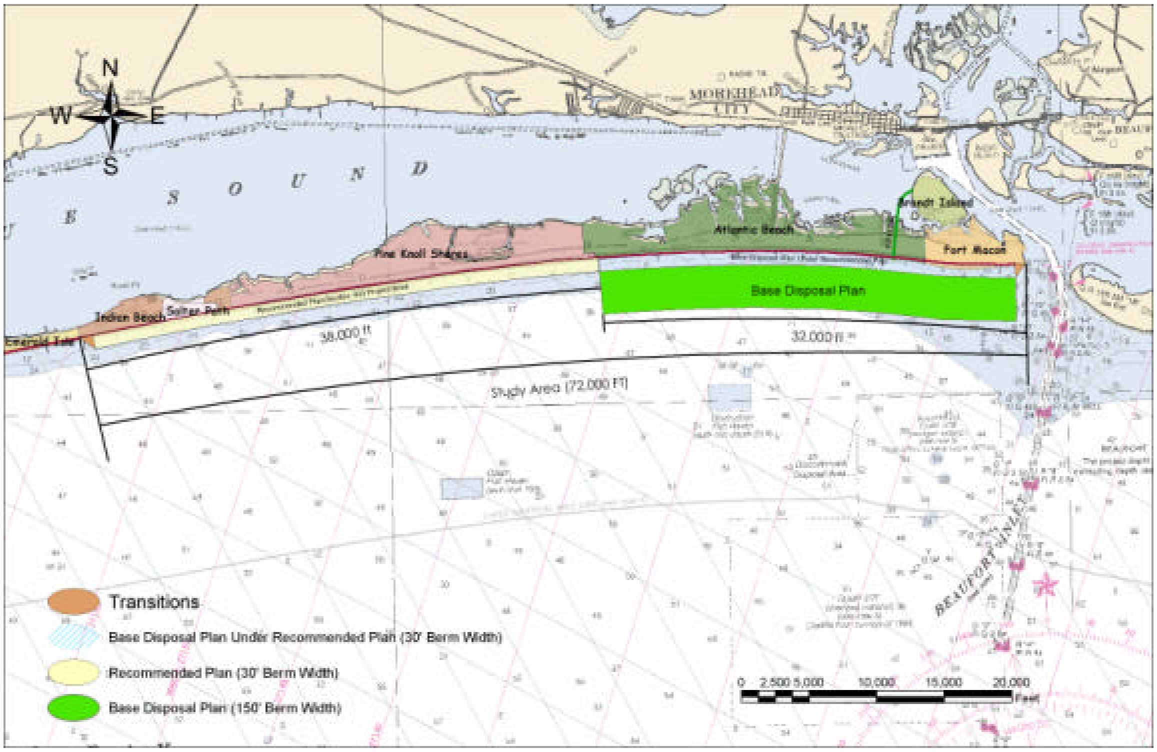

Figure 7. MHC Section 933 Recommended and Base Disposal Plans

PROJECT CONSTRUCTION AND OPERATION

Project construction will make use of approximately 4,466,000 cubic yards of sand for the Recommended Plan. The material will be pumped to the beach by pipeline dredge and/or hopper dredge with pump out capability and shaped on the beach by earth moving equipment.

NAVIGATION PROJECT AREAS AND FILL MATERIAL

Navigation project areas to be dredged and the material to be used for beachfill are located as shown on Figure 3. Based on grain size analysis of samples taken in these areas from the previous placements of material from Brandt Island and Morehead City Harbor maintenance onto Bogue Banks, it is reasonably confident that the navigation project areas contain good quality beach sand, which will be verified prior to placement on the beaches (see Appendix G for additional details on the geotechnical analysis).

Brandt Island, the inner harbor and the entrance channel will be the major sources of sand for the construction of the Section 933 project. The volume of material remaining on the beach immediately following placement will be reworked (sorted) by wave action into a distribution of material sizes from the berm crest seaward to closure depth that will closely mimic the native material distribution. This sorting process will take several months to occur and will result in the removal of the remaining excess material from the design template.

Generally, the material removed by this sorting action will be the finer fraction of the sandy material, which will be transported to offshore depths greater than 27 feet below NGVD.

OPERATION AND MAINTENANCE

There are no operation and maintenance requirements associated with the Section 933 project. All benefits to the Section 933 Project will accrue without operation and maintenance.

GEOTECHNICAL PROCESS

Morehead City Harbor dredge material has traditionally been placed in Brandt Island or on the beach at Atlantic Beach and Fort Macon. The material in Brandt Island was sampled and grain size tests were performed in the mid-1980's prior to the initial pump out in 1986. The quality of the material was determined to be suitable for beach disposal. Brandt Island was pumped out again in 1994 with the material being disposed of on the beach.

The subsurface investigation will include drilling the shoals in Morehead City Harbor and taking beach grab samples, and grain size testing the material collected from these samples. Twenty-one, 10-foot vibracore borings in the Harbor area and the connecting channels with the worst shoals were drilled on March 26, 2003. The borings were performed with the snagboat *SNELL* using a 3 7/8 inch diameter Alpine vibracore drill machine. The tubes were sampled for representative material and at a minimum of one sample for every two feet of recovered length. Each tube is expected to have approximately 3 soil samples for a total of approximately 60 samples. No borings will be performed on Brandt Island as part of this project. It is assumed that the material in Brandt Island is the same as the inner Harbor material tested for this project, since the Inner Harbor material from previous dredging is stored in Brandt Island. Grab samples will be collected from twenty-five profile lines perpendicular to Fort Macon, Atlantic Beach, Pine Knoll Shores, Indian Beach, Emerald Isle, and Bogue Inlet Area for a total of 150 samples. These samples will be tested for grain size, silt content, shell content in accordance with ASTM D 422 using a minimum of 12 sieves. Samples will be classified in accordance with the Unified Soils Classification system.

All the samples collected from the Harbor Shoal material and the beach grab samples will be analyzed to determine the material suitability for beach placement. Based on material removed from the Inner Harbor and Brandt Island in the past, it is expected that the material designated for beach placement as part of this project will be suitable.

REAL ESTATE REQUIREMENTS

Real estate requirements for the Recommended Plan of Improvement include lands, easements, rights-of-way and relocations, and disposal/borrow areas, which are referred to as LERRD's. Existing easements are in places that were acquired by the sponsor for a local, non-federally funded project. The easements incorporated the standard language in the Government Perpetual Storm Damage Reduction Easement. It is anticipated that all work will be completed within the limits of the existing easements and/or seaward of these easements. In order for Real Estate to be certified for this project, the project sponsor will be required to supply CESAS-RE with a map and copies of their existing easements. Per discussion with The North Carolina Department of Administration, the State of North Carolina does not require a permit to place sands below the mean high water line. However, the Local Sponsor will need to furnish the State of North Carolina Department of Administration with a letter of intent to place sand below the Mean High Water Line.

Other things that are to be considered are access to the beach during construction, additional pipeline routes, and temporary work area easements. Access to the beach will be by public access points that are located along the beach area. A previously acquired perpetual pipeline easement will be used for the placement of the pipeline. Should additional pipeline routes be identified, the project sponsor will be responsible for acquisition. Additional details of the Real Estate Requirements are discussed in Appendix F.

PLAN ACCOMPLISHMENTS

The Recommended Plan reduces expected annual damages to structures due to hurricane-wave action and storm induced erosion. As shown in Table 5, existing expected annual damages for hurricane and storm damage are estimated at $14,543,000 without a Section 933 project in place in the Study Area. With the Recommended Plan in place expected annual hurricane and storm damages are reduced to about $5,593,000. Thus, as stated above, the Recommended Plan would reduce hurricane and storm damages by an expected annual amount of $8,950,000 for the 7.2-mile-long Section 933 project area, or about 62 percent.

Although the plan will substantially reduce damages due to hurricane-wave overwash, it should be noted that the Recommended Plan of Improvement provides for storm protection only in terms of protecting development from the action of ocean storm surge and wave action.

BENEFITS

Total expected annual benefits for the Recommended Plan are estimated at $10,655,000 based on October 2002 price levels. An itemized listing of expected annual benefits was presented in Table 6. If the plan is to be recommended for implementation, expected annual costs must be less than this amount. Project costs are discussed below.

PROJECT COSTS

Determination of the economic costs of the Recommended Plan consists of two basic steps. First, project first costs are computed. First costs include expenditures for project design and construction and related costs of supervision and administration. First costs also include the lands, easements, and rights of way for project construction.

Second, interest during construction is added to the project first cost. Interest during construction is computed from the start of PED through the construction period. The project first cost plus interest during construction represents the total investment required to place the project into operation.

These costs consist of interest and amortization of the investment. The expected annual costs provide a basis for comparing project costs to project benefits. A summary of the computations involved in each of these two steps is presented below.

Project First Costs - The total first cost of construction for the Recommended Plan is estimated at $16,354,000, based on October 2002 price levels. An itemized listing of first costs is presented in Table 9.

Interest During Construction - Interest during construction, computed over PED and the construction period, is established at $708,000 for the Section 933 Project Area. The total investment required to place the project into operation would be $17,062,000 for the Section 933 Project Area.

Expected Annual Costs - Expected annual costs include interest and amortization of the investment over an assumed project life of 20 years. As shown in Table 10, expected annual costs for the Selected Plan of Improvement are estimated at $2,178,000 for the Section 933 Project Area.

Benefit-Cost Ratio - The Recommended Plan produces expected annual benefits estimated at $10,655,000 for the Section 933 Project Area. Expected annual costs for the Recommended Plan are estimated at $2,178,000 for the Section 933 Project Area. Thus benefits divided by costs results in a benefit-cost ratio of 4.9 for the Section 933 Project Area. Since project benefits exceed costs, the Recommended Plan is considered economically feasible.

ENVIRONMENTAL IMPACTS

The Recommended Plan of Improvement is considered to be environmentally acceptable, although some environmental impacts are anticipated. Significant resources likely to be affected by the Recommended Plan include biological resources, water quality, aesthetic values, and threatened species. The proposed action will not cause any significant impacts to the environment (see attached EA). No effect on cultural resources is anticipated. Anticipated impacts on each resource are discussed below.

IMPACTS ON BIOLOGICAL RESOURCES

Biological resources will be affected by dredging of material from Brandt Island and the Morehead City Harbor navigation channels for project construction and by placement of this material on the beach. The sediments taken from Brandt Island and the Morehead City Harbor navigation channels is believed to be suitable for placement on the beaches of Bogue Banks. As indicated in the attached EA, Brandt Island has been previously pumped out in FY 1986 and FY 1994 and the resultant dredge material placed on the beaches of Bogue Banks. Expected impacts on biological resources due to dredging and fill placement are discussed on the following pages.

Navigation Project Area Dredging - No significant impact on biological resources is expected due to piping of dredged material from the navigation project areas (including Brandt Island) to the beachfill areas. The pipeline route will extend from the navigation project areas and Brandt Island to the beach and then will follow the shoreline.

There will be some loss of dune vegetation where the pipeline crosses the dune to the beach. Plants growing adjacent to the seaward side of the dunes will be buried by the discharge of dredged material. Dune vegetation disturbed by the pipeline crossing to the beach will be restored to pre-project grade and replanted following project completion.

Negative impacts associated with pipeline routes will be minor and temporary.

Beachfill Construction - The major impacts associated with this type of operation include:

A. Increased turbidity in the surf zone;

B. Effects on the benthic communities;

During disposal operations, there will be an increase in the turbidity of the surf zone in the immediate area of sand disposition. This increase may cause the temporary displacement of various species of sport fish, causing a negative impact to surf fishing in the area of deposition.

A considerable body of information is available on the effects of dredging on benthic communities and specific environmental consequences of beach disposal. However, there are some uncertainties on the degree of impacts on certain resources over the long term. A more detailed discussion is found within the FONSI.

ENDANGERED AND THREATENED SPECIES

As noted previously, species which could be present in the project area during the proposed action are the finback whale, humpback whale, right whale, sei whale, sperm whale, West Indian manatee, piping plover, roseate tern, green sea turtle, hawksbill sea turtle, Kemp's ridley sea turtle, leatherback sea turtle, loggerhead sea turtle, shortnose sturgeon, and sea-beach amaranth. Some of these species may be affected by construction of the Recommended Plan of Improvement. The greatest potential for impacts to the endangered and threatened sea turtle species found within the project area is for beach disposal from 1 May to 15 November of any year, and hopper dredging from April 1 to December 31. Potential project impacts to these species are discussed below and more detailed information is found in the FONSI.

Loggerhead, Kemp's Ridley, and Green Sea Turtles - All of these turtles are known to nest in North Carolina and could nest in the project area. For this reason, they may be affected by the project construction.

In order to minimize impacts on nesting sea turtles, beach disposal sand should match natural sand as closely as possible. Before any dredged maintenance material is pumped from Brandt Island and/or Morehead City Harbor maintenance, onto Bogue Banks beaches, we will assure that the material is suitable for beach disposal. The type of material used for beachfill should not affect sea turtles. Also, beach tilling will be accomplished for the purpose of loosening the sand fill set, which hardens and makes nesting by sea turtles difficult.

Sea turtle monitoring and nest relocation will be required during construction if disposal occurs during the sea turtle nesting season (1 May to 15 November). Sea turtles also occur in the entrance channel proposed for dredging and may be affected (by take) since hopper dredges may be used for maintenance dredging and pump out for beach disposal along the Project Area. To minimize takes by a hopper dredge, work will be restricted from 1 January to 31 March.

As noted above, a monitoring and nest relocation program will be implemented when beach disposal occurs during the nesting season. However, even with this program in place, the possibility of accidental egg loss during nest relocation exists. Therefore, it has been determined that the project may adversely affect the loggerhead, Kemp's ridley, and green sea turtles.

During the period of sea turtle nesting and hatching (1 May through 15 November), all lighting associated with project construction shall be minimized to the maximum extent practicable while maintaining compliance with all safety requirements. Reduced wattage and special fixtures or screens to reduce illumination of adjacent beach and near shore waters shall be used if practical.

Lighting on offshore equipment shall also be minimized to the maximum extent practicable while meeting Coast Guard requirements. Shielded low pressure sodium vapor lights are highly recommended for all lights on the beach or on offshore equipment.

Piping Plover - Because beach disposal may temporarily impact foraging habitat and disrupt nesting that may be attempted along the eroded beach front, it has been determined that the project may affect the piping plover.

Marine Mammals - Marine mammals occur in offshore sites proposed for dredging. It is expected that these species can be detected by use of observers and avoided, therefore a no effect determination is proposed.

Seabeach Amaranth - While beach disposal will restore much of the habitat lost to erosion, disposal on a portion of the beaches in the growing season during project construction may slow population recovery over the short term. Therefore, the project may affect seabeach amaranth.

IMPACTS ON WATER QUALITY

The proposed project will result in elevated turbidity and suspended solids compared to the existing non-storm conditions of the surf zone in the immediate area of beachfill. Due to the low percentage of silt and clay in Brandt Island and the Morehead City Harbor navigation channels (averaging less than 10 percent), this impact is not expected to be greater than the natural increases in turbidity and suspended material during storm events. Discharge of sediment that is predominantly sand would be required for beach disposal. Such discharge would occur within the 3-mile limit and therefore would be subject to regulation under Section 404(b)(1) of the Clean Water Act of 1977, as amended and will require a Section 401 (P.L. 95-217) State of North Carolina Water Quality Certificate.

It is expected that dredged disposal on the beach would result in turbidity and suspended solids concentrations that are elevated over normal background levels in the navigation project areas during dredge excavation and in the surf zone in the immediate area of beach disposal operation. No other water quality parameters are anticipated to be impacted significantly during dredge channel maintenance, pumpout of Brandt Island, and beach disposal.

The degree of water quality impacts associated with navigation maintenance dredging activities and beach disposal has been evaluated during this study and presented in the attached FONSI. Investigations indicated that suitable material would be used for beach disposal; therefore water quality impacts would not be significant.

IMPACTS ON AESTHETIC RESOURCES

Aesthetic impacts of project construction are expected to be both positive and negative. The aesthetics of the beach would temporarily be degraded during beach disposal due to the presence of heavy equipment and pipeline on the beach and elevated turbidity in the surf zone. Noise and exhaust created by the operation of the dredge and other equipment will result in minor increases in noise and air pollution. However, upon completion of the project, the aesthetics and recreational use of the beach should be enhanced due to the wider beach.

IMPACTS ON CULTURAL RESOURCES

The Wilmington District, in consultation with the NC Division of Archives and History Underwater Archaeology Unit, have considered both the potential impact of the project and the nature of the known resources, and have determined that the information does not support a recommendation for an archaeological survey of the entire beach area. However, it is possible during the course of construction that vessel remains will be encountered. Therefore, the Underwater Archaeology Unit has requested that Wilmington District personnel, contractors, and others be aware that the possibility exists that this work may unearth a beached shipwreck. In the event that such occurs, work should move to another area and the Underwater Archaeology Unit should be contacted immediately at telephone number (910) 458-9042. A staff member will be sent to assess the wreckage and, if practical, undertake appropriate documentation.

CUMULATIVE IMPACTS

A cumulative analysis of the impacts of existing, proposed and potential projects involving beach disposal, is found in Attachment E of the Draft Evaluation Report and Environmental Assessment, Morehead City Harbor, Section 933, Carteret County, North Carolina, dated May 2003. General impacts of beach disposal on other North Carolina beaches are considered to be similar to those described herein. The degree of cumulative impact would increase proportionally with the total length of beach impacted. This analysis quantifies these impacts in terms of the percent of North Carolina beaches affected on an annual and total basis by sand disposal for maintenance of Federal navigation channels, and existing, proposed or potential beach disposal projects. Cumulative impacts of the proposed action appear negligible.

SUMMARY OF ENVIRONMENTAL IMPACTS

Adverse environmental impacts associated with the proposed action include (1) Destruction and displacement of intertidal and benthic fauna during construction; (2) temporary increases in turbidity and suspended solids during construction and disposal operations; and (3) it has been determined that the project, as currently proposed, may affect the piping plover, green sea turtle, loggerhead sea turtle, hawksbill sea turtle, leatherback sea turtle, Kemp's ridley sea turtle, and seabeach amaranth. A program of monitoring and nest relocation will be implemented to mitigate adverse impacts on the sea turtles when fill placement overlaps the sea turtle nesting season. Additionally, the Corps will continue to monitor seabeach amaranth during the growing season (1 July to September 30).

MITIGATION REQUIREMENTS
