Introduction

The Federal Government has proposed to offer Outer Continental Shelf (OCS) lands in the Central and Western Gulf of Mexico Planning Areas for oil and gas leasing in OCS Lease Sales 157 and 161. The base case estimates of oil resources (the amount that is likely to be leased, discovered, and produced) as a result of these lease sales are 0.11 billion barrels (Bbbl) for Lease Sale 157 in the Central Gulf of Mexico and 0.04 Bbbl for Lease Sale 161 in the Western Gulf of Mexico. The high case estimates (the amount of oil resources likely to be leased, discovered, and produced as a result of a higher level of activity) are 0.24 Bbbl for the Central Gulf of Mexico and 0.10 Bbbl for the Western Gulf of Mexico. The resource estimates assume that commercial quantities of hydrocarbons exist in the sale areas.

Production for the lease sales is assumed to span a period of 32 years (1998-2029).

Production for the cumulative case (prior sales, the proposed action, and future sales—defined as total planning action [TPA]) is assumed to span a period of 35 years (1996-2030). The resource estimates for the TPA include 1.18 Bbbl for the Western Gulf, 4.73 Bbbl for the Central Gulf, and 0.03 Bbbl for the Eastern Gulf. This report examines the possible occurrence and contact of hypothetical oil spills if leases are issued and commercial quantities of oil are found and produced from OCS Lease Sales 157 and 161.

Because oil spills may occur from activities associated with offshore oil exploration, production, and transportation, the Minerals Management Service (MMS) conducts a formal risk assessment prior to lease sales. When the significance of accidental oil spills is evaluated, it is important to remember that the occurrence of such spills is fundamentally a matter of probability. No one can certify the amount of oil that would be produced, or the size or likelihood of a spill that would occur, during the assumed production life of the lease. Neither can the wind and current conditions during a spill be known for certain. Although some of this uncertainty is due to incomplete and imperfect data, a considerable amount exists simply because it is difficult to estimate future events. For example, a probabilistic event such as an oil-spill occurrence cannot be predicted—only an estimate of its likelihood or probability can be quantified.

However, the possible effects of oil spills that could occur from oil and gas production must be considered in the leasing decision. To maintain perspective, each potential effect must be associated with a quantitative estimate of its probability of occurrence. This report summarizes results of an oil-spill risk analysis (OSRA) conducted for the proposed Gulf of Mexico OCS Lease Sales 157 and 161. The objective of this analysis was to estimate relative risks associated with oil and gas production for the proposed lease sales. The MMS considers the analysis in the environmental impact statement (EIS) prepared for the lease sales. A description of the OSRA model used in this analysis can be found in previous papers (Smith et al., 1982; LaBelle and Anderson, 1985).

The analysis was conducted in three parts corresponding to different aspects of the overall problem.

- The first part dealt with the probability of oil-spill occurrence.
- The second part dealt with the trajectories of oil spills from hypothetical spill locations to various environmental resources.
- The third part combined results of the first two to estimate the overall oil-spill risk if there is oil production as a result of the lease sales.

Summary of the Proposed Action

The proposed action is to offer for lease OCS lands in the Gulf of Mexico. The study area for this analysis extends from latitudes 23.0° N. to 30.5° N. and from longitudes 78.0° W. to 97.5° W. The study area and the 145 hypothetical spill sites, which are used to represent oil-spill risks from anticipated platforms in the proposed lease areas, are shown in figure 1. Existing and potential pipeline and tanker routes are shown in figures 2 through 9 to represent spill risks from oil transportation.

The development scenario assumes production and transportation of the base case oil resource for the proposed action to be 0.11 Bbbl for the Central Gulf of Mexico and 0.04 Bbbl for the Western Gulf of Mexico. In addition, the scenario assumes the high case resource to be 0.24 Bbbl for the Central Gulf of Mexico and 0.10 Bbbl for the Western Gulf of Mexico. The analysis also considers the OCS Gulfwide (GW) oil resources (5.94 Bbbl) and non-OCS imports (67 Bbbl—foreign oil and non-OCS domestic petroleum products) projected over the assumed production life of the proposed sales. The GW resource consists of the TPA estimates of oil resources and reserves for all lease sales during the assumed production life of the proposal. The TPA comprises proposed, existing, and future leases in each of the planning areas. The scenarios and subsequent analyses assume that commercial quantities of hydrocarbons are present in the lease sale areas. The oil is distributed according to each spill site's contribution to the proposed action's total resource estimate.

The development scenario also assumes that all of the oil produced in the areas to be leased will be transported by one or more pipeline routes (figs. 2-6). Only imported oil will be brought to shore by ships. The ships will follow the import routes (fig. 7) and then the fairway routes (fig. 8) to shore. In previous lease sales, it was assumed that some specified amount of the OCS-produced oil would be brought to shore wholly or partly by shuttle tankers. These tankers would follow the shuttle tanker routes shown in figure 9.

Framework of Analysis

The OSRA depends not only on the meteorological and geographical conditions of the study area but also on the environmental resources that are at risk and the estimated volumes of oil resources that are assumed to be discovered, produced, and transported.

Environmental Resources

The locations of 32 environmental resources were digitized in the same coordinate system or base map as that used in the trajectory simulations. Environmental resources were selected by MMS analysts in the Gulf of Mexico OCS Region who prepare the EIS for the lease

sales. Appendix A (figs. A-1 through A-5) contains maps showing the digitized environmental resource locations.

Because the trajectory model simulates an oil spill as a point, environmental resources have been given an areal extent slightly greater than they actually occupy. For example, shoreline environmental resources extend a short distance offshore, thus allowing the model to simulate a spill that approaches, partially contacts the environmental resource, withdraws, and continues on its path.

Please note that the definition of the coastal waters of the Gulf states has been changed from the definition used in the OSRA for Lease Sales 152 and 155. Previously, the coastal waters represented the state shores with no seaward extent. This analysis uses the state territorial waters—the waters from the shore to the claimed seaward extent. Texas and Florida claim out to 9 miles from their shores; Louisiana, Mississippi, and Alabama claim out to 3 miles from their shores. Also, please note that the extent of the environmental resource "Land" (total shoreline extent) has been increased in this OSRA by the inclusion of parts of Cuba, parts of two Bahamian islands, and a small portion of the Mexican coast adjacent to the U.S.-Mexican border.

Each environmental resource was represented as being vulnerable year-round, with the following exceptions: The Aransas Refuge area, western winter menhaden, and central winter menhaden are not vulnerable to simulated oil-spill contact during April through August because the species of concern are not present in these areas at that time of the year. The digitized environmental resources of concern in the Gulf of Mexico OCS Lease Sales 157 and 161, and the figures illustrating their locations, follow:

Environmental Resources (Figure Number)

Land (9)	Survey Block 1 (A-3)
Galveston Bay (A-1)	Survey Block 2 (A-2)
Aransas Refuge (A-1)	Survey Block 3 (A-4)
Tamaulipas, Mexico (A-1)	Survey Block 4 (A-2)
Mobile Bay (A-3)	Survey Block 5 (A-5)
Timbalier Bay (A-3)	Survey Block 6 (A-4)
Barataria Bay (A-3)	Survey Block 7 (A-2)
Mississippi Sound (A-3)	Florida Keys National Marine Sanctuary (A-4)
Caminada Headland (A-5)	Flower Garden National Marine Sanctuary (A-3)
West Plaquemines coastal barrier beaches (A-4)	Texas coastal waters (A-3)
Chandeleur/Breton coastal barrier beaches (A-4)	Louisiana coastal waters (A-2)
East Deltaic Plain marshes (A-5)	Mississippi coastal waters (A-1)
Western winter menhaden (A-3)	Alabama coastal waters (A-2)
Central winter menhaden (A-1)	Florida coastal waters (A-1)
Big Bend seagrass beds (A-5)	Florida Bay seagrass beds (A-2)
Florida Middle Grounds (A-4)	Dry Tortugas (A-1)

Land was further analyzed by dividing the study area coastline into 58 land segments (fig. 10). The segments along the U.S. coast were defined by county/parish boundaries with some land segments spanning more than one county/parish. The following list identifies the county/parish names and their corresponding land segment numbers. Four additional land segments were used in this analysis: the northern coast of Cuba; the western coast of Andros Island, the western coast of Grand Bahama Island; and a segment of the Mexican coast adjacent to the U.S.-Mexican border. With the use of improved and geographically extended ocean circulation modeling and observations of surface currents, these additional areas became possible oil-spill contact points in our analysis. Therefore, we have added them to the list.

County/Parish Name	Segment Number	County/Parish Name	Segment Number

To provide a more detailed analysis of oil-spill contacts with land or land-based environmental resources, the model includes a feature that allows combining results of contacts to specific land segments. The segments, which are vulnerable all year, were grouped in the following combinations to represent the 67 land-based environmental resources listed below.

Environmental Resource	Land Segment Number
South Padre Island coastal barrier beaches	1 and 2
North Padre Island coastal barrier beaches	3 and 4
Mustang Island coastal barrier beaches	5
Saint Joseph Island coastal barrier beaches	6
Matagorda Island coastal barrier beaches	7
Matagorda Peninsula coastal barrier beaches	8
Brazos Headland coastal barrier beaches	9
Galveston Island/Bolivar Peninsula coastal barrier beaches	10
Rollover Pass to Sabine Pass coastal barrier beaches	11
Laguna Madre seagrass beds	1 to 4
Corpus Christi Bay seagrass beds	5
Espiritu Santo/Matagorda seagrass beds	7 and 8
Galveston seagrass beds	10
Espiritu Santo/Matagorda Bays	7 and 8
Galveston Bay	10
Central Texas coastal marshes	6 to 8
Eastern Texas coastal marshes	9 to 11
Brazos/South Padre Islands recreational beaches	1
Padre Island National Seashore/Mustang Island recreational beaches	3 to 5
Matagorda Island recreational beaches	7
Matagorda coastal recreational beaches	8
Brazoria coastal recreational beaches	9
Galveston/Bolivar Peninsula recreational beaches	10
Sea Rim recreational beaches	11
Chenier Plain coastal barrier beaches	12 and 13
Grand Isle/Grand Terre coastal barrier beaches	18
Dauphin Island coastal barrier beaches	22
Gulf Shores coastal barrier beaches	23
Mobile/Perdido seagrass beds	22 and 23
Vermilion/Atchafalaya Bays	14 and 15
Mobile Bay	22 and 23
Chenier Plain marshes	12 and 13
Cameron Parish recreational beaches	12
Fouchon recreational beaches	17

Environmental Resource	Land Segment Number
Grand Isle recreational beaches	18
Mississippi Mainland recreational beaches	21
Dauphin Island recreational beaches	22
Gulf Shores recreational beaches	23
Emerald Coast coastal barrier beaches	24 to 27

Charlotte Harbor mangroves	40 and 41
Everglades mangroves	42 to 44

Estimated Volume of Oil Resources

For this analysis, both benefits and risks are functions of the volume of oil and are mutually dependent. For example, greater volumes of oil are associated with greater economic benefits as well as greater risks. If the benefits are evaluated by assuming production of a specific amount of oil, then the corresponding risks should be stated conditionally, such as "the risks are . . . , given that the volume is" Any statements about the likelihood of a particular volume of oil being present also apply to the likelihood of the corresponding benefits and risks.

The estimated volumes of oil resources used for oil-spill risk calculations in this report correspond to those used by MMS in preparing the EIS for the lease sales. These estimates were allocated to the hypothetical spill sites by analysts in the Gulf of Mexico OCS Region (memoranda from the MMS Regional Supervisor for Resource Evaluation, Gulf of Mexico OCS Region, to the MMS Deputy Associate Director for Resources and Environmental Management, dated July 26, 1994). The conditional undiscovered, economically recoverable oil resource estimates that are assumed to be leased, developed, produced, and transported for OCS Lease Sales 157 and 161 are as follows:

<u>Planning Area</u>	<u>Sales 157 and 161</u>		<u>Total Planning Area</u>
	<u>Base Case</u>	<u>High Case</u>	<u>Total Volume</u>
Western Gulf	0.04 Bbbl	0.10 Bbbl	1.18 Bbbl
Central Gulf	0.11 Bbbl	0.24 Bbbl	4.73 Bbbl
Eastern Gulf	--	--	0.03 Bbbl

The TPA estimate is the sum of estimates from prior sales, the proposed action, and future sales ($TPA = PS + P + F$). Prior sales include known reserves as well as estimates of undiscovered resources on existing leases. Future sales are OCS lease sales expected to occur during the assumed production life of OCS Lease Sales 157 and 161. The volume of undiscovered oil resources is assumed to be produced over a period of 35 years following these sales. It is assumed that an estimated 67 Bbbl of crude oil will be imported to the Gulf of Mexico Region by tankers from outside sources over the same 35-year period (memorandum from Regional Supervisor for Leasing and Environment, Gulf of Mexico, to Chief, Environmental Policy and Programs Division, dated July 26, 1994).

The GW volume was created from the TPA estimates:

$$GW = WTPA + CTPA + ETPA = 5.94 \text{ Bbbl}$$

where :

WTPA = Western TPA

CTPA = Central TPA

ETPA = Eastern TPA

It should be emphasized that these estimates and the following analysis assume that commercial quantities of oil are present. If no commercial quantities of oil are present, no oil-spill risks from OCS production exist.

Oil-Spill Risk Analysis (OSRA)

The OSRA consists of three parts: the probability of an oil spill occurring, the trajectory simulation of the oil spill, and the combination of occurrence probability and trajectory simulation.

Probability of Oil Spills Occurring

The probability of oil spills occurring (given that commercial quantities of oil are present) assumes that spills occur independently of each other as a Poisson process. The Poisson process is a statistical distribution commonly used to model random events. The probability of oil spills occurring is based on spill rates derived from past OCS platform and pipeline experience and tanker experience in U.S. waters and depends on the volume of oil produced and transported. All types of accidental spills greater than or equal to 1,000 barrels (bbl) were considered in this analysis. These spills include not only well blowouts but also other accidents that occur on platforms and during transportation of oil to shore. These accidents were classified as either platform, pipeline, or tanker spills. This classification allows the analyst to compare the risks from each spill source between the proposed action and any alternatives.

Anderson and LaBelle (1995) examined oil-spill occurrence rates applicable to the U.S. Outer Continental Shelf. Their results, adjusted for recent experience and based upon more complete databases than were available for earlier analyses (Anderson and LaBelle, 1990; Lanfear and Amstutz, 1983), indicated some significant changes in the spill rates for platforms and pipelines. In addition, they developed estimated occurrence rates for tanker spills that occurred in U.S. waters. This report uses the updated spill occurrence rates.

Spill rates are expressed as number of spills per billion barrels (spills/Bbbl) of oil produced or transported. Only spills greater than or equal to 1,000 bbl are addressed because smaller spills may not persist long enough to be simulated by trajectory modeling. Another consideration is that a large spill is likely to be identified and reported; therefore, these records are more comprehensive than those of smaller spills. (Small, chronic spillage is addressed in the EIS for OCS Leases 157 and 161 without the use of trajectory modeling.)

Two basic criteria were used in selecting volume of oil handled as the risk exposure variable: (1) the exposure variable should be simple to define, and (2) it should be a quantity that can be estimated. The volume of oil produced or transported was the chosen exposure variable primarily for the following reasons: historic volumes of oil produced and transported are well documented; using these volumes makes the calculation of the estimated oil-spill occurrence rate simple—the ratio of the number of historic spills to the volume of oil produced or transported; and future volumes of oil production and transportation are routinely estimated. Estimates of volume are prepared by MMS Resource Evaluation program analysts; their function and expertise involve the assessment of oil resources by using comprehensive geological and geophysical databases and related models. In addition, the MMS analysts estimate most other exposure variables, such as number of platforms and tanker trips, as a function of the volume of oil produced or transported.

Anderson and LaBelle (1995) analyzed platform and pipeline spills that occurred on the U.S. Outer Continental Shelf from 1964 through 1992, and crude oil tanker spills that occurred in U.S. waters from 1974 through 1992. In these analyses, every spill record was examined and verified to the furthest extent possible. Each spill was classified for size, product spilled, and spill source, according to its applicability to the analysis.

In an earlier analysis (Anderson and LaBelle, 1990), nonparametric tests were applied to determine whether OCS platform and pipeline spills from 1964 through 1987 were random and independent. For these observations, the volume of oil produced and transported between spills appeared to be nonrandom, increasing over time. Extending the data through 1992, Anderson and LaBelle (1995) showed that the OCS platform spill rate continued to decline. However, with the occurrence of four pipeline spills between 1988 and 1992, there was no longer any evidence of a corresponding decrease in the estimated OCS pipeline spill occurrence rate.

For spills greater than or equal to 1,000 bbl, the spill rates are 0.45 spills/Bbbl of produced oil for U.S. Outer Continental Shelf platforms and 1.32 spills/Bbbl of transported oil for U.S. Outer Continental Shelf pipelines. The platform rate reflects the observed decline in spill occurrence mentioned above. The platform spill rate is based on the most recent 73 percent of the production record, which includes only 27 percent of the historic platform spills (3 spills/6.6 Bbbl produced). The pipeline spill rate of 1.32 spills/Bbbl is based on the entire OCS production (transportation) and pipeline spill records (12 spills/9.1 Bbbl transported).

The database of tanker spills in U.S. waters provided substantially more observations than did the OCS pipeline and platform data. Spill rates for tanker spills greater than or equal to 1,000 bbl were calculated directly from the data and were relatively constant from 1974 through 1992. Spill rates for tanker spills occurring "at sea" were calculated separately from those occurring "in port"; these values were 0.51 spills/Bbbl and 0.70 spills/Bbbl of transported oil, respectively, for a total tanker rate of 1.21 spills/Bbbl.

In summary, the spill rates in U.S. waters (expressed as number of spills \geq 1,000 bbl/Bbbl of produced or transported oil) used in this report are as follows:

Spill Source	Spill Rate in U.S. Waters (Spills/Bbbl)
Platforms	0.45
Pipelines	1.32
Tankers	1.21
At Sea	0.51
In Port	0.70

Oil-spill occurrences (spills \geq 1,000 bbl) are considered to be governed by a Poisson process (Smith et al., 1982; Lanfear and Amstutz, 1983; Anderson and LaBelle, 1990; Anderson and LaBelle, 1995). The probability of a specific number of spills $p(n)$ occurring is described by the Poisson distribution:

$$p(n) = \frac{e^{-\lambda} \cdot \lambda^n}{n!}$$

where n is the specific number of spills (0, 1, 2, ..., n), e is the base of the natural logarithm, and λ is the parameter of the Poisson distribution. For oil spills, the Poisson parameter (λ) is equal to the spill rate multiplied by the volume of oil to be produced or transported. The spill rate has dimensions of number of spills/Bbbl, and the volume is expressed in Bbbl. Therefore, λ denotes the mean number of spills estimated to occur as a result of production or transportation of a specific volume of oil.

Oil-spill occurrence estimates for spills greater than or equal to 1,000 bbl were calculated for production and transportation of oil during the assumed production life of the proposed action (1998-2029). Table 1 shows the mean number of spills estimated to occur and the probability of one or more spills occurring in the study area over the assumed production life of the proposed lease sales. The OSRA uses only the oceanic portion of the tanker-related spills, using the "at-sea" spill rate (0.51 spills/Bbbl) in the computations related to analysis of the trajectory modeling. Only one-half of the at-sea rate was applied to the tanker routes that are in the sale area but continue outside. Spills representing the other half of the rate are assumed to occur outside the study area.

Estimates of tanker spills occurring "in port" are based on historical spills that have occurred within bays, estuaries, and harbors, and at pier sites. These spills are not appropriate for trajectory modeling and are not included in this analysis other than as represented below. It was assumed that one-half of the "in-port" spills would occur at each port of call in the study area. The following table presents the estimated mean number of "in port" spills and the probabilities of one or more of these spills occurring from tankers while in the U. S. Gulf of Mexico ports handling crude petroleum.

Port	Base Case Volume Scenario (32 Years)		High Case Volume Scenario (32 Years)		Imports (35 Years)	
	Mean No.	Prob 1+	Mean No.	Prob 1+	Mean No.	Prob 1+
Corpus Christi, Tex.	--	--	--	--	2.35	90%

Oil-Spill Trajectory Simulations

The trajectory simulation portion of the model consists of many hypothetical oil-spill trajectories. The trajectories are the consequence of the integrated action of a temporally and spatially varying wind field and ocean current field on the hypothetical oil spills. Collectively, they represent an assumably statistical ensemble of the winds and currents that will occur over the life of the lease sales.

The analysis uses a combination of observed and theoretically computed ocean currents and winds. Most of the ocean currents used were generated by a numerical model. They were supplemented with many direct observations of the currents in the western Gulf resulting from repetitive deployments of surface drifting buoys. The sea surface winds over the Gulf were derived from observations of sea surface atmospheric pressure with an applied ageostrophic correction. The following discussion briefly describes these fields.

Climatologically representative monthly mean surface currents were provided by Dynalysis of Princeton, Princeton, New Jersey, using the Princeton-Dynalysis Ocean Model (PDOM). The PDOM, an enhanced version of the Mellor-Blumberg Model, is a three-dimensional, time dependent, primitive equation model using orthogonal curvilinear coordinates in the horizontal and a topographically conformal coordinate in the vertical. The use of these coordinates allows for a realistic coastline and bottom topography, including a sloping shelf, to be represented in the model simulation. The model incorporates the Mellor-Yamada turbulence closure model to provide a parameterization of the vertical mixing process through the water column.

The prognostic variables are the velocity, temperature, salinity, turbulence kinetic energy, and turbulence macroscale. The momentum equations are nonlinear and incorporate a variable Coriolis parameter. Prognostic equations governing the thermodynamic quantities, temperature and salinity, account for water mass variations brought about by highly time-dependent coastal upwelling processes. The processes responsible for eddy production, movement, and eventual dissipation are also included in the model physics. Free surface elevation is also calculated prognostically so that the tides and storm surge events can also be simulated. Other computed variables include the density, vertical eddy viscosity, and vertical eddy diffusivity.

A 12-year simulation was performed on the computational grid shown in figure 11. The model was driven by monthly climatological wind stress, heat flux, river flow, and Gulf Stream transport boundary conditions. From this 12-year simulation, a climatologically representative year was selected. Monthly averaged surface currents were then computed from that year and constitute most of the ocean currents used in the trajectory simulations.

Although its skill assessment has not been completed yet, the PDOM is believed to be an improvement over that previously used. It reproduces more features of the Gulf's circulation than was previously resolved, and the magnitude of the model currents are more realistic when compared to available observations.

In addition to the model surface current maps, quasi-Eulerian surface currents were derived from the positions of satellite-tracked drifting buoys. Under the direction of Peter Niiler and Russ Davis of Scripps Institution of Oceanography (La Jolla, California), approximately 340 drifting buoys were deployed from aircraft and three production platforms in a repeated array located southeast of Galveston, Texas (fig. 12). The investigation was called SCULP (Surface Current and Lagrangian-drift Program). Weekly deployments were made from mid-October 1993, running through January 1994, followed by monthly deployments through September 1994. However, only the observations through May 15, 1994, were available for this analysis and then were used only as a mean surface current field over the period October 15, 1993, to May 15, 1994.

The mean surface current field consisted of quasi-Eulerian velocities generated by decomposing the trajectories into geographical "boxes" (fig. 13). Within each box, a velocity was assigned which is the average of 25 or more daily velocities of trajectories occurring in the box over October 15, 1993—May 15, 1994 (fig. 14). The velocity vectors were located at the centers of their respective boxes. Mean velocities were computed when there were 25 or more trajectories within a box.

In the trajectory simulations, the drifting buoy mean velocities were substituted for the Dynalysis model currents in the same geographical area during the time interval October 15-May 15 (in the model year). The substitution was made whenever a hypothetical spill was within one of the SCULP boxes during this time interval. The combination of the SCULP data and the PDOM currents gives the analysts the best determination of the ocean circulation in the Gulf of Mexico available to date.

In addition to the ocean currents, a wind field was employed to add the effect of the direct sea surface winds on the hypothetical spills. Note that this is a different wind field than the climatological field used by Dynalysis to generate the model currents.

The wind field employed was developed by the (former) Naval Oceanographic Research and Development Activity (now Naval Research Laboratory in Mississippi). They computed geostrophic sea surface winds from analyzed atmospheric pressure maps at 12-hour intervals for the 27-year period extending from January 1967 through December 1993. The analyzed pressure maps were compiled by the Fleet Numerical Oceanography and Meteorology Center in Monterey, California. The geostrophic winds were then "corrected" to account for the frictional drag at the sea surface. Details of the compilation and enhancement of the first 16 years of this data set are described in Rhodes, Thompson, and Wallcraft (1989).

The "corrections" for frictional drag at the sea surface were calculated by using a linear regression analysis on the daily averaged geostrophic winds and the observed winds from meteorological stations on moored buoys. The calculations were performed on both wind magnitude and direction. The magnitude correction was nearly constant with time (0.675); however, the direction correction varied seasonally from 8.5 degrees to 26.5 degrees. The resultant wind field is known as the Navy Corrected Geostrophic Wind (NCGW) field. Further details are given in Rhodes, Thompson, and Wallcraft (1989).

This NCGW field is gridded at 1.0° of latitude and longitude every 12 hours for the first 16 years. The final 11 years of winds available to MMS were gridded every 2.5° of latitude and longitude and subsequently were interpolated to the same 1.0° grid as with the first 16 years of data. The first 16 years of wind data were compared with offshore meteorological data to assess representativeness. Time series of wind speed from selected meteorological stations representing the four corners of the Gulf of Mexico Region were compared with the NCGW field. The stations were three National Data Buoy Center moored buoys (number 42001— 26.0° N, 90.0° W, number 42010/11— 29.7° N, 93.4° W, and number 42009— 29.3° N, 87.5° W) and the airport at Key West, Florida— 24.5° N, 81.7° W (fig. 15). The analysts assumed that the winds observed at the Key West station were similar to those offshore, given the low island topography and its distance from the mainland. The time series of the velocity components from the NCGW field were within one standard deviation of the selected buoy wind time series and were visually well correlated. The correlation coefficients between the meteorological buoys and corresponding points on the NCGW grid for the u (eastward) and v (northward) component speeds are listed below:

Station	u	v
42001	0.89	0.90
42010/11	0.75	0.88
42009	0.88	0.91
Key West	0.93	0.95

The directional accuracy was assessed by comparing progressive vector diagrams of buoy and NCGW fields to wind roses. The best agreement was found between the data sets farthest offshore. The near coastal stations had a greater degree of high frequency and diurnal variability, and the buoys had shorter records. Consequently, the qualitative comparison of the progressive vector diagrams showed more variations between the two sets. The wind roses calculated from the buoys and the gridded winds generally were similar in all seasons. The results show that there is a tendency for the buoys to show a slightly higher frequency of southerly winds in winter than the gridded winds. The increase was in the range of 4 to 12 percent in estimates that have standard deviations of as much as 6 percent, thus indicating that these differences are near the statistically normal range.

The comparisons showed that the NCGW data reproduced the seasonal and high-frequency variabilities and the spatial variability of the Gulf of Mexico wind field, as measured by meteorological buoys distributed throughout the Gulf. Consequently, this data set was a good choice for forcing the wind-drift portion of the model.

In August 1994, the MMS acquired an additional 11 years of NCGW data (January 1983 through December 1993), as discussed above. The newer data were qualitatively compared with the older data and with concurrent winds observed from buoy number 42001. Stick plots of the 1983 and 1990 NCGW data and concurrent winds from buoy number 42001 are presented in figure 16. There are some gaps in the buoy data, but most of the 2 years is covered by observations. The time interval in the plots is 12 hours, and the compared NCGW time series was geographically interpolated to coincide with the buoy location.

Clearly, the newer NCGW data are highly coherent with and comparable in magnitude to the observed buoy winds. Therefore, the analysts are confident in using them to extend the NCGW time series to 27 years.

As previously mentioned, the 27-year wind field does not drive the ocean currents used in this analysis. The wind field is used to model the direct wind drift on a hypothetical oil spill. Presently, an empirical "3.5% rule" with a speed-dependent wind deflection angle is used (Samuels, Huang, and Amstutz, 1982). The speed of the wind-induced drift is 3.5 percent of the prevailing wind speed at the standard 10 meters above the sea surface, and the drift angle from the directly downwind direction decreases with increasing speed, approaching zero at 35 m/sec.

To assess fully the environmental conditions throughout the 27 years covered by the wind data set, trajectories of hypothetical spills were started every 4 or 5 days (4.85 days on the average) from an array of sites covering the production areas (fig. 1), pipeline routes (figs. 2-6), and ship transport lanes (figs. 7-9). Two thousand trajectories were generated for every site. At each 12-hour time step, a bilinear spatial interpolation of the wind velocity was made from the 1° (latitude and longitude) grid.

The selection of 4 or 5 days was determined by the length of the NCGW wind record and the choice of 2,000 trajectories per site. The chosen number of trajectories per site was computationally practical and large enough to reduce the random sampling error to an insignificant level. Possible aliasing from weather-scale (2 to 3 days) changes in the winds due to the 4.85-day release rate should not be a problem. Once released, the hypothetical spill is subjected to the 12-hourly winds, which contain the weather-scale variability. Also, the weather is not strictly cyclic, so 4.85-day releases over the 27-year wind record will likely capture the statistics of the weather-scale changes.

Each trajectory was allowed to continue for as long as 30 days. However, if the hypothetical spill contacted land or large islands sooner than 30 days after the start of the spill, the spill trajectory was terminated.

The trajectories simulated by the model represent only hypothetical pathways of oil slicks; they do not involve any direct consideration of cleanup, dispersion, or weathering processes that could alter the quantity or properties of oil that might eventually contact the environmental resources. However, an implicit analysis of weathering and decay can be considered by noting the ages of the simulated oil spills when they contact environmental resources. For this analysis, three time periods were selected: 3, 10, and 30 days after the hypothetical spill occurrence. Spill contacts occurring on or before these elapse times are recorded. An analyst can then use these statistics in conjunction with appropriate assumptions about the effects of oil weathering and containment and cleanup operations to judge the overall impacts.

Conditional Probabilities

The probability that an oil spill will contact a specific environmental resource within a given time of travel from a certain location or spill point is termed a *conditional probability*, the "condition" being that a spill is assumed to have occurred. Conditional probabilities of contact within 3, 10, and 30 days were calculated for each of the proposed and existing hypothetical spill sites and for each pipeline and transportation route segment (figs. 1 through 9). These conditional probabilities of contact with environmental resources and land segments are presented in tables 2 through 7, and on a seasonal basis in appendices B and C.

Combined Analysis of Oil-Spill Occurrence and Oil-Spill Trajectory Simulations

A critical difference exists between the *conditional probabilities* and the *combined probabilities* calculated in this section. Conditional probabilities depend only on the winds and currents in the study area. Combined probabilities, on the other hand, depend not only on the physical conditions, but also on the chance of spill occurrence, the estimated volume of oil to be produced or transported, and the oil transportation scenario. These additional variables make the combined probabilities sensitive to the activities in the lease area, that is, dependent on which tracts are leased or not leased and the implementation of any specific transportation stipulation. The combined probabilities for this analysis of the proposed lease sales are presented in tables 8 through 13.

In calculating the *combined probabilities*, those that represent probabilities of both oil-spill occurrence and contact, the following steps are performed:

1. For a set of n_i environmental resources and n_l launch points, the *conditional probabilities* can be represented in a matrix form. Let $[C]$ be an $n_i \times n_l$ matrix, where each element $c_{i,j}$ is the probability that an oil spill will contact environmental resource i , given that a spill occurs at launch point j . Note that launch points can represent potential spill starting points from production areas or transportation routes.
2. Spill occurrence can be represented by another matrix $[S]$. With n_l launch points and n_s production sites, the dimensions of $[S]$ are $n_l \times n_s$. Let each element $s_{j,k}$ be the estimated mean number of spills occurring at launch point j owing to production of a unit volume (1 Bbbl) of oil at site k . These spills can result from either production or transportation. The $s_{j,k}$ can be determined as a function of the volume of oil (spills/Bbbl). Each column of $[S]$ corresponds to one production site and one transportation route. If alternative and mutually exclusive transportation routes are considered for the same production site, they can be represented by additional columns of $[S]$, thus increasing n_s .
3. Matrix $[U]$ is defined as

$$[U] = [C] \times [S]$$

Matrix $[U]$ —which has dimensions $n_i \times n_s$ —is termed the *unit risk matrix*. Each element $u_{i,k}$ corresponds to the estimated mean number of spills occurring and

contacting environmental resource i , owing to the production of a unit volume (1 Bbbl) of oil at site k .

4. With $[U]$, the mean contacts to each environmental resource are estimated, given a set of oil volumes at each site. Let $[V]$ be a vector of dimension n , where each element v_k corresponds to the volume of oil expected to be found at production site k . Then, if $[L]$ is a vector of dimension n , where each element λ_i corresponds to the mean number of contacts to environmental resource i , the formula is

$$[L] = [U] \times [V]$$

Thus, estimates of the mean number of oil spills that will occur and contact environmental resources (or land segments) can be calculated. (Note that as a statistical parameter, the mean number can assume a fractional value, even though fractions of oil spills have no physical meaning.)

Using Bayesian techniques, Devaney and Stewart (1974) showed that the probability of n oil-spill contacts can be described by a negative binomial distribution. Smith et al. (1982), however, noted that when actual exposure is much less than historical exposure, as is the case here, the negative binomial distribution can be approximated by a Poisson distribution. The Poisson distribution has a significant advantage in calculations because it is defined by only one parameter, the assumed number of spills. Thus, the matrix $[L]$ contains all the information needed to use the Poisson distribution—if $p(n,i)$ is the probability of exactly n contacts to environmental resource i , then:

$$P(n,i) = \frac{\lambda_i^n * e^{-\lambda_i}}{n!}$$

Discussion

This analysis characterizes the oil-spill risks associated with the Central and Western Gulf of Mexico OCS Lease Sales 157 and 161. The three volume scenarios considered for the proposed action were the base case, high case, and GW (table 1). Also considered were the estimated volume for imports and a GW aggregate volume scenario that included the Western, Central, and Eastern Planning Areas. The computed mean numbers of spills due to base case and high case activities are less than 1.0 in both the western and central Gulf (table 1). However, in the cumulative case, the corresponding computed mean numbers of spills in the TPA are greater: 2.0 and 8.0 in the Western and Central Gulf Planning Areas, respectively. The smallest computed mean number of spills, 0.05, is that for the Eastern Gulf TPA, where oil activities are much lower than elsewhere in U.S. Gulf waters. Import tankering, however, demonstrated the largest risk, with a computed mean of 17.0 spills.

Conditional Probabilities: In computing the conditional probabilities of contact, the analysts assume that a spill has occurred and estimate the probability that the assumed (hypothetical) spill will contact a designated environmental resource or land segment. The results indicate

that for the first 3 days oil from only those hypothetical spill sites immediately adjacent to an environmental resource pose a risk. The 3-day conditional probabilities range as high as 90 percent or more. After 10 days, many resources not adjacent to spill sites have probabilities of contact greater than 0.5 percent (the lower limit of model estimation). Again, the probabilities range as high as 90 percent or more. Finally, at 30 days, all of the western and central Gulf spill sites have a probability of contact with Land greater than 0.5 percent, and many other resources have elevated probabilities of contact. It is unlikely, however, that a spill would persist for 30 days without significant levels of weathering and/or cleanup.

Oil-Spill Occurrence: The estimated mean numbers of spills and the probabilities that an oil spill greater than or equal to 1,000 bbl could occur for the scenarios considered are given in table 1. These probabilities are based on the volume of oil assumed to be found, produced, and transported over the lease lifetimes and on the rates that have been calculated for oil spills by Anderson and LaBelle (1995).

The following list shows the probabilities of one or more oil spills greater than or equal to 1,000 bbl occurring as a result of production and transportation of the locally produced oil (i.e., excluding imports) from OCS Lease Sales 157 and 161:

Planning Area	Base-Case Probability	High-Case Probability
Western Gulf	7%	16%
Central Gulf	18%	35%

Combined Probabilities: The combined probabilities include the conditional probabilities of contact and the probability that an oil spill will occur; these probabilities are based on the trajectories, transportation scenarios, oil-spill rates, and the volumes of oil assumed to be found and produced as a result of the lease sales. The MMS Gulf of Mexico analysts generally use the 10-day combined probability tables for the EIS. The combined probabilities for the base case (proposed) and the high case can be found in tables 8 through 13 for the Central and Western Gulf Planning Areas.

The higher probabilities of an oil spill ($\geq 1,000$ bbl) occurring and contacting an environmental resource within 10 days for the proposed action (tables 8 and 10) are as follows:

Environmental Resource	Western Gulf Base Case/High Case	Central Gulf Base Case/High Case
Land	2% / 5%	5% / 10%
Galveston Bay	n / 1%	n / n
Timbalier Bay	n / n	2% / 4%
Barataria Bay	n / n	n / 1%
Caminada Headland	n / n	1%/1%
West Plaquemines coastal barrier beaches	n / n	n / 1%

Environmental Resource	Western Gulf Base Case/High Case	Central Gulf Base Case/High Case
Chandeleur/Breton coastal barrier beaches	n / n	n / 1%
East Deltaic Plain marshes	n / n	1% / 2%
Western winter menhaden	n / n	2% / 5%
Central winter menhaden	n / n	1% / 1%
Survey Block 3	n / n	1% / 1%
Survey Block 4	n / n	1% / 3%
Survey Block 5	n / n	2% / 5%
Survey Block 6	n / n	2% / 5%
Survey Block 7	n / n	2% / 5%
Texas Coastal Waters	2% / 5%	n / n
Louisiana Coastal Waters	n / n	6% / 12%
North Padre Island coastal barrier beaches	n / 1%	n / n
Mustang Island coastal barrier beaches	n / 1%	n / n
Matagorda Peninsula coastal barrier beaches	n / 1%	n / n
Galveston Island/Bolivar Peninsula coastal barrier beaches	n / 1%	n / n
Laguna Madre seagrass beds	n / 1%	n / n
Corpus Christi Bay seagrass beds	n / 1%	n / n
Espiritu Santo/Matagorda seagrass beds	n / 1%	n / n
Galveston seagrass beds	n / 1%	n / n
Espiritu Santa/Matagorda Bays	n / 1%	n / n
Galveston Bay	n / 1%	n / n
Central Texas coastal marshes	1% / 1%	n / n
Eastern Texas coastal marshes	n / 1%	n / n
Padre Island National Seashore/Mustang Island recreational beaches	1% / 1%	n / n
Matagorda County recreational beaches	n / 1%	n / n
Galveston/Bolivar Peninsula recreational beaches	n / 1%	n / n
Chenier Plain coastal barrier beaches	n / n	1% / 2%
Vermilion/Atchafalaya Bays	n / n	1% / 1%
Chenier Plain marshes	n / n	1% / 2%
Cameron Parish recreational beaches	n / n	n / 1%
Fouchon recreational beaches	n / n	n / 1%
Land Segment 5	n / 1%	n / n
Land Segment 8	n / 1%	n / n

Environmental Resource	Western Gulf Base Case/High Case	Central Gulf Base Case/High Case
Land Segment 10	n / 1%	n / n
Land Segment 12	n / n	n / 1%
Land Segment 13	n / n	1% / 1%
Land Segment 14	n / n	n / 1%
Land Segment 16	n / n	2% / 5%
Land Segment 17	n / n	n / 1%
Land Segment 19	n / n	1% / 2%

Note: n = < 0.5% probability

In the base case, the Louisiana coastal waters (now defined as the waters from the Louisiana shore to 3 miles seaward) have a 6-percent probability of contact with a large spill (\geq 1,000 bbl) due to activities in the central Gulf area. In the base case, the Texas coastal waters (now defined as the waters from the Texas shore to 9 miles seaward from the shore) have a 2-percent probability of contact with a large spill from activities in the western Gulf area. These are greater probabilities than have been found previously for a comparable amount of oil production and transport. Most of the increase can be attributed to a more pronounced coastal current off Louisiana and Texas than had been used in previous OSRA modeling; the present model ocean currents are believed to be more realistic. To a lesser extent, the increases associated with the coastal waters and with "Land" (total shoreline extent) are due to the increased geographic extent of these environmental resources, as explained previously in the section on "Environmental Resources."

The probabilities of spilled oil contacting "Land" (shorelines, including those of the barrier islands) are also higher in this OSRA than previously found. Again, use of the enhanced (more realistic) coastal current is believed to be the reason for the increased probabilities. In particular, Land Segments 5, 8, 12, 13, 14, 16, 17, and 19 along Texas and Louisiana have elevated probabilities of contact.

Survey Blocks 3-7, and a few other identified environmental resources have a 1- to 2-percent probability of contact in the base case. In general, the high case combined probabilities are somewhat larger than the base case combined probabilities, with a few more environmental resources being contacted.

For the cumulative case analysis, the combined probabilities of occurrence and contact from oil spilled during the tankering of crude petroleum imports into the Gulf were computed and presented in tables 12 and 13, together with the GW aggregate. The GW aggregate is the set of combined probabilities of contact from all three total planning areas considered together (i.e., $GW = WTPA + CTPA + ETPA$), as defined previously.

Most (70%) of the imported oil comes in through the Yucatan Channel and is then distributed along import routes (fig. 7) that are predominantly much farther offshore than the OCS oil resources. The import routes connect to fairway routes (fig. 8) that bring the

imported oil to receiving terminals. Oil spills from the fairways, which are closer to shore than the import routes, have relatively high conditional probabilities of contact with land. However, oil spills from the import routes, which not only are longer but also farther from shore than the fairways, have very low conditional probabilities of contact with land, even at 30 days (tables 2 to 4). Most of the oil-spill contacts with land occur near the major ports, as indicated by the combined probabilities.

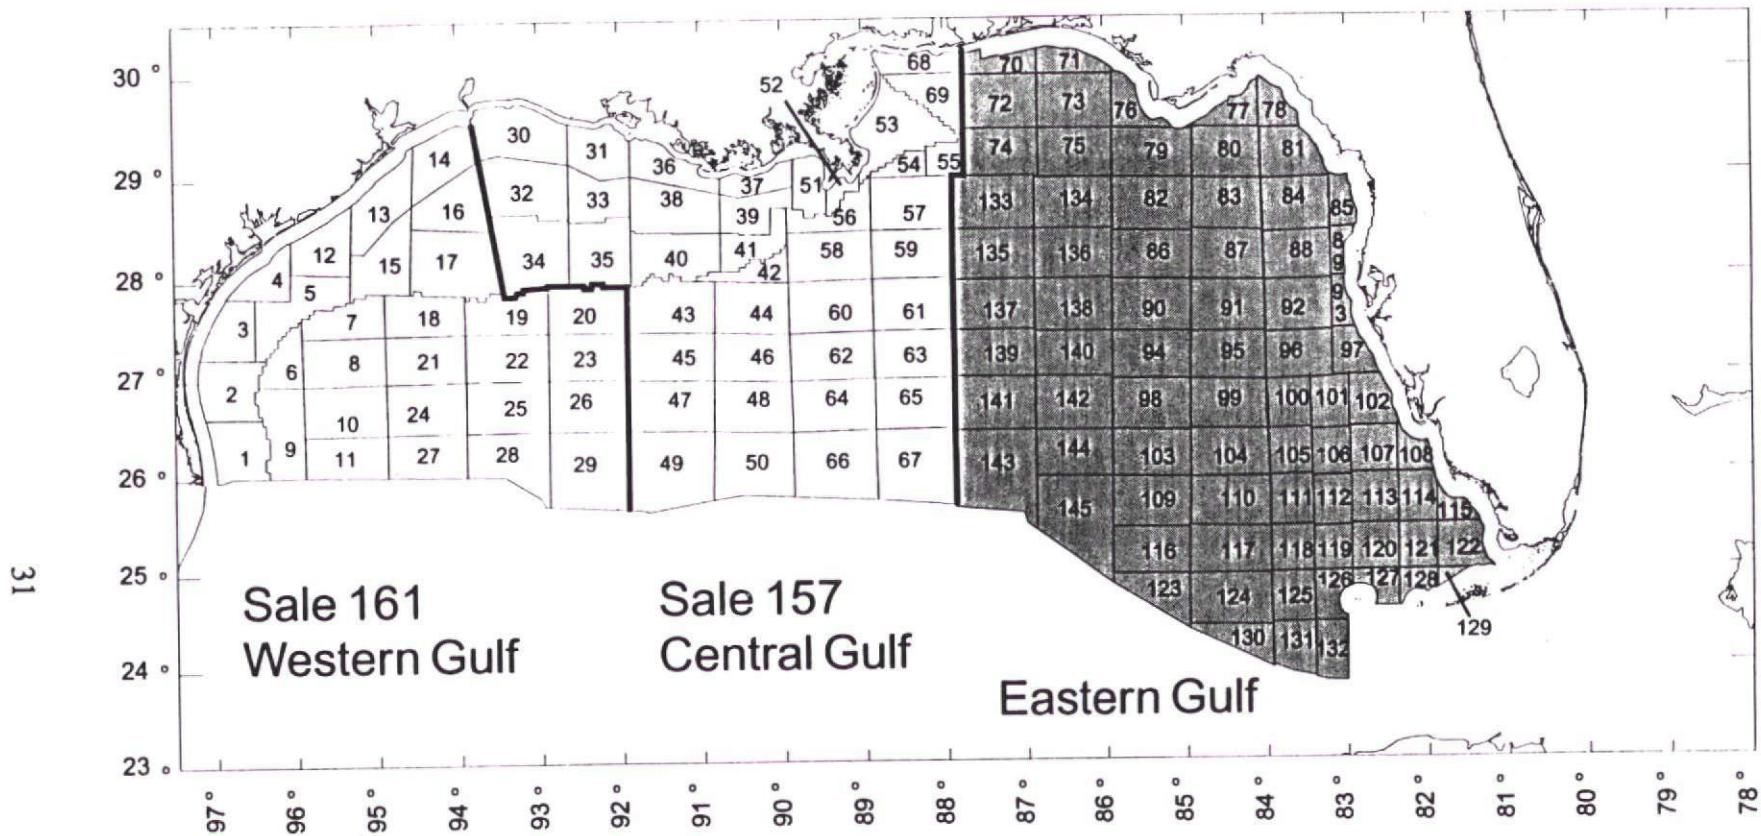

Figure 1. Central, Western, and Eastern Gulf of Mexico Planning Areas and 145 hypothetical spill sites for Gulf of Mexico OCS Lease Sales 157 and 161. Shaded areas in the Eastern Gulf are not included in the proposed lease sale.

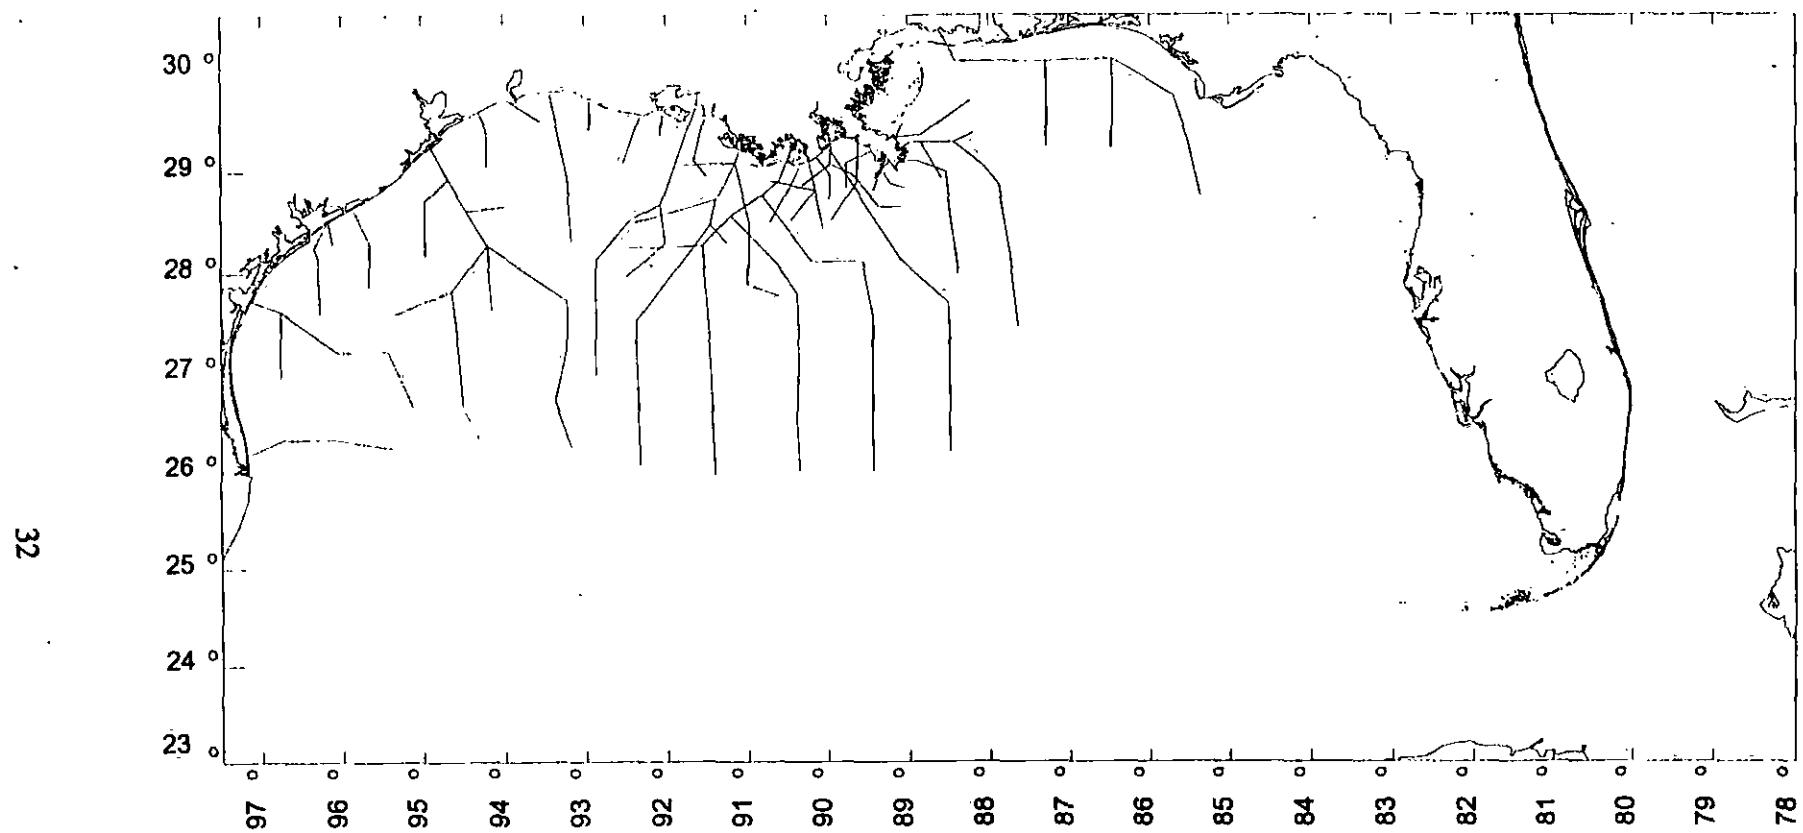

Figure 2. All the pipeline transportation route segments for Gulf of Mexico OCS Lease Sales 157 and 161.

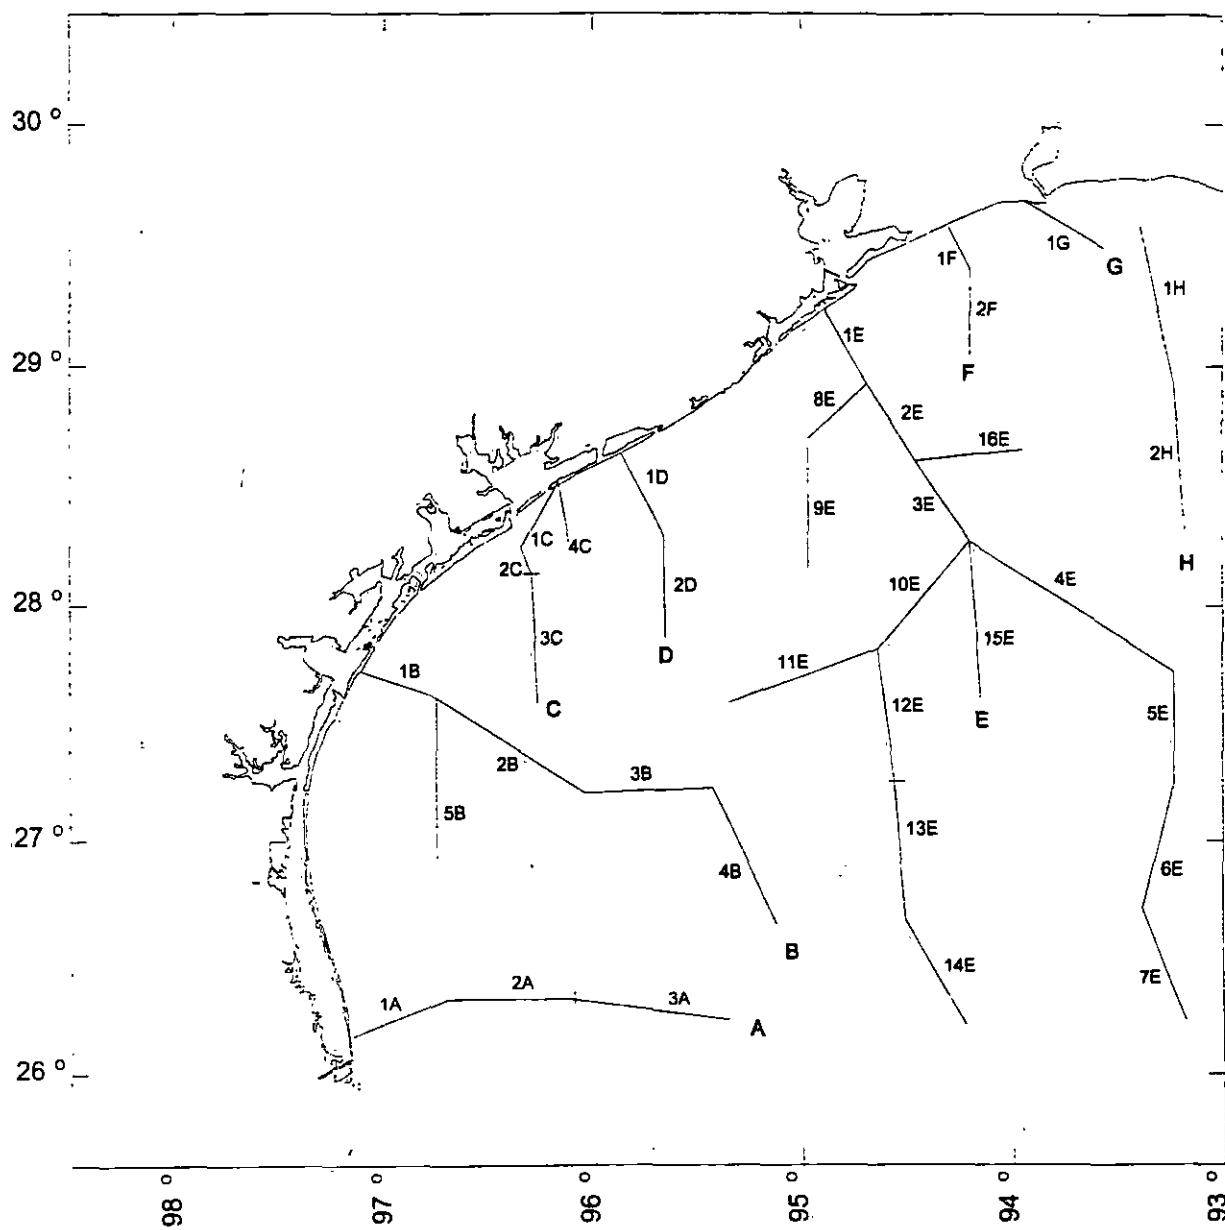

Figure 3. Pipeline route segments (A-H) for the western portion of Gulf of Mexico OCS Lease Sales 157 and 161.

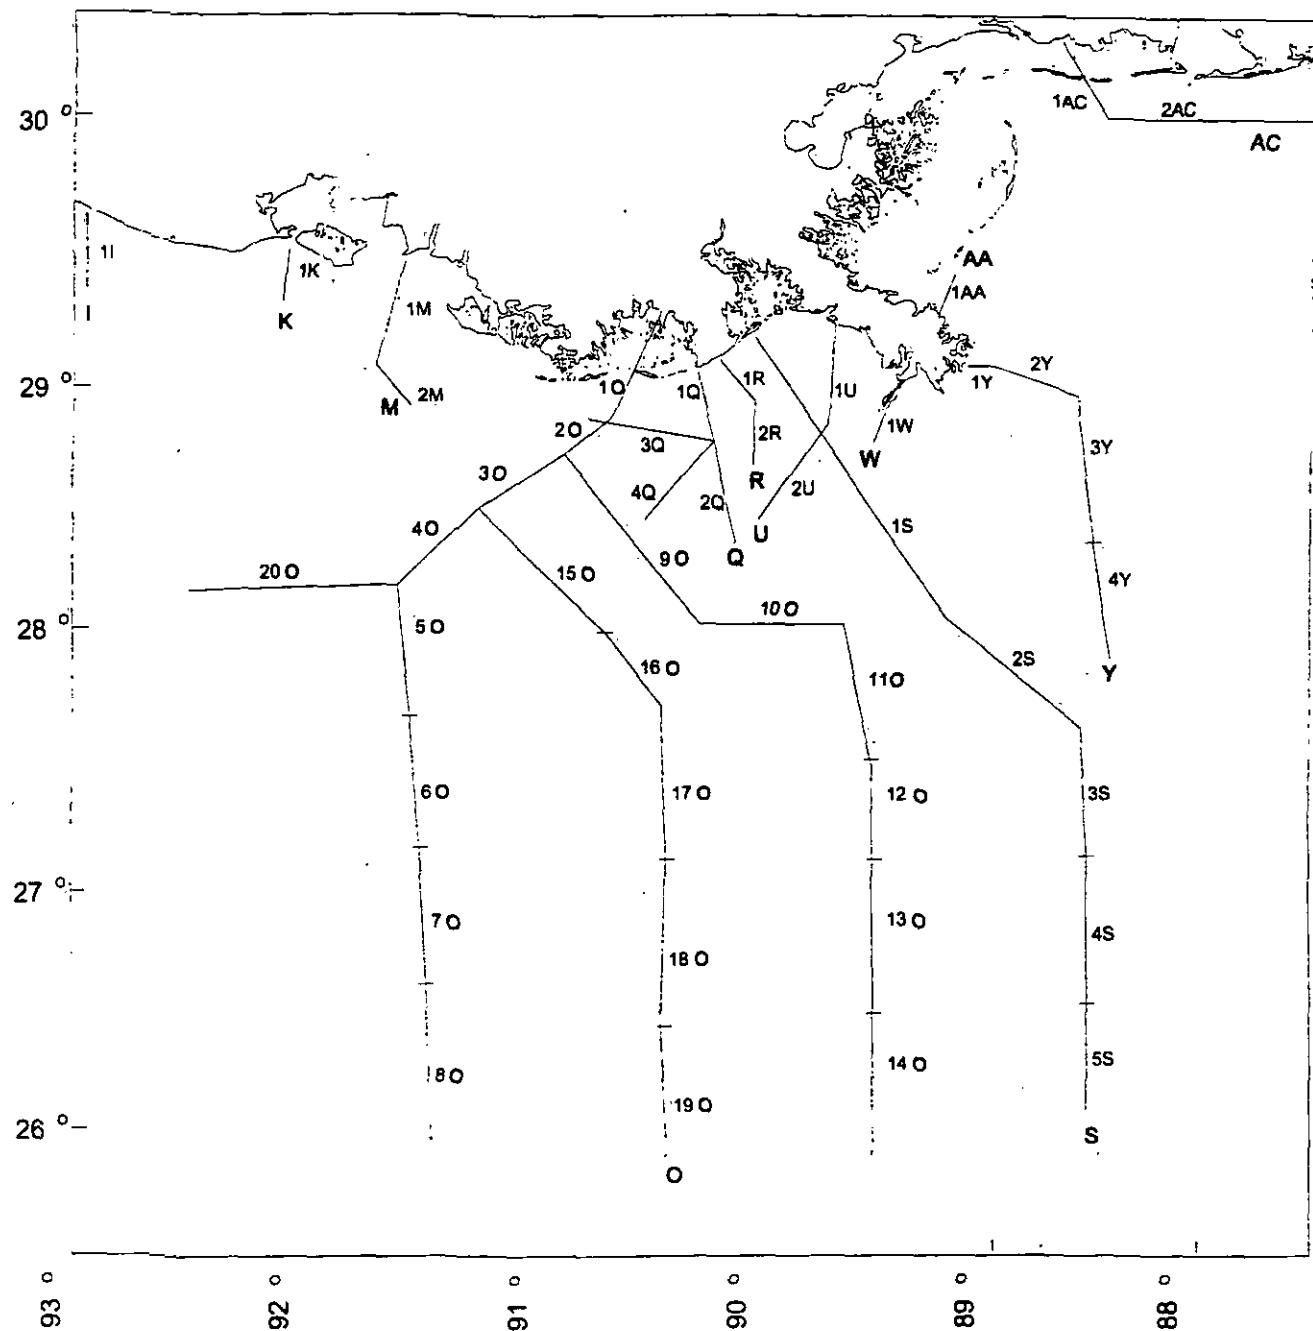

Figure 4. Pipeline route segments (I, K, M, O, Q, R, S, U, W, Y, AA, AC) for the central portion of Gulf of Mexico OCS Lease Sales 157 and 161.

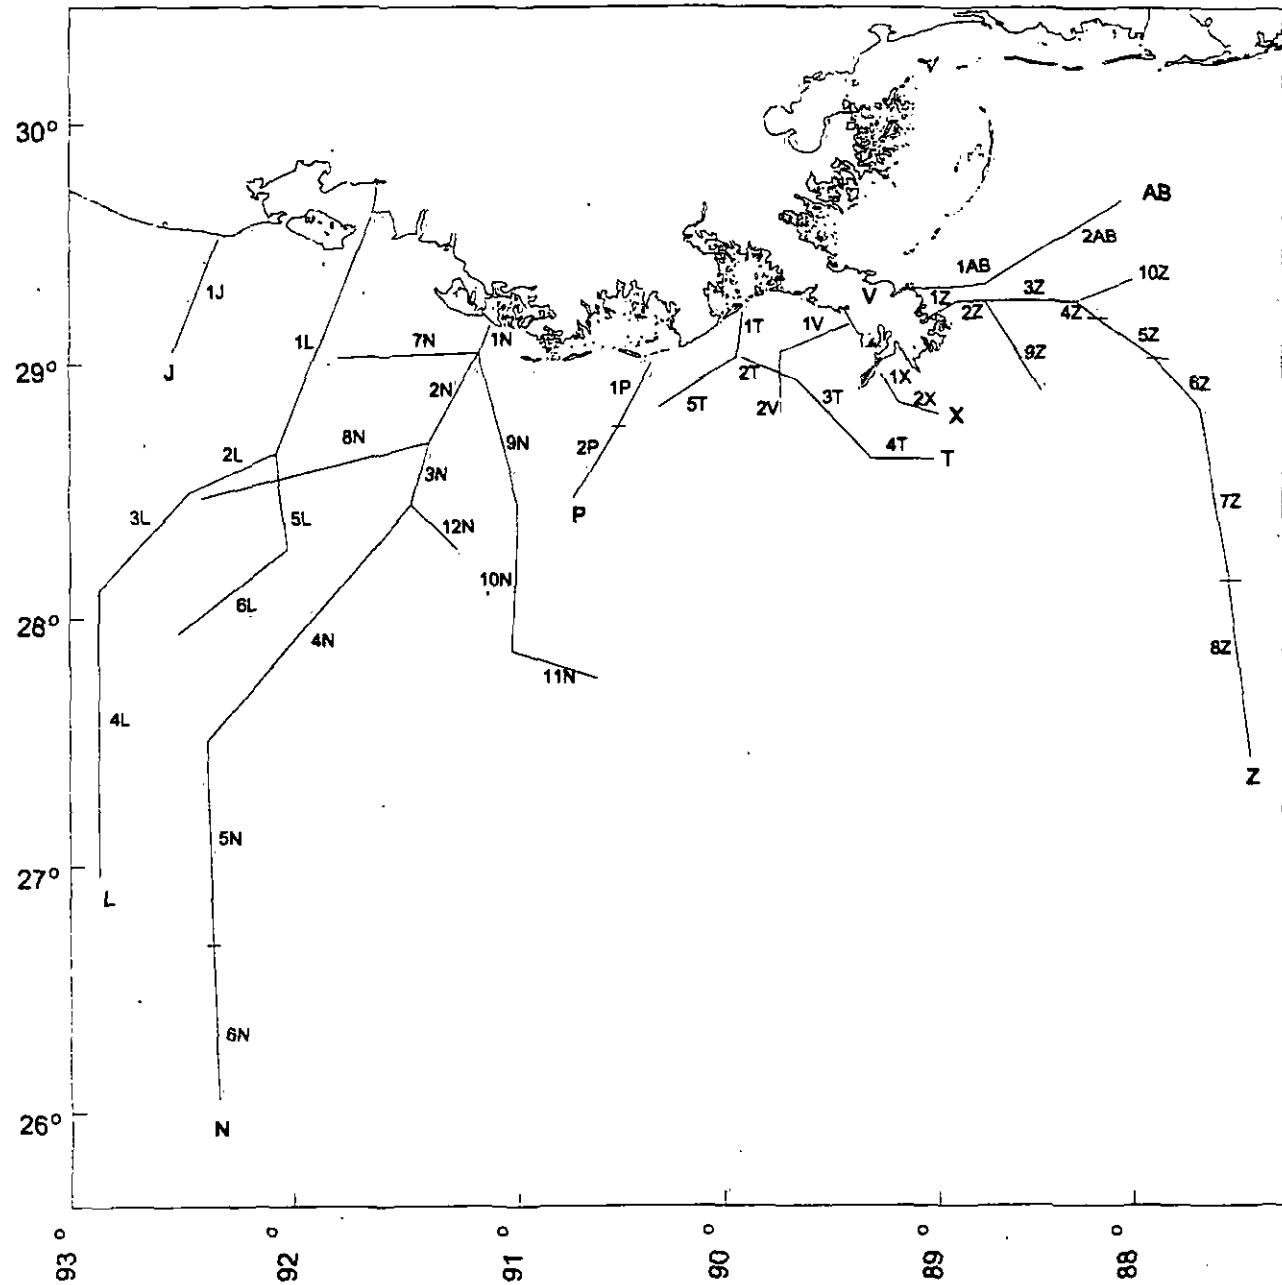

Figure 5. Pipeline route segments (J, L, N, P, T, V, X, Z, AB) for the central portion of Gulf of Mexico OCS Lease Sales 157 and 161

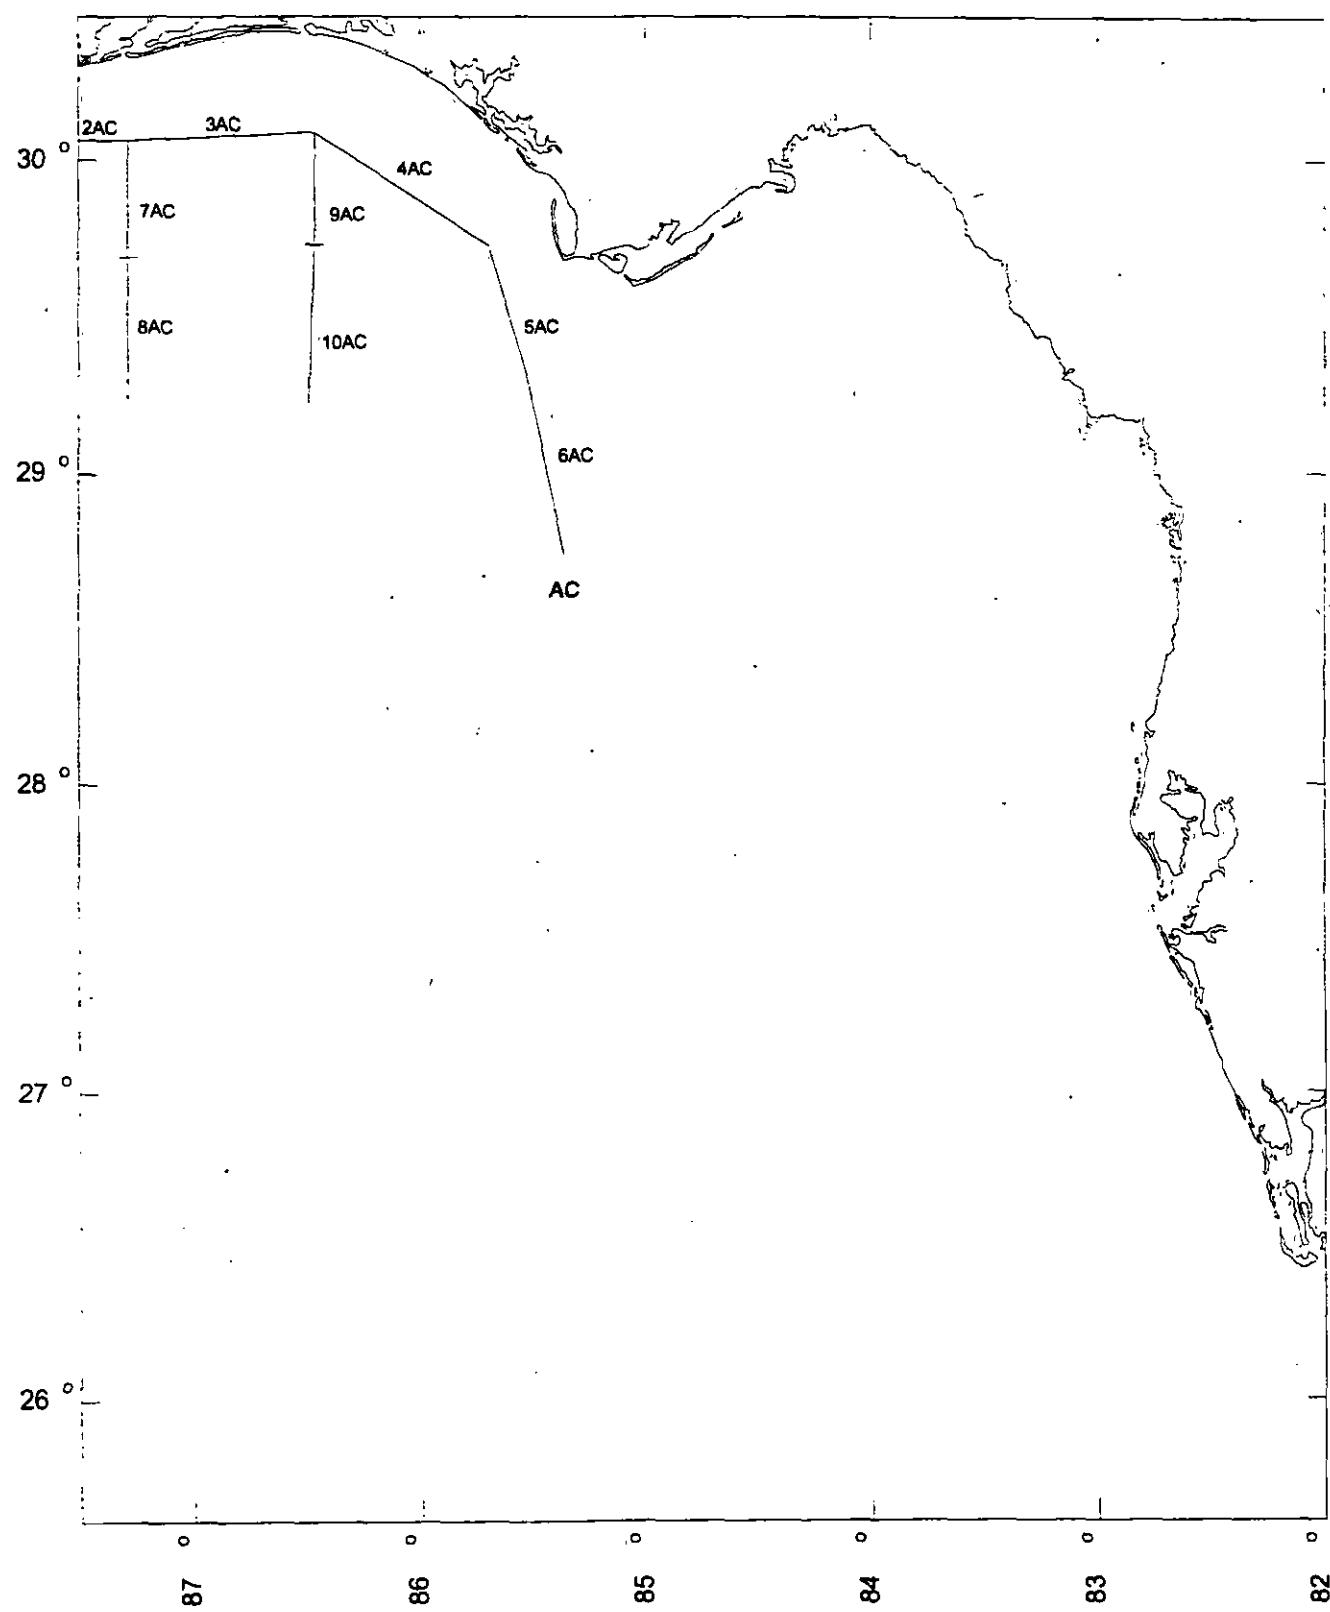

Figure 6. Pipeline route segments (AC) for the eastern portion of Gulf of Mexico OCS Lease Sales 157 and 161.

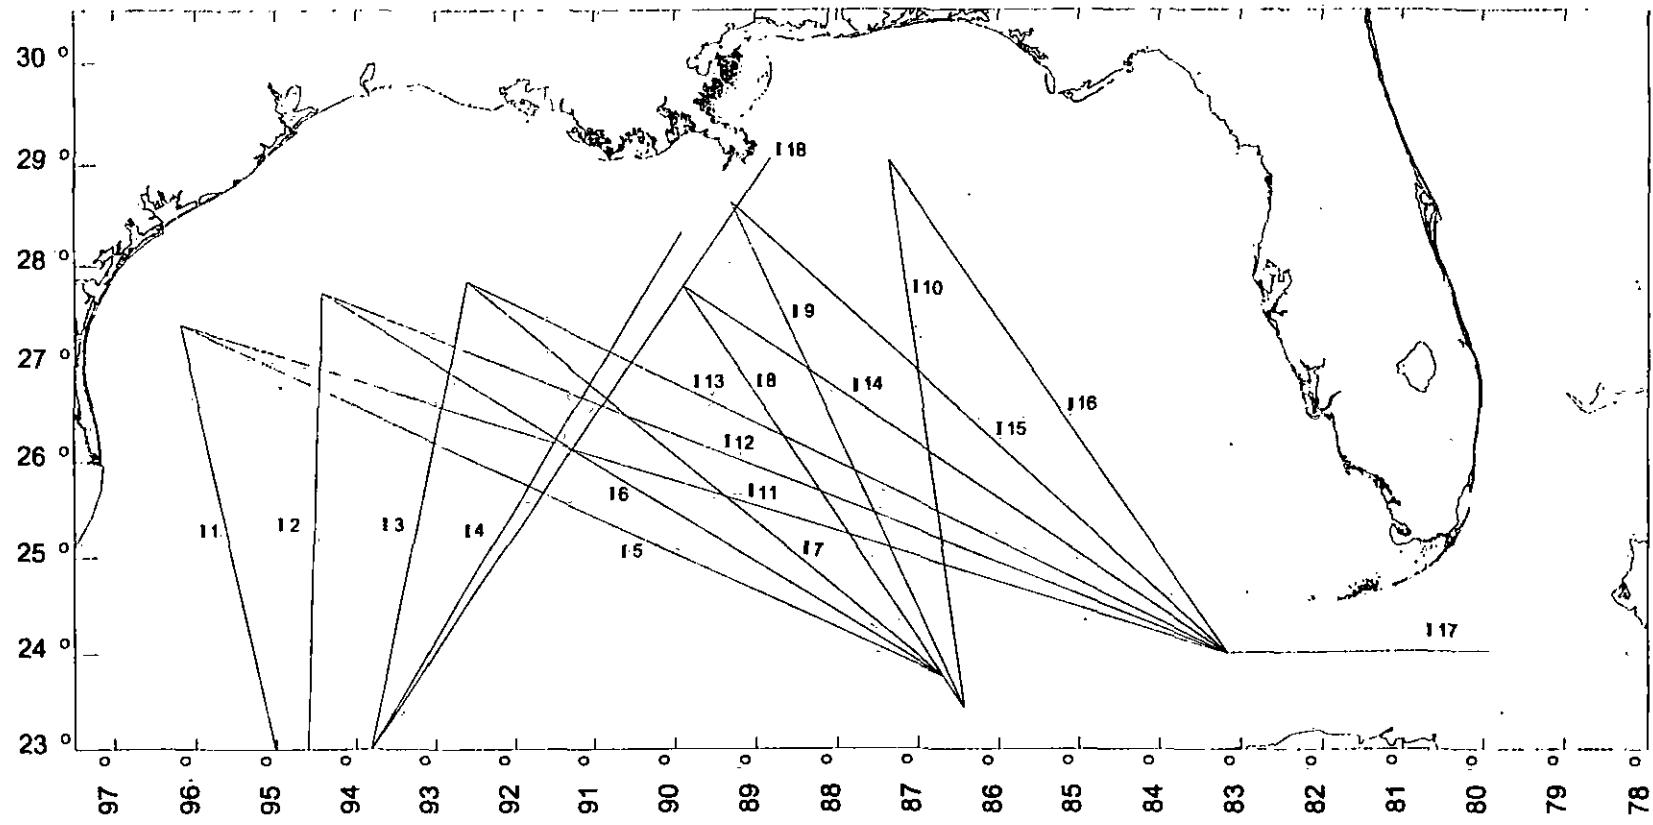

Figure 7. Import tanker route segments (I) for Gulf of Mexico OCS Lease Sales 157 and 161.

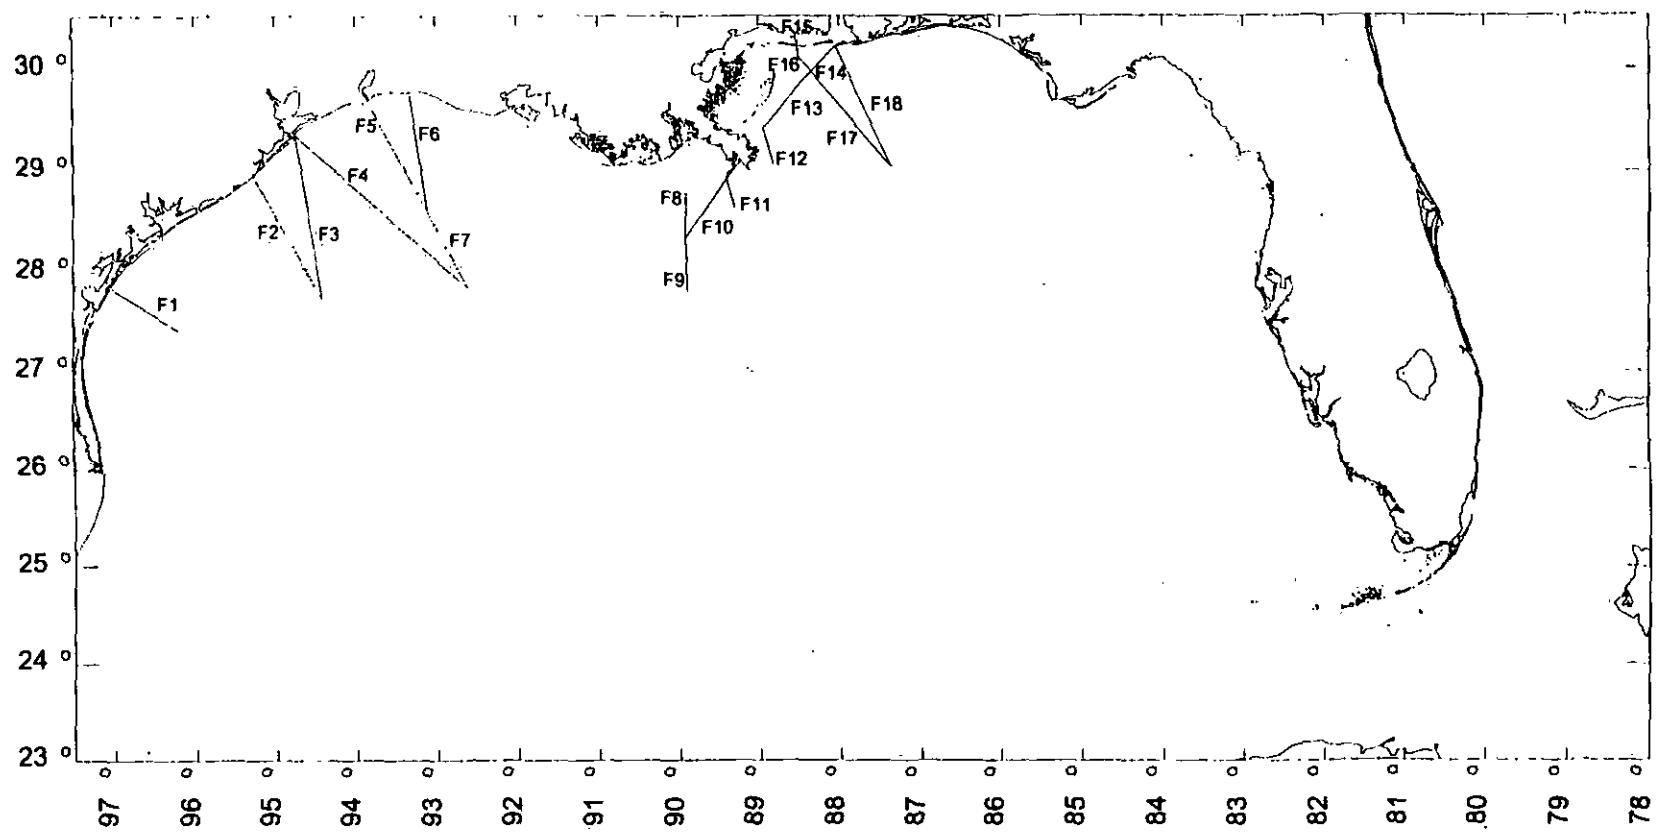

Figure 8. Fairway tanker route segments (F) for Gulf of Mexico OCS Lease Sales 157 and 161.

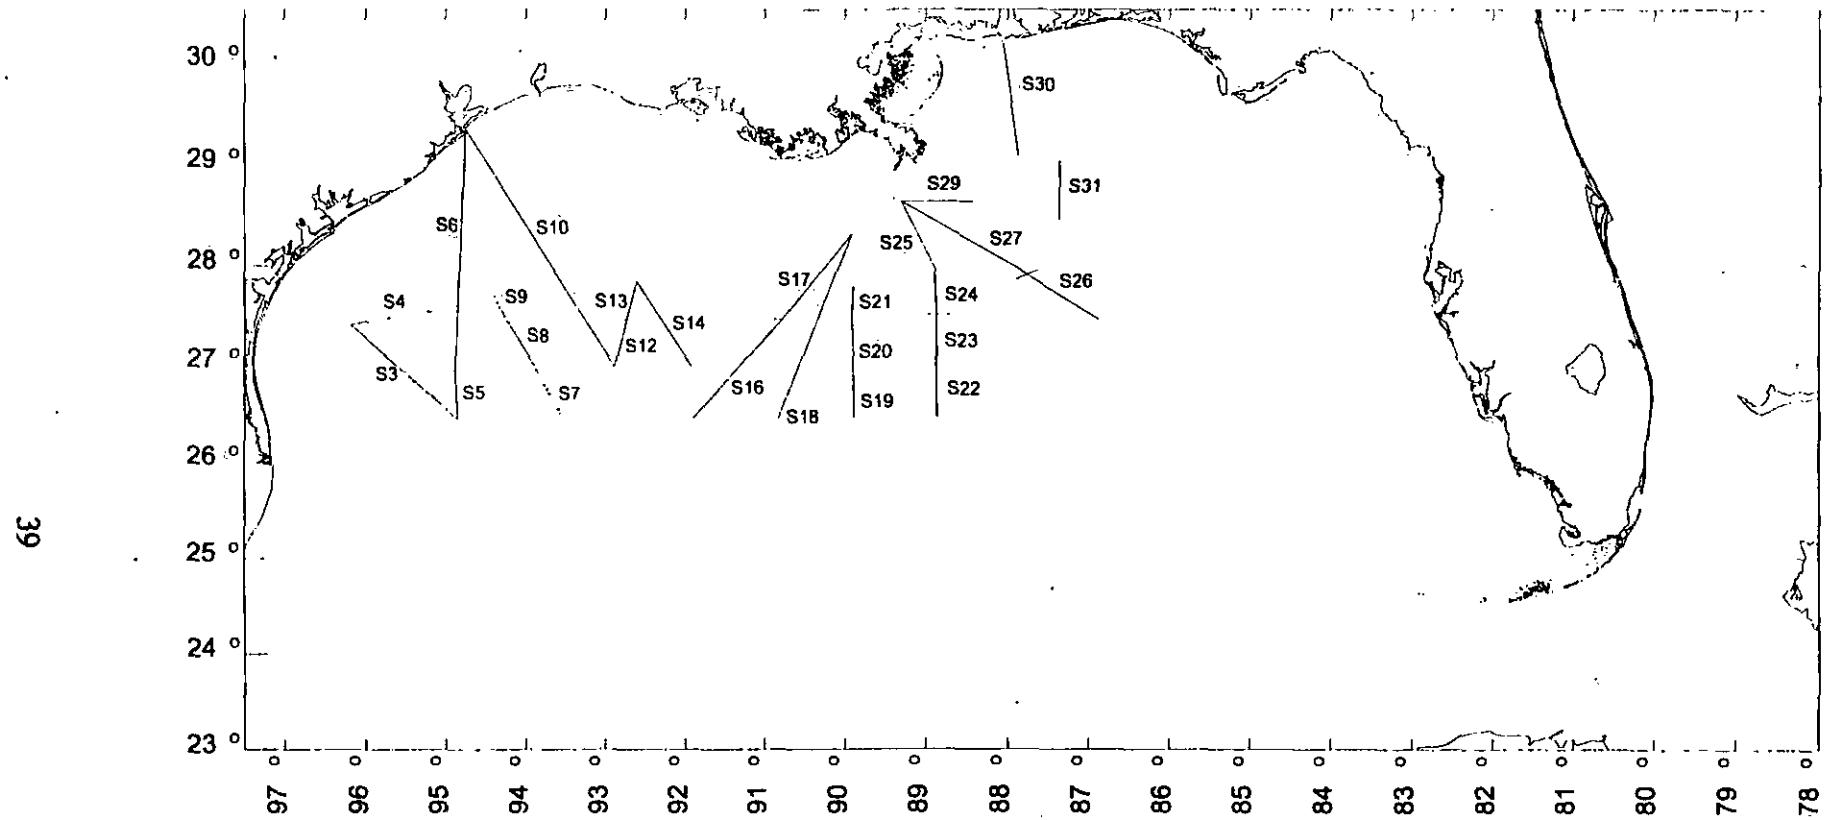

Figure 9. Shuttle tanker route segments (S) for Gulf of Mexico OCS Lease Sales 157 and 161.

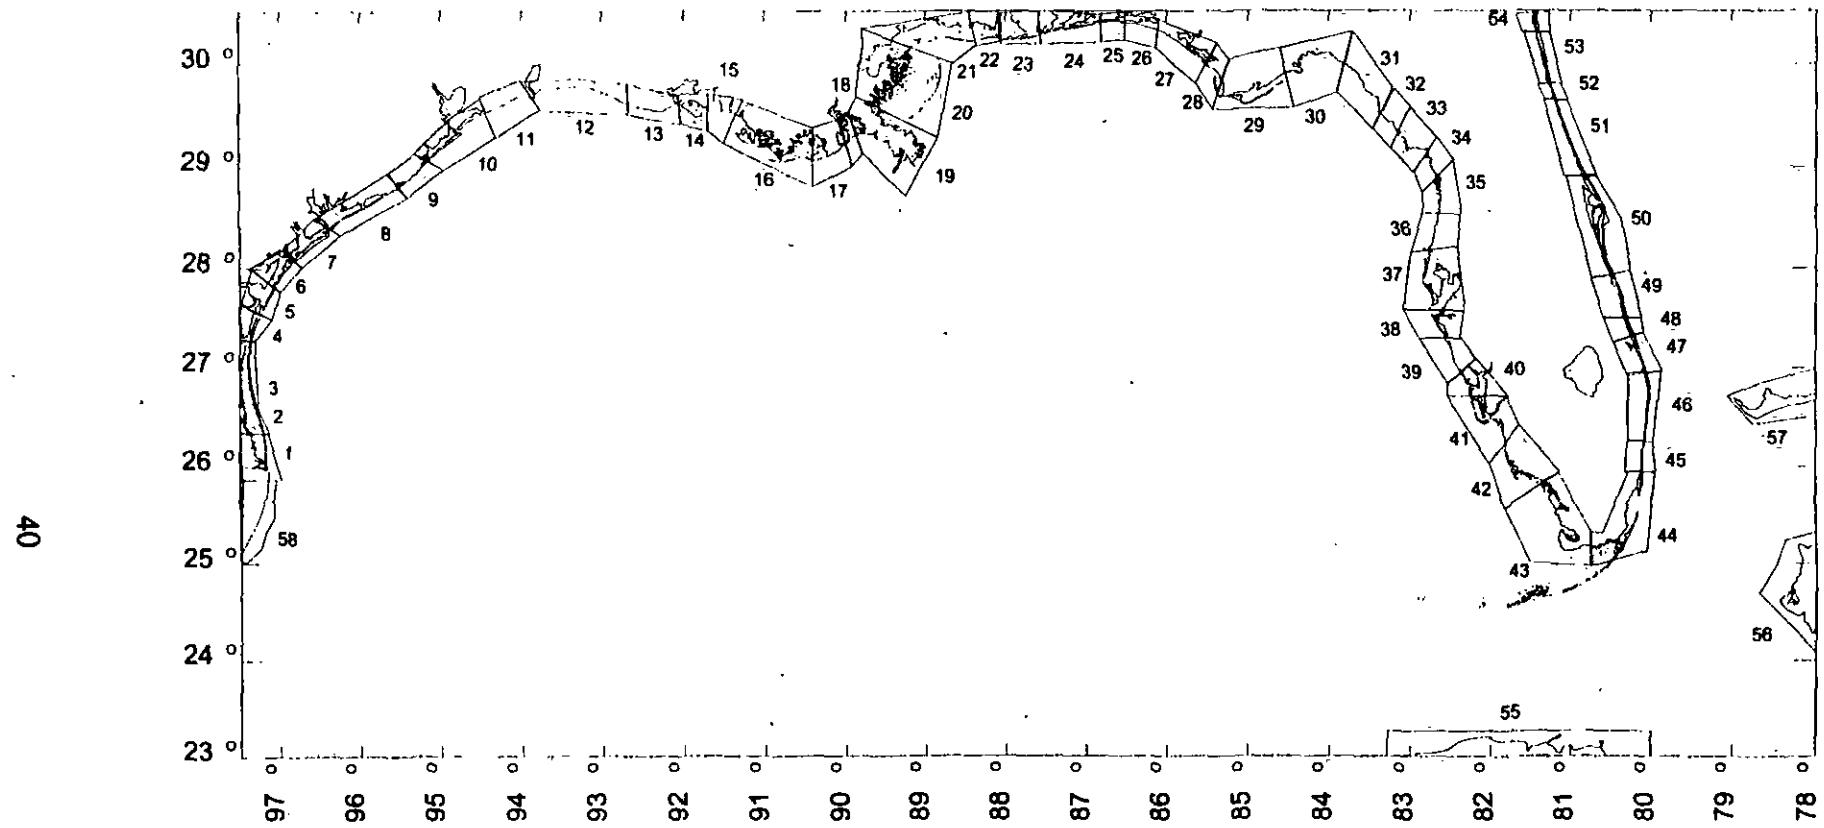

Figure 10. Division of the study area coastline into 58 land segments (representing county/parish boundaries) for Gulf of Mexico OCS Lease Sales 157 and 161. The environmental resource "Land" comprises all 58 land segments.

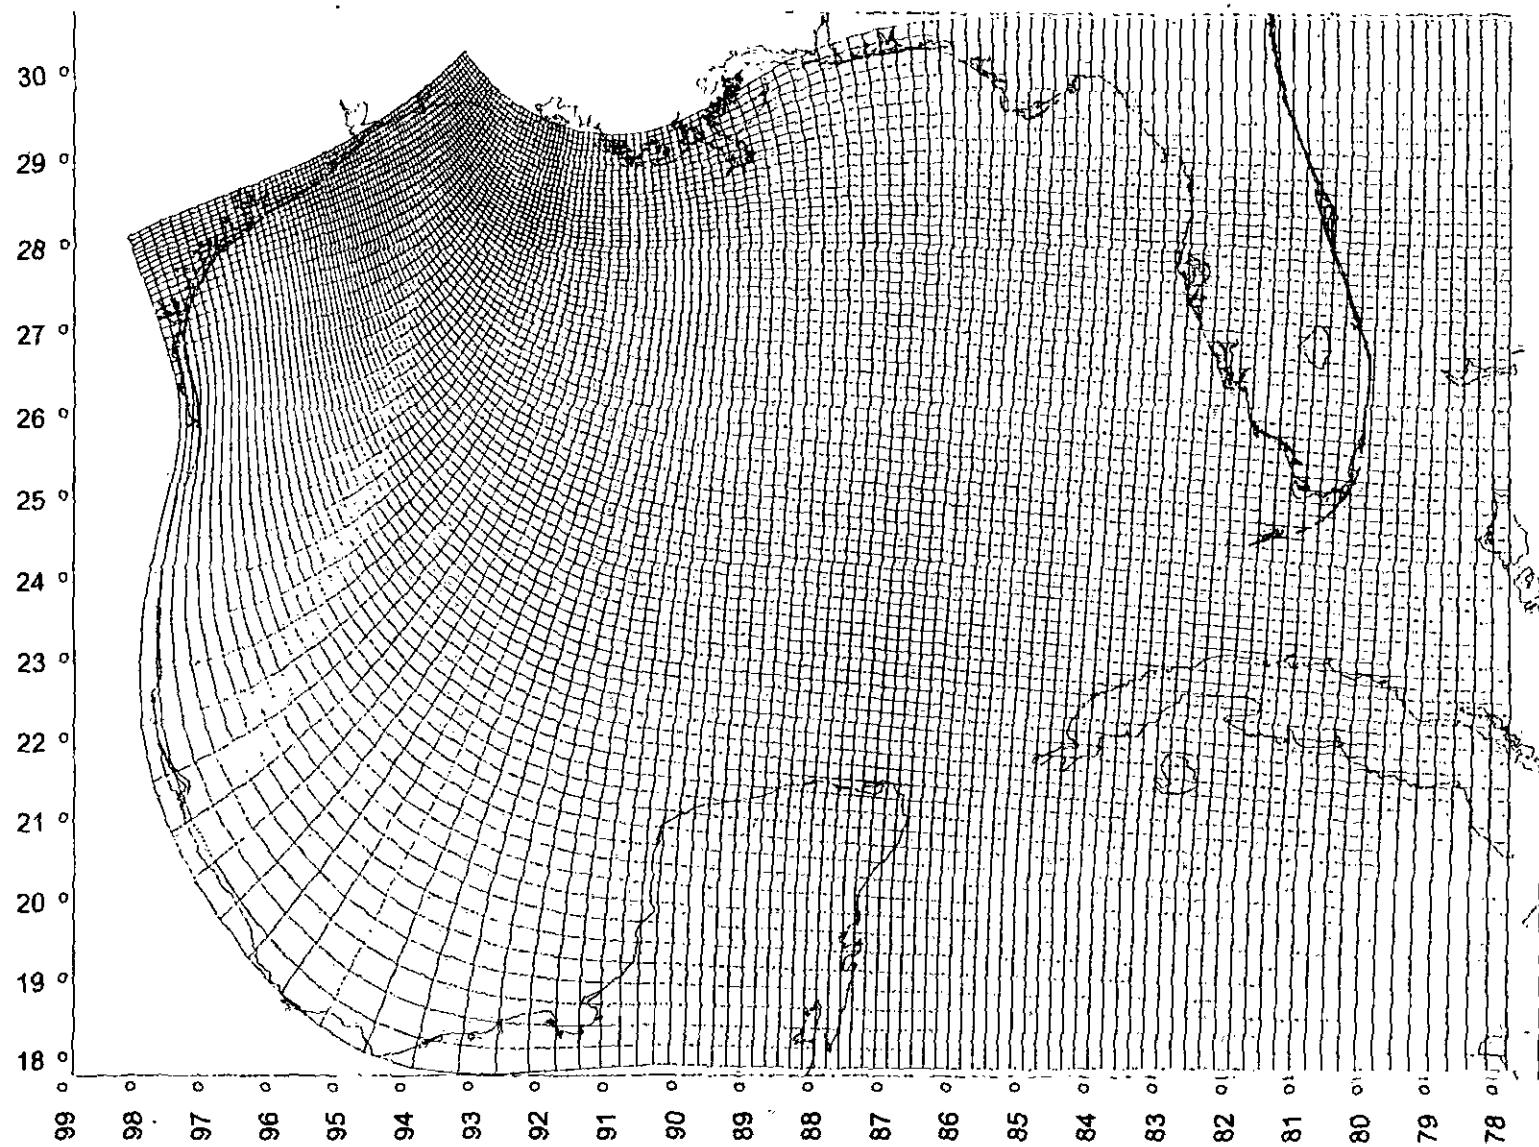

Figure 11. Computational grid used by Dynalysis of Princeton in the Mellor-Blumberg primitive equation model adapted to the Gulf of Mexico.

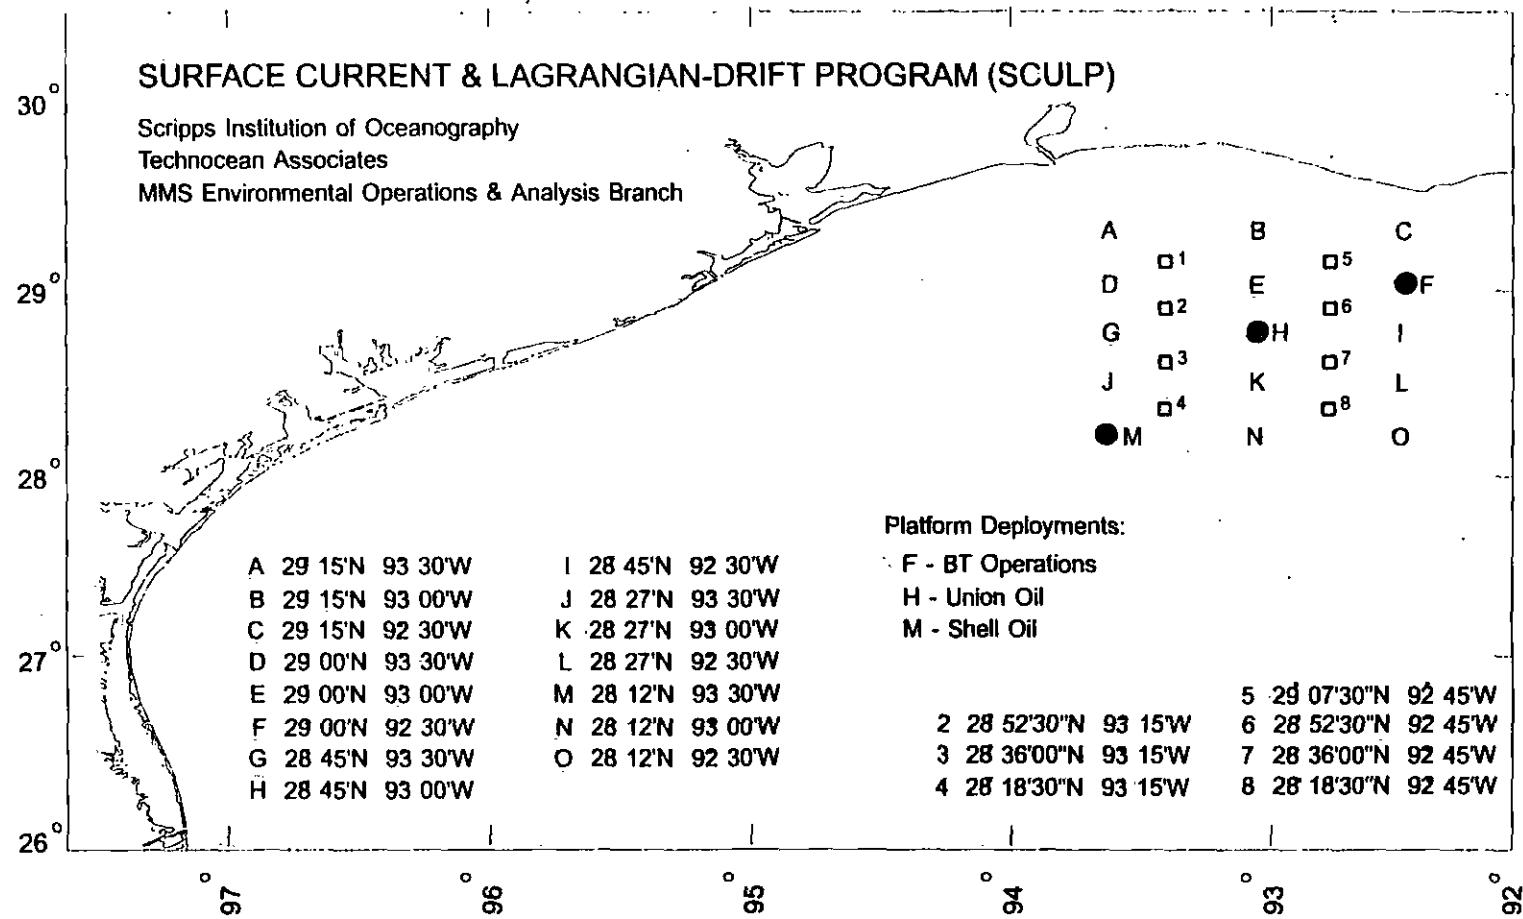

Figure 12. Deployment locations of the SCULP drifters. The letters designate the initial aircraft-deployment locations except for F, H, and M, which were offshore production platforms (filled dots). Buoys were deployed weekly from the platforms and monthly from other lettered stations. Additional aircraft deployments were made from the numbered locations (open boxes).

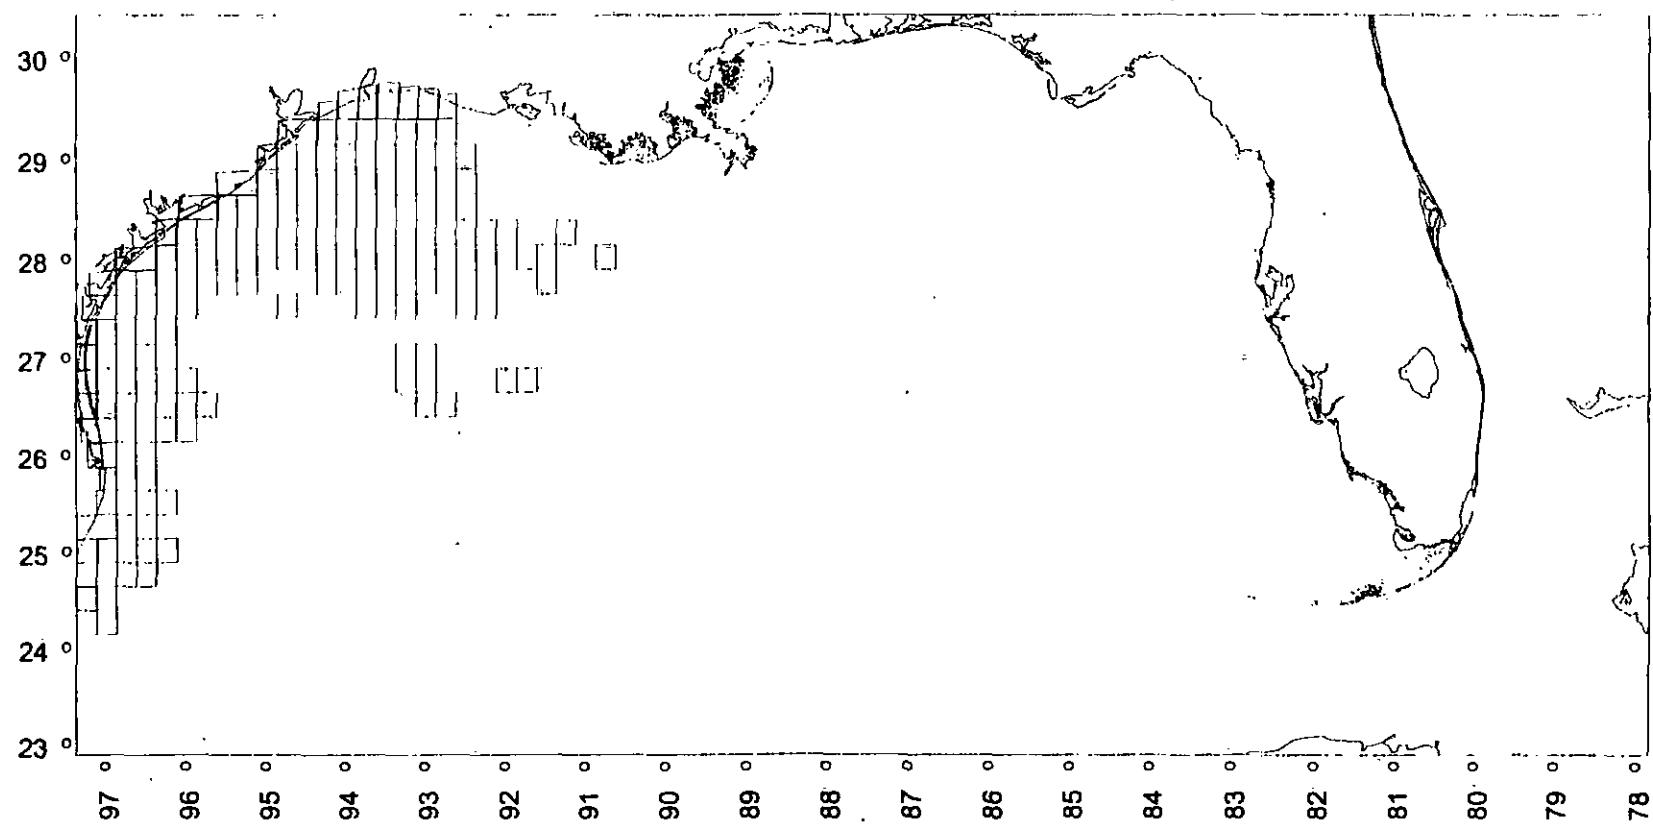

Figure 13. Boxes partitioning the trajectories of the SCULP drifting buoys. A quasi-Eulerian velocity field was created by averaging 25 (minimum) or more daily velocities of the trajectories occurring within a given box. The average velocities are regarded as the velocities of the surface ocean at the centers of the respective boxes.

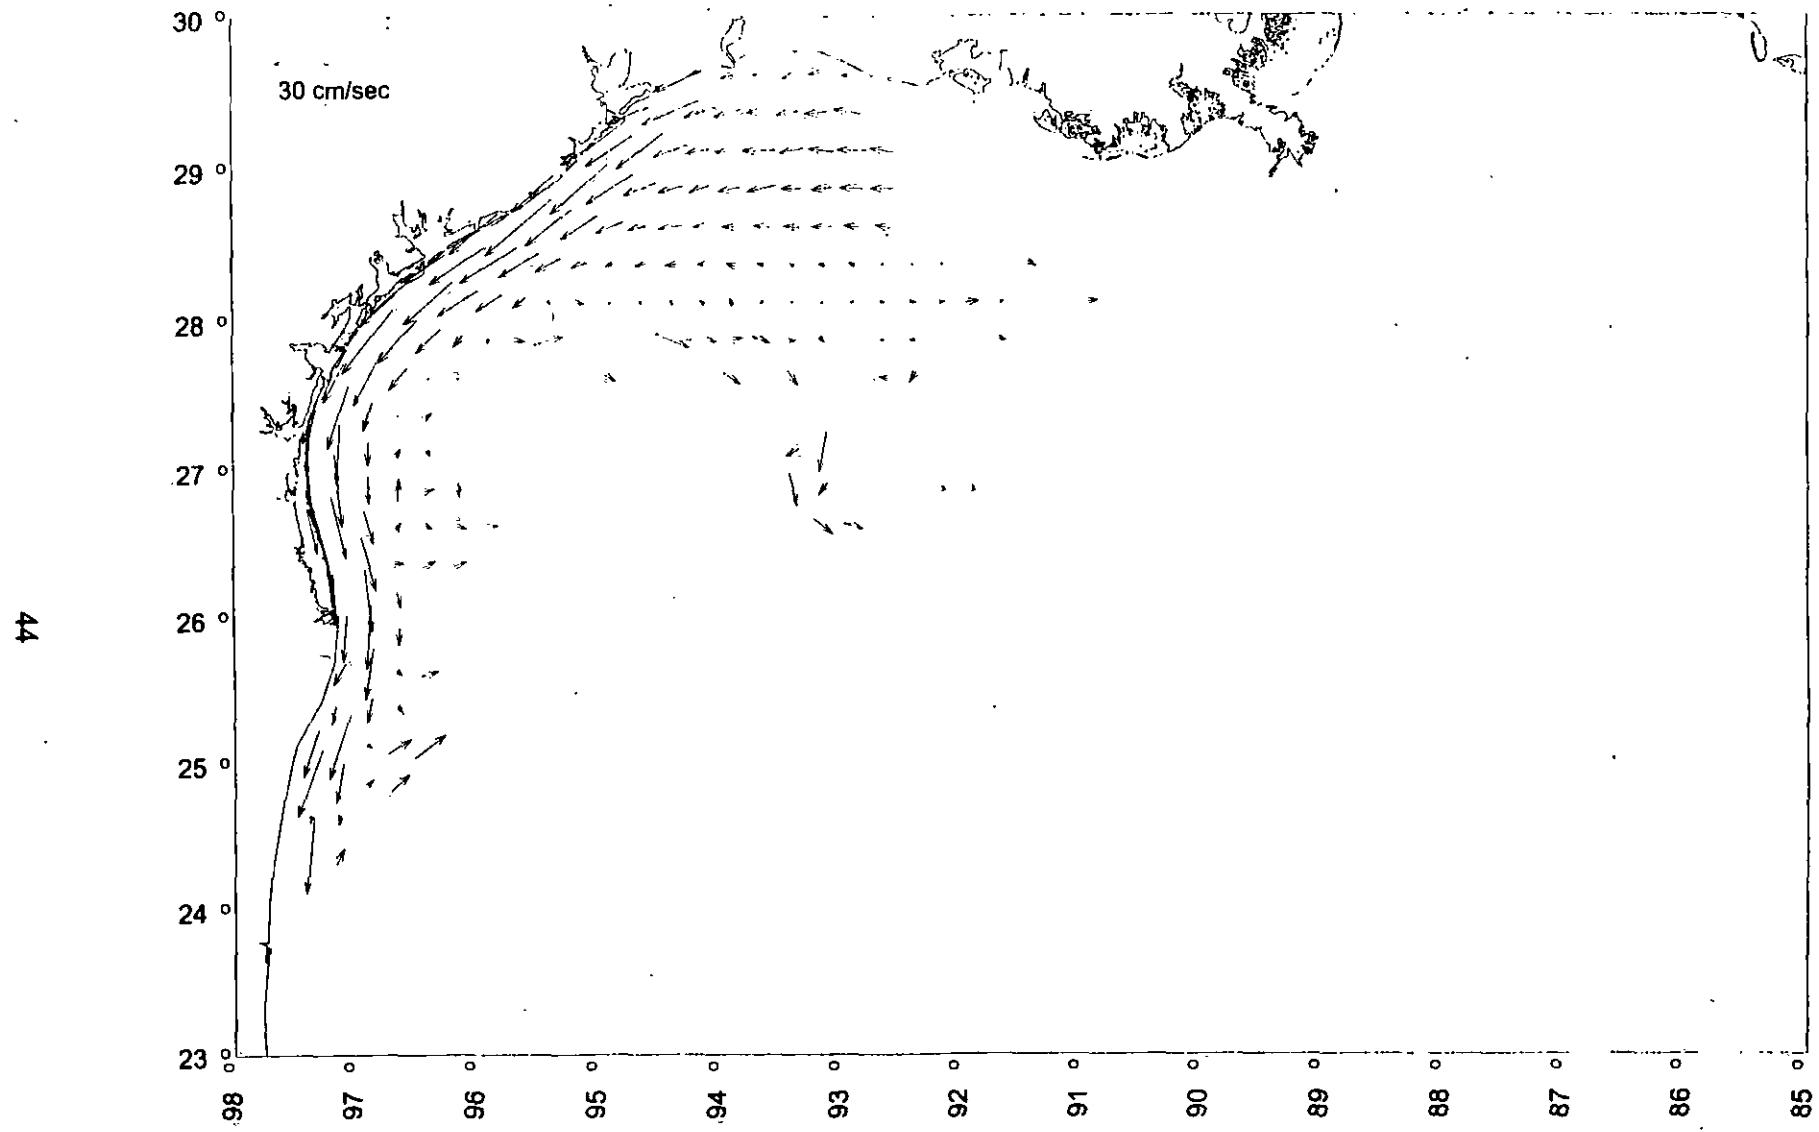

Figure 14. Mean quasi-Eulerian velocity field produced by averaging all the SCULP drifting buoy velocities within their respective boxes over the time period October 15, 1993, through May 15, 1994. The velocity scale is in the upper left corner.

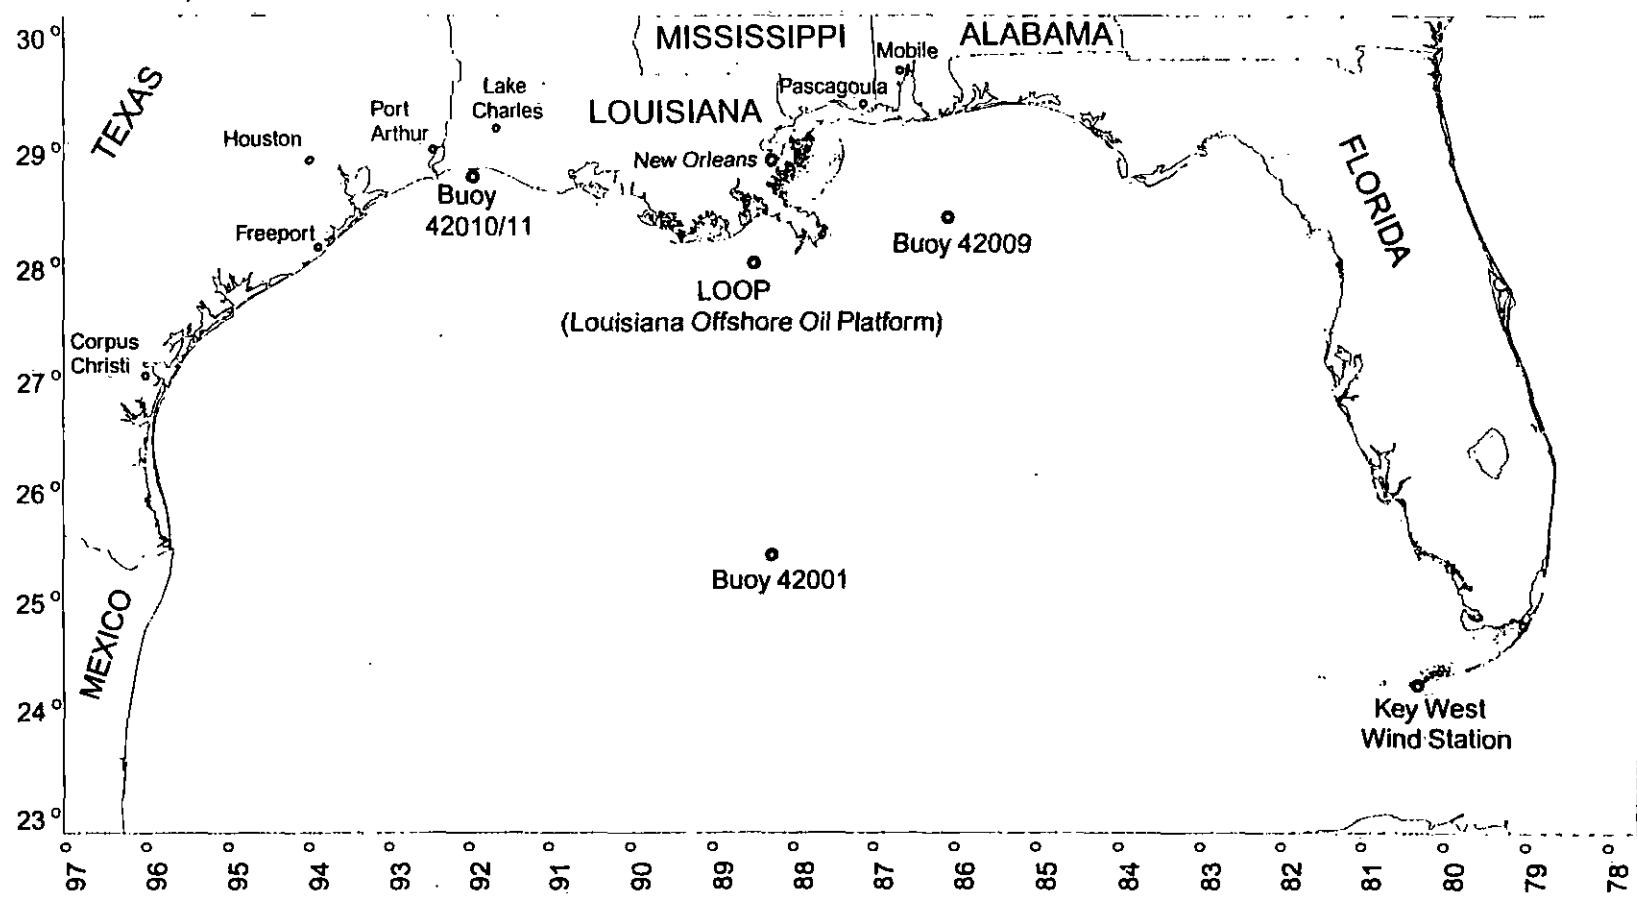

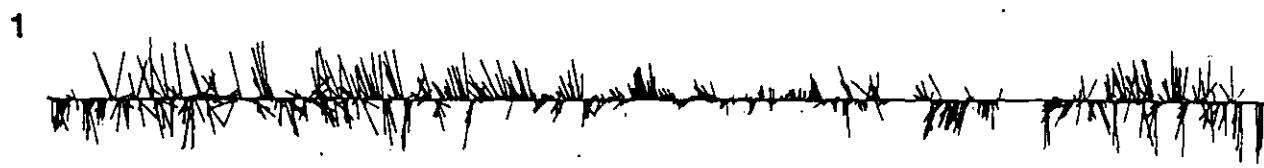

Figure 15. Gulf of Mexico ports handling crude petroleum. The "Mississippi River" ports include New Orleans, Baton Rouge, and other smaller port towns along the lower Mississippi River. Also shown are the locations of moored meteorological buoys operated by the NDBC and a wind station on Key West.

BUOY 42001 FOR: C: 42001.83

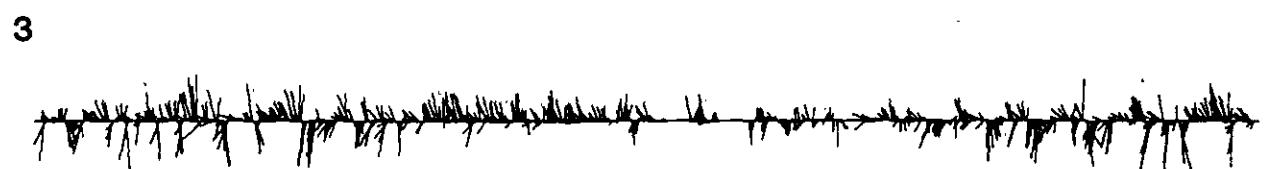

10m/sec

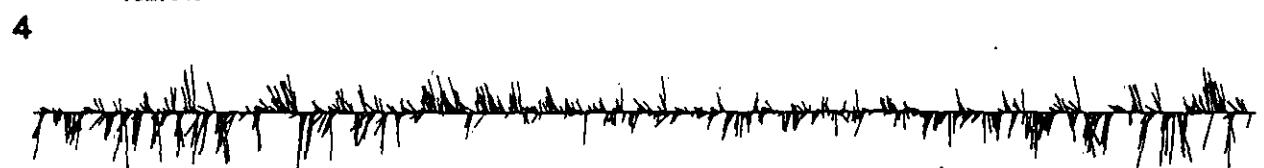

FNOC FOR: C: FNOC.83

BUOY 42001 FOR: C: 42001.90

10m/sec

FNOC FOR: C: FNOC.90

Figure 16. Wind velocities in 1983 and 1990 at the moored NDBC Buoy 42001 (lines 1 and 3) and from the NCGW field (lines 2 and 4) every 12 hours beginning at the left. North is up, east is to the right, and time increases from left to right

Table 1. Oil-spill occurrence probability estimates for spills greater than or equal to 1,000 barrels resulting over the assumed production life of the proposed action (base case and high case), total planning actions, and Gulfwide, and from tankering of crude oil imports into the study area, Gulf of Mexico OCS Lease Sales 157 and 161.

Source	Volume (Bbb)	Mean number of spills from			Mean number of spills (Total)	Probability (% chance) of one or more spills from			Probability (% chance) of one or more spills (Total)
		Platforms	Pipelines	Tankers		Platforms	Pipelines	Tankers	
Proposed Action:

The Department of the Interior Mission

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering sound use of our land and water resources; protecting our fish, wildlife, and biological diversity; preserving the environmental and cultural values of our national parks and historical places; and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to ensure that their development is in the best interests of all our people by encouraging stewardship and citizen participation in their care. The Department also has a major responsibility for American Indian reservation communities and for people who live in island territories under U.S. administration.

The Minerals Management Service Mission

As a bureau of the Department of the Interior, the Minerals Management Service's (MMS) primary responsibilities are to manage the mineral resources located on the Nation's Outer Continental Shelf (OCS), collect revenue from the Federal OCS and onshore Federal and Indian lands, and distribute those revenues.

Moreover, in working to meet its responsibilities, the **Offshore Minerals Management Program** administers the OCS competitive leasing program and oversees the safe and environmentally sound exploration and production of our Nation's offshore natural gas, oil and other mineral resources. The **MMS Royalty Management Program** meets its responsibilities by ensuring the efficient, timely and accurate collection and disbursement of revenue from mineral leasing and production due to Indian tribes and allottees, States and the U.S. Treasury.

The MMS strives to fulfill its responsibilities through the general guiding principles of: (1) being responsive to the public's concerns and interests by maintaining a dialogue with all potentially affected parties and (2) carrying out its programs with an emphasis on working to enhance the quality of life for all Americans by lending MMS assistance and expertise to economic development and environmental protection.
