Appendix I: NHPA Section 106 Summary

I.1 Project Overview

I.1.1 Background

This document provides a summary of the Bureau of Ocean Energy Management's (BOEM's) compliance with Section 106 of the National Historic Preservation Act (NHPA or Section 106) and documents the agency's consultation process for the development of a Programmatic Agreement that will guide Section 106 project-level review of the Construction and Operation Plans (COPs) for six commercial wind energy lease areas (OCS-A 0537, 0538, 0539, 0541, 0542, and 0544) in the New York Bight (NY Bight). This Section 106 summary (Summary) is included as an appendix to the Programmatic Environmental Impact Statement (PEIS) being prepared in compliance with the National Environmental Policy Act (NEPA).

This is the first time that BOEM is developing a Programmatic Agreement for a grouping of lease areas after lease issuance and before submittal of COPs, but it builds from other efforts BOEM has made to identify programmatic solutions for meeting the agency's obligations under Section 106. BOEM has already implemented programmatic agreements pursuant to 36 Code of Federal Regulations (CFR) 800.14(b) to fulfill its obligations under Section 106 of the NHPA for renewable energy activities on the Outer Continental Shelf (OCS) offshore New York and New Jersey. These agreements have been developed for two primary reasons: first, BOEM's decisions to issue leases and approve plans (e.g. Site Assessment Plans [SAPs], COPs, or General Activity Plans [GAPs]) are complex and involve multiple stages of decision-making and multiple undertakings; and second, BOEM will not have the results of archaeological surveys prior to the issuance of leases or grants and, as such, will be conducting historic property identification and evaluation efforts in phases (36 CFR 800.4(b)(2)). The *Programmatic Agreement Among The U.S. Department of the Interior, Bureau of Ocean Energy Management, The State Historic Preservation Officers of New Jersey and New York, The Shinnecock Indian Nation, and The Advisory Council on Historic Preservation Regarding Review of Outer Continental Shelf Renewable Energy Activities Offshore New Jersey and New York Under Section 106 of the National Historic Preservation Act* (NJ-NY PA) was executed June 3, 2016[1] by BOEM, the State Historic Preservation Officers (SHPOs) of New York and New Jersey, and the Advisory Council on Historic Preservation (ACHP). This agreement provides for Section 106 consultation to continue through BOEM's decision-making process and allows for a phased identification and evaluation of historic properties (36 CFR 800.4(b)(2)).

The current programmatic review of the six NY Bight lease areas seeks to compile baseline information, where feasible, and identify key concepts to incorporate into a standardized process that will guide each of the six project-level reviews. By capturing the results in this Summary and a supplemental

[1] https://www.boem.gov/sites/default/files/renewable-energy-program/State-Activities/HP/NY-NJ-Programmatic-Agreement-Executed.pdf

programmatic agreement for NY Bight, BOEM seeks to achieve greater consistency across the six lease areas while reducing the consultation burden for consulting Tribes, SHPOs, ACHP, and other parties.

I.1.2 Consultation with Tribes and Consulting Parties and Public Involvement

On July 15, 2022, BOEM contacted representatives of federally recognized Tribes, other federal agencies, state and local governments, preservation organizations, lessees of the six NY Bight lease areas, and other potentially interested consulting parties to determine their interest in participating as consulting parties. In the course of consultation activities, BOEM has identified additional organizations or agencies that may have an interest in the effects of offshore wind development on historic properties and has continued to invite such parties to participate in the programmatic Section 106 review. Consulting parties for the NHPA Section 106 Consultation of the NY Bight PEIS as of July 1, 2024, are listed in Table I-1. BOEM will continue consulting with federally recognized Tribes, New Jersey SHPO, New York SHPO, ACHP, and other consulting parties regarding the project-level review procedures and the development of Avoidance, Minimization, Mitigation, And Monitoring (AMMM) measures and Recommended Practices (RPs) that could be adopted at the individual COP NEPA-Section 106 review stage to resolve adverse effects on historic properties.

Table I-1. Participating Section 106 consulting parties for the NY Bight

Organization Type	Participating Consulting Parties
Federally Recognized Tribe	Absentee-Shawnee Tribe of Indians of Oklahoma
Federally Recognized Tribe	Delaware Tribe of Indians
Federally Recognized Tribe	Eastern Shawnee Tribe of Oklahoma
Federally Recognized Tribe	Mashantucket (Western) Pequot Tribal Nation
Federally Recognized Tribe	Mashpee Wampanoag Tribe
Federally Recognized Tribe	Mohegan Tribe of Connecticut
Federally Recognized Tribe	Stockbridge-Munsee Community Band of Mohican Indians
Federally Recognized Tribe	The Delaware Nation
Federally Recognized Tribe	The Narragansett Indian Tribe
Federally Recognized Tribe	The Shinnecock Indian Nation
Federally Recognized Tribe	Tuscarora Nation
Federally Recognized Tribe	Wampanoag Tribe of Gay Head (Aquinnah)
Federal Government	U.S. Advisory Council on Historic Preservation
Federal Government	U.S. Army Corps of Engineers
Federal Government	U.S. Bureau of Safety and Environmental Enforcement
Federal Government	U.S. Department of the Navy
Federal Government	U.S. Environmental Protection Agency
Federal Government	U.S. National Park Service
Lessee	Atlantic Shores Offshore Wind Bight (OCS-A 0541)
Lessee	Attentive Energy (OCS-A 0538)
Lessee	Bluepoint Wind (OCS-A 0537)
Lessee	Community Offshore Wind (OCS-A 0539)
Lessee	Invenergy (OCS-A 0542)
Lessee	Vineyard Mid-Atlantic Offshore Wind (OCS-A 0544)

Organization Type	Participating Consulting Parties
Local Government	Atlantic County
Local Government	Avon-by-the-Sea Borough
Local Government	Borough of Beach Haven
Local Government	Borough of Highlands
Local Government	Borough of Point Pleasant Beach
Local Government	Borough of Sea Bright
Local Government	Borough of Seaside Park
Local Government	Borough of Spring Lake
Local Government	Cape May County
Local Government	City of Absecon
Local Government	City of Asbury Park
Local Government	City of Hoboken
Local Government	City of North Wildwood
Local Government	Monmouth County
Local Government	Monmouth County Park System
Local Government	Nassau County
Local Government	Neptune City
Local Government	Suffolk County
Local Government	Town of Babylon
Local Government	Town of Islip
Local Government	Town of Oyster Bay
Local Government	Township of Brick
Local Government	Township of Hamilton
Local Government	Township of Middletown
Local Government	Township of Stafford
Local Government	Village of Bellport
Local Government	Village of Patchogue
Other Potentially Interested Parties	Green-Wood Cemetery
Other Potentially Interested Parties	Hempstead Harbor Protection Committee
Other Potentially Interested Parties	Point O' Woods Association
Preservation Organization	Bay Shore Historical Society
Preservation Organization	Greater Cape May Historical Society
Preservation Organization	Historic Districts Council
Preservation Organization	Historical Society of Highlands
Preservation Organization	Ocean City Historical Museum
Preservation Organization	Preservation Alliance of Spring Lake
Preservation Organization	Romer Shoal Light
Preservation Organization	Save Long Island Beach Inc.
Preservation Organization	The Noyes Museum of Art
Preservation Organization	West Bank Lighthouse
State Government	New Jersey State Museum
State Government	New York State Parks, Recreation & Historic Preservation, Long Island State Parks Region 9
State Government	New York State Parks, Recreation and Historic Preservation

Organization Type	Participating Consulting Parties
State Government (SHPO)	New Jersey Department of Environmental Protection, Historic Preservation Office
State Government (SHPO)	New York State Historic Preservation Office
State Recognized Tribe	Lenape Indian Tribe of Delaware

BOEM conducted Section 106 early coordination meetings with ACHP on September 7, 2022, and with the New Jersey and New York SHPOs and ACHP on September 21, 2022 and January 10, 2023. BOEM conducted a Section 106 consultation meeting with consulting parties on March 13, 2023, to introduce the objectives for the NY Bight programmatic Section 106 review and solicit input on the development of the Programmatic Agreement. BOEM conducted a second Section 106 consultation meeting on August 3, 2023, to present an introduction to BOEM's analysis of impacts on scenic and visual resources including a preview of the development of photo simulations of development scenarios for the NY Bight lease areas and to provide an overview of BOEM's progress on the development of the Programmatic Agreement. BOEM conducted a third Section 106 consultation meeting on February 15, 2024, to present the responses to consulting party comments and the revised Programmatic Agreement. BOEM conducted a fourth Section 106 consultation meeting on June 20, 2024, to present the responses to consulting party comments and the third version of the draft Final Programmatic Agreement.

I.1.3 Programmatic Area of Potential Effect

BOEM has developed a NY Bight programmatic area of potential effects (Programmatic APE) in accordance with implementing regulations at 36 CFR part 800 (Protection of Historic Properties). In 36 CFR 800.16(d), the APE is defined as "the geographic area or areas within which an undertaking may directly or indirectly cause alteration in the character or use of historic properties, if any such properties exist."

BOEM (2020) further defines the APE as the following and pursuant to the Section 106 regulations definition of an APE (36 CFR 800.16(d)):

- The depth and breadth of the seabed potentially impacted by any bottom-disturbing activities;
- The depth and breadth of terrestrial areas potentially impacted by any ground-disturbing activities;
- The viewshed from which renewable energy structures, whether located offshore or onshore, would be visible;
- Any temporary or permanent construction or staging areas, both onshore and offshore.

BOEM has formed the Programmatic APE to facilitate the preliminary identification of historic properties listed in the National Register of Historic Places (NRHP) subject to potential effects from anticipated offshore wind development in the NY Bight area; initiate consultations with consulting parties; and analyze the implementation of potential AMMM measures for avoiding or reducing adverse effects on historic properties. Specific information, such as cable routes, landfall locations, and onshore transmission routes are not available at this time. Based on general information obtained from the lessees and other consulting parties, BOEM has defined a conservative Programmatic APE meant to encapsulate future COP-specific APEs when that information becomes available. BOEM will require each lessee to complete the requisite cultural resource technical studies per BOEM (2020) historic property identification guidelines including, but not limited to, the preliminary delineation of an APE per the COP Project Design Envelope (PDE), completion of associated cultural resource and historic property identification efforts, assessment of potential effects, consideration of relevant RPs as listed in Table 3.6.2-8 of the PEIS, and development of potential AMMM measures for identified historic properties. BOEM will then delineate the COP APE and assess the specific impacts for the PDEs of each NY Bight lease area in COP-specific NEPA and Section 106 reviews and consultations.

For the purposes of this analysis, cultural resources are divided into several types and subtypes as defined in Table I-2. Discussion of the cultural resource types in this section is further organized by their known or potential presence in the Programmatic APE.

Table I-2. Definitions of cultural resource types used in the analysis

Term	Definition
Ancient submerged landform feature	*Ancient submerged landform features* are landforms that have the potential to contain Native American archaeological resources inundated and buried as sea levels rose at the end of the last Ice Age. Additionally, Tribal Nations in the region may consider ancient submerged landform features to be independent or contributing elements to previously subaerial TCPs representing places where their ancestors once lived.
Cultural landscape	The National Park Service (2006) defines a *cultural landscape* as a “geographic area, including both cultural and natural resources and the wildlife or domestic animals therein, associated with a historic event, activity, or person, or exhibiting other cultural or aesthetic values.” In this analysis, cultural landscapes are considered a type of historic aboveground resource.
Cultural resource	The phrase *cultural resource* refers to a physical resource valued by a group of people such as an archaeological resource, building, structure, object, district, landscape, or TCP. Cultural resources can date to the pre-Contact or post-Contact periods (i.e., respectively, the time prior to written records and thereafter) and may be listed on national, state, or local historic registers or be identified as important to a particular group during consultation, including any of those with cultural or religious significance to Tribal Nations. Cultural resources in this analysis are divided into several types and subtypes: marine cultural resources, terrestrial archaeological resources, historic aboveground resources, and TCPs.
Marine archaeological resource	*Marine archaeological resources* are the physical remnants of past human activity that occurred at least 50 years ago and are submerged underwater. They may date to the pre-Contact period (e.g., those inundated and buried as sea levels rose at the end of the last Ice Age) or post-Contact period (e.g., shipwrecks, downed aircraft, and related debris fields).
Historic aboveground resource	*Historic aboveground resources* are subaerial features or structures of cultural significance at least 50 years in age and include those that date to the pre-Contact or post-Contact periods. Example types that are or may have historic aboveground components include standing buildings, bridges, dams, historic districts, cultural landscapes, and TCPs.

Term	Definition
Historic district	A *historic district* is an area composed of a collection of either or both archaeological and aboveground cultural resources.
Historic property	As defined in 36 CFR 800.16(l)(1), the phrase *historic property* refers to any "prehistoric or historic district, site, building, structure, or object included in, or eligible for inclusion in, the [NRHP] maintained by the Secretary of the Interior. The term includes artifacts, records, and remains that are related to and located within such properties." *Historic property* also includes NHLs as well as properties of traditional religious and cultural importance to Native American Tribal Nations that meet NRHP criteria. The NRHP recognizes historic properties that are significant at the national, state, and local levels that possess integrity of location, design, setting, materials, workmanship, feeling, and association and that meet any of Criterion A through D. Criterion A covers a historic property that is associated with events that are significant to the broad patterns of our history. Criterion B covers a historic property associated with the lives of persons significant to our past. Criterion C covers a historic property that embodies distinctive characteristics of a type, period, or method of construction; represents the work of a master or possesses high artistic values; or represents a significant and distinguishable entity whose components may lack individual distinction. Criterion D covers a historic property that yields, or may be likely to yield, information important to prehistory or history.
Terrestrial archaeological resource	*Terrestrial archaeological resources* are the physical remnants of past human activity that occurred at least 50 years ago and are located on or within lands not submerged underwater. They may date to the pre-Contact period (i.e., have associations with Native American populations dating to before European colonization of the Americas) or post-Contact period (i.e., have associations with African American, European American, or Native American populations dating to after European colonization of the Americas).
Traditional cultural property	National Register Bulletin 38 (Parker and King 1990, revised 1992 and 1998) defines a *traditional cultural property* as a "[historic property] that is eligible for inclusion in the National Register because of its association with cultural practices or beliefs of a living community that (a) are rooted in that community's history, and (b) are important in maintaining the continuing cultural identity of the community." TCPs may be locations, places, or cultural landscapes and have either or both archaeological and aboveground elements.

NHL = National Historic Landmark; TCP = traditional cultural property.

I.1.3.1 Marine Portion of the Programmatic APE

When delineating the marine portion of the APE during the COP-stage review, BOEM considers the potential for the construction of offshore project components to physically disturb marine archaeological resources or ancient submerged landforms (ASLFs), either of which may qualify as historic properties. Delineating the area within which such effects may occur requires consideration of the locations where turbines or substations will be anchored to the seafloor within the lease area, as well as the corridors within which the interarray cables, transmission cables, and other project components may disturb the seabed between the lease area and coastal landfall. Other project activities that have the potential to physically disturb marine archaeological resources, such as interarray cables or use of anchors by vessels conducting surveys or supporting construction, may warrant expansion of the Marine APE.

The programmatic review of the NY Bight lease areas does not include delineation of a marine portion of the Programmatic APE due to the lack of complete project-specific design or layouts. In particular, the Programmatic APE has not considered other offshore areas, aside from the six NY Bight lease areas, potentially physically affected by seabed-disturbing activities (i.e., other marine areas in which temporary or permanent construction or staging areas are proposed to occur, such as offshore export cable route corridors and horizontal directional drilling [HDD] locations, which may have physical impacts on historic properties). Therefore, the potential for adverse effects will be considered based on hypothetical project activities that are typical of offshore wind renewable energy projects.

I.1.3.2 Terrestrial Portion of the Programmatic APE

When delineating the terrestrial portion of the APE, BOEM considers the potential for construction of onshore project components to physically disturb archaeological historic properties during ground-disturbing activities. Delineating the area within which such effects may occur requires locational information for where the subsea cables will make landfall, the location of terrestrial substations/converter stations, and the proposed routes for transmission, none of which are currently available. In addition to the location for such project components, the terrestrial APE needs to consider the maximum horizontal area and maximum vertical depth of ground disturbance at those locations.

The programmatic review of the NY Bight lease areas does not include delineation of a terrestrial portion of the Programmatic APE due to the lack of project-specific information about onshore areas potentially physically affected by ground-disturbing activities. Instead, the potential for adverse effects will be considered based on hypothetical project activities that are typical of offshore wind renewable energy projects.

I.1.3.3 Visual Portion of the Programmatic APE

When delineating the visual portion of the APE, BOEM considers the potential for offshore project components to cause adverse effects on onshore aboveground historic properties in those instances where a maritime view is a character-defining feature of the historic property and the introduction of the offshore wind facilities would reduce the integrity of that view. Delineating the area within which such effects may occur requires consideration of the viewshed modeling that is conducted according to BOEM’s guidance for Visual Impacts Analysis (VIA).

For the programmatic review of the six lease areas in the NY Bight, BOEM has established a general study area for the visual analysis based on preliminary viewshed modeling (see Figure I-1). In general, the study area considers the visibility of a wind turbine generator (WTG) from the water level to the tip of an upright rotor blade at a height of 1,312 feet (400 meters), which is the maximum height of turbines considered in the PEIS Representative Project Design Envelope (RPDE) (refer to Chapter 2, Table 2-2 of the PEIS). This can be broken down to consider visibility from ground level or from an elevated viewpoint (such as the lookout room of a lighthouse or upper floors of a multi-story hotel). Such modeling can also consider visibility of the safety lights at the mid-level of the turbine, the hub of the turbine blades, or even the tip of the blades.

Geographic information system analysis was used to refine the study area and define a programmatic visual APE methodically through a series of steps. Once the study area was established (maximum theoretical distance WTGs could be visible), the analysis then accounted for how distance and Earth curvature impede visibility as the distance increases between the viewer and WTGs. This area was refined through computer modeling with the addition of a land cover vegetation layer to account for large areas of tall vegetation that limit projected visibility to a NY Bight project. Data layers for building footprints and building heights were then added to account for existing development projected to screen views to the NY Bight lease areas. Locations with unobstructed views of offshore elements then constituted the offshore visual APE (see Figure I-2).

The visual portion of the APE also includes consideration of the potential for onshore activities to include project components that cause adverse effects on onshore aboveground historic properties where introduction of the modern infrastructure would be incompatible with the historic character of the affected historic property. Such components may include cable landing locations, connection points where underground transmission lines connect aboveground, substations, switching stations, and overhead transmission line routes.

For the programmatic review of the six lease areas in the NY Bight there is not enough detail known about where the onshore project components will be located, so the onshore visual portion of the Programmatic APE has not been delineated. At the project specific review stage, these elements will be sited and can be mapped. Consultation regarding the potential for visual adverse effects on onshore aboveground historic properties will focus on the types of impacts caused by onshore facilities that typically support offshore wind developments, rather than specific effects to specific historic properties.

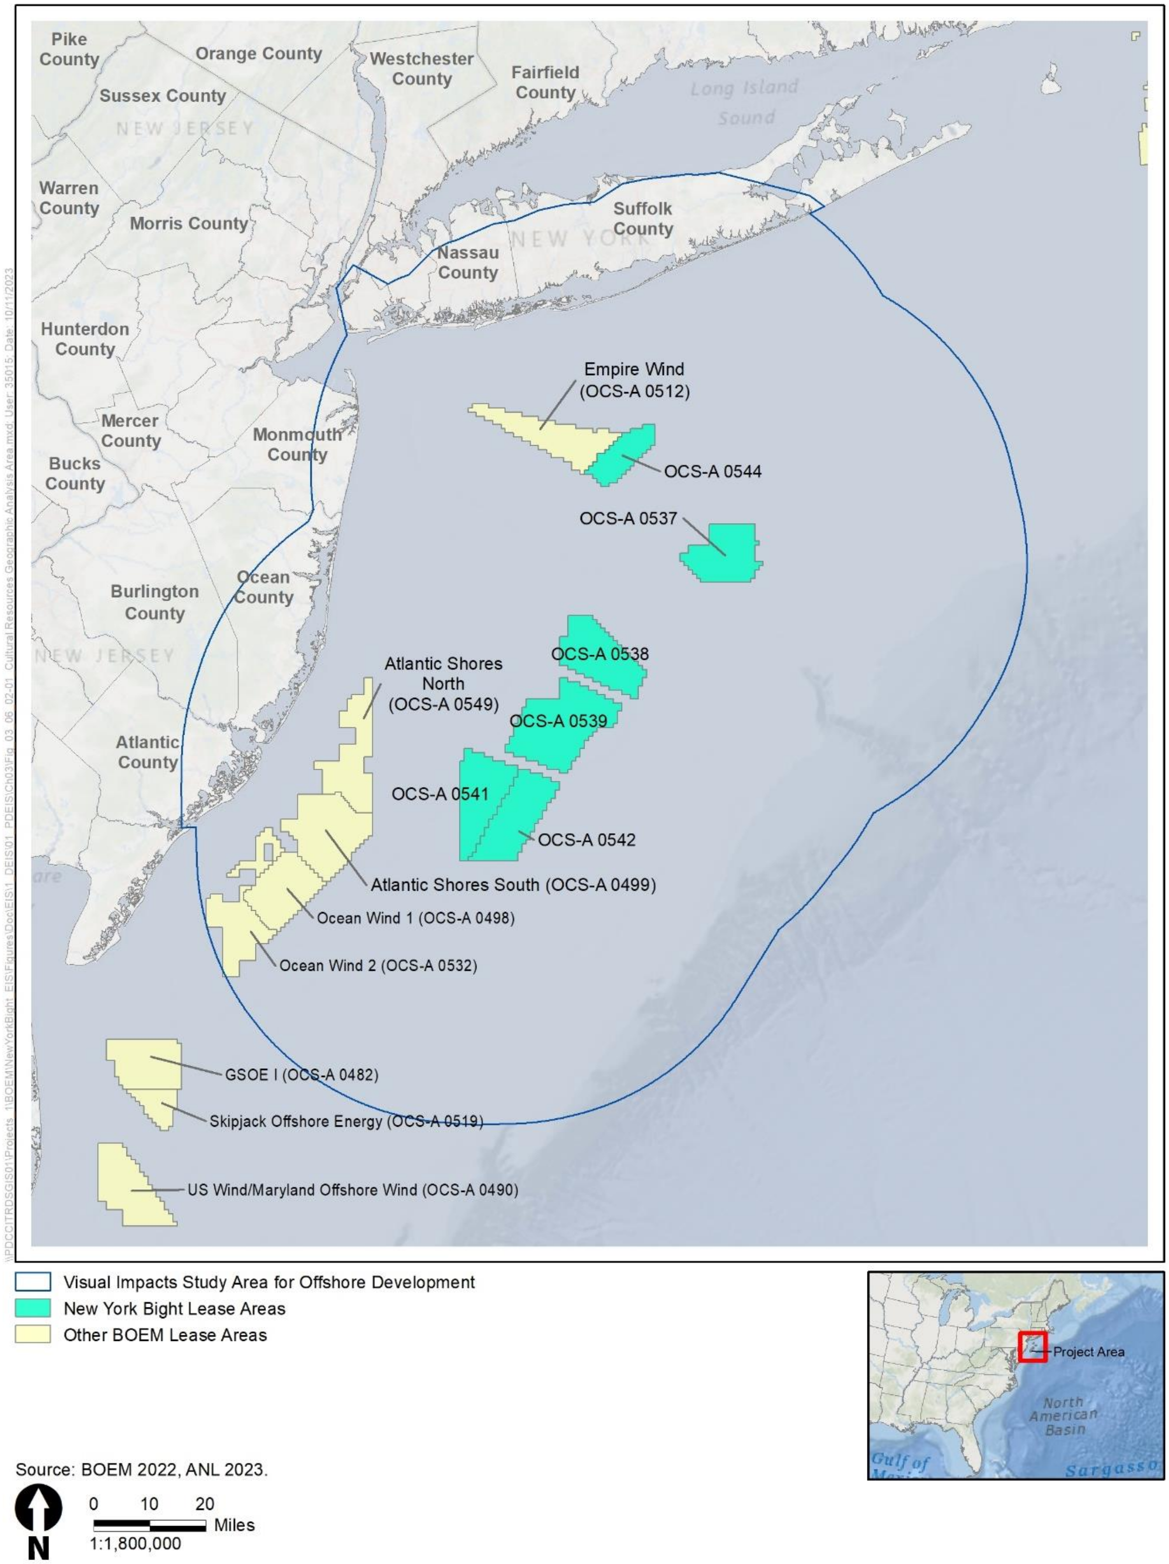

Figure I-1. Offshore visual impacts study area

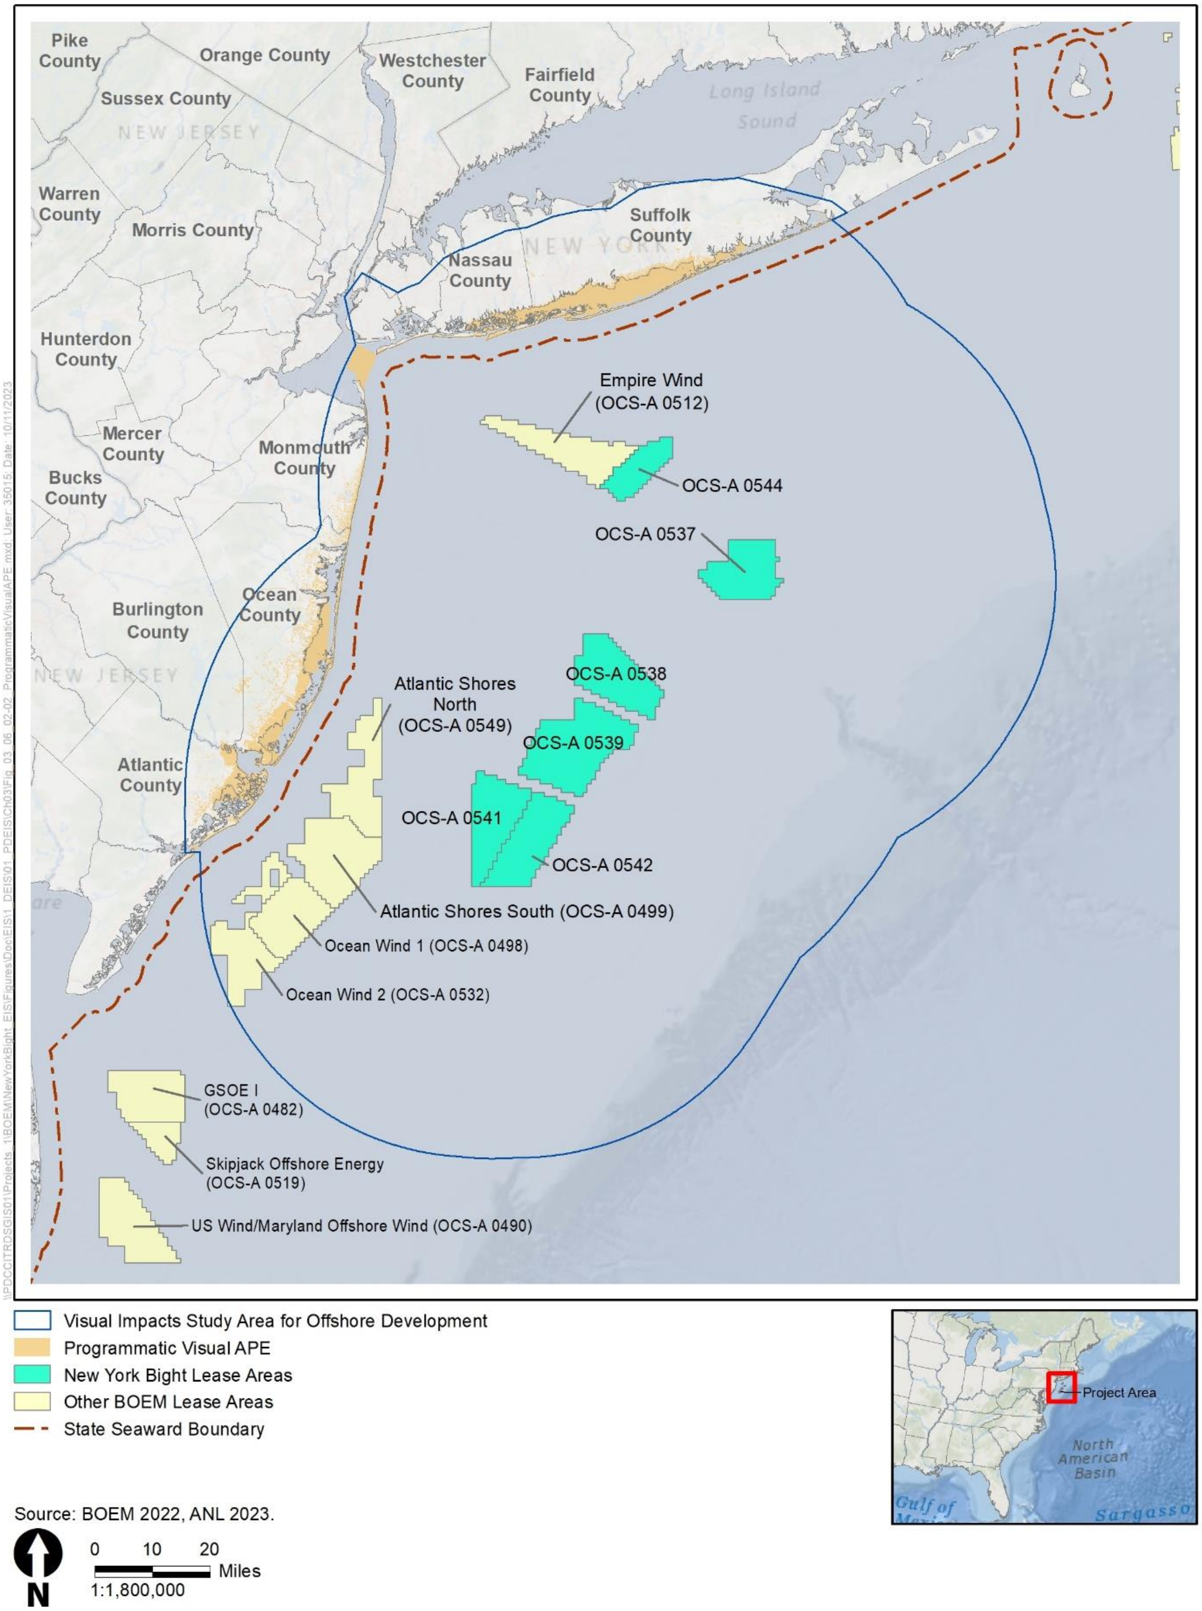

Figure I-2. Programmatic offshore visual APE

I.2 Historic Property Identification

I.2.1 Background Research

Background research and development of cultural and historic contexts were conducted by BOEM for the 2021 NY Bight Environmental Assessment, which assessed the potential impacts of the issuance of leases within the NY Bight wind energy areas (WEAs) and granting of easements, rights-of-way, and rights-of-use (BOEM 2021). These contexts have been incorporated into the PEIS and this Summary.

Table I-3 summarizes the cultural context of the Programmatic APE in New Jersey and New York (BOEM 2021).

Table I-3. Cultural context for the New York Bight cultural resources geographic analysis area

Period	Date	Description
Pre-Contact (Paleoindian)	15,000–10,000 BP	Semi-nomadic hunting and gathering populations. Use of broad spectrum of plants and animals for subsistence. Characteristic fluted projectile points used to hunt now-extinct large megafauna (mammoth and mastodon). Landscape of spruce forest. Sea levels about 330 feet (100 meters) below present-day levels. Sea level rise occurred with episodes of melting of the North American ice sheet. Deeply incised drainages along the OCS would have been estuarine environments utilized as a source of food and fresh water and habitation by Paleoindian populations. Flooding of these drainages allowed for sediment flows to bury possible Paleoindian sites.
Pre-Contact (Archaic)	10,000–3,000 BP	Period subdivided into Early (10,000–8,000 BP), Middle (8,000–6,000 BP), and Late (6,000–3,000 BP) phases. Gradual shift to modern environmental conditions with overall warmer temperatures and less precipitation relative to previous period. Spruce and pine forests gradually transition to mixed deciduous forest (hickory, oak, chestnut). Sea level had risen to about 75 feet (23 meters) below present-day levels by the Early Archaic and stabilized around 1.5–6.5 feet (0.5–2 meters) below present-day levels by the Late Archaic. Mobility of hunting and gathering populations decreased as environmental conditions stabilized. Population density increased and seasonal settlements were common with introduction of a broad range of seasonal food sources, including shellfish and other riverine and marine resources. Diverse types of stone tools used including ground stone vessels.
Pre-Contact (Woodland)	3,000–400 BP	Period subdivided into Early (3,000–2,000 BP), Middle (2,000–1,000 BP), and Late (1,000–400 BP) phases. Cooler and wetter climate in Early Woodland, then warming and drying trend begins in Middle Woodland. Mixed deciduous forests persist. Terrestrial foraging and intensive exploitation of marine food sources. Increasing sedentism with use of agriculture. Use of ceramic pots for cooking and storage. Triangular projectile points with introduction of bow and arrow by Late Woodland.
Post-Contact	17th Century AD	Native Americans settle in sedentary villages supported by agriculture and seasonal camps targeting large and small game, plants, riverine, and marine resources. Similar technologies to Late Woodland but increasing use of European trade goods. Interactions occur among Native Americans and European colonists. Dutch, Swedish, English colonies established. New Amsterdam colony established on Manhattan Island in 1625. New Sweden colony established in New Jersey in 1638. English colonists control the region by 1664.

Period	Date	Description
Post-Contact	18th Century AD	Shipbuilding and fish, tobacco, and fur trade industries thrive. First lighthouses on the Atlantic Seaboard are completed, including Sandy Hook in 1764. Ongoing conflicts between English and French colonists and their Native American allies. During the American Revolutionary War, many engagements between British and Continental forces took place in New Jersey and New York. Statehood granted to New Jersey in 1787 and to New York in 1788.
Post-Contact	19th Century AD	Manufacturing drives the economy during the Industrial Revolution. Cities grow as electricity is introduced and transportation improved through growth of public roadways, railroads, and canals. Iron and zinc mines become leading industries in New Jersey. New York City is a financial center during the American Civil War and remains a major ocean port and immigration hub. Ellis Island opened 1892.
Post-Contact	20th Century AD	African American populations increase with post-Civil War northward migrations. New Jersey and New York shipyards, factories, and refineries support military efforts in World War I and World War II. Many forts and training camps are active, and Port of New York used for troop deployments. Rail connections with larger urban areas and later improved roadways for automobiles led to growth of seaside communities. Urban decay in 1950s resulting from suburban growth.

Source: BOEM 2012; BOEM 2021.
AD = Anno Domini; BP = before present.

I.2.2 Historic Properties in the Marine Portion of the Programmatic APE

Marine cultural resources in the region include pre- and post-Contact marine archaeological resources and ASLFs on the OCS (BOEM 2012). Based on known historic and recent maritime activity in the region, the NY Bight lease areas have a high probability for containing shipwrecks, downed aircraft, and related debris fields that may be subject to potential impacts by seabed-disturbing activities from offshore wind development in the NY Bight area (BOEM 2012, 2021). These resources include both known and potential shipwrecks and related debris fields from the post-Contact period or last 50 years. ASLFs also have a high probability of occurrence on the OCS (BOEM 2012).

BOEM is consulting with the Naval History and Heritage Command on the potential marine resources as well as pertinent regulations protecting those resources. According to the Naval History and Heritage Command, within the cultural resources geographic analysis area for New York Bight, there are expected to be over 100 sunken military craft. These craft range in age from the late eighteenth to the twenty-first century. Several of these craft are owned by the Department of the Navy, whereas the remainder are owned by other U.S. government agencies, are foreign military craft, or their country of origin is unidentified. The type of craft represented in the Department of the Navy collection spans a wide spectrum, including, but not limited to, wooden sailing vessels, steamboats, destroyers, submarines, and aircraft. All sunken military craft are protected from unauthorized disturbance by the Sunken Military Craft Act of 2004. While the larger study area hosts a large number of sunken military craft, there are presently no known sunken military craft within the six lease areas themselves. (Krueger 2024.)

BOEM does not have enough information at this time about specific marine archaeological resources or ASLFs that may be present in the Programmatic Marine APE. BOEM will require each NY Bight lessee to conduct identification efforts for marine archaeological resources and ASLFs and present findings in a Marine Archaeological Resources Assessment (MARA) report prepared in partial fulfillment of a sufficient COP. This should include incorporation of information about marine cultural resources that have been identified as historic properties in the course of NEPA and Section 106 review of other nearby COPs (e.g., Empire Wind Offshore Wind [OCS-A 0512]), as the APE for those projects may overlap with the Programmatic APE for the NY Bight lease areas.

I.2.3 Historic Properties in the Terrestrial Portion of the Programmatic APE

The programmatic review of the NY Bight lease areas does not include delineation of a terrestrial portion of the Programmatic APE due to the lack of project-specific information about onshore areas potentially physically affected by ground-disturbing activities, and thus background research performed at this stage is unable to identify specific terrestrial archaeological resources for the programmatic review. BOEM will require each NY Bight lessee to conduct identification efforts for terrestrial archaeological resources and present findings in a Terrestrial Archaeological Resources Assessment (TARA) report prepared in partial fulfillment of a sufficient COP. This should include incorporation of information about terrestrial archaeological resources that have been identified as historic properties in the course of NEPA and Section 106 review of other lease areas that have already progressed into or completed NEPA and Section 106 review for their COPs, as the APE for those projects may overlap with the Programmatic APE for the NY Bight lease areas.

I.2.4 Historic Properties in the Visual Portion of the Programmatic APE

The viewshed of hypothetical offshore renewable energy structures constructed within the six NY Bight lease areas encompasses historically developed and densely occupied coastal areas of New Jersey and New York. As such, a large number of historic aboveground resources are anticipated to be located in the Programmatic Visual APE, of which a proportion are anticipated to be historic properties or potential historic properties listed or eligible for listing in the NRHP. These aboveground historic properties may include buildings, historic districts, cultural landscapes, and traditional cultural properties (TCPs). BOEM will require each NY Bight lessee to conduct identification efforts for historic aboveground resources and present findings in a Historic Resource Visual Effects Assessment (HRVEA) report prepared in partial fulfillment of a sufficient COP. BOEM will fully analyze impacts on such resources in COP-specific NEPA and Section 106 reviews and consultations.

I.3 Assessing Effects on Historic Properties

The effects of the NY Bight projects on historic properties cannot be fully analyzed at this time, as the layout and design details for each project are not yet known. However, in the course of conducting the analysis for the PEIS, and through input gained during the Section 106 consultation meetings, BOEM has been able to draw certain assessments and recommendations about types of effects that are likely to occur. The following section discusses the thresholds and methods for considering effects during the COP-level reviews, and is intended to create consistency across the six projects, which in turn will support more focused and meaningful project-level Section 106 consultation.

I.3.1 Criteria of Adverse Effect

The Criteria of Adverse Effect under NHPA Section 106 (36 CFR 800.5(a)(1)) states that an undertaking has an adverse effect on a historic property if the following occurs: “when an undertaking may alter, directly or indirectly, any of the characteristics of a historic property that qualify the property for inclusion in the National Register in a manner that would diminish the integrity of the property’s location, design, setting, materials, workmanship, feeling, or association.…Adverse Effects may include reasonably foreseeable effects caused by the undertaking that may occur later in time, be farther removed in distance or be cumulative.” According to regulation, adverse effects on historic properties include, but are not limited to (36 CFR 800.5(a)(2)):

i. Physical destruction of or damage to all or part of the property;

ii. Alteration of a property, including restoration, rehabilitation, repair, maintenance, stabilization, hazardous material remediation, and provision of handicapped access, that is not consistent with the Secretary of the Interior’s standards for the treatment of historic properties (36 CFR part 68) and applicable guidelines;

iii. Removal of the property from its historic location;

iv. Change of the character of the property’s use or of physical features within the property’s setting that contribute to its historic significance;

v. Introduction of visual, atmospheric, or audible elements that diminish the integrity of the property’s significant historic features;

vi. Neglect of a property, which causes its deterioration, except where such neglect and deterioration are recognized qualities of a property of religious and cultural significance to an Indian Tribe or Native Hawaiian organization; and

vii. Transfer, lease, or sale of property out of federal ownership or control without adequate and legally enforceable restrictions or conditions to ensure long-term preservation of the property’s historic significance.

I.3.2 Marine Cultural Resources

Marine cultural resources in the region include pre- and post-Contact marine archaeological resources and ASLFs on the OCS (BOEM 2012). Based on known historic and recent maritime activity in the region, the NY Bight lease areas, composing the knowable Programmatic Marine APE, have a high probability for containing shipwrecks, downed aircraft, and related debris fields that may be subject to potential impacts by seabed-disturbing activities from offshore wind development in the NY Bight area (BOEM 2012, 2021). However, as mentioned in Section 3.6.2, *Cultural Resources,* the totality of cultural resources and historic properties in the Programmatic APE is not knowable at this time, and, therefore, while the background research performed at this stage has informed development of the cultural context and general sensitivity for marine cultural resources and ASLFs, BOEM does not have enough information to identify any specific marine archaeological resources or ASLFs that may be present in the Programmatic Marine APE.

Marine cultural resources such as shipwrecks and downed aircraft may be individually eligible for listing in the NRHP under Criterion A, B, or D. ASLFs may be individually eligible for listing in the NRHP or considered contributing elements to a TCP eligible for listing in the NRHP. ASLFs in the marine APE are considered archaeologically sensitive. If undiscovered archaeological resources are present within the identified ASLFs and they retain sufficient integrity, these resources could be eligible for listing in the NRHP under Criterion D, which is a resource that yields or may be likely to yield information important in prehistory or history. Furthermore, ASLFs are considered by Tribal Nations in the region to be culturally significant resources as the lands where their ancestors lived and as locations where events described in tribal histories occurred prior to inundation. BOEM recognizes these landforms could be eligible for listing in the NRHP under Criterion A.

The severity of project effects would depend on the extent to which integral or significant components of affected marine archaeological resources or ASLFs are disturbed, damaged, or destroyed, resulting in the loss of contributing elements to the historic property’s eligibility for listing in the NRHP.

I.3.3 Terrestrial Archaeological Resources

The severity of effects would depend on the extent to which integral or significant components of affected archaeological resources are disturbed, damaged, or destroyed, resulting in the loss of contributing elements to the historic property’s eligibility for listing in the NRHP.

I.3.4 Historic Aboveground Resources

BOEM’s delineation of the visual portion of the Programmatic APE utilized a conservative viewshed from which hypothetical offshore wind structures in all six NY Bight lease areas measuring 1,312 feet (400 meters) in height would be visible (1,312 feet [400 meters] is the maximum height of turbines considered in the PEIS RPDE [refer to Chapter 2, Table 2-2]). As the developer for each lease area finalizes the layout within the lease area and the specifications for their offshore wind structures, the lease-specific preliminary APE can be delineated using the same methods that were used for the Programmatic APE. It is reasonable to expect that the viewsheds for each of the lease areas will be different from the hypothetical scenario analyzed in the programmatic review. The development of those APEs and the analysis that follows will be more credible in general, and consistent between lease areas, by using the methods developed during the programmatic review.

Assessing the effect of offshore project components generally involves the following steps:

1. Briefly summarize the historical significance of the historic property.
2. Characterize the views that comprise the character-defining views as they relate directly to the significance of the historic property. Include all character-defining views, both maritime and otherwise.

3. Describe what can be identified from Google Earth or Street View about other features in the vicinity that currently affect views from the historic property toward the character-defining maritime views (such as tall buildings between the property and the ocean, or if the property is on elevated ground).
4. Explain what can be extrapolated from the VIA performed for scenic resources, focusing on the nearest key observation point (KOP) and associated visual simulations.
5. State how all of the above would alter the historical integrity of the character-defining views, discussing the aspects of integrity related to feeling and setting relative to how one experiences the maritime character-defining views, and the aspect of association relative to how one understands the functional role of the ocean in the property's significance.
6. Conclude with a recommended finding of effect.

I.3.4.1 NY Bight Programmatic Visual Impact Analysis Key Observation Points

BOEM conducted an assessment of seascape, landscape, and visual impacts for the NY Bight lease areas, which is presented in Appendix H, *Seascape, Landscape, and Visual Impact Assessment*, and includes information on KOPs in the geographic analysis area and viewshed maps that depict what onshore areas will have visibility of the WTGs in the NY Bight lease areas. Visual simulations of the NY Bight projects and other ongoing and planned offshore wind projects in the geographic analysis area, produced by Truescape under contract to BOEM, are posted to BOEM's website for NY Bight: https://www.boem.gov/renewable-energy/state-activities/new-york-bight.

Designated KOP distances to the NY Bight projects' WTG and offshore substation (OSS) array would range from:

- 44.7 miles (71.9 kilometers) from KOP-30 Shinnecock Inlet near the northern extent of the study area;
- 24.1 miles (38.8 kilometers) from KOP-37 Point O' Woods, the closest New York KOP to the WTG array;
- 31.2 miles (50.2 kilometers) from KOP-09 Barnegat Jetty, the closest New Jersey KOP to the WTG array; and
- 49.1 miles (79.0 kilometers) from KOP-01 Ocean City Music Hall at the southern extent of the study area.

Figure I-3 illustrates the location of the KOPs relative to the visibility distances for the tower base (yellow), OSS (blue), mid-tower light (orange), hub, nacelle, and aviation lights (pink), and rotor tip blade (purple) for 1,312-foot (400-meter) WTGs. A total of 40 KOPs were selected for analysis as part of NY Bight's programmatic VIA. Of these, 26 locations were selected for their usefulness to the Section 106 programmatic review and consultation; these are the KOPs shown on Figure I-3. Table I-4 provides information about the 26 KOPs that represent historic properties or other locations relevant to the Section 106 programmatic review.

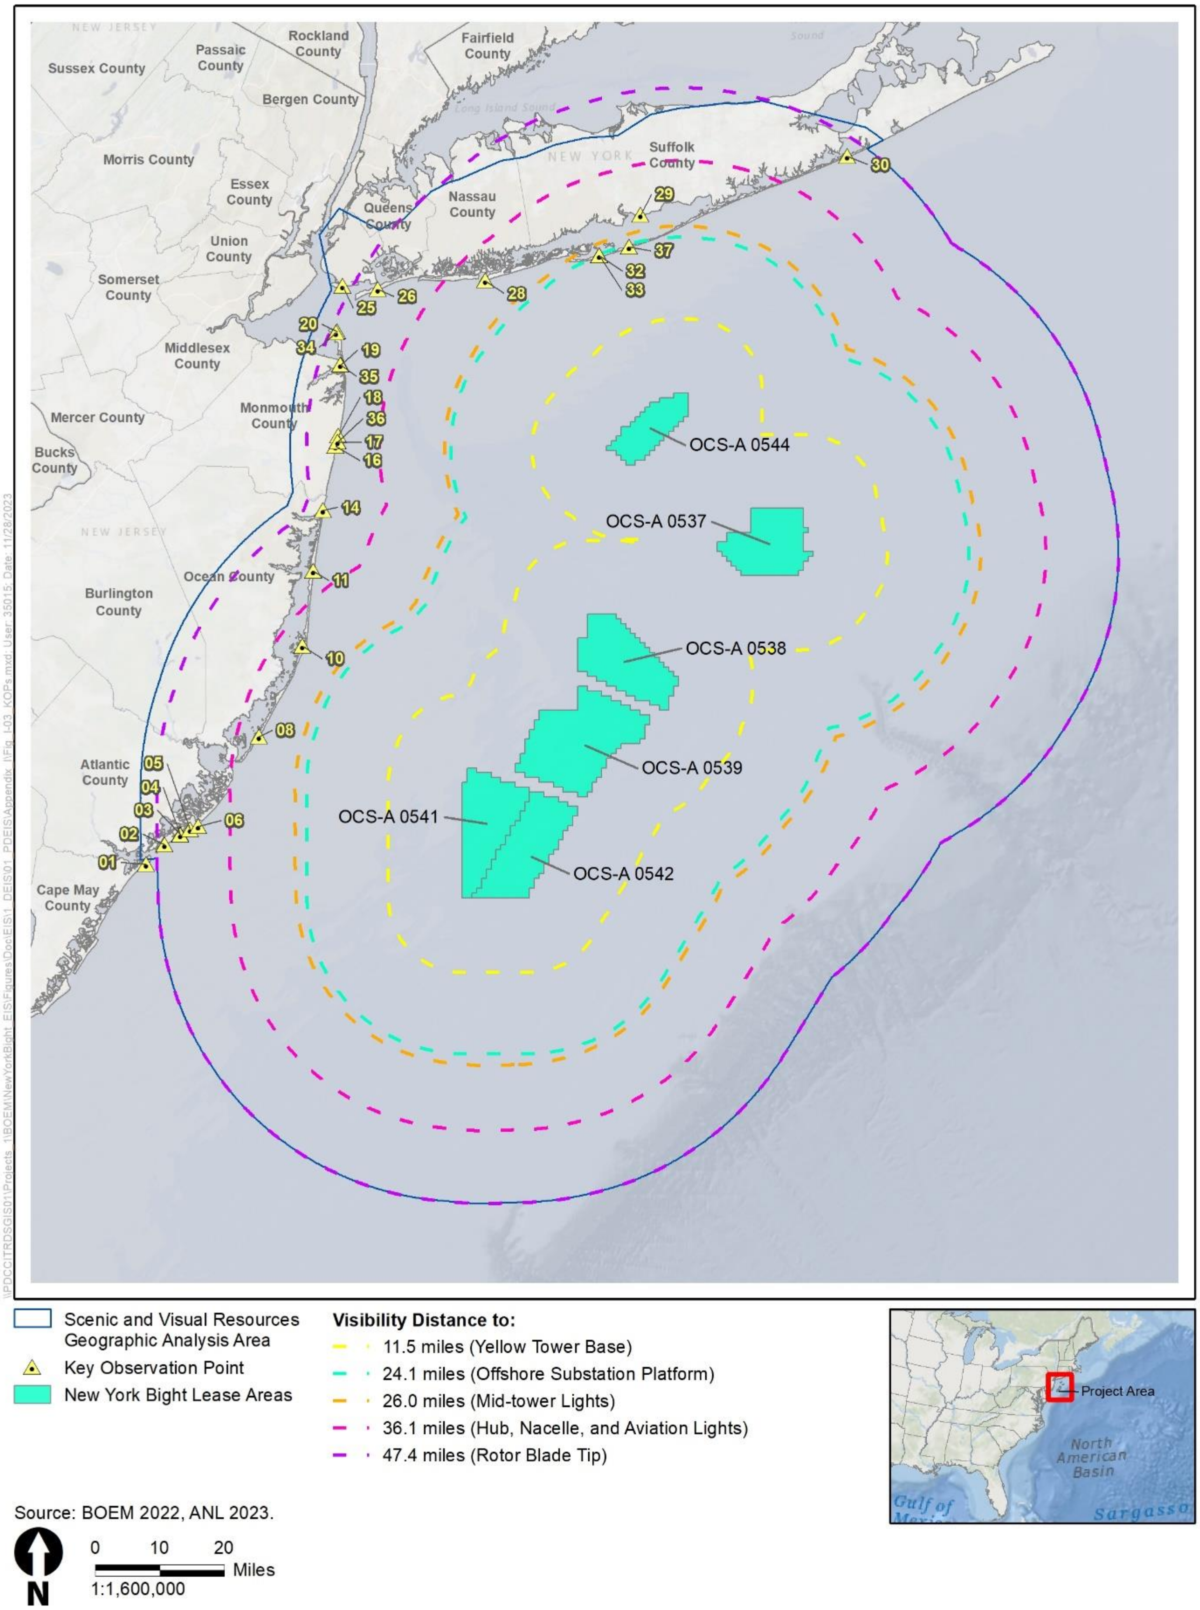

Figure I-3. Key observation points for NY Bight programmatic visual impact analysis

Table I-4. Key observation points that are also historic properties

KOP No.	Name	Rationale for Inclusion	Distance (miles) to nearest WTG/OSS	Simulation?
1	Ocean City Music Hall	Potential historic property	49.1	No
2	Lucy the Margate Elephant NHL	NHL with maritime setting/ocean view	46.3	Yes
3	Stafford Historic District/John Stafford Hall - Boardwalk	Historic property	43.8	No
4	Stafford Historic District/John Stafford Beach Entrance	Historic property	43.8	Yes
5	Atlantic City Convention Hall (Jim Whelan Hall) - Balcony	NHL with maritime setting/ocean view	42.3	Yes
6	Atlantic City Boardwalk - Ocean Casino Boardwalk View	Potential historic property	41.0	No
8	Beach Haven Historic District (Day and Night)	Historic property	32.6	Yes
10	Barnegat Lighthouse	Historic property	32.3	Yes
11	US Life Saving Station #14	Historic property	39.3	No
14	Bayhead Historic District	Historic property	44.5	No
16	Ocean Grove Historic District	Historic property	42.9	No
17	Asbury Park Beach and Convention Hall Balcony	Potential historic property	42.6	No
18	Allenhurst Residential Historic District	Historic property	42.5	Yes
19	Navesink Twin Lights NHL	NHL with maritime setting/ocean view	44.0	No
20	Sandy Hook Light NHL	NHL with maritime setting/ocean view	46.3	No
25	Coney Island Boardwalk	NHL with maritime setting/ocean view	48.8	No
26	Fort Tilden/Jacob Riis Park Historic District	Historic property	43.7	Yes
28	Jones Beach	Historic property	31.4	Yes
29	Rudolph Oyster House	NHL with maritime setting/ocean view	28.4	No
30	Shinnecock Inlet	Near Tribal territory	44.7	Yes
32	Fire Island Lighthouse - Upper Deck	Historic property	24.2	Yes
33	Fire Island Lighthouse - Base	Historic property	24.2	No
34	Sandy Hook Observatory NHL	NHL with maritime setting/ocean view	46.4	No
35	Navesink Light Station - Twin Lights Lighthouse NHL	NHL with maritime setting/ocean view	44.1	Yes
36	Asbury Park Hall	Potential historic property	42.6	Yes
37	Point O' Woods	Potential historic property	24.1	Yes

NHL = National Historic Landmark
Historic property = previously identified as eligible for or listed in the NRHP
Potential historic property = identified by BOEM or a consulting party as the location of a resource that requires further study to determine if it qualifies as an historic property.

I.3.5 Representative Visual Effects Analysis

The objective of a visual effects analysis is to assess how the introduction of offshore development (WTGs, OSSs) would change the relationship between an individual historic property and its maritime views, which could alter several aspects of historical integrity including feeling, setting, and association. It is important to note that not every historic property that has a view of the ocean necessarily relies on that maritime view to define its historical integrity. Each lessee will prepare project-level documentation of historic properties located within the preliminary APE for their lease, and must include a discussion of whether the maritime view is a character-defining feature of each NRHP eligible or listed historic property.

The effects of the project, and of cumulative effects of multiple projects, will need to be individually assessed for each historic property, based on its unique historical significance, relationship with the maritime view, and interpretation of the visual simulations for the nearest KOP. The programmatic consideration of potential effects is based on two WTG heights corresponding to the maximum and minimum heights in the PEIS RPDE: 1,312 feet (400 meters) and 853 feet (260 meters). By evaluating both heights, the analysis discloses the maximum and minimum impacts that may occur as a result of development in the six NY Bight lease areas.

In general, for each historic property whose historical significance is associated with the maritime setting and that has retained the integrity of its maritime view, if the visual simulation from either that location or a comparable KOP location indicate that the WTGs would be visible, a finding of adverse effect is appropriate. For example, the simulated view of maximum visibility from KOP 03 Stafford Beach Entrance (Figure I-4) shows that the proposed development of 1,312-foot-tall (400-meter-tall) WTGs located 43.8 miles (70.5 kilometers) away would result in imperceptible changes to the maritime view. Historic properties with historically significant maritime views located in proximity to this KOP are unlikely to experience a visual adverse effect.

By contrast, the simulated view from KOP 32 Fire Island Lighthouse (Figure I-5) located 24.2 miles (39 kilometers) away and taken from an elevated view shows that the proposed offshore wind development with WTGs as short as 853 feet (260 meters) would be clearly visible and would degrade the integrity of the maritime setting and views. Historic properties that rely on a maritime view from an elevated vantage point as part of their NRHP eligibility and that are located in proximity to this KOP are likely to experience a visual adverse effect.

These examples illustrate multiple variables that are involved in the analysis of visual adverse effects and the importance of conducting a careful analysis of project specifics against the unique qualities that qualify each historic property for listing in the NRHP.

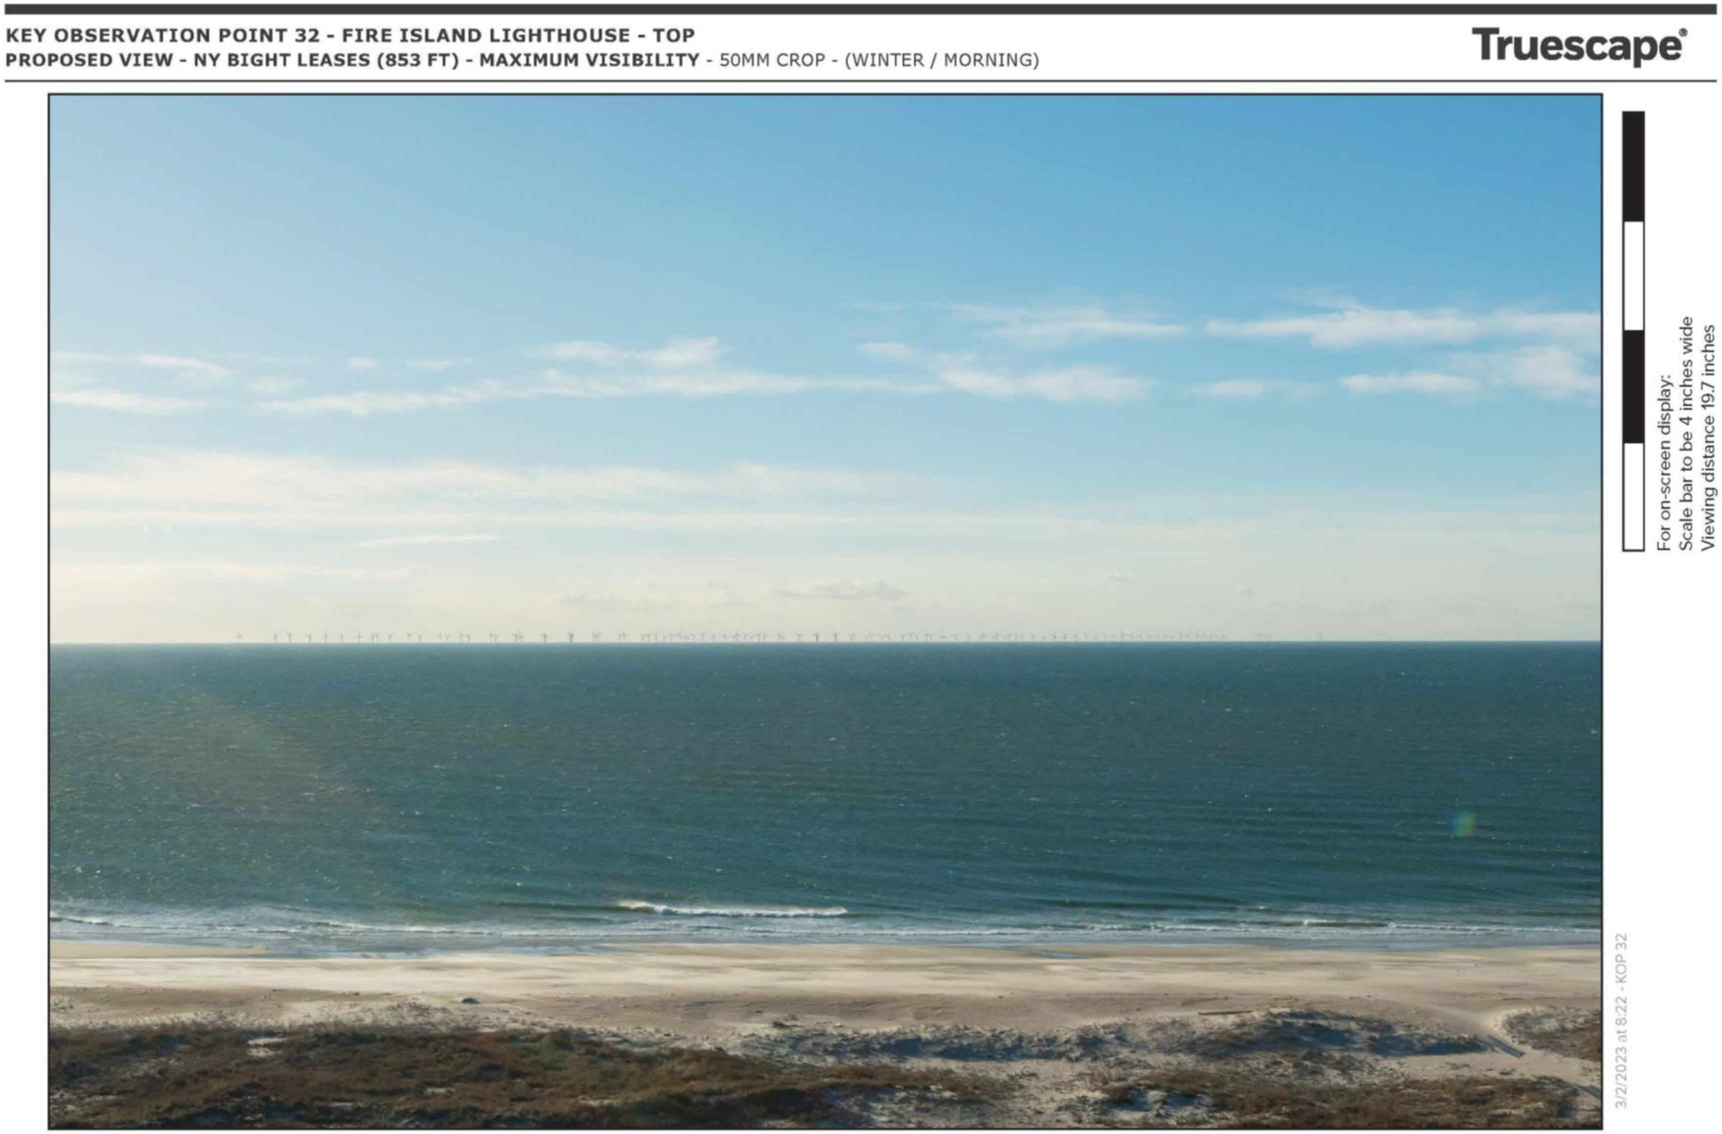

Figure I-5. KOP 32 Fire Island Lighthouse

BOEM does not anticipate that it will be necessary to prepare visual simulations for each of the historic properties located within each project's visual APE. However, it is unlikely that the visual simulations prepared for the PEIS will be sufficient, as project-specific details such as the height and spacing of the WTGs are likely to differ from the RPDE and the 853-foot (260-meter) and 1,312-foot (400-meter) assumptions used as a basis for creating the PEIS simulations. BOEM will review effects recommendations provided in the COP documents to determine sufficiency, and will consult with federally recognized Tribes, New Jersey SHPO, New York SHPO, ACHP, and other consulting parties regarding BOEM's preliminary findings of effect.

I.4 Avoidance, Minimization, Mitigation, and Monitoring Measures

As an outcome of the Section 106 programmatic review of the NY Bight, the Programmatic Agreement for the NY Bight offshore wind activities will include a list of potential resolution measures that can be selected in the event that adverse effects to historic properties are identified during project-level review. One or more potential resolution measures will resolve an adverse effect on a historic property in the event that an adverse effect cannot be avoided. BOEM also encourages lessees to consider relevant RPs as listed in Table 3.6.2-8 of the PEIS during consultation to resolve adverse effects on historic properties.

The types of avoidance measures may include an agreement to completely avoid impacts on known or potential marine cultural resources identified during high-resolution remote sensing surveys. To facilitate complete avoidance of cultural resources may require the relocation of cables or WTGs through micrositing. Avoidance buffer zones will be designated for marine cultural resources (i.e., marine archaeological resources, such as known and potential shipwrecks and associated debris fields; and ASLFs) to ensure that any adverse bottom-disturbing activities do not occur near the cultural resources. In the event the known or potential cultural resource and/or its buffer zones cannot be completely avoided or in the event the cultural resource will be destroyed during construction activities, an archaeological investigation of the resource may be required to further determine appropriate mitigation measures or to completely document the cultural resources prior to the site's disturbance or destruction.

To minimize impacts on marine cultural resources, BOEM may also specify minimization measures that reduce impacts on sites. This may include the use of specific construction techniques, methods, or technologies/equipment that reduce the amount of seafloor impact or adverse effects on a cultural resource.

Implementing a combination of the following measures may avoid visual adverse effects: adjust WTG size, scale, and location to reduce visibility; implement sustainable outdoor lighting prescriptions that reduce impacts on night skies and visibility from coastlines; and place WTGs at distances to where the WTGs are not visible. BOEM will analyze implementation of these measures to determine levels of visual effect during the project specific review stage. If BOEM determines that adverse effects are present, then BOEM will provide recommended specifications that could feasibly meet the threshold of no visual adverse effect.

Potential minimization measures for visual effects include the following: use uniform WTG design, speed, height, and rotor diameter to reduce visual contrast and decrease visual clutter; apply a consistent color to the WTGs prior to commercial operation to reduce visual contrast during daytime hours; use uniform spacing of WTGs to decrease visual clutter; and use an aircraft detection lighting system (ADLS) to limit the time in which WTG lights are on and visible from adversely affected properties.

Based on the type of effect and the historic property adversely affected, possible mitigation measures can include the preparation of documentation in accordance with National Park Service guidance (https://www.nps.gov/subjects/heritagedocumentation/index.htm); historic preservation–related activity that could extend a historic property's existence and use following the Secretary of the Interior's Standards for the Treatment of Historic Properties (https://www.nps.gov/orgs/1739/secretary-standards-treatment-historic-properties.htm); education-related deliverables that enhance the public's understanding of the historic property's original setting and context (e.g., ethnographic research; website highlighting the local community or historic property's history; interpretation of heritage collections; historic preservation planning for that particular historic property or the types of historic properties in a municipality; climate change–related activities that would help extend the use of historic properties that are adversely affected such as a climate change resiliency plan).

BOEM has included measures for avoiding or reducing impacts on historic properties in the PEIS as part of the AMMM measures analyzed in Alternative C (refer to PEIS Section 3.6.2 and Appendix G, *Mitigation and Monitoring,* for a description of these measures). The AMMM measures are consistent with similar measures being developed in the NY Bight Programmatic Agreement for phased identification, post-review discoveries, consideration of potential resolution measures, and preparation of treatment plans when adverse effects cannot be avoided. BOEM has consulted with the Section 106 consulting parties to receive feedback about the anticipated effectiveness of these measures, and to identify any additional measures for inclusion in the Programmatic Agreement and Final PEIS.

Appendix J: Introduction to Sound and Acoustic Assessment

J.1 Sources of Underwater Sound

Ocean sounds originate from a variety of sources. Some come from non-biological sources such as wind and waves, while others come from the movements or vocalizations of marine life (Hildebrand 2009). In addition, humans introduce sound into the marine environment through activities like oil and gas exploration, construction, military sonars, and vessel traffic (Hildebrand 2009). The acoustic environment or “soundscape” of a given ecosystem comprises all such sounds—biological, non-biological, and anthropogenic (Pijanowski et al. 2011). Soundscapes are highly variable across space, time, and water depth, among other factors, due to the properties of sound transmission and the types of sound sources present in each area. A soundscape is sometimes called the “acoustic habitat,” as it is a vital attribute of a given area where an animal may live (i.e., habitat) (Hatch et al. 2016).

J.2 Physics of Underwater Sound

Sounds are created by the vibration of an object within its medium (Figure J-1). This movement generates kinetic energy (KE), which travels as a propagating wave away from the sound source. As this wave moves through the medium, the particles undergo tiny back-and-forth movements (*particle motion*) along the axis of propagation, but the particles themselves do not travel with the wave. Instead, they oscillate in roughly the same location, transferring their energy to surrounding particles. The vibration is transferred to adjacent particles, which are pushed into areas of high pressure (i.e., compression) and low pressure (i.e., rarefaction). Acoustic pressure is a non-directional (i.e., scalar) quantity, whereas particle motion is an inherently directional quantity (i.e., a vector) taking place in the axis of sound transmission. The total energy of the sound wave includes the potential energy (PE) associated with the sound pressure as well as the KE from particle motion.

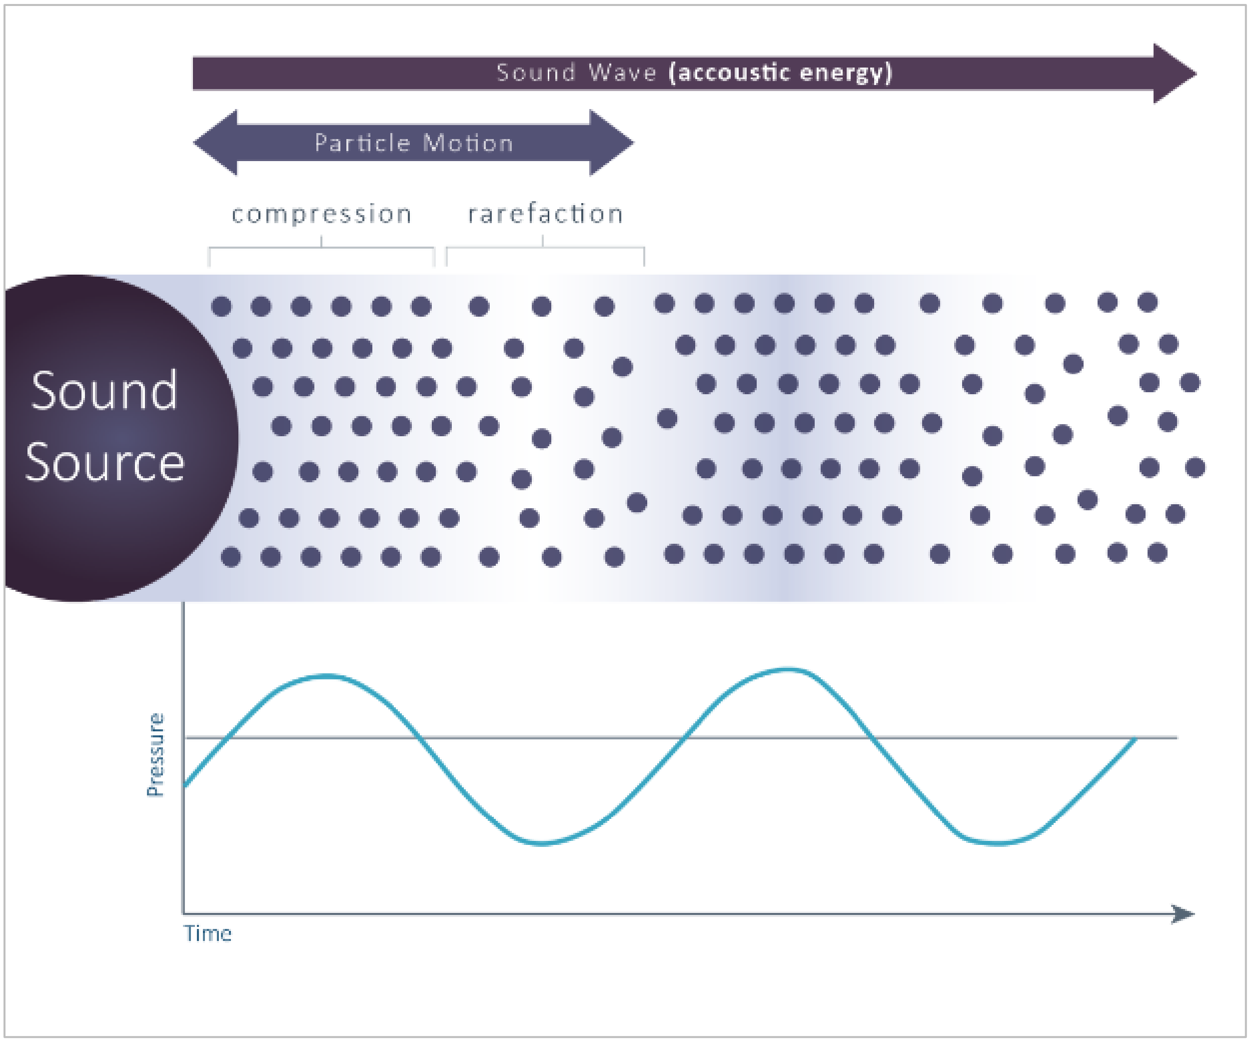

Figure J-1. Basic mechanics of a sound wave

J.2.1 Units of Measurement

Sound can be quantified and characterized based on a number of physical parameters. A complete description of the units can be found in ISO 18405:2017. Some of the major parameters and their International System of Units (SI) units (in parentheses) are as follows.

Acoustic pressure (pascal, Pa): The values used to describe the acoustic (or sound) pressure are peak pressure, peak-to-peak pressure, and root-mean-square (rms) pressure deviation. The peak sound pressure is defined as the maximum absolute sound pressure deviation within a defined time period and is considered an instantaneous value. The peak-to-peak pressure is the range of pressure change from the most negative to the most positive pressure amplitude of a signal (Figure J-2). The rms sound pressure represents a time-averaged pressure and is calculated as the square root of the mean (average) of the time-varying sound pressure over a given period (Figure J-2). The peak level (L_{pk}), peak-to-peak level ($L_{pk\text{-}pk}$), and sound pressure level (L_{rms} or SPL) are computed by multiplying the logarithm of the ratio of the peak or rms pressures to a reference pressure (1 microPascal [µPa] in water) by a factor of 20 and are reported in decibels, see **Sound levels** below.

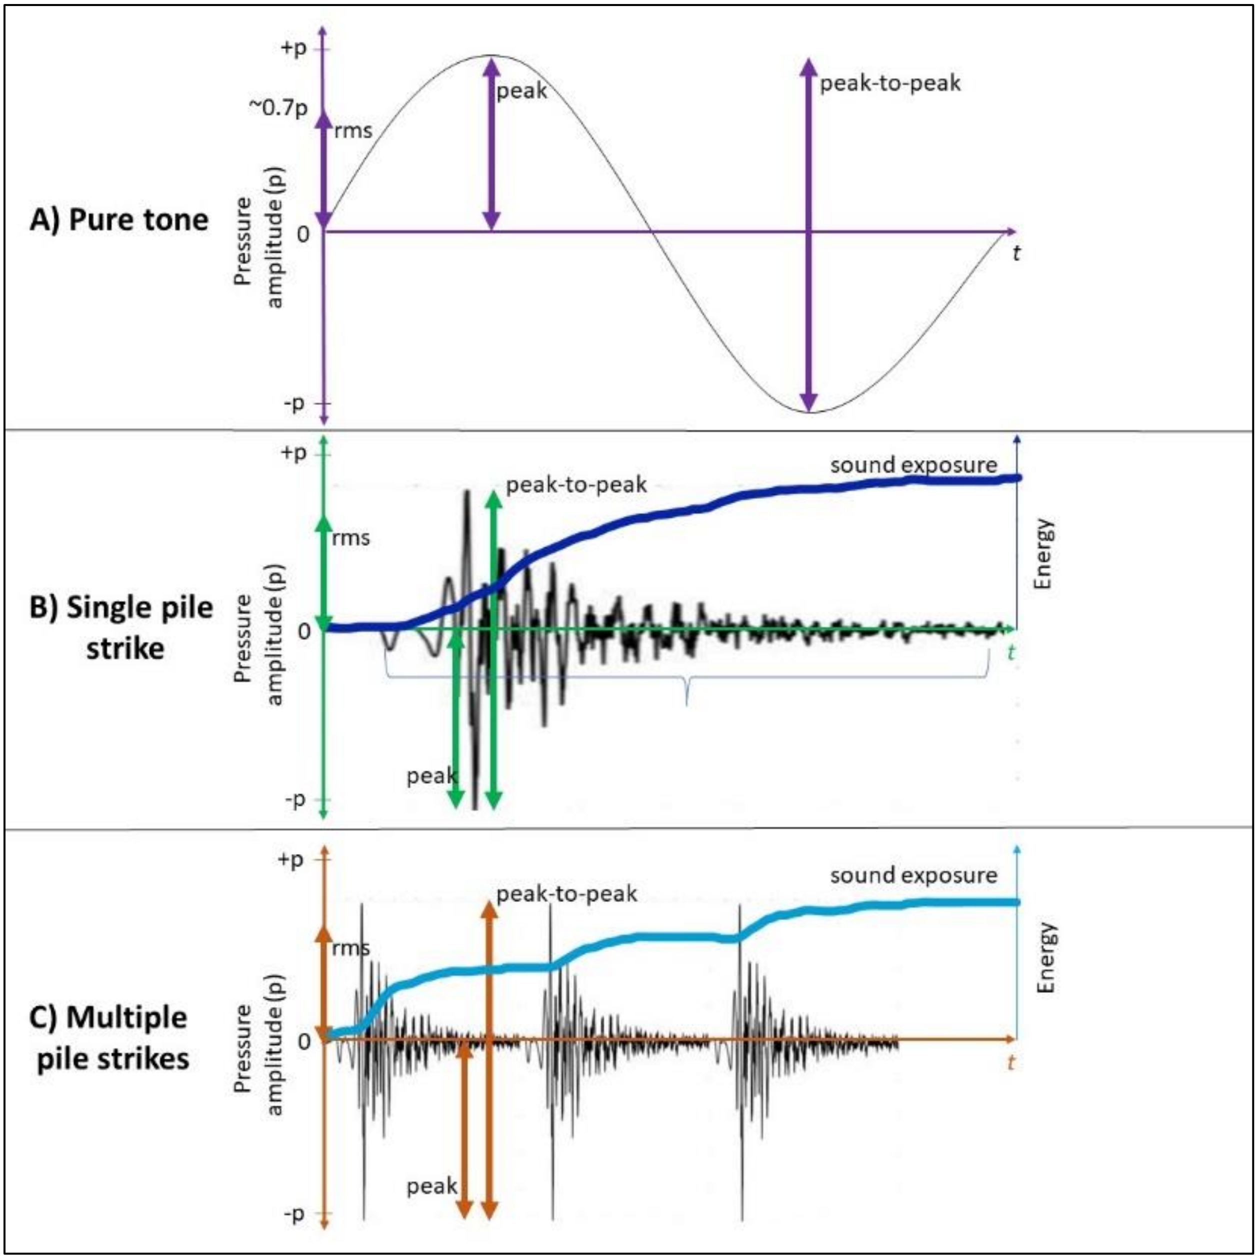

Figure J-2. Sound pressure wave representations of four metrics: root-mean-square (L_{rms}), peak (L_{pk}), peak-to-peak ($L_{pk\text{-}pk}$), and sound exposure level (SEL)

A) A sine wave of a pure tonal signal with equal positive and negative peaks, so peak-to-peak is exactly twice the peak and rms is approximately 0.7 x peak.

B) A single pile-driving strike with one large positive pulse and a large negative pulse that isn't necessarily the same magnitude. In this example, the negative pulse is more extreme so is the reported peak value, and the peak-to-peak is less than double that. Sound exposure is shown as it accumulates across the time window. The final sound exposure would be considered the "single-shot" exposure, and the rms value is that divided by the duration of the pulse.

C) Three consecutive pile-driving strikes with peak and peak-to-peak assessed the same way as in (B). Sound exposure is shown accumulating across all three strikes, and rms is the total sound exposure divided by the entire time window shown. The cumulative sound exposure for this series of signals would be considered the total energy from all three pile-strikes.

Particle velocity (meter per second, m/s): Particle velocity describes the change in position of the oscillating particles about its origin over a unit of time. Similar to sound pressure, particle velocity is dynamic and changes as the particles move back and forth. Therefore, peak particle velocity and root-mean-square particle velocity can be used to describe this physical quantity. One major difference between sound pressure and particle velocity is that the former is a scalar (i.e., without the directional component) and the latter is a vector (i.e., includes both magnitude and direction). Particle acceleration can also be used to describe particle motion, and is defined as the rate of change of velocity of a particle with respect to time. It is measured in units of meters per second squared, or m/s^2.

Sound exposure (pascal-squared second, or Pa^2-s): Sound exposure is proportional to the acoustic energy of a sound. It is the time-integrated squared sound pressure over a stated period or acoustic event (see Figure J-2). Unlike sound pressure, which provides an instantaneous or time-averaged value of acoustic pressure, sound exposure is cumulative over a period of time.

Acoustic intensity (watts per square meter, or W/m^2): Acoustic or sound intensity is the amount of acoustic energy that passes through a unit area normal to the direction of propagation per second. It is the product of the sound pressure and the sound velocity. With an idealized constant source, the pressure and particle velocity will vary in proportion to each other at a given location, but the intensity will remain constant.

Sound levels: There is an extremely wide dynamic range of values when measuring acoustic pressure in pascals, so it is customary to use a logarithmic scale to compress the range of values. Aside from the ease it creates for comparing a wide range of values, animals (including humans) perceive sound on a logarithmic scale. These logarithmic acoustic quantities are known as sound levels and are expressed in decibels (dB), which is the logarithmic ratio of the measurement in question to a fixed reference value. Underwater acoustic sound pressure levels are referenced to a pressure of 1 µPa (equal to 10^{-6} pascals [Pa] or 10^{-11} bar). Note: airborne sound pressure levels have a different reference pressure: 20 µPa.

The metrics previously described (sound pressure, sound exposure, and acoustic intensity) can also be expressed as levels, and are commonly used in this way:

- Root-mean-square sound pressure level (L_{rms} or SPL, units of dB re 1 µPa)
- Peak pressure level (L_{pk}, units of dB re 1 µPa)
- Peak-to-peak pressure level (L_{pk-pk}, units of dB re 1 µPa)
- Sound exposure level (SEL, units of dB re 1 $\mu Pa^2 s$)

Note: A few commonly used time periods are used for SEL, including a 24-hour period (used in the United States for the regulation of noise impacts on marine mammals (SEL_{24}), or the duration of a single event, such as a single pile-driving strike or an air gun pulse, called the single strike SEL (SEL_{ss}). A sound exposure for some other period of time, such as the entire installation of a pile, may be written without a subscript (SEL), but in order to be meaningful, should always denote the duration of the event.

Source level: Another commonly discussed concept is source level. Source level is a representation of the amount of acoustic power radiated from the sound source being described. It describes how loud a particular source is in a way that can inform expected received levels at various ranges. It can be conceptualized as the product of the pressure at a particular location and the range from that location to a spherical (omnidirectional) source in an idealized infinite lossless medium. The source level is the sum of the received level and the propagation loss to that receiver. It is often discussed as what the received level would be 1 meter (m) from the source, but this can lead to confusion as an actual measurement at 1 m is likely to be impossible for large or non-spherical sources. The most common type is an SPL source level in units of dB re 1 µPa-m, though in some circumstances a SEL source level (in dB re 1 $\mu Pa^2 s\text{-}m^2$) may be expressed; peak source level (in units of dB re 1 µPa-m) may also be appropriate for some sources.

J.2.2 Propagation of Sound in the Ocean

Underwater sound can be described through a source-path-receiver model. An acoustic source emits sound energy that radiates outward and travels through the water and the seafloor. The sound level decreases with increasing distance from the acoustic source as the sound travels through the environment. The amount by which the sound levels decrease between the theoretical source level and a receiver is called *propagation loss.* Among other things, the amount of propagation loss that occurs depends on the source-receiver separation, the geometry of the environment the sound is propagating through, the frequency of the sound, the properties of the water column, and the properties of the seafloor and sea surface.

When sound waves travel through the ocean, they may encounter areas with different physical properties that will likely alter the propagation pathway of the sound, compared to a homogenous and boundaryless environment. For example, near the ocean's surface, water temperature is usually higher, resulting in relatively fast sound speeds. As temperature decreases with increasing depth, the sound speed decreases. Sounds bend toward areas with lower speeds (Urick 1983). Ocean sound speeds are often slowest at mid-latitude depths of about 1,000 m, and because of sound's preference for lower speeds, sound waves above and below this "deep sound channel" often bend towards it. Sounds originating in this layer can travel great distances. Sounds can also be trapped in the mixed layer near the ocean's surface (Urick 1983). Latitude, weather, and local circulation patterns influence the depth of the mixed layer, and the propagation of sounds near the surface is highly variable and difficult to predict.

At the boundaries near the sea surface and the sea floor, acoustic energy can be scattered, reflected, or attenuated depending on the properties at the surface (e.g., roughness, presence of wave activity, or bubbles) or seafloor (e.g., bathymetric features, substrate heterogeneity). For example, fine-grain sediments tend to absorb sounds well, while hard bottom substrates reflect much of the acoustic energy back into the water column. The presence of ice on the ocean's surface can also affect sound propagation. For example, the presence of solid ice may dampen sound levels by blocking surface winds. The presence of ice can also increase sound levels when pieces of ice break or scrape together (Urick 1983). The effect will also depend on the thickness and roughness of the ice, among many other factors related to the ambient conditions. As a sound wave moves from a source to a receiver (i.e., an animal), it may travel on multiple pathways that may be direct, reflected, refracted, or a combination of these mechanisms, creating a complex pattern of transmission across range and depth. The patterns may become even more complicated in shallow waters due to repeated interactions with the surface and the bottom, frequency-specific propagation, and more heterogenous seafloor properties. All of these variables contribute to the difficulty in reliably predicting the sound field in a given marine environment at any particular time.

J.2.3 Sound Source Classification

In the current regulatory context, anthropogenic sound sources are divided into four types: impulsive, non-impulsive, continuous, and intermittent, based on their differing potential to affect marine species (National Marine Fisheries Service [NMFS] 2018). Specifically, when it comes to potential damage to marine mammal hearing, sounds are classified as either impulsive or non-impulsive, and when considering the potential to affect behavior or acoustic masking, sounds are classified as either continuous or intermittent.

Impulsive noises are characterized as having (ANSI S1.13-2005):

- Broadband frequency content
- Fast rise-times and rapid decay times
- Short durations (i.e., <1 s)
- High peak sound pressures

Whereas the characteristics of non-impulsive sound sources are less clear but may be:

- Variable in spectral composition (i.e., broadband, narrowband, or tonal)
- Longer rise-time/decay times, and total durations compared to an impulsive sound
- Continuous (e.g., vessel engine radiated noise), or intermittent (e.g., echosounder pulses).

Impulsive sounds associated with offshore wind development include explosions, sparkers, boomers, and impact pile-driving; it is generally accepted that impulsive sources have a greater likelihood of causing hearing damage than non-impulsive sources (note: explosions are further considered for non-auditory injury; see Thresholds for Non-Auditory Injury in Programmatic Environmental Impact Statement [PEIS] Section 3.5.6.1.3). At close distances to impulsive sounds, physiological effects on an animal are likely, including temporary threshold shift and permanent threshold shift, although these effects are also possible after exposure to non-impulsive sounds if the duration of exposure is long enough. This binary, at-the-source classification of sound types, therefore, provides a conservative framework upon which to predict potential adverse hearing impacts on marine mammals.

For behavioral effects of anthropogenic sound on marine mammals, NMFS classifies sound sources as either intermittent or continuous (NMFS 2018). Continuous sounds, such as drilling or vibratory pile-driving, remain “on,” i.e., above ambient noise, for a given period of time, though this is not well-defined. An intermittent sound typically consists of bursts or pulses of sound on a regular on-off pattern, also called the duty-cycle. Examples of intermittent sounds are those from scientific echosounders, sub-bottom profilers, and even pile-driving. It is important to recognize that these delineations are not always practical in application, as a continuous yet moving sound source (such as a vessel passing over a fixed receiver) could be considered intermittent from the perspective of the receiver.

In reality, animals will encounter many signals in their environment that may contain many or all of these sound types, called complex sounds. And even for sounds that are impulsive at the source, as the signal propagates through the water, the degree of impulsiveness decreases (Martin et al. 2020). While there is evidence, at least in terrestrial mammals (Hamernik and Hsueh 1991), that complex sounds can be more damaging than continuous sounds, there is not currently a regulatory category for this type of sound. One current approach for assessing the impulsiveness of a sound that has gained attention is to compute the *kurtosis* of that signal. Kurtosis is a statistical measure that describes the prevalence of extreme values within a distribution of observations, in other words the “spikiness” of the data. By definition, a sound with a kurtosis value of 3 or less has very few extreme values and is generally considered *Gaussian* (i.e., normally distributed) noise. Martin et al. (2020) showed that a kurtosis value greater than 40 represents a distribution of observations with many extreme values and is very spiky. This generally describes an impulsive noise. A distribution of sound level observations from a time series with a kurtosis value somewhere in between these two values would be considered a complex sound.

J.3 Sound Sources Related to Offshore Wind Development

J.3.1 Geophysical and Geotechnical Surveys

Geophysical and geotechnical surveys are conducted to characterize the bathymetry, sediment type, and benthic habitat characteristics of the marine environment. They may also be used to identify archaeological resources or obstacles on the seafloor. These types of surveys occur in the site assessment phase in order to inform the placement of offshore wind foundations but may also occur intermittently during and after turbine construction to identify, guide, and confirm the locations of turbine foundations. The suite of high-resolution geophysical (HRG) sources that may be used in geophysical surveys includes side-scan sonars (SSS), multibeam echosounders (MBES), magnetometers and gradiometers, parametric sub-bottom profilers, compressed high-intensity radiated pulses (CHIRP) sub-bottom profilers, boomers, and sparkers. Seismic airguns are not expected to be used for offshore wind applications. These HRG sources may be towed behind a ship, mounted on a ship’s hull, or deployed from remotely operated vehicles (ROVs) or autonomous underwater vehicles (AUVs).

Many HRG sources are active acoustic sources, meaning they produce sound deliberately in order to obtain information about the environment. With the exception of some MBES and SSS, they produce sounds below 180 kilohertz (kHz) and thus may be audible to marine species. Source levels vary widely depending on source type and operational power level used, from ~145 dB re 1 μPa-m for towed sub-bottom profilers up to 245 dB re 1 μPa-m for some multibeam echosounders (Crocker and Fratantonio 2016). Generally speaking, sources that emit sound in narrow beams directed at the seafloor are less likely to affect marine species because they ensonify a smaller portion of the water column, thus reducing the likelihood that an animal encounters the sound (Ruppel et al. 2022). While sparkers are omnidirectional, most other HRG sources have narrower beamwidths (e.g., MBES: up to 6°, parametric SBPs: 30°, boomers: 30–90°) (Crocker and Fratantonio 2016). Most HRG sources emit short pulses of sound, with periods of silence in between. This means that only several "pings" emitted from a vessel towing an active acoustic source would reach an animal below, even if the animal was stationary (Ruppel et al. 2022). HRG surveys may occur throughout the construction area with the potential for greater effort in some areas.

Geotechnical surveys may use vibracores, jet probes, bottom-grab samplers, deep borings, or other methods to obtain samples of sediments at each potential turbine location and along the cable route. For most of these methods, source levels have not been measured, but it is generally assumed that low-frequency, low-level noise will be introduced as a byproduct of these actions. It is likely that the sound of the vessel will exceed that generated by the geotechnical method itself.

The potential impacts of geophysical and geotechnical surveys during construction activities on marine mammals and sea turtles are analyzed in Chapter 3, *Affected Environment and Environmental Consequences,* of the PEIS.

J.3.2 Unexploded Ordnance Detonations

Unexploded Ordnances (UXOs) may be discovered on the seabed in offshore wind lease areas or along export cable routes. While non-explosive methods may be employed to lift and move these objects, some may need to be detonated. Underwater explosions of this type create a shock wave with a nearly instantaneous rise in pressure, followed by a series of symmetrical bubble pulses. Shock waves are supersonic, so they travel faster than the speed of sound. The explosive sound field is extremely complex, especially in shallow waters. In 2015, von Benda-Beckmann et al. measured received levels of explosions in shallow waters at distances ranging from 100 to 2,000 m from the source, in water depths ranging from 6 to 22 m. The measured SEL from the explosive removal of a 263 kilogram (kg) charge was 216 dB re 1 $\mu Pa^2 s$ at a distance of 100 m and 196 dB re 1 $\mu Pa^2 s$ at 2,000 m. They found that SELs were lower near the surface than near the seafloor or in the middle of the water column, suggesting that if an animal is near the surface, the effects may be less damaging. Most of the acoustic energy for underwater explosions is below 1,000 hertz (Hz). The potential impacts of UXO detonations on marine mammals and sea turtles are analyzed in PEIS Chapter 3.

As an alternative to traditional detonation, a newer method called deflagration allows for the controlled burning of underwater ammunition. Typically, an ROV uses a small, targeted charge to initiate rapid burning of the ordnance; once this process is complete, the remaining debris can be cleared away. Recent work has demonstrated that both L_{pk} and SEL measured from deflagration events may be as much as 20 dB lower than equivalently sized high-order detonations (Robinson et al. 2020).

J.3.3 Construction and Installation

J.3.3.1 Impact and Vibratory Pile-Driving

At present, the installation of turbine foundations is largely done using pile-driving. There are several techniques, including impact and vibratory driving, and many pile designs and sizes, including monopile and jacket foundations. Impact pile-driving employs a hammer to strike the pile head and force the pile into the sediment with a typical hammer strike rate of approximately 30 to 50 strikes/minute (sm). Typically, force is applied over a period of less than 20 sm, but the pile can generate sound for upwards of 0.5 s. Impact pile-driving noise is characterized as impulsive because of its high peak pressure, short duration, and rapid onset time. Underwater sound levels generated during pile-driving depend on many factors including the pile material and size, characteristics of the substrate, penetration of the pile in the seabed, hammer energy and size, and water depth. Currently the design envelope for most offshore wind turbine installations anticipates hammer energy between 2,500 and 4,000 kilojoules (kJs), but generally speaking, with increasing pile diameter, greater hammer energy is used. The propagation of pile-driving sounds depends on factors such as the sound speed in the water column (influenced by temperature, salinity, and depth), the bathymetry, and the composition of sediments in the seabed, and will therefore vary among sites. Due to variation in these features, sounds may not radiate symmetrically outward from a pile.

Thus far, there are only a few measurements from construction of offshore wind turbines in United States waters. Two monopiles (7.8-m diameter) were installed off the coast of Virginia (27-m water depth) in 2020. Dominion Energy (2020) recorded sounds during this process; without noise mitigation, L_{pk} source levels were back-calculated to be 221 dB re 1 µPa-m, but with a double bubble curtain, L_{pk} source levels were around 212 dB re 1 µPa-m. The unmitigated SPL source level was 213 dB re 1 µPa-m; the mitigated SPL source level was 204 dB re 1 µPa-m.

Jacket foundations are also common, if not for the main turbine structures, for other structures associated with the wind farm such as the offshore substations (OSSs). Jacket foundations are installed using pin piles, which are generally significantly smaller than monopiles, on the order of 2 to 5 m in diameter, but more pin piles are needed per foundation. The sound levels generated will vary depending on the pile material, size, substrate, hammer energy, and water depth.

At the Block Island Wind Farm (BIWF), Amaral et al. (2018a) measured sound levels at various distances during pile-driving of jacket foundations (50 -inch pile diameter, 30-m water depth). It should be noted that the piles were installed at an angle (from vertical), which influenced the directionality of the noise produced, so caution is encouraged with interpretation. Nonetheless, the authors reported SPL received levels between 150 and 160 dB re 1 µPa at approximately 750 m from the piles. The maximum single strike SEL measured at 750 m from the jacket foundations at BIWF ranged from 160–168 dB re 1 µPa^{2}s, nearly 10 dB lower than at Coastal Virginia Offshore Wind (CVOW) (OCS-A 0497). Using measurements combined with acoustic modeling, the peak-peak source levels for pile-driving at BIWF were estimated to be between 233 and 245 dB re 1 µPa-m (Amaral et al. 2018b).

The potential impacts of impact pile-driving on marine mammals and sea turtles are analyzed in PEIS Chapter 3.

Vibratory hammers may be used as an alternative to impact pile-driving. The vibratory hammer continuously exerts vertical vibrations into the pile, which causes the sediment surrounding the pile to liquefy, allowing the pile to penetrate the substrate. The vibratory hammer typically oscillates at a frequency of 20 to 40 Hz (Matuschek and Betke 2009) and produces most of its acoustic energy below 2 kHz. Buehler et al. (2015) measured sound levels at 10-m distance from a 72-inch steel pile, and found them to be 185 dB re 1 µPa, but this is significantly smaller than the sizes expected for offshore wind. While no measurements of vibratory piling for large monopiles have been conducted, modeling predictions from South Coast Wind (OCS-A 0521), for example, estimate that SPL received levels could exceed the behavioral harassment threshold for marine mammals (120 dB re 1 µPa) at distances > 40 kilometers (km) for a 16-m-diameter monopile (LGL Ecological Research Associates 2022). Vibratory pile-driving is a non-impulsive sound source and the hammer produces sound continuously, so different criteria are used for assessing behavioral and physiological effects on marine mammals.

The potential impacts of vibratory pile-driving on marine mammals and sea turtles are analyzed in PEIS Chapter 3.

A technique that is quickly gaining use for installation in hard rock substrates is down-the-hole (DTH) pile-driving, which uses a combination of percussive and drilling mechanisms, with a hammer acting directly on the rock to advance a hole into the rock, and also advance the pile into that hole (Guan et al. 2022). Noise characteristics for DTH pile-driving include both impulsive and non-impulsive components. The impulsive component of DTH pile-driving is the result of a percussive hammer striking the bedrock, while the non-impulsive component is from drilling and air-lifting of cuttings and debris from the pile. While only limited studies have been conducted on DTH pile-driving noise, its characteristics strongly resemble those of impact pile-driving, but with a higher hammer striking rate (approximately 10 to 15 Hz). The dominant frequencies from DTH pile-driving are below 2 kHz, similar to conventional impact pile-driving. Due to the high rate of hammer striking, along with the sounds of drilling and debris clearing out, sound levels in between the pulses are much higher than conventional impact pile-driving (Guan et al. 2022).

Various noise abatement technologies, such as bubble curtains, arrays of enclosed air resonators, or segmented nets of rubber or foam, may be employed to reduce noise from impact pile-driving. Measurements from European wind farms have shown that a single noise abatement system can reduce broadband sound levels by 10–15 dB, while using two systems together can reduce sound levels as much as 20 dB (Bellmann et al. 2020). Based on RODEO measurements from CVOW (OCS-A 0497), double Big Bubble Curtains (dBBC) are shown to be most effective for frequencies above 200 Hz, and greater noise reduction was seen in measurements taken in the middle of the water column compared to those near the seabed. Approximate sound level reduction is 3 to 5 dB below 200 Hz, and 8 to 20 dB above 200 Hz, depending on the characteristics of the bubble curtain (Amaral et al. 2020).

J.3.4 Drilling

Drilling associated with offshore wind activities may involve geotechnical surveys, HDD at the export cable landfalls, and, if necessary, removing large boulders at the site of foundation installation. Sounds from drilling are generally considered to be non-impulsive and are nearly continuous in nature, though they may be highly variable depending on the type of substrate that is encountered (Richardson et al. 1995). There could be tonal sound generated by the drill bit, mechanical noise transferred through the ship's hull, and noise from the vessels and dynamic positioning systems. HDD uses equipment that is generally located on shore, and the sound that propagates into the water is expected to be negligible. Geotechnical drilling SPLs (in the 30–2000 Hz band) have been measured up to 145 dB re 1 µPa-m from a jack-up platform (Erbe and McPherson 2017), and up to 162 dB re 1 µPa-m from an anchored drilling vessel (Huang et al. 2023). If drilling is required for foundation installation, a large drill bit at the bottom of the pile would slowly rotate to break up the material inside the pile, and the liquefied material would be pumped out. While measurements of these operations specifically for offshore wind installation have not been conducted, the closest proxy is from oil and gas-related operations, where a 6-m-diameter drill bit was used for the excavation of mudline cellars (Austin et al. 2018). Austin et al. (2018) measured received levels at 1,000 m from the operations and back-calculated the SPL source levels to be between 191 and 193 dB re 1 µPa-m.

J.3.4.1 Vessels

During construction, vessels and aircraft may be used to transport crew and equipment. See Section J.3.5, *Operations and Maintenance,* for further detail about sounds related to those activities. Large vessels will also be used during the construction phase to conduct pile-driving, and may use Dynamic Positioning (DP) systems. DP is the process by which a vessel holds station over a specific seafloor location for some time period using input from gyrocompasses, motion sensors, Global Positioning Systems (GPS), active acoustic positioning systems, and wind sensors to determine relative movement and environmental forces at work. Generally speaking, most acoustic energy is <1,000 Hz, often below 50 Hz, with tones related to engine and propeller size and type. The sound can also vary directionally, and this directionality is much more pronounced at higher frequencies. Because this is a dynamic operation, the sound levels produced will vary based on the specific operation, DP system used (e.g., jet or propeller rotation, versus a rudder or steering mechanism), and factors such as the blade rate and cavitation, in some cases. Representative sound field measurements from the use of DP are difficult to obtain because the sound transmitted is often highly directional and context specific. The direction of sound propagation may change as different DP needs requiring different configurations are applied.

Many studies have found that the measured sound levels of DP alone are, counterintuitively, higher than those of DP combined with the intended activities such as drilling (Jiménez-Arranz et al. 2020; Kyhn et al. 2011; Nedwell and Edwards 2004) and coring (Warner and McCrodan 2011). Nedwell and Edwards (2004) reported that DP thrusters of the semi-submersible drill rig *Jack Bates* produced periodic noise (corresponding to the rate of the thruster blades) with most energy between 3 and 30 Hz. The received SPL measured at 100 m from the vessel was 188 dB re 1 µPa. Warner (2011) found that most DP-related sounds from the self-propelled drill ship, R/V *Fugro Synergy* were in the 110 to 140 Hz range, with an estimated source level of 169 dB re 1 µPa-m. Sounds in this frequency range varied by 12 dB during DP, while the broadband levels, which also included diesel generators and other equipment sounds, varied by only 5 dB over the same time period. All of the above sources report high variability in levels with time. This is due in part to the intermittent usage and relatively slow rotation rates of thrusters used in DP. It is also difficult to provide a realistic range of source levels from the data thus far because most reports do not identify the direction from which sound was measured relative to the vessel, and DP thrusters are highly directional systems.

The active acoustic positioning systems used in DP can be additional sources of high frequency sound. These systems usually consist of a transducer mounted through the vessel's hull and one or more transponders affixed to the seabed. The Kongsberg High Precision Acoustic Positioning (HiPAP) system produces pings in the 10 to 32 kHz frequency range. The hull-mounted transducers have source levels of 188 to 206 dB re 1 µPa-m depending on adjustable power settings (Kongsberg Maritime AS 2013). The fixed transponders have maximum source levels of 186 to 206 dB re 1 µPa-m depending on model and beam width settings from 15 to 90° (Jiminez-Arranz et al. 2020). These systems have high source levels, but beyond 2 km, they are generally quieter than other sound components from DP vessels for various reasons including: their pulses are produced in narrowly directed beams, each individual pulse is very short, and their high frequency content leads to faster attenuation. The potential impacts of vessel noise on marine mammals and sea turtles are analyzed in PEIS Chapter 3.

J.3.4.2 Site Preparation

Prior to offshore wind project foundation and export cable installation, boulder clearance and pre-lay grapnel runs may be conducted to clear the area of obstructions. This may involve the use of a displacement plow, a subsea grab or, in shallower waters, a backhoe dredger. Sandwave clearance may also be conducted in advance of export cable installation to remove mobile sediments using a suction hopper dredger, controlled flow excavation, or plow. At landfall locations, export cables may be installed using HDD, which may require mechanical dredging of the HDD exit pit.

Sounds from site preparation activities are considered non-impulsive and are nearly continuous in nature. Dredging produces distinct sounds during each specific phase of operation: excavation, transport, and placement of dredged material (Central Dredging Association 2011; Jiminez-Arranz et al. 2020). Engines, pumps, and support vessels used throughout all phases may introduce low-level, continuous noise into the marine environment. The sounds produced during excavation vary depending on the sediment type—the denser and more consolidated the sediment is, the more force the dredger needs to impart, and the higher sound levels that are produced (Robinson et al. 2011a). Sounds from mechanical dredges occur in intervals as the dredge lowers a bucket, digs, and raises the bucket with a winch. During the sediment transport phase, many factors—including the load capacity, draft, and speed of the vessel—influence the sound levels that are produced (Reine et al. 2014). SPL source levels during backhoe dredge operations range from 163 to 179 dB re 1 µPa-m (Nedwell et al. 2008; Reine et al. 2012). As a whole, dredging activities generally produce low-frequency sounds, with most energy below 1,000 Hz and frequency peaks typically occurring between 150 and 300 Hz (McQueen et al. 2018). Additional detail and measurements of dredging sounds can be found in Jiminez-Arranz et al. (2020), McQueen et al. (2018), and Robinson et al. (2011a).

The potential impacts of site preparation activities on marine mammals and sea turtles are analyzed in PEIS Chapter 3.

J.3.4.3 Trenching and Cable-Laying

The installation of cables can be done by towing a tool behind the installation vessel to simultaneously open the seabed and lay the cable, or by laying the cable and following with a tool to embed the cable. Possible installation methods for these options include jetting, vertical injection, control flow excavation, trenching, and plowing. Burial depth of the cables is typically 1–2 m. Cable installation vessels may utilize dynamic positioning to lay the cables, which can introduce considerable levels of noise into the marine environment (see Section J.3.4.1, *Vessels*).

Nedwell and Edwards (2004) measured sounds from a 130-m-long trenching vessel and found that sound levels were similar to those produced during pipeline-laying in the same area, with the exception of a 20 kHz tonal sound, which they attributed to the vessel's DP thrusters. Nedwell et al. (2003) recorded underwater sound 160 m away from trenching activity (water depth 7–11 m) and back-calculated the SPL source level of trenching to be 178 dB re 1 µPa-m (assuming propagation loss of 22logR). They described the sound as generally spanning a wide range of frequencies, variable over time, and accompanied by some tonal machinery noise and transient noises associated with rock breakage.

Johansson and Andersson (2012) recorded underwater noise levels during both pipelaying and trenching. The mean SPL measured (at 1,500 m from the pipeline) during pipelay operations was 130.5 dB re 1 µPa, nearly 20 dB higher than average background noise at the same location. There were eight support vessels in the vicinity during pipelaying operations. During trenching, with only one vessel in the vicinity, received levels were 126 dB re 1 µPa, and the authors back-calculated the SPL source level to be 183.5 dB re 1 µPa, similar to that of commercial vessels in the region.

J.3.5 Operations and Maintenance

J.3.5.1 Aircraft

Staffed aircraft consist of propeller and jet engines, fixed-wing craft, as well as helicopters. Unmanned systems also exist. For jet engine aircraft, the engine is the primary source of sound. For propeller driven aircraft and helicopters, the propellers and rotors also produce noise. Aircraft generally produce low-frequency sound below 500 Hz (Richardson et al. 1995). While aircraft noise can be substantial in air, penetration of aircraft noise into the water is limited because much of the noise is reflected off the water's surface (Richardson et al. 1995). The noise that penetrates into the water column does this via a critical incident angle or cone. With an idealized flat sea surface, the maximum critical incident angle is

~13 degrees (Urick 1983); beyond this, sound is reflected off the surface. When the sea surface is not flat, there may be some additional penetration into the water column in areas outside of this 13-degree cone. Nonetheless, the extent of noise from passing aircraft is more localized in water than it is in air.

Jiménez-Arranz et al. (2020) reviewed Richardson et al.'s (1995) sound measurements recorded below passing aircraft of various models. These SPL measurements included 124 dB re 1 µPa (dominant frequencies between 56 and 80 Hz) from a maritime patrol aircraft with an altitude of 76 m, 109 dB re 1 µPa (dominant frequency content below 22 Hz) from a utility helicopter with an altitude of 152 m, and 107 dB re 1 µPa (tonal, 82 Hz) from a turbo propeller with an altitude of 457 m. Recent published levels associated with unmanned aircraft (Christiansen et al. 2016; Erbe et al. 2017) indicate source levels around or below 100 dB re 1 µPa-m. The potential impacts of aircraft noise on marine mammals and sea turtles are analyzed in PEIS Chapter 3.

J.3.5.2 Vessels in Transit

During operations, small vessels may be used to transport crew and supplies. Noise from vessel transit is considered to be continuous, with a combination of broadband and tonal sounds (Richardson et al. 1995; Ross 1976). Transiting vessels generate continuous sound from their engines, propeller cavitation, onboard machinery, and hydrodynamics of water flows (Ross 1976). The actual radiated sound depends on several factors, including the type of machinery on the ship, the material conditions of the hull, how recently the hull has been cleaned, interactions with the sea surface, and shielding from the hull, which reduces sound levels in front of the ship.

In general, vessel noise increases with ship size, power, speed, propeller blade size, number of blades, and rotations per minute. Source levels for large container ships can range from 177 to 188 dB re 1 µPa-m (McKenna et al. 2013) with most energy below 1 kHz. This low-frequency noise can travel extremely far distances and has been shown to be detectable at 125 km from the source (Aulanier et al. 2017). Smaller vessels typically produce higher-frequency sound concentrated in the 1 to 5 kHz range. Kipple and Gabriele (2003) measured underwater sound from vessels ranging from 14 to 65 feet long (25 to 420 horsepower) and back-calculated source levels to be 157 to 181 dB re 1 µPa-m. Similar levels are reported by Jiménez-Arranz et al. (2020), who provide a review of measurements for support and crew vessels, tugs, rigid hull inflatable boats, icebreakers, cargo ships, oil tankers, and more.

During transit to and from shore bases, survey vessels typically travel at speeds that optimize efficiency, except in areas where transit speed is restricted. The vessel strike speed restrictions that are in place along the Atlantic Outer Continental Shelf (OCS) are expected to offer a secondary benefit of underwater noise reduction. For example, recordings from a speed reduction program in the Port of Vancouver (210- to 250-m water depths) showed that reducing speeds to 11 knots reduced vessel source levels by 5.9 to 11.5 dB, depending on the vessel type (MacGillivray et al. 2019). Furthermore, Findlay et al. (2023) documented how small reductions in cargo vessel speed in the Port of Vancouver can substantially reduce noise impacts on marine mammals. Vessel noise is also expected to be lower during geophysical and geotechnical surveys, as they typically travel around 5 knots when towing instruments. The potential impacts of vessel noise on marine mammals and sea turtles are analyzed in PEIS Chapter 3.

J.3.5.3 Turbine Operations

Once wind farms are operational, low-level sounds are generated by each wind turbine generator (WTG), but sound levels are much lower than during construction. This type of sound is considered to be continuous, omnidirectional radially from the pile, and non-impulsive. Most of the energy associated with operations is below 120 Hz. Sound levels from wind turbine operations are likely to increase somewhat with increasing generator size and power ratings, as well as with wind speeds. Recordings from BIWF indicated that there was a correlation between underwater sound levels and increasing wind speed, but this was not clearly influenced by turbine machinery; rather it may have been explained by the natural effects that wind and sea state have on underwater sound levels (Elliott et al. 2019; Urick 1983).

A recent compilation (Tougaard et al. 2020) of operational noise from several wind farms, with turbines up to 6.15 megawatts (MW) in size, showed that operational noise generally attenuates rapidly with distance from the turbines, falling to near ambient sound levels within ~1 km from the source; the combined noise levels from multiple turbines is lower or comparable to that generated by a small cargo ship. Tougaard et al. (2020) developed a formula predicting a 13.6 dB increase for every 10-fold increase in WTG power rating. This means that operational noise could be expected to increase by 13.6 dB when increasing in size from a 0.5 MW turbine to a 5 MW one, or from 1 MW to 10 MW. The least squares fit of that dataset would predict that the SPL measured 100 m from a hypothetical 15 MW turbine in operation in 10 m/s (19 kilotons [kt] or 22 miles per hour [mph]) wind would be 125 dB re 1 µPa. However, all 46 data points in Tougaard et al. (2020), with the exception of the two from BIWF, were from WTGs operated with gear boxes of various designs rather than the newer use of direct-drive motor technology, which is expected to generate less underwater noise (Stöber and Thomsen 2021; Betke and Bellmann 2023). An additional compilation by Stöber and Thomsen (2021) made predictions for source levels of 10 MW turbines based on a linear extrapolation of maximum received levels from WTGs with ratings up to 6.15 MW. The linear fit is likely inappropriate, and the resulting predictions may be exaggerated. A recent study by Holme et al. (2023) indicated that the Tougaard et al. (2020) equations may overestimate underwater sound levels generated by operating WTGs, particularly at short distances from the foundation, suggesting that SPLs may drop below the behavioral threshold at shorter distances than predicted. Holme et al. (2023) examined underwater noise measurements recorded within and outside operating offshore wind farms consisting of 6.3 MW (with direct-drive motors) and 8.3 MW (with planetary gear box) turbines, respectively. The results imply that there is no significant relationship between the broadband underwater noise levels and turbine activity for any of the examined wind farms in the monitored distances (up to 70 m) (Holme et al. 2023). An additional study by Betke and Bellmann (2023) examined turbines up to 8 MW and did not find an upward trend in underwater noise with rated power (a proxy for turbine size), whereas both Tougaard et al. (2020) and Stöber and Thomsen (2021) included piles up to 6 MW and found a statistically significant relationship. Bellmann et al. (2023) suggest that the modeling approaches by Tougaard et al. (2020) and Stöber and Thomsen

(2021) for operational noise are primarily based on a few types of smaller turbine types (often with gear boxes), so that predictions of the noise conditions of existing offshore windfarms of the latest generation (e.g., Holme et al. 2023) lead to overestimations of the measured operational noise of turbines of up to 8 dB.

Underwater noise has been characterized in two locations in Scotland using a five-turbine array of 9.5-MW semi-submersible foundations with gear boxes in Kincardine, and 6-MW floating spar buoys with direct drive motors located in "Hywind Scotland" (Risch et al. 2023). Source levels for turbine operational noise (25 Hz–20 kHz) increased with wind speed at both recording locations. At a wind speed of 15 m/s, operational noise levels were found to be about 3 dB higher at Kincardine (148.8 dB re 1 µPa) as compared to Hywind Scotland (145.4 dB re 1 µPa), which might be a function of the different power ratings, gear box vs. direct drive technology, or the difference in mooring structure of the two turbines (i.e., semi-submersible vs. spar-buoy). Assuming 15 m/s wind speed, predicted noise fields for unweighted SPLs were above median ambient noise levels in the North Sea for maximum distances of 3.5–4.0 km from the centroid of the Kincardine five-turbine array, and 3.0–3.7 km for the five-turbine array at Hywind Scotland (Risch et al. 2023).

Tougaard et al. (2020) point out that received level differences among different pile types could be confounded by differences in water depth and turbine size. In any case, additional data is needed to fully understand the effects of size, foundation type properties (e.g., structural rigidity and strength), and drive type on the amount of sound produced during turbine operation. The potential impacts of operational turbine noise on marine mammals and sea turtles are analyzed in PEIS Chapter 3.

J.3.6 Decommissioning

The methods that may be used for decommissioning are not well understood at this time. It is possible that explosives may be used (see Section J.3.2, *Unexploded Ordnance Detonations*). However, given the general trend of reducing the use of underwater explosives that has been observed in the oil and gas industry, it is likely that offshore wind structures will instead be removed by cutting. While it is difficult to extrapolate directly, some insights can be gleaned from a recent study that measured received sound levels during the mechanical cutting of well conductor casings on oil and gas platforms in California. The cutters operated at 60 to 72 revolutions per minute (RPM), and the cutting time varied widely between cuts (on the order of minutes to hours). At distances of 106 to 117 m from the cutting, received SPLs were 120 to 130 dB re 1 µPa, with most acoustic energy falling between 20 and 2000 Hz (Fowler et al. 2022). This type of sound is considered to be non-impulsive and intermittent (i.e., continuous while cuts are actually being made, with quieter periods between cuts). Additional noise from vessels (see Section J.3.4.1, *Vessels*) and other machinery may also be introduced throughout the decommissioning process.

J.3.7 Non-pile-driving Foundations and Noise Abatement

BOEM encourages the consideration of low-noise foundation types first, and if use of low-noise foundation types is not possible, BOEM encourages the application of one or more noise-abatement systems during impact pile-driving and other low noise best practices. There are three ways to reduce noise during foundation installation of offshore wind farms. The various methods for reducing underwater noise are described briefly here based on the European experience as summarized in Bellmann et al. 2020.

1. One way to reduce noise impacts is to *avoid pile-driving all together* by selecting a different foundation type. There are several foundation types that are under consideration in the New York (NY) Bight, including monopiles, jacket piles, suction mono-bucket, suction bucket jacket, tri-suction pile caisson, and gravity-based structures. See Section J.3.3, *Construction and Installation*, on the various foundation types. The reader is referred to ICF 2021 for a description of the various site conditions required for each foundation type (ICF 2021, Table 10) and the effects by foundation type (ICF 2021, Table 11). While there are no known acoustic measurements of installation, both suction buckets and gravity-based foundations are expected to produce less noise than the installation of monopiles:

    - Suction buckets are installed by pumping water into the suction bucket as it penetrates the seafloor, and then pumping the water out to force it further into the seafloor. This pumping action produces noise but is not likely to exceed noise limits set to protect marine life.

    - Gravity foundations are composed of heavy material that weighs them down to the seafloor. The installation of these may require site preparation work, such as dredging, to ensure the seafloor beneath the foundation is flat so it will not move. For an understanding of dredging noise and its potential effects, the reader is referred to PEIS Section 2.1.2.1.1 on site preparation.

    - In all installation approaches there is also noise associated with the vessels required for conducting these activities, which may include dynamic positioning for certain activities. Several vessels and different types may be needed, including a barge for towing the gravity base, or a dedicated installation vessel for the impact pile-driving hammer.

2. If an alternative foundation type cannot be used, technology can be applied such that pile-driving noise can be *reduced as it is produced*. These technologies include:

    - Vibratory pile-driving. A vibratory hammer provides a method for partially driving piles at lower sound levels than impact pile-driving. Injury is less likely from vibratory hammering as the impulsive nature of impact hammer strikes produces a greater likelihood of injury. Vibratory hammers will be insufficient to completely drive foundation piles and some impact hammering will be required.

    - The IQIP BLUE hammer. IQIP EQ-Piling uses a longer impact force from a contained water mass to transfer energy to the pile and estimates a 20-dB reduction in sound levels relative to equivalent impact hammer strikes (IQIP 2024a).

    - The IQIP Pulse Unit. The IQIP Pulse Unit uses an impact hammer with a volume of water between the hammer and pile to reduce the amplitude of the pile-driving strike. Noise reduction up to 6–10 dB (SEL) is estimated from this device (IQIP 2024b).

- The Menck Noise Reduction Unit. The Menck Noise Reduction Unit augments the force applied by the hammer to the pile head with noise level reductions of 9–12 dB (Acteon 2024).

3. Finally, a common way to reduce noise impacts from pile-driving is by reducing the amount of noise that gets *transmitted through the water*. Technologies that can be used to dampen the sound in the water column include:

    - The Hydro-Sound Damper uses sound absorbing elements attached to a net deployed circumferentially around the pile to reduce the sound levels by 10 to 12 dB (SEL) (Bellmann et al. 2020).

    - The AdBm Noise Mitigation System similarly utilizes volumes of air contained in plastic Helmholtz resonators deployed around the pile with published reductions of 8 dB (SEL) (Wochner 2019).

    - The HydroNas is a deployable fabric sleeve that inflates to surround the pile with a layer of air. The manufacturers advertise a reduction of 25 dB (SEL) (HydroNas 2023).

    - The IQIP Noise Mitigation Screen uses an impedance mismatch (like the aforementioned systems) to reduce the propagated noise levels between 13 and 17 dB (Bellmann et al. 2020).

    - The Grout Annulus Bubble Curtain is a bubble curtain that is generated between a pile sleeve, like the IQIP Noise Mitigation Screen, and the pile with noise reductions of 2–7 dB (Bellmann et al. 2020).

    - Big Bubble Curtains are generated around pile-driving locations from hoses that emit pressurized air in configurations of up to three concentric hoses to introduce an impedance mismatch to reduce the propagated sound levels by up to 20 dB (Bellmann et al. 2020). The Big Bubble Curtains can be used in most if not all projects and have been used in all U.S. offshore wind projects to date.

Many of these near-field resonator systems are tunable to reduce certain frequencies of sound, with lower frequencies being more difficult to target. The options outlined here may not be comprehensive; other systems may exist or be under development that are similar in principle to the approaches outlined here. In addition to the Bellmann et al. (2020) and ICF (2021) reports, a recent workshop was conducted that identified the advantages and disadvantages of the various noise-mitigation systems available today (Green et al. 2023). As an example, none of the systems to date reduce noise associated with pile-driving in the substrate. This will be an area for future innovation. Many of these options are not mutually exclusive; however, thus far, only one near-field system (i.e., Hydro-Sound Damper, AdBm Noise Mitigation System, HydroNas, IQIP Noise Mitigation Screen, and Grout Annulus Bubble Curtain) has been used at a time. Capacity, logistics, imagination, and motivation are the only limiting factor to the combined use of, for example, the IQIP Noise Mitigation Screen and Hydro-Sound Damper. These near-field systems can also be used in combination with bubble curtains for further noise reduction. The

IQIP Blue hammer, IQIP Pulse Unit, and Menck Noise Reduction Unit cannot be used together and therefore only one would be usable for a project.

J.4 Acoustic Assessment

Chapter 3 of the PEIS provides a high-level qualitative assessment of impacts of sound on marine life based on the information available related to the NY Bight alternatives and the mitigations contained within these alternatives. This section supplements the Chapter 3 findings by providing more detail on potential acoustic impacts and uses a relativistic risk assessment framework to discuss tradeoffs to marine mammals associated with the alternatives and select avoidance, minimization, mitigation, and monitoring (AMMM) measures under consideration.

Over the last decade, Bureau of Ocean Energy Management (BOEM) has funded the development of a risk assessment framework that can be used to assess the relative risk to marine mammals of acoustic disturbances associated with different development scenarios. This relativistic risk assessment framework is the foundation for the analyses in this section. The framework was most recently used for oil and gas activity in the Gulf of Mexico (Southall et al. 2021a) and for potential offshore wind development in New England waters (Southall et al. 2021b). The framework identifies risk to marine mammals based on the exposure, or the spatio-temporal-spectral overlap of noise-generating activities with the marine mammals, and considers numerous contextual variables that define the vulnerability of a species to acoustic disturbances. The framework has been effective in comparing the *relative risk* of different development scenarios and the *relative risk* of each scenario between species.

Due to the programmatic nature of this PEIS and the long lead times in the regulatory process, many details needed to fully complete the risk assessment framework for the NY Bight projects are still unknown. Therefore, this assessment draws on thematical findings from a completed hypothetical case study (Southall et al. 2021b) that analyzes the development of two wind farms off New England and serves as the best available proxy for the NY Bight analysis at this time.

Using this case study, the analysis to follow focuses on tradeoffs associated with NY Bight alternatives and associated mitigation measures being considered in the PEIS to lessen the extent of acoustic disturbance on marine mammals associated with pile-driving and, to a lesser extent, vessel noise. This analysis is done through assessing the potential changes in exposure risk of marine mammals to noise with different AMMM measures. The vulnerability of a species is also an important factor in assessing the overall risk of offshore wind development on marine life, but this factor cannot be directly controlled for in this analysis and therefore is not analyzed further.

The use of this framework does not replace sound field modeling and other standard numeric modeling exercises at the project level, which are needed for specific purposes such as informing take estimates and mitigation zones.

J.4.1 NY Bight Alternatives

The PEIS analyzes three alternatives:

- **Alternative A (No Action Alternative):** No development would occur on any of the six NY Bight lease areas. There would be no acoustic impacts associated with the development of the six NY Bight lease areas under Alternative A. This alternative is not discussed further in this assessment. However, note that Section 3.5.6.3 of the PEIS still discusses noise impacts on marine mammals associated with the No Action Alternative that exist regardless of the presence of any NY Bight project development.
- **Alternative B – No Identification of AMMM Measures at the Programmatic Stage:** Alternative B considers the potential impacts of future offshore wind development for the NY Bight area without the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts.
- **Alternative C (Proposed Action) – Identification of AMMM Measures at the Programmatic Stage:** Alternative C consists of two sub-alternatives:
    - **Sub-alternative C1 (Preferred Alternative): Previously Applied AMMM Measures.** Sub-alternative C1 analyzes the AMMM measures that BOEM has required as conditions of approval for previous activities proposed by lessees in Construction and Operations Plans submitted for the Atlantic OCS or through related consultations. The analysis for Sub-alternative C1 is presented as the change in impacts from those discussed under Alternative B.
    - **Sub-alternative C2: Previously Applied and Not Previously Applied AMMM Measures.** Sub-alternative C2 analyzes the AMMM measures under Sub-alternative C1 plus the AMMM measures that have not been previously applied. Therefore, under this alternative, the analysis is presented as the change in impacts from those discussed under Sub-alternative C1. In the case where there are no AMMM measures applied under Sub-alternative C1, the analysis for Sub-alternative C2 is described as the change in impacts from those discussed under Alternative B.

Alternatives B and C analyze impacts at both a single project level and across all six proposed projects. The acoustic impacts associated with the development of the six NY Bight lease areas under Alternative B and C will be discussed, to the extent possible, in sections later in this document.

J.4.2 Overview of Relativistic Risk Assessment Framework

A team of experts recently developed the newest iteration of their acoustic risk assessment framework for marine mammals (Wood et al. 2012); the most recent framework considers aggregate acoustic exposures from the construction and operation of multiple wind farms (Southall et al. 2021b, 2023). The framework was intentionally designed to be tunable to allow users to assess specific scenarios based on the temporal, spatial, and spectral overlap of noise-generating activities and marine species. Their case study for offshore wind development in New England (Southall et al. 2021b, 2023) provides a useful analog to the potential development in the NY Bight and is used here to consider the relative risks posed by the alternatives and associated mitigations considered in the PEIS.

This framework is based on an exposure index (representing the probability of exposure of a species to an activity) and the vulnerability index (representing the inherent vulnerability of a given species to anthropogenic disturbance) (Figure J-3). The resultant risk value is calculated for each species and each month of a specified scenario, providing high-level insights about the spatio-temporal-spectral interactions and risk trade-offs associated with different development scenarios.

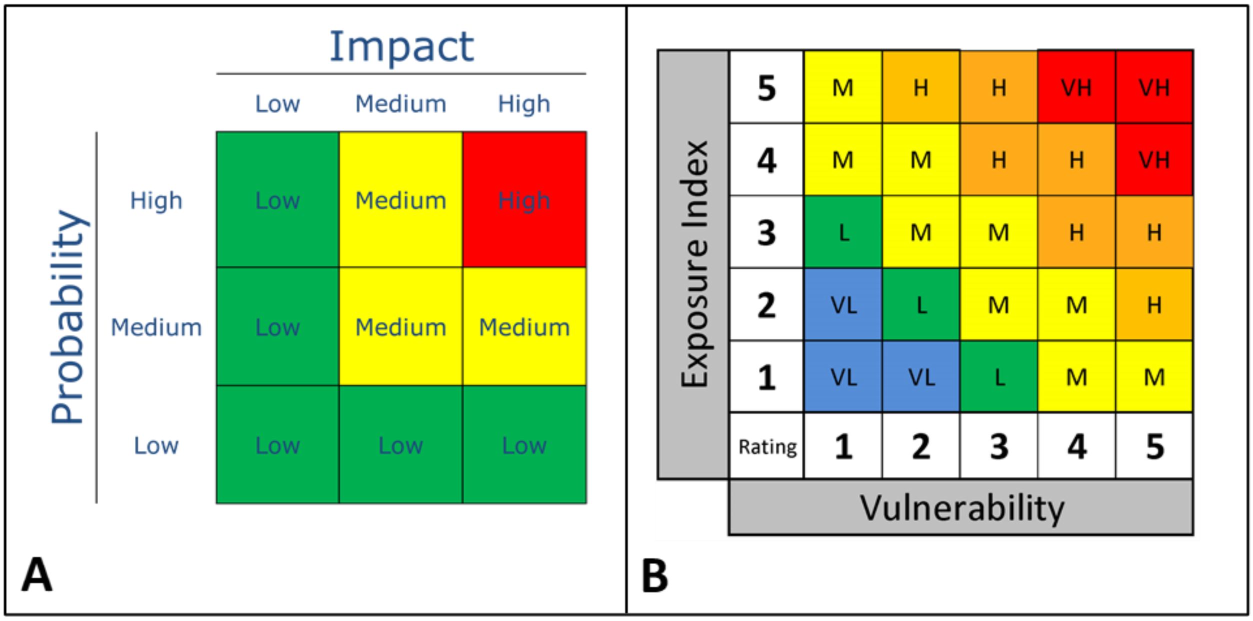

Figure J-3. Generic risk assessment matrix (left) and risk assessment matrix from Southall et al. (2021b, 2023) (right)

A. Example risk assessment matrix.
B. Risk assessment matrix from Southall et al. (2021b, 2023). The exposure index reflects the spatial, spectral, and temporal overlap of the noise event and the species at hand, and the vulnerability axis reflects species-specific contextual factors.

J.4.2.1 Exposure Index

The exposure index aims to quantify the “severity” of a given noise event by considering the spatio-temporal extent of a noise-generating activity and its overlap with the spatio-temporal presence of a species. The spatial component of the exposure index is based on the area within which a behavioral response is likely to occur (but can be tuned to reflect any type of response, ranging from auditory detection to auditory injury). The temporal component considers the proportion of a population present at a given time in the spatial area that is exposed, in comparison to the overall population present over a larger geographic zone or region at the same time. The spectral content of the noise source is considered to focus on the portion of the noise that actually overlaps with the hearing range of each marine mammal hearing group (Southall et al. 2007). The exposure index is calculated separately for each wind farm, month, and species combination. An aggregate exposure index also can be calculated for an individual species for a defined project development scenario by summing the monthly exposure index values across a year. This value is normalized by the number of animals in the geographical zone (or local population as may be referred to here) to obtain a percentage, such that the aggregate exposure index percentage represents the portion of the population that would be exposed.

J.4.2.2 Vulnerability Index

The vulnerability index aims to quantify the baseline vulnerability of a given population. Therefore, it is species-specific, and includes the following factors: (1) the spatio-temporal presence of the species in the activity area, (2) the species' ecological use of the activity area and environmental risk factors of the specific area considered, (3) the hearing capabilities of the species, and (4) the general trends in the size and health of the population. As these factors may change over time, these are evaluated at a monthly resolution to capture the temporal variation in vulnerability associated with these factors.

J.4.2.3 Final Risk Score

The final integrated risk score for a species is assessed by intersecting the exposure index and vulnerability index on a five-by-five matrix (which is skewed toward the exposure index), depicting the relative risk with a color bar reflecting highest, higher, moderate, lower, and lowest risk. Because the parameters of both the exposure index and vulnerability index are specified for each development scenario of interest, a separate risk matrix will be obtained for each specific geographic area, species, and activities considered and should only be used to assess *relative* risk within the scenarios analyzed. This analysis should not be considered a measure of absolute risk.

J.4.2.4 What the Framework Is and Is Not

Due to the broad temporal and spatial resolution of this framework in its current form, it cannot be used to evaluate specific interactions between individual animals and individual noise-generating events. The framework provides a broader view of the effect of larger-scale or longer-term projects on a given population and gives insight about *relative* risk of the multiple scenarios under consideration and the *relative* risk posed to each species. In its current form, the framework makes no attempt to differentiate between the types of effects (i.e., injury, behavior, or masking) because acoustic disturbance is considered more generally as an exposure term; however, the exposure term could later be tuned to consider specific types of effects. This framework also does not include noise propagation modeling, individual animal movement, or energetic model assumptions; these factors will be considered at the project level.

J.4.3 Overview of Hypothetical New England Wind Farm Case Study

The acoustic risk assessment framework was most recently used to explore the trade-offs associated with hypothetical wind farm development in southern New England waters (Southall et al. 2021b), herein referred to as the "case study." This case study provides a useful analog for offshore wind farm development in the NY Bight due to similarities in geographic location and trends in species occupancy in the area. The case study is being introduced and described here to provide insight about the possible spatio-temporal-spectral factors that should be considered with respect to the alternatives being considered for offshore wind in the NY Bight.

The hypothetical wind farms considered in the case study include two wind farms in southern New England, located ~35 km apart (Figure J-4). This distance was chosen so that the wind farms would be near to each other, but any acoustic impact radii associated with the two wind farms would be expected to be non-overlapping. Although the parameters of these wind farms are realistic, they were not intended to represent a specific project.

- Wind farm 1 (WF1): 25 by 25 km^2 area (150,000 acres), 180 monopiles
- Wind farm 2 (WF2): 10 by 20 km^2 area, (50,000 acres), 60 monopiles

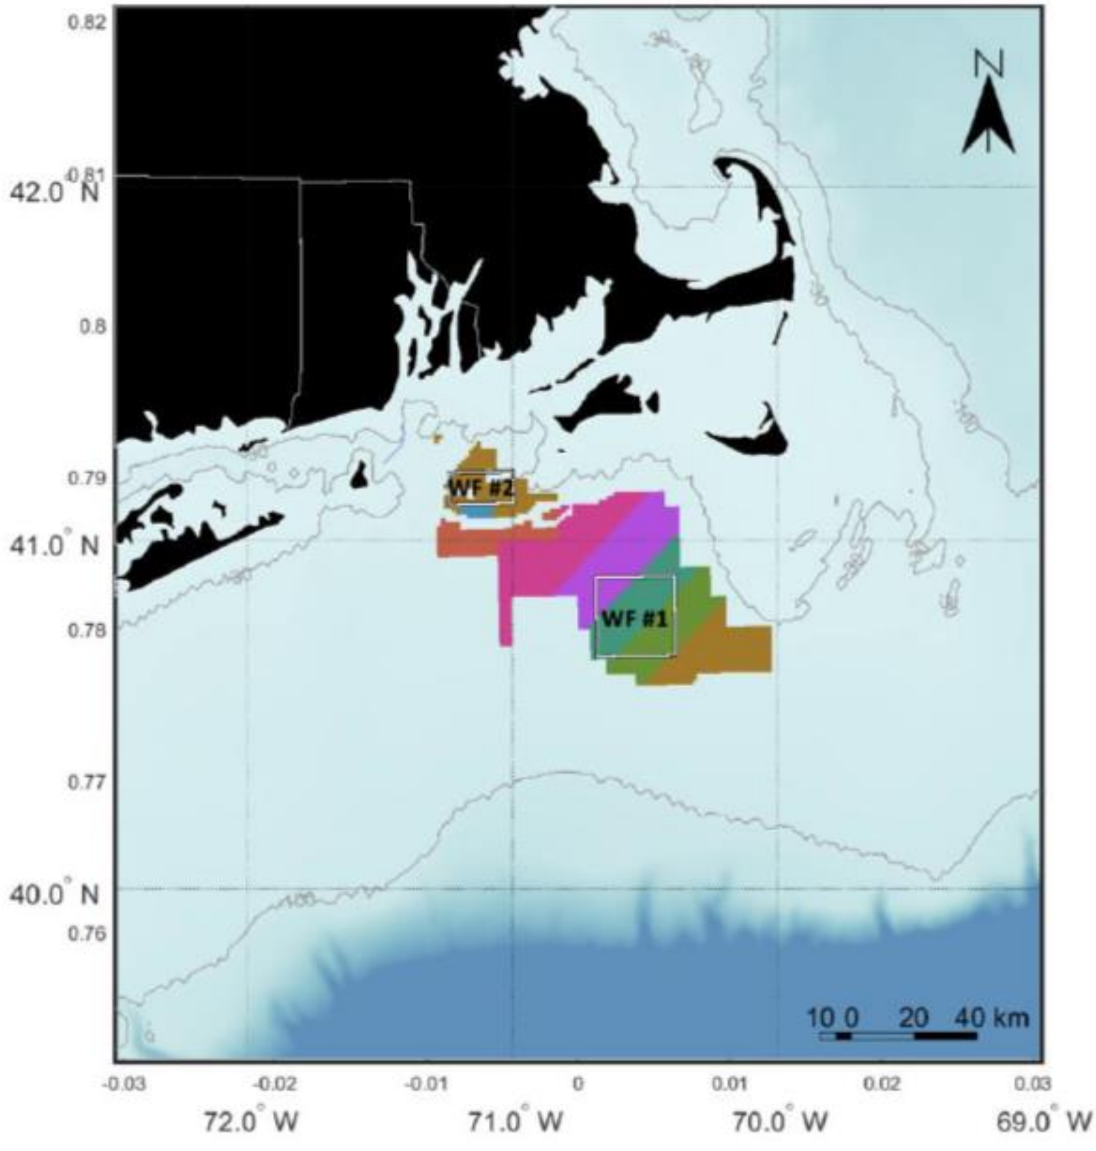

Figure J-4. Hypothetical New England wind farm locations off Massachusetts

Offshore leased areas shown in colored polygons, with two white rectangles outlining the locations of the two wind farms assessed.
Source: Southall et al. (2021b).

The team assessed the relative risk to these focal species for the following reasons:

- **North Atlantic Right Whale (NARW)**: Endangered Species Act (ESA) and Marine Mammal Protection Act (MMPA) listed and in the low-frequency hearing group.
- **Humpback whale (humpback)**: not ESA listed but a relatively common whale in the low-frequency hearing group.
- **Common dolphin (dolphin)**: an odontocete in the mid-frequency hearing group; very common in the geographic analysis area.
- **Harbor porpoise (porpoise)**: a less common odontocete but particularly sensitive to noise; represents the high-frequency hearing group.
- **Gray seal (seal)**: represents the phocid pinniped group; increasingly common in the geographic analysis area, although less so in the open ocean of the continental shelf.

For simplicity, these species are referred throughout by the short-hand term listed next to the species name in parentheses in the previous list.

The spatio-temporal presence of these species in the geographical locations of the hypothetical wind farms was obtained from the Roberts et al. (2020)[1] marine mammal density data set. A monthly risk matrix was calculated for each of the five species for a 3-year time span. See Southall et al. (2021b) for complete details of the New England case study and risk assessment process, including components not further discussed here (e.g., masking).

J.4.3.1 Exposure Index Calculations

Year 1

The objective of the Year 1 assessment was to explore the trade-offs associated with construction timing, the duration of pile-driving each day, and the use of mitigation (noise abatement). The following details provide the parameters and assumptions used in calculating the exposure index for all five species in Year 1.

J.4.3.2 Scenarios

- 120 foundations were installed on WF1; pile-driving was the main contributor of noise.
- Option of either unmitigated or mitigated pile-driving (using noise abatement).

[1] Although gray seal is the species specified here, the Roberts et al. (2020) data is not specific to that species of seal. This specific species was considered for obtaining information relevant to other components of the vulnerability score.

J.4.3.3 Spatial Component

- The authors used measurements made during the installation of a 7.8-m monopile with (mitigated) and without (unmitigated) a double bubble curtain during the construction of the Coastal Virginia Offshore Wind Farm (OCS-A 0497) (Ørsted 2020) to calculate the radial distance around each pile at which the received levels to behavioral impact would be exceeded.
    - Harbor porpoise
        - Behavioral disturbance would occur at a received level of 120 dB re 1 µPa; this sound level was exceeded at distances up to:
            - 20 km for the unmitigated scenario.
            - 15 km for the mitigated scenario.
    - Other four marine mammals considered
        - Behavioral disturbance would occur at received levels of 160 dB re 1 µPa; this sound level was exceeded at distances up to:
            - 10 km under the unmitigated scenario.
            - 5 km for the mitigated scenario.

J.4.3.4 Temporal Component

- Three potential construction start dates explored: March 1, May 1, or July 1.
- Option of either one pile driven per day or two piles driven per day:
    - Total duration of pile-driving: 4 months for one pile/day.
    - Total duration of pile-driving: 2 months for two piles/day.

J.4.3.5 Spectral Component

The spectral index is calculated by multiplying the species abundance number by a coefficient that indicates the spectral overlap of the noise and the functional hearing (Southall et al. 2007) of the marine mammal species under consideration. This calculation deemphasizes the exposure (essentially decreasing the number of animals exposed) if the spectral energy in a signal is outside the frequencies that the species hears best. To do this weighting a spectrum of the source signal was needed. For pile-driving, a spectrum from HDR (2020) was used from the pile-driving installation of a 7.8-m monopile measured within 3 km of the monopile.

J.4.3.6 Year 2

The objective in the Year 2 assessment was to explore the relative interactions and cumulative effects associated with installation of more than one wind farm, as well as the trade-offs associated with the timing of installation.

J.4.3.7 Scenarios

- 60 foundations were installed on WF1, and 60 installed on WF2; pile-driving was the main contributor of noise.
- Only considered unmitigated pile-driving and installation of one pile/day.

J.4.3.8 Spatial Component

- Same as Year 1 unmitigated scenarios (20 km for porpoises and 10 km for all other species considered).

J.4.3.9 Spectral Component

- Same as Year 1.

J.4.3.10 Temporal Component

- The analysis explored three installation timing scenarios that affected the temporal component of the exposure index. The scenarios all assumed installation of only one pile/day but varied in the degree of overlap between the two nearby windfarms:
  - *Sequential installation*: WF1 construction July/August, WF2 construction September/October (total of 4 months to install 120 foundations).
  - *Partial overlap*: WF1 construction July and August; WF2 construction August and September (total of 3 months to install 120 foundations).
  - *Total overlap*: WF1 and WF2 construction August and September (total of 2 months to install 120 foundations).

J.4.3.11 Year 3

The objective in the Year 3 assessment was to explore the relative risk associated with the operational phase of offshore wind development. The following assumptions were made for Year 3.

J.4.3.12 Scenario

- Both WF1 and WF2 were fully operational.

- Operational noise from each turbine and vessel noise (defined by vessel type, number of trips, speed, and trip duration) were the main contributors of noise.

J.4.3.13 Spatial Component

- *Operational noise:* The radial distance to the behavioral thresholds for an operating turbine was considered to be 100 m for all species (Tougaard et al. 2020). It is worth noting that the spatial extent of exposure for turbine operations was also a function of the number of operating turbines and thus was twice as large for WF1 than WF2.
- *Vessel noise:* The exposure associated with vessel noise was calculated as a function of vessel speed in the wind farm area (31 km/hour), average length of a vessel trip (4 hours), and the radius of behavioral response, which was assumed to be 0.5 km from a vessel (Holt et al. 2021). These estimates were based on a crew transfer vessel, which is expected to be the most prevalent in the area during operations and maintenance times.

J.4.3.14 Temporal Component

- *Operational noise* was considered to be uniform throughout the year.
- *Vessels* were assumed to make 30.8 trips each month to WF1 and 10.3 trips each month to WF2, with a uniform distribution across the year.

J.4.3.15 Spectral Component

- *Operational turbine:* The authors used a spectrum measured by Ingemansson Technology AB (2003) during wind speeds of 14 m/s, measured within 83 m of the turbine.
- *Vessel noise:* The authors used a spectrum measured by Hermannsen (2014) at 100 m from a vessel transiting at 30 km/hour.

For complete details of the New England case study and risk assessment process, including components not further discussed here (e.g., masking and vulnerability index), see the full report by Southall et al. (2021b). Note: the utility of the risk assessment framework for offshore wind has been summarized in Southall et al. 2023.

J.4.4 Overview of Findings from the New England Case Study

Overall, the New England case study identified several key results and mitigative principles.

J.4.4.1 Results

- The lowest exposure risk associated with pile-driving coincided with times of lowest animal abundance.

- Mitigated pile-driving reduced the overall exposure indices in comparison to unmitigated pile-driving.
- Of the scenarios explored, there was no common strategy for minimizing exposure risk to each species with the installation scenarios explored (i.e., *sequential installation, partial overlap, total overlap*).
- The exposure risk associated with the construction of multiple wind farms is not additive and depends heavily on the spatio-temporal overlap of the animals and the activity. Higher relative exposure risk is expected when activity overlaps most in time and space with the location of the animals.
- The relative noise exposure risk of offshore wind development on marine mammals is higher for low frequency cetacean (LFC) than mid frequency cetacean and high frequency cetacean due to the low frequency nature of the noises most-commonly generated during offshore wind development (i.e., pile-driving and vessel noise).

J.4.4.2 Mitigative Principles

- A reduction in noise at the source could reduce the spatial extent of potential exposure to all species.
- Focusing activity (pile-driving or vessel activity) to times when animals are not present or are in very low abundance in the area could decrease the risk to marine mammals. As no time exists when no animals are present, the specific trade-offs to certain species would have to be weighed against conservation needs and priorities.
- Increased monitoring could lead to increased opportunities to further mitigate effects on marine mammals.
- For some species, some temporal overlap in construction windows could reduce aggregate impacts, while for other species, it may increase it. During project planning, careful consideration should be given to the spatio-temporal distribution of species of interest with the overlap of the spatio-temporal aspects of development. With an adaptable development timeline, risks to marine mammal species of interest could be reduced.

The details of these results follow. The discussion focuses on results from the one pile/day unmitigated scenario as these parameters were used consistently across Years 1 and 2 in the New England case study. Examples from other scenarios will be used to highlight key points and will be specifically called out. Each species had a different vulnerability index, which is a critical component of the overall risk assessment but is not discussed further here as the primary purpose is to consider the ways that different development scenarios affect the exposure index.

J.4.4.3 Year 1

The difference in the results across the three start time scenarios for a given species was primarily driven by the animal abundance, with the lowest risk occurring when pile-driving coincided with the times of lowest animal abundance. Animal abundance can change drastically over a year for some species. For the NARW and harbor porpoise, the lowest aggregate exposure resulted from a July start, while for humpbacks and seals, it was a May start, and for common dolphins, a March start (Table J-1).

Table J-1. Aggregate exposure index percentages over the course of the year for each construction start time scenario by species for the one pile/day, unmitigated scenarios

Species	March Start	May Start	July Start
NARW	3.1915	2.8316	2.3398
Humpback	1.1440	0.8271	0.8649
Dolphin	0.1747	0.2540	0.4438
Porpoise	1.3046	1.0413	0.8522
Seal	0.7096	0.1470	0.1671

In comparing the one pile/day versus the two piles/day unmitigated scenarios, when pile-driving started in July, the two piles/day scenario posed a lower exposure risk to all species except porpoise (Table J-2). In contrast, when pile-driving started in either March or May, the exposure index was higher for every species (except dolphins) in the two piles/day scenario (Table J-2). *This suggests that pile-driving noise exposure, and consequently the overall risk to the five marine mammal species considered here, can be substantially lowered by concentrating pile-driving efforts when the fewest animals are present in the area.*

Table J-2. Aggregate exposure index percentages for each construction start time scenario by species for the two piles/day, unmitigated scenarios

Species	March Start	May Start	July Start
NARW	4.1906	3.6195	2.0325
Humpback	1.3793	0.9281	0.7206
Dolphin	0.1357	0.2141	0.2965
Porpoise	1.4826	1.1235	0.9537
Seal	0.9322	0.2398	0.1074

However, given that not all species are affected equally due to their different distributions throughout the year, the specific trade-offs to certain species would have to be weighed against conservation needs and priorities, and care is needed when considering the timing of these events. It is important to emphasize that for some species, the risk would increase for two piles/day versus one pile/day if the timing does not coincide with periods of lowest abundance. For example, a March start date with the two piles/day scenario led to higher exposure indices than one pile/day for certain species (NARW, porpoise, seal). That is because these species have higher densities in the geographical area during March than in July. Thus, when animals are more abundant, the exposure index is higher in a two piles/day scenario.

Intuitively, the exposure index was always lower in the mitigated scenarios versus the unmitigated scenarios because the spatial component of the exposure index was smaller. For a reduction in the behavioral impact range from 10 km down to 5 km, the decrease in the resulting exposure index was four-fold, since the area exposed is reduced as a function of r^2. This consistently led to a change in the integrated risk assessment score by at least one step (e.g., lower to lowest) when comparing the mitigated and unmitigated case of the same scenario, although in many cases the risk decreased by multiple steps (e.g., from highest to moderate). *This finding suggests that anything that can be done to reduce the spatial extent of noise exposure will reduce overall risk from noise across species.*

This overall synthesis demonstrates the utility of this framework for identifying the risks and tradeoffs to multiple species associated with different potential development scenarios. It also demonstrates that, with an adaptable development timeline, risks to marine mammals can be reduced.

J.4.4.4 Year 2

The Year 2 analysis considered only the unmitigated one pile/day conditions for the construction of 60 piles at each of two wind farms in either a sequential, partial overlap, or total overlap construction scenario. Based on the Year 1 findings, only the late summer/fall seasons (July–October) were considered for pile-driving as this was the period with the lowest overall risk to the species analyzed.

When comparing the three installation timing scenarios, the lowest aggregate exposure for three of the five species (NARW, dolphin, seal) occurred with the partial overlap scenario, while the sequential construction led to the lowest aggregate exposure for humpback whales and total overlap led to the lowest aggregate exposure for porpoise (Table J-3). *These results suggest that for the scenarios explored in the New England case study, a condensed construction timeline may help to reduce the exposure for marine mammals, but consideration needs to be given with respect to species of interest, their density, and distribution at each of the construction sites for the times when construction is anticipated, as no common reduction was seen across all species by condensing construction. Similar trade-offs would likely exist if additional species were also considered, and in the case of the NY Bight.*

Table J-3. Aggregate exposure index percentages for each construction timeline approach by species

Species	Sequential Construction	Partial Overlap	Total Overlap
NARW	1.8415	1.6665	1.6775
Humpback	2.1419	2.2610	2.3287
Dolphin	0.2592	0.2341	0.3358
Porpoise	0.7455	0.5649	0.5090
Seal	0.3579	0.3327	0.3715

To understand the difference in aggregate exposure of two wind farms near each other being constructed instead of one wind farm, this analysis compared the Year 1, unmitigated, one pile/day, July start scenario with Year 2 sequential installation results. In both scenarios, a total of 120 piles were driven over 4 months. There was no common trend across all species; for some species (i.e., humpbacks and seals), the construction of one wind farm led to lower aggregate exposure, whereas for other species (i.e., NARW, dolphins, and porpoise), the construction of two wind farms led to lower aggregate exposure (Table J-4). The differences across species were driven by small-scale differences in animal densities at WF1 versus WF2, underscoring *the need for careful consideration of the spatio-temporal distribution of species of interest with the overlap of the spatio-temporal aspects of development during planning.*

Table J-4. Aggregate exposure index percentages for Year 1 and Year 2 by species

Species	Year 1	Year 2
NARW	2.3398	1.8415
Humpback	0.8649	2.1419
Dolphin	0.4438	0.2592
Porpoise	0.8522	0.7455
Seal	0.1671	0.3579

Notes: **Year 1**: unmitigated, one pile/day, July start scenario of Year 1 construction of WF1; **Year 2**: unmitigated, one pile/day, Year 2 sequential construction of WF1 and WF2.

These results demonstrate that there are species-specific differences in the magnitude and direction of change in aggregate exposure associated with the development of one versus multiple wind farms, linked to the specific location of the wind farms and construction timing, which interact differently with the unique spatio-temporal distribution of the species. In terms of the NY Bight, this is surely to be the case. For example, one of the NY Bight lease areas is located closer to shore than the other five. As a result, there are clear differences in the density magnitude of certain species there than at the other lease areas, although there are similar seasonal presence trends at all of the NY Bight lease areas. In particular, dolphins are present in lower numbers and seals are present in higher numbers at the more coastal lease area than in comparison to the other lease areas. Because many of the species considered are migratory animals there are also differences that can be expected due to the latitudinal range of a species. Therefore, it seems reasonable to expect different exposure risk across the lease areas. The cumulative exposure associated with the build-out of two or more wind farms simultaneously will depend on the construction timing and wind farm locations. For the NY Bight, if multiple wind farms will be constructed simultaneously (e.g., sequentially, or some degree of overlap), this relative risk framework can be used to identify a construction scenario that reduces aggregate exposure for priority species.

J.4.4.5 Year 3

Both vessel noise (primarily from wind farm maintenance) and turbine operational noise were considered in Year 3. Because the exposure index results were higher for vessel operations than operating turbines, the exposure index results reported were only a function of vessel operations. The authors of the analysis emphasized caution in using the results of the Year 3 analysis as there were no large-scale wind farms in operation in the United States from which to build the necessary assumptions for this part of the case study. Therefore, the case study was informed by the best available, albeit cursory, knowledge of likely vessel use during the operational phase of a wind farm; the assumption is that vessels would primarily be used to transfer crew for maintenance of the turbines.

The case study assumed that vessel use would be uniform across the year, leading to a higher aggregate exposure for several species (NARW, humpback, and gray seals) for the Year 3 scenario compared to the Year 1, July start scenario. The case study demonstrated this result despite generally *lower* exposure risk associated with vessel noise in any given month. Because the aggregate exposure index is calculated by summing across all months with the assumption that there was vessel activity in every month, the aggregate exposure index percentage associated with vessel noise was *higher* than for pile-driving, assumed to occur for only 2 to 4 months of a given year. It is worth noting that exposure risk in this analysis does not specifically mean risk of auditory injury, but rather the potential risk to some noise effect. A uniform distribution was assumed for vessel activity across the year, leading to high aggregate exposure. Similar to restricting pile-driving activity to certain times of the year, *there may be decreased relative risk to marine mammals if maintenance of wind farms could coincide with periods of low marine mammal abundance.* For example, for humpback whales and the NARW, concentrating maintenance activity to the summer and early fall could lead to the lowest relative risk for these species. *Because the seasonality of marine mammals is similar in the NY Bight and New England waters, this potential mitigation could also hold true for the NY Bight.*

Although this analysis focused on vessel noise, the results also are relevant to vessel strike risk. Minimizing the exposure to vessel activity in general could mitigate both vessel noise and vessel strike risk.

J.4.4.6 Final Remarks on New England Case Study

A final observation of this analysis is that there are still limitations in our understanding of where and when animals are present on the OCS, in particular the lack of data on species vulnerability. This gap was particularly the case for seals and harbor porpoise in the area where the scenarios were being considered. *This deficiency may be overcome with increased long-term, continuous, and comprehensive monitoring efforts. Long-term Passive Acoustic Monitoring (PAM) to collect additional information about the presence and distribution of marine mammals is an AMMM measure considered for the NY Bight.*

While considering the results for the New England case study, it is important to keep a few things in mind. These results are provided here to understand how noise exposure might be reduced with different approaches and the trade-offs for each approach. This understanding is the emphasis of this analysis, not the absolute numbers presented from the case study. By staying within the limiting parameters (similar seasonality and overall abundance between the NY Bight and southern New England, for example), valid conclusions can still be extrapolated from even relative results for specific and well-chosen questions.

The results and mitigative principles from the New England case study informed the identification of noise-related AMMM measures and guided the discussion of the acoustic impacts of the alternatives.

J.4.5 Comparison of Southern New England and NY Bight

The United States East Coast can be divided into different ecoregions based on species distributions, ecological processes, geology, oceanography, biology, environmental threats, among other factors

(Greene et al. 2010). The NY Bight/southern New England area forms one ecoregion. Relative to the rest of the Atlantic OCS, the NY Bight and southern New England are fairly similar and likely to serve similar ecosystem services. Therefore, the presence, abundance, and ecological use of the NY Bight lease areas by marine mammals is not expected to differ greatly from the area of the hypothetical wind farms in the New England case study, and the case study can be used to make inferences about potential wind farm development in NY Bight.

To confirm that this assumption was reasonable, BOEM used the marine mammal data that informed the case study (Roberts et al. 2020) to compare the densities of marine mammals in the New England case study area to the lease areas under consideration in the PEIS. Since the completion of the case study, however, the marine mammal density data has been updated (Roberts et al. 2016, 2023), so BOEM also compared marine mammal densities between the two areas using the more recent models (Figure J-5). In most cases, the marine mammal densities at the New England locations were similar to or greater than the densities for the NY Bight, which means the results of the case study are somewhat conservative and can potentially serve as an upper bound for potential risk in similar scenarios. However, for common dolphins, the density in the NY Bight was generally higher than New England, so the potential risk identified in the case study is likely an underestimate for this species.

- Harbor porpoise and seal density in the New England case study was generally similar both in magnitude and seasonality to the NY Bight lease areas, though for WF2 the largest peak in seal density was in winter as opposed to in the spring for WF1 and the NY Bight lease areas. The overall trend remained the same: seals were present in high numbers in both locations in the winter and spring and not present, or present in low numbers, in the summer and early fall.

- For the NARW, the seasonality patterns were similar; there were few animals present in summer and fall, but more animals were present in winter and spring. However, the number of animals in the New England wind farms were much higher, suggesting the results from the New England case study should serve as an upper bound for the NARW in the NY Bight.

- For humpback whales, there was a 1-month difference in the timing of the peak humpback density in the fall. This peak occurred in September for New England and October for the NY Bight.

- For common dolphins, the general distribution across the year was similar, but the number of animals in the NY Bight lease areas was higher than in the New England wind farm locations. One outlier in the NY Bight leases was OCS-A 0544, the most coastal of the NY Bight leases. This area had lower overall densities across the year than the other NY Bight lease areas and represents a more coastal location than the other lease areas. This trend is similar to the magnitude difference in the New England wind farms, where WF2 (the more coastal site) has lower overall numbers of animals in comparison to WF1. Therefore, the two New England wind farm locations capture the variation seen in common dolphin density between coastal and offshore locations in the NY Bight lease areas.

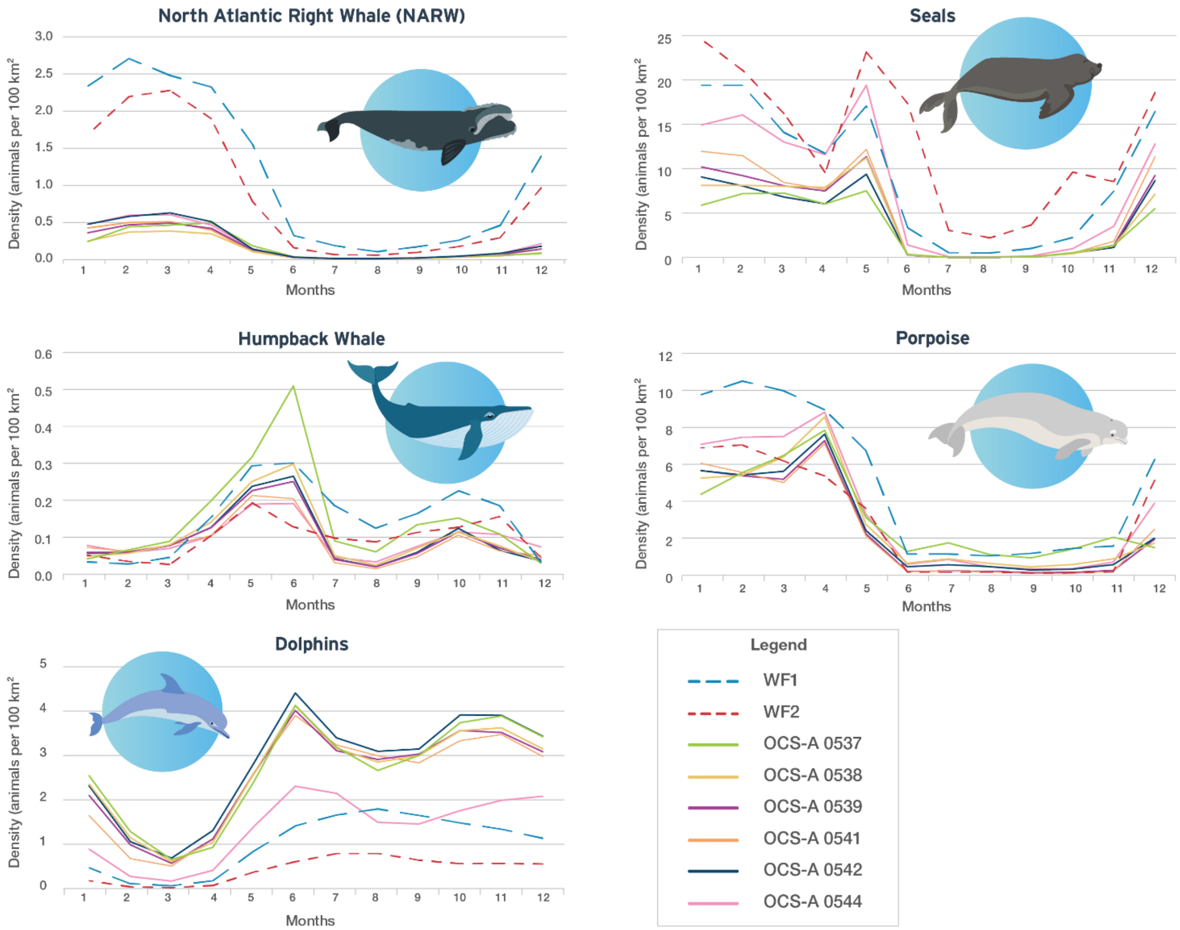

Figure J-5. Comparison of average animal density in the New England hypothetical wind farm areas (WF1 and WF2) with the average animal density in the NY Bight lease areas (OCS-A 0537, 0538, 0539, 0541, 0542, and 0544)

Note: The y-axis scales are different among the plots.
Source: Roberts et al. (2022).

In summary, the density distribution differences identified for each species between the New England wind farms and NY Bight lease areas point to only a few shortcomings in the overall applicability of the New England case study findings to the NY Bight. First, that the densities associated with the common dolphin, particularly those associated with WF1, may be less than for the NY Bight, which could underestimate the risk to common dolphins. However, common dolphins had the lowest assessed risk of any of the species considered in the New England case study, in part, due to their low vulnerability. Second, some species' densities in the NY Bight lease areas exceed those of the hypothetical wind farms at certain times of the year, such as for humpback whales in spring and early summer at OCS-A 0537. However, this difference is acceptable because this programmatic-level assessment considers the general trend in density distribution across the year rather than on a single month resolution.

J.4.6 Discussion of Acoustic Impacts Under Alternative B

Under Alternative B, AMMM measures are not identified at the programmatic stage and the largest spatio-temporal extent of noise associated with the development of offshore wind in the NY Bight has the potential to be realized. Pile-driving would be expected to be the greatest contributor to potential noise-associated effects on marine mammals.

Under Alternative B, pile-driving would not be excluded in certain time periods, including periods when species of greatest concern such as the NARW could be present, and periods when other species are in high abundance in the area and on the lease site. At the programmatic level, there would not be measures in place to monitor for marine mammals or modify activities should an animal be exposed to impactful levels of sound. Baleen whales and seals would be especially susceptible, as their hearing range overlaps with the low frequency sounds produced during offshore construction activities.

It is difficult to predict the spatio-temporal impact of the project build-outs under Alternative B without an understanding of many of the construction specifics of the NY Bight projects, e.g., construction effort within a day (e.g., number of piles driven in a day), order of construction among the leases, whether construction on one project will overlap in time with one another, and whether construction on a single project will occur all in one year. A few example scenarios using what is known either from the representative project design envelope (RPDE), or what can be built from the New England case study, are provided to help illuminate the subject. These are only illustrations of what could be, and should not be considered as the only possibilities. Until more details are known, these scenarios should only be considered as hypothetical.

J.4.6.1 Build-out of One Project

Marine Mammals Exposed

Year 1 unmitigated results of the New England case study, as previously described, may provide the best available hypothetical example of the relative risk and aggregate exposure associated with the build-out of one project for the NY Bight. However, some limitations should be considered. The case study considered construction of 120 foundations in 1 year, and more construction activity would increase the chance of exposure.

Exposure Time

Based on the RPDE, a maximum of 280 foundations is anticipated for a single wind farm in the NY Bight. If pile-driving takes 4 hours per pile and one pile is driven per day, then 16.66% of a 24-hour period would have pile-driving noise occurring. If the rate increases to two piles/day, the time of pile-driving noise increases to 33.33%. It would take a minimum of 9.33 months to install 280 foundations in a one pile/day scenario, or 4.67 months with two piles/day. (As a reminder, in the case study it took 4 months or 2 months, respectively, to drive 120 piles). In either scenario, or with more piles driven per day for the same total number of foundations, construction noise would occur for 12.78% of the year. The difference is in the amount of “quiet time” per day at or near the pile-driving location, which could be an important factor for animals in the vicinity (i.e., recovery of fatigued auditory systems, offering a break from masking, etc.). If construction occurred continuously in a single year, under a one pile/day scenario, construction during periods when more animals are in the area would be unavoidable for many species, as no seasonal restrictions would be in place at the programmatic level under Alternative B.

Exposure Area

The spatial extent of behaviorally impactful noise levels under Alternative B during a single pile-driving event is anticipated to be of a similar order of magnitude as the unmitigated scenarios in the New England case study, unless mitigation were to be conducted at the project level. The unmitigated pile-driving scenario considered in Southall et al. (2021b) predicted potential effects on marine mammal behavior within 10 km of the foundation being installed. This radius would represent a potential exposure area of 314 km^2 (180% the smallest NY Bight lease area, i.e., 174 km^2; or ~62% of the largest NY Bight lease area, i.e., 510 km^2). Overlapping sound fields would not occur as a result of pile-driving in the build-out of one wind farm unless multiple pile-driving events were conducted at the same time.

J.4.6.2 Build-out of Six Projects

Because so many of the construction details are unknown at the time of this programmatic acoustic assessment, there are countless ways in which six projects could be built out, and it is difficult to predict what the effect of simultaneous build-out of six wind farms would look like. As shown in the New England case study, the aggregate marine mammal exposure associated with the build-out of one wind farm versus build-out of two *was not additive* and was dependent on the site-specific density patterns of a species at the time of construction. However, BOEM does assume that the spatio-temporal exposure would be greater for six wind farms than one and would vary by species. Though the relativistic risk assessment framework would not be used at the programmatic level under Alternative B, it could be used at the project level to predict the relative exposure risk to the marine mammal species of interest by considering the species density and distribution at the construction sites at the time of year planned for construction.

The simultaneous build-out of six wind farms has the potential, albeit unlikely, for overlapping sound fields if concurrent pile-driving is pursued at two close proximity sites. It is not likely that the isopleths associated with injury or behavioral effects (NMFS 2022) associated with construction on lease areas OCS-A 0544 and OCS-A 0537 would overlap with any other NY Bight lease area due to the distance of these wind farms from the other NY Bight lease sites, which exceeds 28 km at their closest points (Figure J-6). For the other lease areas, overlapping sound fields would be unrealistic due to safety concerns between the two operations, equipment logistics, and equipment bottlenecks. However, if pile-driving were to occur simultaneously, the spacing between concurrent pile-driving would have to be within 5 km for the sound fields to add in a meaningful way that could potentially change the impact ranges.

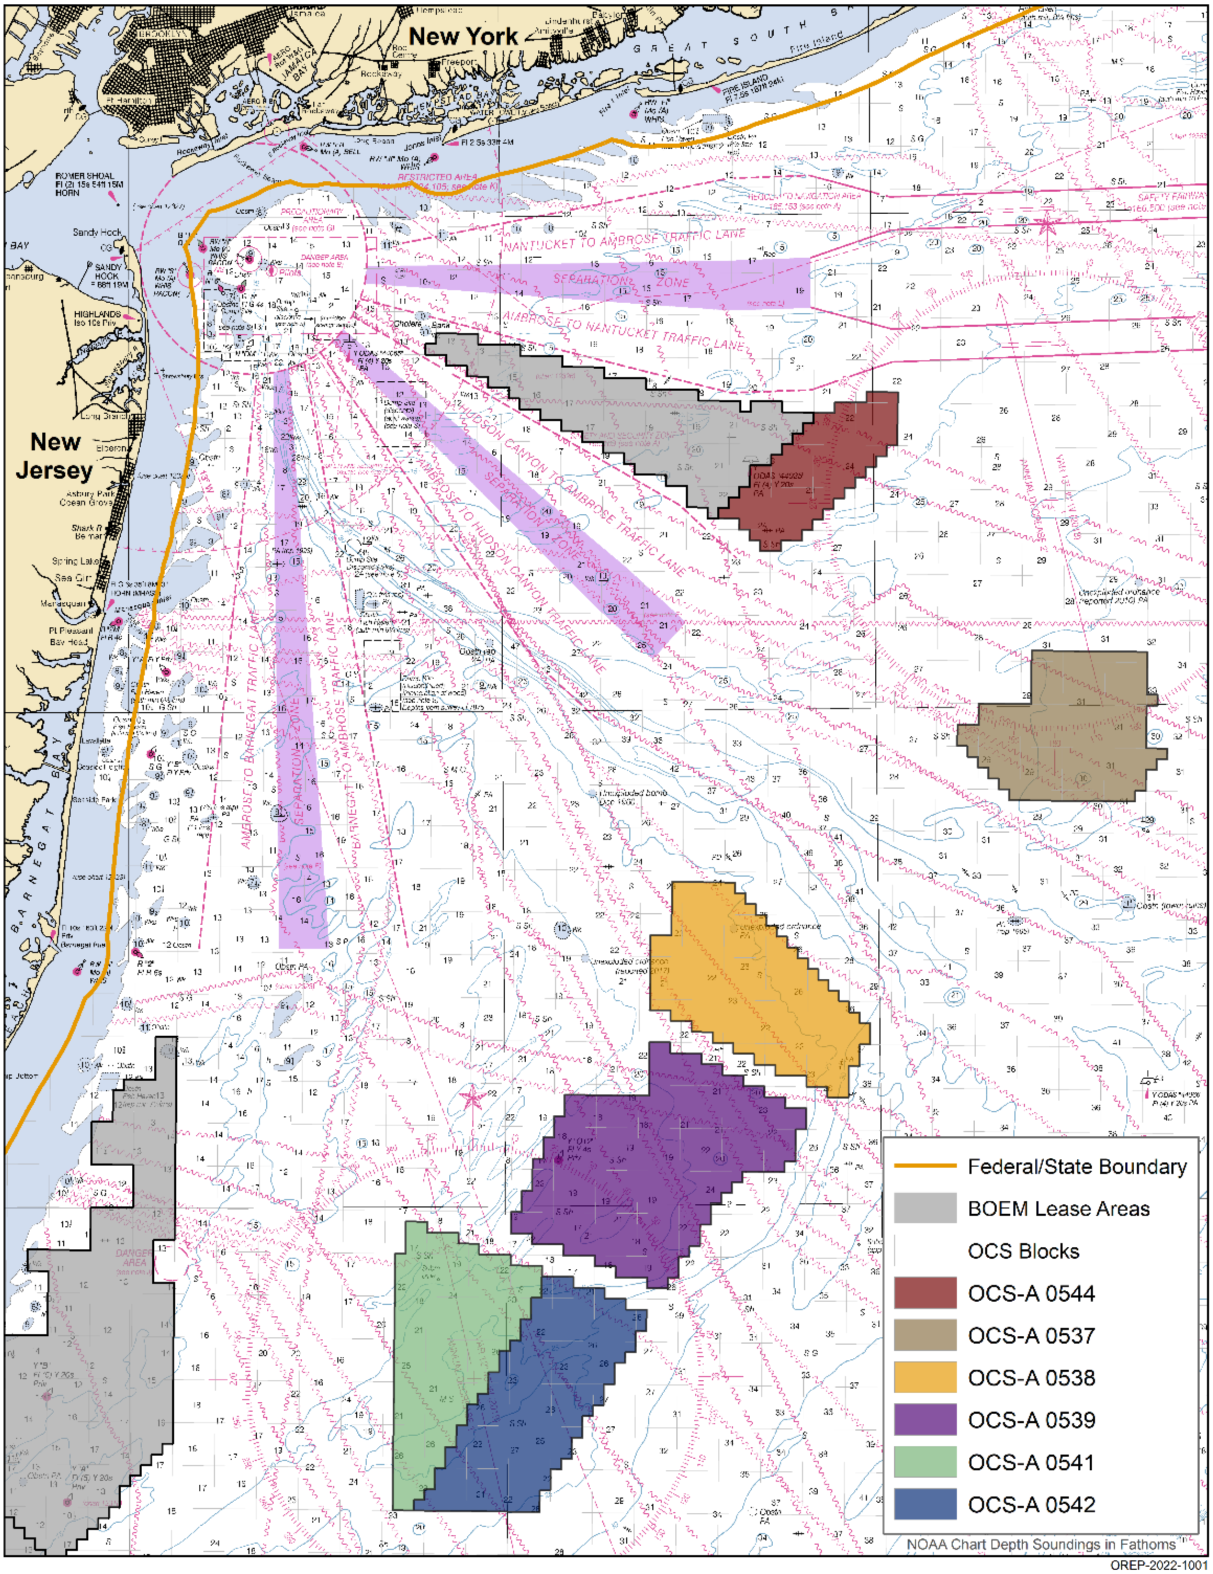

Figure J-6. NY Bight lease areas

J.4.7 Identification of AMMM Measures and Recommended Practices to Reduce Noise Impacts for the NY Bight

The results and mitigative principles from the New England case study were used to inform the identification of AMMM measures and Recommended Practices (RPs) that can potentially reduce noise impacts on marine mammals in the NY Bight. These AMMM measures and RPs fall into several themes. Note that there are other noise-related AMMM measures and RPs that are not discussed further as they neither directly (e.g., reporting requirements) nor indirectly reduce acoustic impacts on marine mammals. The complete list of noise-related AMMM measures and RPs is provided in Table J-5 for reference.

J.4.7.1 Noise-related AMMM Measure and RP Themes

Modifications in offshore wind development activity schedules that limit temporal exposure to noise include:

- Prohibiting or minimizing construction during periods when species of the highest conservation concern (the NARW) are expected to be present in greater numbers in the region (covered under MMST-4).
- Using daytime-only pile-driving (covered under MMST-4).
- Considering increased construction effort in periods with lowest animal density to complete more of the work and shorten total construction timelines:
    - Considering night-time and low-visibility conditions and enhance monitoring (MMST-6, MMST-1).

Measures and RPs that limit the spatial extent of noise include:

- Using equipment, technology, and best practices that produce the least amount of noise practicable to avoid and minimize noise impacts on the environment (MUL-5).
- Prioritizing low noise foundations when practicable (MUL-6).
- Received Sound Level Limit (RSLL): Limiting noise levels above the injury threshold for LFC to below a fixed distance from pile-driving (MUL-22).
- Following current International Maritime Organization (IMO) Guidelines for the reduction of underwater radiated noise from vessels to the extent practicable (MUL-7).
- Using soft start for pile-driving (MUL-20).

Use of real-time and near-real time monitoring to inform adaptive mitigation measures include:

- Monitoring clearance/shutdown zones using visual observation and real-time PAM during pile-driving (covered under MMST-2, MMST-4).
- Visually monitoring clearance/shutdown zones during HRG surveys (MMST-12).
- Using real-time PAM detection of marine mammals and alert system for operators near other concentrated development activities (e.g., transit or cable-laying corridor) or between lease areas to increase overall alertness of operators and readiness to implement shut-downs as needed (MM-2).
- Conducting Sound Field Verification (SFV) at every pile at 750 m (abbreviated "SFV"). "Thorough SFV" monitoring (defined as recording along a minimum of two radials with at least one radial containing recorders at three or more distances) must be conducted for the first three foundations of a project, and the first installation represented by each modeling scenario used. If levels measured in any SFV (Thorough or Abbreviated) imply the exceedance of agency-identified ranges to regulatory thresholds, the lessee must take mitigative actions in consultation with the federal permitting agencies. The lessee must submit an SFV plan for review, which, among other things, should include approximations of the expected variation of key parameters (e.g., difficulty to drive, predicted number of necessary strikes, foundation type, pile size, installation method, hammer energy rating, water depth, seabed composition, and season) across the project and an estimate of how many thorough monitoring locations will be required to cover this variability (MUL-29).
- Using sound field measurements to verify or adjust monitored impact zones and protected species observer (PSO) coverage (MMST-3, MMST-5).

Collection of baseline information to better anticipate potential impacts and further mitigate effects on marine mammals in the future includes:

- Conducting long-term PAM or contribute to a research fund to support PAM on the lease area for 1 year before construction through at least 3 years but no more than 10 years of operations (MM-3).
- Archiving SFV data (MUL-29).

A final point to make about the identification of AMMM measures and RPs is that the NARW is the species of greatest concern. Therefore, many AMMM measures and RPs are designed specifically in consideration of the NARW and, in certain circumstances, may increase risk to other species (e.g., seasonal construction window). In other instances, AMMM measures and RPs provide similar benefits to other species. Table J-5 lists the noise-related AMMM measures and RPs for the NY Bight; for the full details of each measure, see Appendix G, *Mitigation and Monitoring*, of the PEIS.

Table J-5. Noise AMMM measures and RPs for the NY Bight

Measure ID	Measure	Discussed in this Analysis	AMMM or RP	Previously Applied?
MM-1	Reporting of all NARW detections	--	AMMM	Yes
MM-2	Real-time PAM monitoring and alert system for baleen whales	Yes	RP	--
MM-3	Long-term PAM monitoring	Yes	AMMM	Yes
MMST-1	Reduced Visibility Monitoring Plan/Nighttime Pile Driving Monitoring Plan	Yes	AMMM	Yes
MMST-2	Marine Mammal and Sea Turtle Monitoring Plan for Pile-Driving	Yes	AMMM	Yes
MMST-3	Pile-driving clearance and shutdown zone adjustments	Yes	AMMM	Yes
MMST-4	Establishment of foundation pile-driving measures	Yes	AMMM	Yes
MMST-5	PSO coverage of expanded pile-driving clearance/shutdown zones	Yes	AMMM	Yes
MMST-6	Pile-driving visibility requirements	Yes	AMMM	Yes
MMST-7	PSO coverage and training requirements for pile-driving	--	AMMM	Yes
MMST-10	Reporting of ESA-Listed Species within Shutdown Zone During Active Pile Driving	--	AMMM	Yes
MMST-12	Marine mammal and sea turtle geophysical survey clearance and shutdown zones and mitigations	Yes	AMMM	Yes
MUL-5	Low noise best practices	Yes	RP	--
MUL-6	Low noise foundations	Yes	RP	--
MUL-7	Vessel noise reduction guidelines	Yes	RP	--
MUL-20	Soft start for impact pile-driving	Yes	AMMM	Yes
MUL-22	Received Sound Level Limit (RSLL)	Yes	AMMM	No
MUL-29	Sound Field Verification (SFV) Process, Plan and Reporting	Yes	AMMM	Yes
MUL-32	Weekly, monthly, and final PSO reporting requirements (including foundation pile-driving)	--	AMMM	Yes
MUL-34	Detected or impacted protected species reporting	--	AMMM	Yes

J.4.8 Discussion of Acoustic Impacts Under Alternative C

Under Alternative C there are two sub-alternatives:

- Sub-alternative C1 (Preferred Alternative), Previously Applied AMMM Measures.
- Sub-alternative C2, Previously Applied and Not Previously Applied AMMM Measures.

In addition to the AMMM measures identified under each sub-alternative, BOEM is recommending lessees consider analyzing the RPs in Table G-2 in Appendix G. For completeness, the acoustic impacts associated with the implementation of the RPs are also discussed here.

Under both sub-alternatives, pile-driving would be expected to contribute the greatest to potential effects on marine mammals associated with noise. However, there are several ways it would differ from Alternative B due to the AMMM measures. With the AMMM measures in Sub-alternative C1 or Sub-alternative C2, the spatial extent of noise associated with pile-driving in the NY Bight would be reduced with respect to Alternative B. In addition, the temporal overlap of construction activities with times when the NARW are present would be avoided to the extent possible. Procedures would be in place such that if animals came into the area in which noise effects may occur, the area would be monitored both visually and acoustically such that any marine mammal in the area should be detected. Procedures would be in place such that if an animal was detected pile-driving would stop, if safe to do so, until the animal(s) left the area. These issues and any differences between Sub-alternative C1 and C2 are further discussed in the sections that follow.

J.4.8.1 Impacts of Noise AMMM Measures

Exposure Time

Under both Sub-alternative C1 and Sub-alternative C2, there are four ways in which exposure time is reduced. These are related to the timing of pile-driving activity: (1) a seasonal restriction on pile-driving between January 1 and April 30 (covered under MMST-4), (2) a time-of-day restriction to daylight hours (covered under MMST-4), (3) a requirement for an alternative monitoring plan if construction were to occur outside daylight hours (MMST-1), and (4) low visibility condition requirements for pile-driving (MMST-6). With the implementation of a seasonal construction restriction, pile-driving would not be allowed to occur during periods when the NARW have historically been present in relatively higher numbers in the NY Bight/southern New England ecoregion (i.e., January 1–April 30) and further would not be allowed to occur in December unless a developer requests and is approved to do so. Exposure to pile-driving for the NARW would be minimized due to this seasonal restriction. This seasonal restriction would likely benefit other species with a similar phenology, or seasonal occurrence, as the NARW, such as harbor porpoise and seals. However, it may be less beneficial to species that may be present in higher numbers when construction is allowed, such as humpback whales, dolphins (Figure J-5), and other species not examined as part of this work. The benefit of a time-of-day restriction is that observers can visually monitor the area around pile-driving activity for marine mammals reliably. With additional low visibility and night-time monitoring requirements, enhanced monitoring (such as the use of technology to aid or supplement visual monitoring) would increase the likelihood of detecting marine life in the area. If pile-driving occurs only in daylight hours, this effectively means there is a period of time, i.e., during the night, when no pile-driving noise is produced. This measure may provide periods of time when animals that are present could recover from auditory fatigue or use the area in ways that they were unable to when construction noise was present. One advantage of pile-driving at any time of the day is that construction could be condensed to periods when animals are not present or in low abundance, effectively reducing the time that construction would occur when animals are present or in higher abundance. The risk assessment framework provides a tool for exploring such scenarios, as the value of either approach will depend on the specific context under consideration (i.e., species of interest, construction location, etc.). Additional modifications could also be made to fine-tune the construction window and further reduce potential exposure to the NARW and other species of interest by using the relative risk assessment framework.

Exposure Area

There are four identified AMMM measures and RPs related to the spatial extent of noise exposure: (1) use of low noise foundations and/or the best available quieting technology (MUL-6); (2) received sound level limit to keep noise levels that exceed the injury threshold for LFC to within a fixed distance from a foundation (MUL-22); (3) adherence to the IMO Guidelines for vessel quieting, where practicable (MUL-7); and (4) soft start for pile-driving (MUL-20).

With MUL-6, the spatial extent of noise associated with pile-driving could be reduced with the use of foundation types other than impact-pile-driven monopiles, such as gravity-base, suction buckets, and other designs that do not require pile-driving. There are different noises associated with the installation of other foundation types; however, they are generally not as loud or as impulsive as impact pile-driving. If the use of non-pile-driving foundations was not possible, the best available quieting technology should be applied. The New England case study simulated the effect of noise mitigation technology on impact pile-driving by reducing the behavioral effect ranges from 20 km and 10 km to 15 km and 5 km for harbor porpoise and other marine mammals, respectively. This reduction is a reasonable expectation of the order of magnitude that noise mitigation could help to reduce the spatial exposure extent of noise under Alternative C. Adherence to the IMO Guidelines on vessel quieting may lead to decreases in vessel noise, which would decrease the risk of masking associated with vessel noise to marine mammals in the area. A final AMMM measure that may have benefits to marine life is the requirement for a soft start during pile-driving (MUL-20). The purpose of this AMMM measure is to capitalize on a potential avoidance response of some marine life by requiring that pile-driving begin at reduced power and strike rate (i.e., fewer strikes per time period) to elicit an avoidance response of any animals in the area before the sound reaches potentially impactful levels. There is no clear evidence for the effectiveness of this mitigation.

In addition to the previously mentioned measures, Sub-alternative C2 would require a received sound level limit (MUL-22). MUL-22 would further limit the spatial extent of sound exposure around impact pile-driving. This AMMM measure was designed to ensure that injurious sound levels to LFC may only occur within a short and fixed distance from the pile-driving source such that the area can be sufficiently monitored for marine mammals. Although this AMMM measure would likely result in decreased noise exposure to all species, it prioritizes LFC. Therefore, it may have greater benefits to those species in comparison to others if, for example, the target was achieved by focusing only on a reduction of the lowest frequencies of pile-driving sound. Reaching the RSLL could be achieved in several ways, including the application of various noise mitigations or the installation of low noise foundations.

Other Potential Reductions in Impacts on Marine Mammals

Several of the other AMMM measures in place in Sub-alternatives C1 and C2 provide opportunities to detect marine mammals or sea turtles during construction and other development activity. With increased opportunities to detect marine mammals, there would be more opportunities to mitigate potential impacts should they arise.

For example, clearance and exclusion zones would be monitored visually and acoustically with real-time PAM during pile-driving (covered under MMST-2, MMST-4). If a marine mammal is detected in those zones, procedures would be triggered to cease pile-driving, to the extent practicable, thereby avoiding a potential exposure that could cause injury or behavioral disturbance to an animal. Clearance and exclusion zones also would be visually monitored during HRG surveys for marine mammals and sea turtles, allowing for a potential exposure to be avoided by shutting down the activity should a marine mammal be present (MMST-12).

Several other monitoring AMMM measures and RPs could directly or indirectly lead to reduced impacts on marine mammals by updating our baseline understanding of marine mammals and potential noise impacts. For example, through long-term PAM monitoring (MM-3), information about marine mammal presence, density, and phenology can be obtained, which can be used to update AMMM measures like the seasonal restrictions. However, under MM-3, data is likely to be collected on a yearly basis, and it is unclear how quickly, or even if, that information could be incorporated into the same project from which the data was collected. The data collected during sound field verification (MUL-29) may be used to adjust a project's shutdown, clearance, and monitoring zones if the sound field differs from what was authorized (MMST-3). In addition, sound field data may also be archived to inform the development of AMMM measures for subsequent projects.

Sound field verification AMMM measures (MUL-29) would not directly change the impact of noise on marine mammals, but the information collected during sound field verification would inform regulators whether the sound produced is within the allowable limits. If not, two AMMM measures (MMST-3 and MMST-5) are in place to ensure adequate monitoring of the area for marine mammals should they be present during construction. MMST-3 would allow for the adjustment of the monitored impact zones based on the sound field measurements, and MMST-5 would modify the number of visual observers based on the adjusted monitoring impact zones. These measures would ensure that any assumptions made in setting up the initial monitoring zones are met, and, if not, modifications are made to ensure adequate monitoring for marine mammals.

If MM-2 (RP) was implemented, real-time PAM would be conducted near any other concentrated development activities, such as laying cables or near a designated transit corridor. Any detections would be communicated to operators on the water. Although this measure would lead to increased opportunities to detect marine mammals in the area and increase operator vigilance of their presence, there is no mitigation directly tied to this AMMM measure. Therefore, any benefits would be indirect, such as if a vessel operator was able to use the detection to identify a marine mammal that it might otherwise have not visually observed. In this case, other AMMM measures are in place that would require the operator to avoid the marine mammal.

The preceding discussion applies to the build-out of one or six projects. The sections that follow provide additional information specifically about these build-outs. However, without an understanding of many of the construction specifics of the NY Bight projects, it is difficult to predict the spatio-temporal impact of the build-out of one or six projects. Consequently, the discussions that follow are only illustrations of potential impacts and should not be considered as the only possibilities. Until more details are known, these should only be considered as hypothetical.

J.4.8.2 Build-out of One Project

Exposure Area

Under RP MUL-5, operators are encouraged to use equipment, technology, and best practices that produce the least amount of noise practicable to avoid and minimize noise impacts on the environment. With the implementation of noise mitigation technology, a project would reduce the area exposed to noise. For example, under the mitigated pile-driving scenarios in the New England case study, the behavioral impact radius was 5 km, or a 79-km^2 area, around a pile during a single impact pile-driving event. This dimension would equate to an area 45.4% of the size of the smallest NY Bight lease area (i.e., 174 km^2) or 15.5% of the size of the largest NY Bight lease area (i.e., 510 km^2).

With MUL-22, a physical distance limit to injurious sound levels to LFC would be in place. A received level limit at 1 km around a pile would equate to an area 3.14 km^2 (i.e., 1.8% the smallest NY Bight lease area or 0.62% of the largest NY Bight lease area) ensonified by noise exceeding the LFC acoustic injury threshold.

J.4.8.3 Build-out of Six Projects

Exposure Area

Under Alternative C, if pile-driving occurred on a single lease site at a time, the space exposed during pile-driving would not differ from the build-out of one project. If pile-driving occurred simultaneously on each of the six leases with no overlapping spatial exposure and RP MUL-5 is implemented with the use of noise mitigating technology, a reduced area of exposure—as in the New England case study—could be achieved. As an example from the case study, a 5-km radius of exposure around each pile-driving event for potentially behavioral impactful sound levels would equate to an area equivalent to 471 km^2 (or 24% of the total leased NY Bight area). Under Sub-alternative C2. MUL-22 and a 1-km radius for injury levels for LFC would equate to an 18-km^2 (or 0.95% of the total leased NY Bight area) area exposed to potentially behavioral impactful sound levels.

J.4.8.4 Conclusion

The AMMM measures and RPs identified in this analysis serve key functions in reducing noise impacts. The AMMM measures focused on reducing the spatio-temporal overlap of noise with marine life may have the greatest potential to reduce impacts. However, these AMMM measures and RPs are built on a foundation of knowledge that would not be possible without continued environmental monitoring to understand where and when animals are present and to characterize the sound fields associated with noise-generating activities. Therefore, the monitoring AMMM measures and RPs are also critical in ensuring that the spatio-temporal AMMM measures are most effective and are based on the best available and current information.

Appendix L: Glossary

L.1 Glossary

Term	Definition
affected environment	Environment as it exists today that could be potentially affected by the Proposed Action or other action alternatives
algal blooms	Rapid growth of the population of algae, also known as *algae bloom*
allision	A moving ship running into a stationary ship
Avoidance, Minimization, Mitigation, and Monitoring measures	The programmatic avoidance, minimization, mitigation, and monitoring (AMMM) measures
anthropogenic	Generated by human activity
archaeological resource	Historical place, site, building, shipwreck, or other archaeological site
below grade	Below ground level
benthic	Related to the bottom of a body of water
benthic resources	The seafloor surface, the substrate itself, and the communities of bottom-dwelling organisms that live on and within these habitats
biogenic habitat	Benthic habitats created by structure-forming species (e.g., eelgrass, mussel beds, worm tubes)
Cetacea	Order of aquatic mammals made up of whales, dolphins, and porpoises
coastal habitat	Coastal areas where flora and fauna live, including salt marshes and aquatic habitats
coastal waters	Waters in nearshore areas where bottom depth is less than 98.4 feet (30 meters)
coastal zone	The lands and waters starting at 3 nautical miles (5.6 kilometers) from the land and ending at the first major land transportation route
commercial fisheries	Areas or entities raising and catching fish for commercial profit
commercial-scale wind energy facility	Wind energy facility usually greater than 1 megawatt (MW) that sells the produced electricity
concrete mattress	Concrete mat used to protect underwater pipelines or stabilize soil or the seabed; can be formed underwater by divers rolling out geosynthetic mattress fabric, zipping it together, and using a pump to fill it with highly fluid small aggregate concrete
criteria pollutant	One of six common air pollutants for which the United States Environmental Protection Agency sets National Ambient Air Quality Standards: carbon monoxide, lead, nitrogen dioxide, ozone, particulate matter, or sulfur dioxide
critical habitat	Geographic area containing features essential to the conservation of threatened or endangered species
cultural resource	Historical districts, objects, places, sites, buildings, shipwrecks, and archaeological sites on the American landscape, as well as sites of traditional, religious, or cultural significance to cultural groups, including Native American Tribes
culvert	Structure, usually a tunnel, allowing water to flow under an obstruction (e.g., road, trail)
deflagration	Combustion of an explosive at subsonic speeds, driven by transfer of heat
demersal	Living close to the ocean floor
demosponge	Class of sponges that account for more than 90% of all sponges alive, including bath, boring, barrel, carnivorous, and freshwater sponges

Term	Definition
dredging	Removal of sediments and debris from the bottom of lakes, rivers, harbors, and other waterbodies
duct bank	Underground structure that houses the onshore export cables, which consists of polyvinyl chloride pipes encased in concrete
ecosystem	Community of interacting living organisms and nonliving components (such as air, water, soil)
electromagnetic field	A field of force produced by electrically charged objects and containing both electric and magnetic components
embayment	Recessed part of a shoreline
endangered species	A species that is in danger of extinction in all or a significant portion of its range
Endangered Species Act–listed species	Species listed under the Endangered Species Act (ESA) of 1973 (as amended)
ensonification	The process of filling with sound
environmental protection measure	Measure proposed to avoid or minimize potential impacts
environmental consequences	The potential direct, indirect, and cumulative impacts that the construction, operations and maintenance (O&M), and decommissioning of a proposed project would have on the environment
Communities with environmental justice concerns	Minority and low-income populations potentially affected by a proposed project, as defined by both federal and applicable state criteria
epifauna	Fauna that lives on the surface of a seabed (or riverbed), or is attached to underwater objects or aquatic plants or animals
essential fish habitat	"Those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity" (50 Code of Federal Regulations [CFR] part 600)
export cable	Cable connecting the offshore wind facility to the onshore electrical grid power
export cable corridor	Area identified for routing the entire length of the onshore and offshore export cables
federal aids to navigation	Visual references operated and maintained by the United States Coast Guard (USCG), including radar transponders, lights, sound signals, buoys, and lighthouses, that support safe maritime navigation
finfish	Vertebrate and cartilaginous fish species, not including crustaceans, cephalopods, or other mollusks
for-hire commercial fishing	Commercial fishing on a for-hire vessel (i.e., a vessel on which the passengers contribute to a person having an interest in the vessel in exchange for carriage)
for-hire recreational fishing	Fishing from a vessel carrying a passenger for hire who is engaged in recreational fishing
foundation	The bases to which the wind turbine generators (WTGs) and offshore substations (OSSs) are installed on the seabed; seven types of foundations are considered in the RPDE: monopile, piled jacket, suction mono-bucket, suction bucket jacket, tri-suction pile caisson, and gravity-based
frond mattress	Anti-scour protection consisting of aerated polyethylene fronds that when installed on the seabed will naturally float to resemble natural seaweed; as local currents transport sediment through the frond mattress strands encouraging sand, silt, or soil to be deposited onto the mattress, the frond mattress forms a natural fiber reinforced sand bank to protect the area in question
geomagnetic	Relating to the magnetism of the Earth

Term	Definition
gravity-based structure	Typically constructed of steel, concrete, or a combination of both; gravity-based structures sit on top of the seafloor and are not pile driven
hard-bottom habitat	Benthic habitats composed of hard-bottom (e.g., cobble, rock, and ledge) substrates
historic property	As defined in 36 CFR 800.16(l)(1), a prehistoric or historic district, site, building, structure, or object that is eligible for or already listed in the National Register of Historic Places (NRHP); also includes any artifacts, records, and remains (surface or subsurface) related to and located within such a resource
historical resource	There is no common or consistent legal definition for a historic resource; therefore, it is defined the same as an historic property; a prehistoric or historic district, site, building, structure, or object that is eligible for or already listed in the NRHP; also includes any artifacts, records, and remains (surface or subsurface) related to and located within such a resource
horizontal directional drilling	Trenchless technique for installing underground cables, pipes, and conduits using a surface-launched drilling rig
hull	Watertight frame or body of a ship
infauna	Fauna living in the sediments of the ocean floor (or river or lake beds)
interarray cables	Cables connecting the wind turbine generators to the electrical service platforms
Interdunal	Habitat between dunes
invertebrate	Animal with no backbone
jacket foundation	Latticed steel frame with three or four supporting piles driven into the seabed
jack-up vessel	Mobile and self-elevating platform with buoyant hull
jet excavation	Process of moving or removing soil with a jet
jet plowing	Plowing in which the jet plow, with an adjustable blade, or plow, rests on the seafloor and is towed by a surface vessel; the jet plow creates a narrow trench at the designated depth, while water jets fluidize the sediment within the trench
knot	Unit of speed equaling 1 nautical mile (1.8 kilometer) per hour
landfall site	The shoreline landing site at which the offshore cable transitions to onshore
marine mammal	Aquatic vertebrate distinguished by the presence of mammary glands, hair, three middle ear bones, and a neocortex (a region of the brain)
marine waters	Waters in offshore areas where bottom depth is more than 98.4 feet (30 meters)
mechanical cutter	Method of submarine cable installation equipment that involves a cutting wheel or excavation chain to cut a narrow trench into the seabed allowing the cable to sink under its own weight or be pushed to the bottom of the trench via a cable depressor
mechanical plow	Method of submarine cable installation equipment that involves pulling a plow along the cable route to lay and bury the cable; the plow's share cuts into the soil, opening a temporary trench, which is held open by the side walls of the share, while the cable is lowered to the base of the trench via a depressor; some plows may use additional jets to fluidize the soil in front of the share
metocean	The syllabic abbreviation of meteorology and oceanography; a metocean study is used to estimate the environmental conditions including the wind, wave, and climate conditions found at a certain location
monopile or monopile foundation	A long steel tube driven into the seabed that supports a tower
mooring dolphin	Isolated marine structure used for mooring and securing vessels near pier structures to control the transverse movement of vessels while docked
nautical mile	A unit used to measure sea distances and equivalent to approximately 1.15 miles (1.85 kilometers)

Term	Definition
NY Bight area	The New York Bight (NY Bight) is the geological identification applied to the roughly triangular indentation, regarded as a bight, along the Atlantic coast of the United States that extends northeasterly from Cape May Inlet in New Jersey to Montauk Point on the eastern tip of Long Island
NY Bight lease areas	Commercial Lease Areas OCS-A 0537, OCS-A 0538, OCS-A 0539, OCS-A 0541, OCS-A 0542, and OCS-A 0544
NY Bight projects	Hypothetical projects that may be proposed within the six NY Bight lease areas
offshore project area	The offshore components that collectively make up the NY Bight offshore project area include the lease areas, WTGs, OSSs, scour protection for foundations, interarray and substation interconnection cables, and offshore export cables
offshore substation	The interconnection point between the WTGs and the export cable; the necessary electrical equipment needed to connect the interarray cables to the offshore export cables
onshore project area	The onshore components that collectively make up the NY Bight onshore project area include the landfall sites, the sea-to-shore transition that connects the offshore export cables to the onshore export cables, onshore export cable routes to onshore substations or converter stations, and the connection from the onshore substations or converter stations to the existing grid
onshore substation	Substation connecting a project to the existing bulk power grid system
operations and maintenance facilities	Would include offices, control rooms, warehouses, shop space, and pier space
Outer Continental Shelf	All submerged land, subsoil, and seabed belonging to the United States but outside of states' jurisdiction
permanent threshold shift	Affecting animals as a result of sound exposure, permanent threshold shift or PTS is an irreversible loss of hearing due to hair cell loss or other structural damage to auditory tissues
pile	A type of foundation akin to a pole
pile-driving	Installing foundation piles by driving them into the seafloor
pinnipeds	Carnivorous, semiaquatic marine mammals with fins, also known as seals
pin pile	Small-diameter pipe driven into the ground as foundation support
plume	Column of fluid moving through another fluid
private aids to navigation	Visual references on structures positioned in or near navigable waters of the United States, including radar transponders, lights, sound signals, buoys, and lighthouses, that support safe maritime navigation; permits for the aids are administered by USCG
Proposed Action	Specifically Alternative C, is the identification of AMMM measures such that the potential impacts described in Alternative B may be avoided, reduced, or mitigated
Preferred Alternative	Specifically Sub-alternative C1, Previously Applied AMMM Measures, analyzes the AMMM measures that BOEM has required as conditions of approval for previous activities proposed by lessees in Construction and Operations Plans submitted for the Atlantic Outer Continental Shelf or through related consultations.
protected species	Endangered or threatened species that receive federal protection under the ESA of 1973 (as amended)
quay	Concrete, stone, or metal platform lying alongside or projecting into water for loading and unloading ships
Representative Project Design Envelope (RPDE)	The range of technical parameters that describe a wind energy project that could occur within the NY Bight lease areas

Term	Definition
rock bags	Bags constructed of mesh material filled with rock or rip rap, making it a flexible protection system for marine construction work
scour protection	Protection consisting of rock and stone that would be placed around all foundations to stabilize the seabed near the foundations as well as the foundations themselves
scrublands	Plant community dominated by shrubs and often also including grasses and herbs
seabed spacer	An underwater cable system designed to hold and protect cables
sessile	Attached directly by the base
silt substrate	Substrate made of a granular material originating from quartz and feldspar, and whose size is between sand and clay
soft-bottom habitat	Benthic habitats that include soft-bottom (i.e., unconsolidated sediments) and hard-bottom (e.g., cobble, rock, ledge) substrates, as well as biogenic habitat (e.g., eelgrass, mussel beds, worm tubes) created by structure-forming species.
spud barge	Sometimes called a jack-up barge, a spud barge is a specialized type of barge commonly used for marine construction operations; the barge is moored by steel shafts or through-deck piling, which are essentially pipes driven right into the soil or sand at the bottom of the water to provide stability
substrate	Earthy material at the bottom of a marine habitat; the natural environment that an organism lives in
suction-bucket jacket	Latticed steel frame with three to four supporting suction-bucket foundations securing the structure to the seabed
suspended sediments	Very fine particles that remain in suspension in water for a considerable period of time without contact with the bottom; such material remains in suspension due to the upward components of turbulence and currents, or by suspension
temporary threshold shift	Affecting animals as a result of sound exposure, temporary threshold shift or TTS is a relatively short-term (e.g., within several hours or days), reversible loss of hearing following noise exposure, often resulting from hair cell fatigue
threatened species	A species that is likely to become endangered within the foreseeable future
tidal energy project	Project related to the conversion of the energy of tides into usable energy, usually electricity
tidal flushing	Replacement of water in an estuary or bay because of tidal flow
trawl	A large fishing net dragged by a vessel at the bottom or in the middle of sea or lake water
turbidity	A measure of water clarity
utility right-of-way	Registered easement on private land that allows utility companies to access the utilities or services located in that area
vibracore	Technology/technique for collecting core samples of underwater sediments and wetland soils
viewshed	Area visible from a specific location
visual resource	The visible physical features on a landscape, including natural elements such as topography, landforms, water, vegetation, and anthropogenic structures
wetland	Land saturated with water, and includes marshes and swamps
wind energy	Electricity from naturally occurring wind
wind energy area	Areas with significant wind energy potential and defined by Bureau of Ocean Energy Management (BOEM)
wind turbine generator	Component that puts out electricity in a structure that converts kinetic energy from wind into electricity

Appendix M: List of Preparers and Reviewers

M.1 List of Preparers and Reviewers

Table M-1. Bureau of Ocean Energy Management contributors

Name	Role/Resource Area
Ajilore, Ololade	Navigation and Vessel Traffic
Arzt, Tamara	Endangered Species Act (ESA) Sections
Aspromonti, Lauren	Representative Project Design Envelope (RPDE)
Honeycutt, Arianna	Navigation and Vessel Traffic
Baker, Kyle	Marine Mammals; Sea Turtles
Beser, Todd	Coastal Habitat and Fauna; Wetlands
Bigger, David	Bats; Birds; Coastal Habitats
Brune, Genevieve	Land Use and Coastal Infrastructure
Bucatari, Jennifer	Other Uses (Marine Minerals)
Chaiken, Emma	Commercial Fisheries and For-Hire Recreational Fishing; Recreation and Tourism
Chaky, Sindey	Environmental Justice; Land Use and Coastal Infrastructure; Recreational Fishing
Cornelison, Meghan	Demographics, Employment, and Economics; Environmental Justice; Scenic and Visual Resources
Davidson, Megan	Deputy Project Manager
Dawson, Elizabeth	Cumulative Impacts
Draher, Jennifer	Water Quality
Ehrhorn, Annette	Other Uses (Military Use)
Fulling, Gregory	Marine Mammals; Sea Turtles
Gange, Joshua	Other Uses (Transmission Lines)
Gentry, Lisa	Navigation and Vessel Traffic
Gallagher, Gwendolyn	AMMM Measures
Hayes, Tyler	Navigation and Vessel Traffic
Hogan, Charissa	Air Quality
Hooker, Brian	Commercial Fisheries and For-Hire Recreational Fishing
Horrell, Christopher	Cultural Resources
Hosch, Peter	RPDE
Houghton, Bonnie	Other Uses (Military Use and Aviation)
Howard, Bernard	Tribal Consultation
Howson, Ursula	Benthic Resources; Coastal Habitats; Commercial Fisheries and For-Hire Recreational Fishing; Finfish, Invertebrates, and Essential Fish Habitat (EFH); Other Uses; Wetlands
Jensen, Brandon	Benthic Resources; Commercial Fisheries and For-Hire Recreational Fishing; Finfish, Invertebrates, and EFH
Jensen, Mark	Demographics, Employment, and Economics; Recreation and Tourism
Jordan, Brian	Cultural Resources
Kates Varghese, Hilary	Acoustics
Lewis, Jo’Anne	Navigation and Vessel Traffic
Mansfield, Laura	Environmental Justice
Martin, Morgan	Acoustics

Name	Role/Resource Area
McCarty, John	Recreation and Tourism; Scenic and Visual Resources
McGuffin, Andrew	Other Uses (Cables and Radars); RPDE
Moshier, Marissa	Cultural Resources
Le, Jennifer	RPDE
O’Connell, Daniel	RPDE
Oliver, Elizabeth	Tribal Consultation
Pollock, Jayson	Commercial Fisheries
Price, Franklin	Cultural Resources
Remsen, Andrew	Water Quality
Renick, Hillary	Tribal Consultation
Richards, Renee	Other Uses (Unexploded Ordnances)
Schnitzer, Laura	Cultural Resources
Sharuga, Stephanie	Water Quality; Wetlands; ESA Sections; Benthic Resources
Slayton, Ian	Air Quality; Cumulative Impacts
Staaterman, Erica	Acoustics
Stokely, Sarah	Cultural Resources
Strain, Courtney	Project Manager
Sullivan, Kimberly	Environmental Justice
Tarbox, Mary Margaret	AMMM Measures
Vishnubhotla, Srinivas	RPDE
Washington, Travis	Water Quality
White, Timothy	Bats; Birds
Wisman, Jeri	Marine Mammals; Sea Turtles
Wolf, Jacob	Air Quality
Wolvovsky, Eric	Air Quality; Cumulative Impacts
Yerkes, Russell	Graphics

Table M-2. Reviewers

Name	Title	Agency
Bureau of Ocean Energy Management (BOEM) and U.S. Department of the Interior (DOI) Reviewers		
Baker, Karen	Chief, Office of Renewable Energy	BOEM
Bosyk, Jennifer	Chief, Branch of Environmental Communication and Coordination	BOEM
Diamond, David	Deputy Chief for Atlantic Operations, Office of Renewable Energy	BOEM
Frank, Wright	Chief, Renewable Energy Policy Group	BOEM
Hildreth, Emily	Policy Analyst	BOEM
Jordan, Brian	Chief, Branch of Environmental Learning and Analysis	BOEM
Landers, Lisa	Chief, NEPA Section	BOEM
Lewandowski, Jill	Chief, Division of Environmental Assessment	BOEM
Sauls, Marilyn	Chief, Engineering and Technical Review Branch	BOEM
Stromberg, Jessica	Chief, Environment Branch for Renewable Energy	BOEM
Meléndez-Arreaga, Pedro	Lead Attorney-Advisor, Office of the Solicitor	DOI
Monroe, Lori	Office of the Solicitor	DOI
Vorkoper, Stephen	Office of the Solicitor	DOI

Name	Title	Agency
Cooperating Tribal Government and Cooperating and Participating Agency Reviewers		
Arzt, Tamara	Supervisory Environmental Protection Specialist	Bureau of Safety and Environmental Enforcement
Kozak, Mark	Mechanical Engineer, Project Lead	Bureau of Safety and Environmental Enforcement
Lan, Christy	Senior Technical Advisor for Renewable Energy	Bureau of Safety and Environmental Enforcement
Martin, Shannon	Ecologist – Protected Species	Bureau of Safety and Environmental Enforcement
Tuttle, Graham	Environmental Protection Specialist	Bureau of Safety and Environmental Enforcement
Hay, Stormy	Deputy Tribal Historic Preservation Officer	Mashantucket Pequot Tribal Nation
Johnson, Michael Kickingbear	Tribal Historic Preservation Officer	Mashantucket Pequot Tribal Nation
Soleau, Tyler	CZM Assistant Director	Massachusetts Office of Coastal Zone Management
Boeri, Robert	Project Review Coordinator	Massachusetts Office of Coastal Zone Management
Andel, Kristin	Northeast Region Energy Specialist	National Park Service
Krueger, Mary	External Energy Coordinator	National Park Service
Bailey, Blair	General Counsel	New Bedford Port Authority
Regan, John	Director	New Bedford Port Authority
Brunatti, Megan	Deputy Chief of Staff	New Jersey Department of Environmental Protection
Lange, Elizabeth	Environmental Specialist 2	New Jersey Department of Environmental Protection
Nolan, Katherine	Team Leader, Renewable Energy and Offshore Wind	New Jersey Department of Environmental Protection
Benjamin, Sharon	NEPA Policy Analyst	National Marine Fisheries Service
Brancart, Kendall	NOAA Affiliate-Offshore Wind, Environmental Specialist	National Marine Fisheries Service
Cardiasmenos, Timothy	NEPA Coordinator, Greater Atlantic Regional Fisheries Office	National Marine Fisheries Service
Crocker, Julie	Chief, ESA Fish, Energy, and Ecosystems Branch	National Marine Fisheries Service
Daly, Jaclyn	MMPA Offshore Wind Team Lead	National Marine Fisheries Service
Pentony, Michael	Regional Administrator	National Marine Fisheries Service
Tuxbury, Susan	Fishery Biologist/Wind Coordinator	National Marine Fisheries Service
Reid, Cristi	NMFS National (Acting) and Headquarters NEPA Coordinator, Office of Policy	National Marine Fisheries Service
Dillon, Kevin	Clean Energy Specialist	New Jersey Board of Public Utilities

Name	Title	Agency
Lawrence, Kira	Senior Policy Advisor	New Jersey Board of Public Utilities
Semel, Hilary	Director and General Counsel	New York City Mayor's Office of Environmental Coordination
Gaidasz, Karen	Project Manager	New York State Department of Environmental Conservation
Hepner, Tyler	Attorney	New York State Department of Environmental Conservation
Haight, Terra	Ocean & Lakes Policy Analyst	New York State Department of State
McLean, Laura	Ocean and Lakes Policy Analyst	New York State Department of State
Bendremer, Jeffrey	Tribal Historic Preservation Officer	Stockbridge-Munsee Community Band of Mohican Indians
Handell, Naomi	Regulatory Program Manager	U.S. Army Corps of Engineers
Pritts, Jared	NEPA Subject Matter Expert	U.S. Army Corps of Engineers
Creelman, Matthew	Marine Transportation Specialist, District 5	U.S. Coast Guard
Desautels, Michele	Maritime Energy and Marine Planning	U.S. Coast Guard
Sheehy, Jennifer	Navigation Standards Division	U.S. Coast Guard
Austin, Mark	Environmental Engineer	U.S. Environmental Protection Agency
Nyer, Samantha	Physical Scientist	U.S. Environmental Protection Agency
Rosenblatt, Anne	Remedial Project Manager	U.S. Environmental Protection Agency
Ciappi, Michael	Senior Fish and Wildlife Biologist	U.S. Fish and Wildlife Service
Drew, Ian	Field Supervisor - New York Field Office	U.S. Fish and Wildlife Service
Ming, Jaron	Branch Chief, Air and Water Resources, National Wildlife Refuge System	U.S. Fish and Wildlife Service
Papa, Steve	Senior Fish and Wildlife Biologist	U.S. Fish and Wildlife Service
Vail-Muse, Stephanie	Regional Energy Coordinator	U.S. Fish and Wildlife Service

Table M-3. Consultants

Name	Role/Resource Area
ICF	
Baer, Sarah	Land Use and Coastal Infrastructure
Birnbaum, David	Cultural Resources
Brown, Sheri	Scenic and Visual Resources
Cherry, Kenneth	Support Editor
Diller, Elizabeth	Program Director
Ernst, David	Air Quality
Hatfield, Teresa	Navigation and Vessel Traffic
Irvin, Elizabeth	Support Editor

Name	Role/Resource Area
Johnson, David	Project Manager; Bats; Birds; Wetlands
Jost, Rebecca	Other Uses
Larsen, Rick	Wetlands
Lassell, Susan	Cultural Resources and Section 106 Lead
Lundstrom, Kristen	Lead Editor
Mahoney, Elisabeth	Deputy Project Manager; Administrative Record; Other Uses
Mountain-Castro, Jenelle	Publications Specialist
Muntz, Alice	Cultural Resources
Olsen, Karin	Programmatic Tiering, Public Involvement
Piggott, Jennifer	Facilitator and Public Involvement Lead
Powell, Drew	Bats; Birds
Read, Brent	Geographic Information Systems
Stoll, Jean	Cultural Resources
Sullivan, Neil	Senior Advisor
CSA Ocean Sciences Inc.	
Barkaszi, Mary Jo	Marine Mammals; Sea Turtles
Cady, Robert	Quality Assurance/Quality Control (QA/QC)
Cahill, Melanie	CSA Project Manager
Gifford, Kathleen	Water Quality
Hartigan, Kayla	Sea Turtles
Martin, Tony	Finfish, Invertebrates, and Essential Fish Habitat
McMahon, Adrianna	Benthic Resources
Stevens, Tara	Marine Mammals
Tiggelaar, John	Commercial Fisheries and For-Hire Recreational Fishing
Ward, Vanessa	Geographic Information Systems

Appendix N: Distribution List

The Final Programmatic Environmental Impact Statement (PEIS) is available in electronic form for public viewing at https://www.boem.gov/renewable-energy/state-activities/new-york-bight. Hard copies and digital copies of the Final PEIS can be requested by contacting the Bureau of Ocean Energy Management (BOEM), Office of Environmental Programs in Sterling, Virginia at (703) 787-1703. Publication of the Draft PEIS initiated a 45-day comment period where government agencies, Tribal Nations, members of the public, and interested stakeholders could provide comments and input. On February 29, 2024, BOEM announced an extension to the comment period. BOEM accepted comments received or postmarked no later than March 13, 2024, in any of the following ways:

- In hard copy form, delivered by mail, enclosed in an envelope labeled "NY BIGHT PEIS" and addressed to Chief, Division of Environmental Assessment, Office of Environmental Programs, Bureau of Ocean Energy Management, 45600 Woodland Road (VAM-OEP), Sterling, Virginia 20166
- Through the regulations.gov web portal by navigating to https://www.regulations.gov/, searching for docket number "BOEM-2024-0001," and clicking the "Comment" button.
- By attending one of the public meetings at the location and dates listed in the Notice of Availability and providing written or verbal comments.

BOEM used comments received during the public comment period to inform its preparation of the Final PEIS, as appropriate. Notification lists for the PEIS are provided in Tables N-1 through N-4.

N.1 Notification List

Table N-1. Cooperating federal agencies

Agency	Contact
National Oceanic and Atmospheric Administration (NOAA), National Marine Fisheries Service (NMFS)	Michael Pentony, Susan Tuxbury, Julie Crocker, Jaclyn Daly, Cristi Reid, Timothy Cardiasmenos, Keith Hanson, Kendall Brancart
National Park Service (NPS) Region 1	Mary Krueger, Kristin Andel
U.S. Department of the Interior (DOI), Bureau of Safety and Environmental Enforcement (BSEE)	Tamara Arzt, Shannon Martin

O.1 Introduction

On July 15, 2022, the Bureau of Ocean Energy Management (BOEM) published a Notice of Intent (NOI) to prepare the New York Bight (NY Bight) Programmatic Environmental Impact Statement (PEIS), which will analyze potential impacts from wind energy development activities in the NY Bight region. The initial 30-day public comment period opened on July 15, 2022. The period was extended to August 30, 2022. Public input was collected via regulations.gov (docket BOEM-2022-0034). Through October 7, 2022, BOEM received a total of 43 comments, all of which were unique.

The comments came from a variety of stakeholders including federal, State, non-governmental associations, and individual commenters. This report indicates the commenters that made particular arguments, as represented by footnotes following summary statements. The footnotes include the names of individuals and organizations. The footnotes following summary statements provide representative examples of commenters providing particular arguments, and are not meant to be exhaustive of each commenter providing a similar argument.

Public comments were analyzed using the CommentWorks® software product. As a first step, comments submitted to regulations.gov and received via email were downloaded and processed to be imported into CommentWorks. A hierarchical outline was developed to include key issues provided by BOEM staff. Analysts reviewed the comment letters, identifying the substantive excerpts within each submission ("bracketing"), and used the issue outline to associate each excerpt to the issue(s) to which it applies ("coding"). The comments were then summarized by issue as presented in this report. The full text of all public scoping comments received can be viewed online at http://www.regulations.gov by typing "BOEM-2022-0034" in the search field.

Table O-1 lists the commenters.

Table O-1. Index of comment submissions sorted by submission number

NGO = non-governmental organization

O.1.1 General Comments

General comments are discussed in this section.

O.1.1.1 General Support

One commenter expressed general support for the NY Bight offshore wind project and said that the currently available wind turbine generators (12–14+ megawatts [MW]) coupled with decades of European construction and operating experience allows for competitive pricing and strong capacity factors. The commenter added that successful pilot programs in United States waters (Block Island, Dominion) provide additional supportive data and experience.[1]

O.1.1.2 General Opposition

The commenter expressed opposition to the current location and size of the NY Bight project.[2]

O.1.1.3 Other General Topics

One commenter recommended using the United States Environmental Protection Agency's (EPA's) NEPAssist web-based application tool for the project as well as for future projects to facilitate the environmental review process and aid in project planning. The commenter said that NEPAssist is a useful tool for identifying environmental resources in the area and could indicate potential environmental issues at the earliest stage of project development.[3]

[1] T. Barten.
[2] K. Dreher.
[3] EPA.

O.2 Purpose and Need

Comments associated with the Proposed Action's purpose and need are discussed in this section.

O.2.1 Purpose and Need for Action

Approximately 10 commenters provided feedback on the purpose and need for the Proposed Action.

Several commenters listed the threat climate change poses to the natural environment, including fisheries, as a reason for developing offshore wind in the NY Bight area. The commenters further stated that offshore wind would help achieve the Biden Administration's clean energy goals, for example deploying 30 gigawatts (GW) of offshore wind by 2030.[4]

One commenter expressed support for the purpose of the Proposed Action in the PEIS "to identify, analyze, and adopt, as appropriate, issues, degree of potential impacts, and avoidance, minimization, mitigation, and monitoring (AMMM) measures" but expressed concern that the need is framed within the context of reaching various States' goals for offshore wind generation.[5] A commenter said that deferring to Executive Orders as the "purpose and need" for offshore wind development in the Bight, rather than identifying the scientific need for these projects and how they would fulfil it, demonstrates that BOEM's course of action is already foreclosed. The commenter stated that following a course in such a predetermined way violates the National Environmental Policy Act (NEPA). The commenter stated that rather than relying on Executive Order goals to justify the development in question, the PEIS should include a thorough greenhouse gas emissions analysis for the entire life cycle of these projects, especially with respect to how long it would take for the projects to offset the amount of greenhouse gas emissions that would be required to construct, operate, maintain, and decommission them.[6]

One commenter wrote that the PEIS should clearly explain the rationale for a tiered environmental review process for NY Bight offshore wind development and that both the purpose and need along with the scope of the analysis must be clearly stated for a meaningful review process.[7] Another commenter said that the purpose and need of offshore wind is to provide needed power and to reduce greenhouse gas emissions but that this has already been done or is in the process of happening in the United States. The commenter stated that this fact needs recognition in the PEIS.[8]

O.2.2 Regulatory Jurisdiction/Statutory Authority

Three commenters provided feedback on BOEM's regulatory jurisdiction or statutory authority.

---

[4] Atlantic Shores Offshore Wind, LLC; New Jersey Offshore Wind Coalition; Citizens Campaign for the Environment; R. Griffin; Attentive Energy LLC; Community Offshore Wind.
[5] Responsible Offshore Development Alliance.
[6] Clean Ocean Action.
[7] EPA.
[8] J. Binder.

One commenter disagreed with BOEM making the fulfillment of State renewable energy goals the primary goal of NY Bight development. The commenter said that BOEM's current approach is backwards, stating that it subordinates a federal, statutorily authorized process to State legislation. The commenter stated that the Purpose and Need for the Proposed Action should thus be revised.[9] Contrarily, a commenter said that, in the New York State Public Service Law Article VII review, the New York State Department of Public Service (NYSDPS) would be reviewing the proposed facility design for conformity with criteria adopted by the NYSDPS for electromagnetic field (EMF) levels "at right-of-way (ROW) edge."[10] Another commenter generally stated that BOEM has authority to regulate permitting in the outer continental shelf.[11]

O.2.3 Scope of the PEIS

Approximately 10 commenters listed additional factors that should be included in the scope of the PEIS, including:

- State commitments (project labor agreements [PLAs], prevailing wage standards, monitoring of wildlife, etc.), as they are formative to project development.[12]
- Creation of quality, family-sustaining, union jobs throughout the lifetime of the project.[13]
- Expansion of domestic manufacturing along a robust domestic supply chain.[14]
- Delivery of community benefits with attention to stakeholder engagement.[15]
- Protection of wildlife and marine ecosystems by avoiding, minimizing, mitigating, and monitoring impacts over the course of site assessment and project development, including through the utilization of the best available science and data.[16]
- Inclusion of an impact analysis that is comprehensive, transparent, objective, and quantitative, that accounts for uncertainty and addresses data gaps, considers reasonable alternatives and mitigation, assesses cumulative impacts, and requires monitoring and adaptive management.[17]
- Expansion of the PEIS to include the New Jersey Wind Energy Area (WEA), defined by lease areas Outer Continental Shelf (OCS) A–0498, 0532, A–0499, and A-0549.[18] With this expansion of the PEIS, the commenter said that additional mitigation measures should be discussed, including the

[17] National Wildlife Federation et al.
[18] Borough of Beach Haven; Save Long Beach Island, Inc.; Fisheries Survival Fund.

consideration of the project's visible impact on historic properties on Long Beach Island, New Jersey; consideration of the project's impact on the State's coastal zone and its conflicts with the visual resource protection elements of the State's coastal zone management rule; and consideration of the impact of operational turbine noise on fin and humpback whales that frequent the inner part of the project area.[19]

- Expansion of the PEIS to include alternative WEAs.[20]
- Inclusion of substantive programmatic AMMM measures to address issues including the cumulative impacts of construction and operational noise on the migration of the North Atlantic right whale, the cumulative impact of multiple vessel surveys, and the cumulative impact on migratory birds.[21]
- Inclusion of the following items when evaluating impacts on the human environment and on a range of onshore components:[22]
    - The New York State Department of Transportation (NYSDOT) Utility Accommodation Plan.
    - The location of State highway ROW boundaries and road classifications for onshore planning of transmission line siting.
    - Coordination between local, State, and federal partners when transportation planning.
    - Consideration of the siting pathway options for the transmission line location when determining the location of points of interconnection.
    - Acknowledgement of the role of NYSDOT in evaluating transportation as a component of the human environment and involve the New York State transportation real property and engineering experts in all proposals for onshore transmission siting impacting State roads and highways.
    - Adherence to the NYSDOT Standard Specifications when installing utilities within a State highway ROW.
    - Recognition that any proposal to locate a transmission facility within a State highway ROW should minimize impacts on highway use, safety, maintenance, aesthetics, and future highway improvements.
- Consideration of impacts to National Oceanic and Atmospheric Administration (NOAA) trust resources from the full build-out of the six lease areas and a holistic, ecosystem approach to considering AMMM measures to reduce those impacts. This includes fully evaluating interactions among all impact-producing factors and associated responses by marine trust resources,

[19] Save Long Beach Island, Inc.
[20] Save Long Beach Island, Inc.
[21] Save Long Beach Island, Inc.
[22] New York State.

oceanographic and atmospheric processes, and fishing activities across all lease areas within the NY Bight. Specifically, the commenter recommended that the PEIS consider impacts on ocean circulation, citing Department of the Interior guidance. The commenter also added that the PEIS should consider impacts on affected resources and fishery operations at an initial stage and that such consideration will necessitate the development of alternatives to a full build-out of the six lease areas.[23]

- Distinguishing carefully and realistically at the PEIS level between impacts that are “moderate to major” (for which project-specific analysis is required), and those that are “negligible to minor” (for which a programmatic analysis may suffice).[24] Addressing the appropriateness and relative importance of the selected scale against which impacts are being assessed, in terms of both temporal and spatial stressors and receptors.[25]
- Consideration of the lease areas being located in one of the prime hurricane zones in the United States[26]

O.2.4 Other Comments on the Purpose and Need for the Proposed Action

Six commenters provided other comments on the purpose and need for the Proposed Action.

One commenter generally expressed support for the goals and intent of the PEIS process.[27] Another commenter encouraged BOEM to prepare supporting documentation and studies that could quantify the monetary value of cleaner energy sources, good-paying jobs, and historic investments in American energy-supply chains, as well as account for losses that result without full utilization of the lease area in question. The commenter recommended that BOEM incorporate this information into the Purpose and Need of the PEIS.[28]

A commenter expressed concern that BOEM has no intent to disapprove a project or part of a project if its Purpose and Need is to fulfill a developer’s power purchase agreement with a utility or to fulfill the nameplate capacity of a project as submitted in the Construction and Operations Plan (COP). The commenter further stated that BOEM must rescind its recent NEPA standardization and conform its process, including the NY Bight PEIS process, to a full consideration of alternatives, including those that might not meet a developer’s proposed nameplate capacity or speculative power purchase agreement.[29] Another commenter said that the PEIS should provide a detailed discussion on the goals of the six NY Bight lessees and the renewable energy goals of New York and New Jersey that the six lease areas are designed to serve. The commenter remarked that the applicants’ goals form the basis (along with other

[29] Seafreeze Shoreside, Seafreeze Ltd.

factors) for BOEM's Purpose and Need for the Proposed Action and are used as screening criteria for alternatives to be analyzed in detail in a project-specific Environmental Impact Statement (EIS).[30]

One commenter said that BOEM must evaluate the tradeoffs associated with various levels of power generation against the economic and cultural importance of regional fisheries in this PEIS. Pursuing too narrow an analytical approach in this PEIS, the commenter wrote, would predetermine all project parameters and limit the range of possible mitigation measures when a project-specific EIS is conducted, thus resulting in many otherwise appropriate mitigation measures being excluded from consideration at any point in the process.[31] Regarding BOEM's *Process for Identifying Alternatives for Environmental Reviews of Offshore Wind COPs pursuant to the National Environmental Policy Act NEPA*, published in June of 2022, a commenter expressed concern that BOEM changed the wording of a document that would be the basis for the purpose and need for an EIS for any COP.[32]

O.3 Proposed Action and Alternatives

Comments associated with the overall Proposed Action and its alternatives are discussed in this section below.

O.3.1 Proposed Action's Adoption of AMMM Measures for the NY Bight Lease Areas

Approximately 20 commenters listed AMMM measures that they said should be adopted or considered for the NY Bight lease areas, such as:

- Those that incorporate ecological design elements, such as the use of recycled or "environmental concrete," into offshore wind infrastructure as they significantly increase species settlement, richness, and abundance.[33]
- Those that minimize impacts on benthic habitats, pelagic habitats, and fisheries. The commenter stated that benthic habitat impact minimization should remove high value habitat areas, identified by surveys and mapping areas from consideration of development; that pelagic habitat impact minimization analyze an alternative that would consider the impact of the full build-out development along with other proposed offshore wind development in the region on pelagic habitats in the NY Bight, including the Mid-Atlantic Cold Pool; and that fisheries impact minimization should consider consistent wind turbine generator spacing across lease areas to increase the likelihood that fishing can still occur. Also listed were those that coordinate and consolidate routes for export cables, that ensure all export cable routes for interconnections with the grid avoid crossing through estuaries and embayments, that consider all feasible avoidance and minimization measures in the project design and incorporate all available AMMM measures as mandatory

[30] Invenergy Wind Offshore LLC.
[31] Responsible Offshore Development Alliance.
[32] Long Island Commercial Fishing Association.
[33] ECOncrete.

conditions of COP approval, or that incorporate no avoidance and minimization alternatives or AMMM measures.[34]

- Those that primarily avoid negative impacts on valuable fisheries, as opposed to a reliance on mitigation techniques to be employed after lease development.[35]

- Those that first address different options for full build-out and that incorporate up-front avoidance and minimization approaches (e.g., high value habitat that should be avoided). The commenter recommended that these alternatives consider a range of AMMM measures that provide minimal to maximum feasible protection. Further, thorough evaluations of available data on existing resources could help facilitate optimal project design that avoids and minimizes impacts on trust resources throughout the NY Bight while also achieving energy generation goals. The commenter also recommended that the PEIS' Proposed Action be described as the "*full build out* of all six lease areas while incorporating AMMMs" and that mitigation measures be evaluated for their efficacy under each alternative considered by the PEIS.[36]

- Those that create measurable criteria for excluding areas from development when the risk to the physical and human environment exceeds acceptable thresholds, and apply those on regional and project-specific bases in the NY Bight and all regions.[37]

- Those that are technically and commercially feasible, and thus reasonable under NEPA, cautioning that combined AMMM measures should be examined for whether they would cumulatively threaten the viability of projects.[38]

- Those that assess the impacts of project design ranges for each lease area. Further, BOEM should apply this approach for all impact assessments to ensure that the PEIS assessments and AMMM measures capture the reality of the wide range of scenarios.[39]

- Those that include the mitigation considerations identified in BOEM's draft Fisheries Mitigation Guidelines in the PEIS, especially those mitigation guidelines set forth in subparts B (Project Siting, Design, Navigation, and Access) and D (Environmental Monitoring) of the Fisheries Mitigation Guidelines.[40]

- Those that consider larger turbine sizes to reduce windfarm footprints, that complement offshore wind structures with nature inclusive designs to further enhance the artificial reef effect, that

[34] National Marine Fisheries Services.

[37] Responsible Offshore Development Alliance.
[38] Vineyard Offshore LLC.
[39] OW Ocean Winds East, LLC.
[40] Fisheries Survival Fund.

ensure the ability of recreational anglers to fish within turbine arrays, and that standardize environmental monitoring across projects.[41]

- Those that incorporate the needs and decision-making of cooperating agencies, that evaluate the effect and effectiveness of programmatic AMMM measures, and that reflect the best available scientific and technological information.[42]
- Those that require an adaptive management plan, whereby if environmental impacts are substantially different than anticipated, operational modifications could be evaluated and executed.[43]

One commenter said that BOEM should refrain from adopting any AMMM measures through this programmatic approach that would jeopardize the Country's ability to address the climate crisis. The commenter suggested that BOEM adhere to its new NEPA alternatives screening criteria in developing the AMMM measures, and recommended that each AMMM measure be technically and economically practical and not undermine any project's future specific purpose and need statements. In particular, the commenter cited a BOEM provision on the prevention of waste and stated that alternatives and AMMM measures should be evaluated based on whether and to what extent they would have foreseeable impacts on the energy generation potential of an offshore wind lease. Furthermore, the commenter stated that BOEM's alternative analysis should exclude project design alternatives and instead focus on the implementation of AMMM measures.[44] A commenter remarked that in order to determine if the subsequent site-specific COPs would have greater, equal, or fewer impacts than those analyzed in the PEIS, it is important that the programmatic AMMM measures provide a metric that allows for a comparison of a project that employs the best practice AMMM measures (lowest impact) and the No Action Alternative (highest impact).[45] Another commenter recommended redefining the Proposed Action to include the development of the lease areas with no AMMM measures and include the implementation of different AMMM measures in other alternatives.[46]

Regarding AMMM measures, one commenter stated that BOEM should focus primarily on moderate or major impacts in individual COPs instead of duplicating analyses in areas that have been determined to cause only minor impacts or no impacts in the EIS.[47] A commenter said that each AMMM measure should be analyzed separately, as individually defined alternatives or sub-alternatives, as well as cumulatively. The commenter wrote that this would allow the public to better understand the impact each measure has on mitigation, particularly if individual projects propose using only a subset of the measures in a COP. Further, the commenter remarked that development of the AMMM measures from the PEIS should serve as a baseline for the minimal level of mitigation expected by a lessee for any

[41] American Saltwater Guides Association.
[42] Invenergy Wind Offshore LLC.
[43] New York State.
[44] American Clean Power Association.
[45] National Wildlife Federation et al.
[46] EPA.
[47] Citizens Campaign for the Environment.

project. Merely adopting the programmatic measures is not expected to be sufficient to remedy the impacts from offshore wind development and should not be viewed as a cap for any mitigation measure, regardless of the scale of the impact: negligible, minor, moderate, or major. The commenter added that a future PEIS should be provided prior to lease auctioning because of the importance of siting to environmental impacts and that future, project-specific alternative analyses should be conducted in EISs rather than environmental assessments. The commenter also expressed disappointment that the PEIS did not include Empire Wind, Atlantic Shores, and Ocean Wind projects; the commenter stated that these projects are in the immediate region and that they should include programmatic AMMM measures similar to any adopted for the NY Bight because of common cumulative impacts.[48]

One commenter stated that BOEM's AMMM analysis should be sufficiently flexible as to avoid foreclosing the use of AMMM measures that may evolve after the PEIS analysis is complete but prior to project implementation, and that would also achieve the same or lesser level and type of impacts. The commenter requested that BOEM ensure that, through consultation with the lessees, the AMMM measures evaluated will be both technically and economically feasible.[49]

A commenter remarked that BOEM should provide clarity in the PEIS on how it would determine whether a particular programmatic AMMM measure applies to a given NY Bight project. The commenter also recommended that BOEM identify required mitigation outcomes and representative examples of approaches that could serve to mitigate project impacts, without mandating specific technologies as programmatic AMMM measures.[50] One commenter expressed concern that BOEM would adopt the current Draft Fisheries Mitigation Guidance document as an AMMM measure in the upcoming NY Bight PEIS as a way to downgrade major fisheries impacts. The commenter stated that this guidance document is procedurally and substantively deficient and referred to its comment on the Draft Fisheries Mitigation Guidance document for further detail.[51] A commenter recommended that BOEM use this PEIS to adopt AMMM measures based on the forthcoming final Guidance for Mitigating Impacts of Offshore Wind Energy Projects on Commercial and Recreational Fisheries.[52] Another commenter expressed concern that the Draft Guidance emphasizes compensation too heavily and that AMMM measures for the NY Bight should be analyzed individually in order to prioritize avoidance of impacts.[53]

O.3.2 Comments on Reasonable Alternatives

Seven commenters recommended alternatives for BOEM or developers to consider or implement in offshore wind development in the NY Bight area, including:

- Alternatives for Manufacturing, Staging, and Assembly

48 Responsible Offshore Development Alliance.
49 Community Offshore Wind.
50 Attentive Energy LLC.
51 Seafreeze Shoreside, Seafreeze Ltd.
52 New England and Mid-Atlantic Fishery Management Councils.
53 Responsible Offshore Development Alliance.

  - Evaluate available alternatives for staging and assembly of offshore wind components including utilizing jack-up barges and platforms in the NY Bight.[54]

- Alternatives for Appurtenant Structures
  - Identify scenarios for co-locating with offshore infrastructure such as existing and future transmission infrastructure, telecommunications, and battery storage projects.[55]

- Alternative Submarine Cable Configurations
  - Evaluate co-locating submarine cables to minimize impacts on sensitive environmental resources, including but not limited to, complex benthic habitats, saltmarshes, and submerged aquatic vegetation (SAV).[56]

- Alternative Turbine Layouts
  - Evaluate a range of turbine layout scenarios to ensure sufficient energy generation and promote co-existence with fishing industries.[57]

- Alternative Habitat Impact Minimization Measures
  - Include a conceptual habitat impact minimization alternative to avoid highly sensitive and significant habitat types and possibly avoidance areas.[58]

- Alternative Construction Methodologies
  - Evaluate alternative offshore installation methodologies that allow simultaneous trenching and cable lay to minimize impacts on water quality and benthic habitat.[59]

- Locating the project in the Hudson South Call Area, which is 30 to 57 miles offshore, where turbines would not be visible.[60]

- Land based alternatives, which the commenter characterized as the most rapid and efficient efforts to achieve energy efficiency, resource conservation, and global warming mitigation, and to prevent the Jersey Shore ocean from becoming a “dumping ground.”[61]

One commenter said that an alternatives analysis must consider a pilot project. The commenter stated that a small, local pilot project that uses the proposed technology and could be robustly evaluated

[60] K. Dreher.
[61] Borough of Seaside Park.

before, during, and after construction is the only way to address shortcomings in the project (e.g., a need for quantitative and qualitative scientific observation, logistical planning, clearance of military hazards) and begin the path toward responsible development of offshore wind energy in the NY Bight waters through a process that reflects fair, responsible, and good governance. The commenter stated that research on the impacts of wind development in regions other than the NY Bight should not be relied upon because of the unique characteristics of the NY Bight. The commenter provided descriptions of conditions in other wind development regions that differ from those of the NY Bight, stating that postponing development in the NY Bight would allow more time to recover unexploded munitions and mustard gas.[62] Similarly, another commenter said that a limited test project alternative must be considered. A test project would facilitate gathering information on benefits and impacts before a large project is implemented.[63]

A commenter requested that BOEM apply the screening criteria for the alternatives described in its 2022 "Process for Identifying Alternatives for Environmental Reviews of Offshore Wind Construction and Operation Plans pursuant to the National Environmental Policy Act (NEPA)" guidance in determining the reasonable range of alternatives for the PEIS. The commenter stated that by defining a reasonable approach to the alternatives analysis, the PEIS could appropriately reflect BOEM's extensive process of analyzing and leasing the WEA, preserve the goals of the applicants who have secured leases based on investment-backed expectation of wind energy output, and identify proposed and alternative AMMM measures that adequately address environmental impacts.[64]

One commenter said that the PEIS should acknowledge and consider the considerable pre-auction reduction in the NY Bight WEAs, given that prior reduction of any alternatives that further significantly reduce site utilization would both be unnecessary and run counter to federal and State clean energy goals. The commenter stated that PEIS alternatives should maximize site utilization in order to preserve project viability and added that BOEM should seek buy-in from other agencies to minimize environmental review work to be conducted after the PEIS stage.[65]

O.3.3 Comments on No Action Alternative

Five commenters provided feedback on the No Action Alternative.

One commenter recommended that BOEM implement the No Action Alternative until all relevant and essential scientific information has been accumulated, thoroughly reviewed, and disseminated to the public.[66]

A commenter said that BOEM's No Action Alternative should acknowledge the unsettling effects of a project denial on cumulative economic benefits due to disruption in supply chain investments.[67] Another

[62] Clean Ocean Action.
[63] J. Binder.
[64] Invenergy Wind Offshore LLC.
[65] OW Ocean Winds East, LLC.
[66] Borough of Seaside Park.
[67] American Clean Power Association.

commenter stated that a robust analysis of the benefits of clean energy should be included in all alternatives and be compared to the impacts (air quality, water quality, etc.) that would flow from fossil fuel use inherent in the No Action Alternative.[68]

One commenter remarked that the No Action Alternative is supposed to serve as a comparative tool for the Proposed Action, but currently allows for little understanding of efficacy of the AMMM measures of the Proposed Action. The commenter recommended redefining the Proposed Action to include the development of the lease areas with no AMMM measures and include the implementation of different AMMM measures in other alternatives.[69] Another commenter said that the PEIS must provide a comprehensive, transparent, and fair analysis of the potential risks and impacts associated with offshore wind energy development activities in the New York and New Jersey Bight, and thus, from the outset, should include an alternatives analysis that contains both a pilot project and a true No Action Alternative.[70]

O.4 Resource and Stressor Topics

Comments associated with individual resources and impacts are discussed this section.

O.4.1 Air Quality

Five commenters provided feedback on air quality issues.

A couple of commenters recommended that the PEIS include National Ambient Air Quality Standards (NAAQS) to better understand the level of air pollutants impacts of wind energy development.[71] Similarly, a few commenters asked that the PEIS consider the impacts of "construction, operation & maintenance, and decommissioning" of wind energy projects on air quality and that these impacts be extensively reviewed as part of the PEIS.[72]

One commenter recommended that preparation of the PEIS include consultation with the EPA and the New York State Department of Environmental Conservation (NYSDEC) in order to include the most accurate information about air quality impacts. The same commenter asked that the environmental impact assessment include an evaluation of changes to air circulation from wind turbines and that the PEIS describe its compliance with federal and State emissions and air quality regulations. They also listed a number of air emission controls for BOEM to consider, including parts per million (ppm) restrictions on diesel generators, ppm restrictions on vessel fuels, and vessel and boiler standards.[73]

Another commenter recommended that the PEIS consider sources of pollution that would impact air quality or violate federal or State ambient air quality standards. The same commenter asked that the

[68] OW Ocean Winds East, LLC.
[69] EPA.
[70] Clean Ocean Action.
[71] New York State; EPA.
[72] Borough of Seaside Park; New York State; EPA.
[73] New York State.

PEIS include options that "explore diesel controls, cleaner fuel and construction practices" or other technology that reduces emissions from wind energy development.[74]

One commenter asserted that BOEM should focus its analysis of the climate benefits of offshore wind development and stated that the benefits from substituting clean energy for fossil fuel generation apply to BOEM's air quality analyses.[75]

O.4.2 Areas of Special Concern

Five commenters provided feedback on areas of special concern.

A couple of commenters discussed a proposal to designate the Hudson Canyon a National Marine Sanctuary. Specifically, one commenter asserted that BOEM should prepare for the impacts of such a designation, especially with possible changes to vessel traffic and fishing activity in the surrounding areas, and account for such changes in the PEIS.[76] Another commenter mentioned the ongoing process of designation and urged BOEM to work with the NOAA, New York and New Jersey, and Tribal Nations to "identify boundaries that avoid overlap with existing wind leases."[77]

One commenter asked that BOEM enforce restrictions on construction and operations of wind energy development on certain areas where migration, spawning events, and other marine processes take place at certain times of the year. The same commenter also asked that BOEM "implement the precautionary principle" for areas of sensitive habitat, spawning areas, and access management areas for fisheries.[78]

One commenter asserted that the PEIS should account for and investigate the impacts on waterways and coastal habitats caused by all stages of wind energy development and went on to cite a number of areas of particular importance, including estuaries in New York and New Jersey and a few Research Reserves.[79]

One commenter discussed both the Holgate Wildlife Refuge and the Forsythe National Wildlife Refuge as areas of particular importance to bird species and criticized the lack of studies on the impact of the proposed project on such refuges.[80]

O.4.3 Avoidance, Minimization, Mitigation, and Monitoring (AMMM) Measures (Including Stipulations)

Approximately 10 commenters offered both general and issue-specific comments on AMMM measures.

---

[74] EPA.
[75] American Clean Power Association.
[76] Fisheries Survival Fund.
[77] New Jersey Offshore Wind Coalition.
[78] Responsible Offshore Development Alliance.
[79] Clean Ocean Action.
[80] K. Dreher.

O.4.3.1 General

A couple of commenters urged BOEM to adopt an "adaptive management" framework or process for AMMM measures in order to ensure that these measures can account for technology and information changes.[81] One of the commenters asserted that BOEM should use a "step-wise" approach that considers avoidance of impacts before mitigation and, at last resort, compensation. In the event that compensation is necessary, the commenter recommended that compensation be implemented on a regional scale in order to allow for in-kind and onsite measures to be considered for difficult-to-replace resources. The commenter cited its own guidance as further indicating that offsetting mitigation provisions should be generous to allow for uncertainty in the mitigation's efficacy.[82]

A few commenters debated whether AMMM measures might be more effective on a regional instead of a project-specific level: one commenter stated that BOEM could evaluate at which scale AMMM measures would be more effective,[83] another asserted that compensatory mitigation should be implemented on a regional scale,[84] and another asserted that conducting evaluations of the effectiveness of different AMMM measures could be done on a "project-specific basis."[85]

One commenter encouraged BOEM to support environmental monitoring plans in coordination with federal, State, and industry partners and require data from those plans to be made publicly available.[86] Another commenter asserted that offshore wind should be developed in a manner that is environmentally responsible, mitigates impacts on wildlife, engages involved stakeholders, and continuously monitors impacts on habitats and ocean wildlife.[87] Yet another commenter asserted that AMMM measures will in turn inform COP risk mitigation for addressing important environmental and economic issues during offshore wind development.[88]

A commenter discussed BOEM's intent to focus on impacts from "representative projects" rather than speculation of potential impacts, asserting that this process is a better way to identify AMMM measures.[89]

A commenter listed a number of guidelines for what they believe AMMM measures should look like, such as:

- AMMM measures should be "methodologies, not mandates."
- AMMM measures should be grounded in best available science and best practices informed by developer collaboration and through State and regional initiatives.

[81] National Marine Fisheries Services; The Nature Conservancy.
[82] National Marine Fisheries Services.
[83] New York State.
[84] National Marine Fisheries Services.
[85] Community Offshore Wind.
[86] Responsible Offshore Development Alliance.
[87] Bluegreen Alliance.
[88] Aspen Institute.
[89] The Nature Conservancy.

- AMMM measures should attempt to support appropriate alternatives and address identified risks, effects, and impacts.
- AMMM measures should attempt to balance efficacy, intent, and safety.

The commenter encouraged BOEM to coordinate with different agencies to design AMMM measures.[90]

One commenter urged BOEM to use the PEIS to "assess the efficacy of AMMMs" and identify other appropriate AMMM measures.[91]

One commenter recommended that BOEM use the PEIS scoping process to inform their mitigation approach, and stated that monitoring and mitigation activities may occur outside of the lease area, especially for species that are highly mobile.[92] Another commenter urged BOEM to require further monitoring for areas in which data is sparse.[93]

O.4.3.2 Issue-Specific

A few commenters discussed AMMM measures specific to construction and operational impacts:

- A commenter encouraged the development of standards regarding foundation design and cable installation to ensure that impacts on protected species are minimized. They also asked that standards for night and low-visibility construction and protocols for coordination between project activities designed to avoid the generation of sound fields and other construction and operational impacts be required, schedules for construction and drilling be adapted to avoid impacts on migratory and time of year dependent species, and that "third-party protected species observers" be required to help implement mitigation and monitoring measures.[94]
- The same commenter also encouraged several monitoring measures related to construction and operation of wind energy development, including monitoring impacts of noise levels during construction, operation, and maintenance; impacts of the physical presence of turbines; and displacement of and changes to fishing activity around the lease areas, among others. They also urged consideration of multiple project designs that can better minimize impacts on important resources, such as changes to foundations and cable burying procedures, and recommended that BOEM develop standards for determining when foundation designs that do not rely on pile-driving would be appropriate. Additionally, the commenter recommended that BOEM require routine clean ups of ghost gear and other debris around foundations[95]
- A commenter referenced the "Fisheries Mitigation Guidelines" as a resource to consider for the impacts of wind energy development on the commercial fishing industry. They asserted that AMMM

[90] Atlantic Shores Offshore Wind, LLC.
[91] National Marine Fisheries Services.
[92] The Nature Conservancy.
[93] New Jersey Offshore Wind Coalition.
[94] National Marine Fisheries Services.
[95] National Marine Fisheries Services.

measures should implement standards that integrate closely with these guidelines, such as incorporating design elements that maximize fishery access, reducing space-use conflicts through infrastructure planning, coordination of cable routes and turbine layouts, and other consistent and standardized measures.[96]

- One commenter expressed concern about project development–based cumulative impacts on different species, such as light, noise, and EMF disruptions and recommended that BOEM and other agencies develop monitoring plans in addition to AMMM measures in order to better track such disruptions.[97]

- Another commenter urged close consideration of site design and layout in order to avoid and mitigate impacts on fishing, benthic resources, and more. They also encouraged time of year/day restrictions on construction in order to protect certain species and asked that Horizontal Directional Drilling (HDD) installation methods be reviewed.[98]

- Another commenter urged BOEM to consider changes to offshore wind layout and design as a way of mitigating overlaps with the fishing community. They also listed a number of key measures for fisheries mitigation for BOEM's consideration, such as monitoring fisheries impacts for the life of projects; assessing cumulative impacts of offshore wind on whales and other protected resources through all project phases; conducting species-specific studies for fish stocks that may experience unique impacts; and analyzing impacts of impingement and entrainment, increased water temperature, and larval and juvenile fish mortality.[99]

- A commenter suggested that BOEM include accidental releases and spill mitigation measures and a Spill Prevention, Containment and Countermeasure Plan in the PEIS and urged BOEM to consider spills and accidental releases as long-term issue.[100]

A couple of commenters offered AMMM measures specific to the presence of turbines and cables, including vessel strike risks, entanglement concerns, and more:

- One commenter expressed concern about the increased risk of vessel strike from offshore wind development and asserted that reducing all vessel speeds to 10 knots or less could be an effective and even vital mitigation technique for BOEM to consider.[101]

- The same commenter also discussed turbine collision risks for birds and bats and listed some AMMM measures for preventing and mitigating those risks, such as installing collision detection

[96] Fisheries Survival Fund.
[97] National Park Service.
[98] New York State.
[99] Responsible Offshore Development Alliance.
[100] EPA.
[101] National Wildlife Federation et al.

capabilities in turbines, setting turbine height limits, and committing to monitoring collisions to inform how best to avoid them in the future.

- They recommended that BOEM adopt a number of measures to monitor for and mitigate entanglement with turbines and their foundations, including constant monitoring of strain on mooring lines and cables and visual inspection of turbine platforms and cables.

- They also offered some AMMM measures for avoiding the negative impacts of offshore wind cables, including using "jet plow" technology for installation, requiring cable burial during some seasons, avoiding open loop cooling systems due to their negative impact on marine life, and working with fishery managers to better understand adverse impacts on marine life from turbine cables.[102]

- A commenter asserted that BOEM should "avoid routing export cables through estuaries and embayments" due to their being a home for many sensitive habitats and resources. They also listed a number of minimization and mitigation techniques as they apply to cables, including using cable export corridors that avoid important resources, identifying areas that would allow for full cable burial without scour protection, and considering many different project designs that might best minimize the negative impacts of cables.[103]

A couple of commenters discussed AMMM measures for protecting certain species and their habitats:

- A commenter asserted that standards for protected species monitoring should be adopted. They also stated that protocols for addressing unexploded ordnances should be implemented with a focus on avoiding or mitigating exposure to protected species and habitats.[104]

- The same commenter asserted that "compensatory mitigation" should be a requirement for any unavoidable impacts on protected species and their habitats, and that lessees should contribute to this strategy. They also discussed a number of measures for monitoring impacts on important species and habitats, including assessing changes to the seafloor; continuous Passive Acoustic Monitoring (PAM) of marine mammals, turtles, and fish; regular oceanographic sampling; and monitoring efforts through the Regional Wildlife Science Collaborative for Offshore Wind (RWSC).[105]

- One commenter asked that BOEM conduct studies specific to species that might experience unique impacts, especially those deemed protected species like whales.[106]

O.4.4 Bats

Two commenters provided comments on issues in the NY Bight PEIS related to bats.

---

[102] National Wildlife Federation et al.
[103] National Marine Fisheries Services.
[104] National Marine Fisheries Services.
[105] National Marine Fisheries Services.
[106] Responsible Offshore Development Alliance.

One commenter expressed concerns about behavioral and physiological impacts on bats from offshore wind turbines and asked that the PEIS identify distribution and migration routes, and sonar and echolocation practices. The commenter also recommended that the PEIS examine the Block Island Wind Farm acoustic surveys to better understand the impact of offshore wind construction on bats.[107]

One commenter listed several species of bats found at areas relevant to the NY Bight PEIS, including Gateway and Fire Island National Seashore.[108]

O.4.5 Benthic Resources

Five commenters provided feedback on issues in the NY Bight PEIS related to benthic resources.

A few commenters generally discussed impacts on benthic resources from offshore wind construction and development, including degradation of the seabed, disruptions to the benthic ecosystem, adverse effects on sediment biogeochemistry, and general energy emission impacts, such as those from noise, vibration, and EMFs.[109] One commenter expressed concern about offshore wind development changing how fish species utilize soft-bottomed and nearshore benthic habitat.[110]

One commenter asserted that the PEIS must include a thorough analysis of the impacts of offshore wind development on benthic resources in the area, in part because information about short- and long-term impacts is currently lacking.[111] Another commenter discussed benthic environments around Gateway and Fire Island National Seashore and criticized the fact that the "issue of potential landfall locations for power cables" is not currently addressed in the NOI, and urged BOEM to address it in the PEIS.[112]

A commenter encouraged BOEM to identify benthic resources like important areas for deep water corals as well as existing benthic and shellfish resources. They asked that the PEIS evaluate impacts from excavation and sediment dispersal, as well as disturbance that might be caused by construction and other maintenance activities. They also urged the PEIS to "quantify cable and scour protection disturbance areas," evaluate construction monitoring, and generally minimize impacts on benthic habitat. The commenter also recommended that BOEM include "nature-inclusive designs," such as using material alternatives to concrete mattresses.[113]

One commenter asserted that a growing body of research points toward the benthic effects of offshore wind and asked that the PEIS thoroughly consider such impacts.[114]

[110] National Wildlife Federation et al.
[111] Clean Ocean Action.
[112] National Park Service.
[113] New York State.
[114] Fisheries Survival Fund.

O.4.6 Birds

Nine commenters provided feedback on issues in the NY Bight PEIS related to birds.

O.4.6.1 Comments on Species

Some commenters generally discussed the abundance of birds in and around the NY Bight area, including but not limited to species of plovers, terns, gulls, shorebirds, waterfowl, hawks, egret, sandpiper, ducks, owls, skimmers, osprey, and more, many of which are considered endangered or threatened.[115] One commenter asserted that there are over 400 different species of birds in New Jersey and 503 species in New York,[116] while another commenter stated that around 333 avian species have been found in the Fire Island National Seashore area and around 326 species have been found in the Jamaica Bay Wildlife Refuge.[117]

A few commenters specifically mentioned the presence of the threatened Piping Plover in the NY Bight area, expressing concern about the effects of wind energy development on that species' survival and wellbeing.[118] One commenter specifically asked that the piping plover receive a review under the Endangered Species Act (ESA).[119] Another commenter stated the importance of the Holgate and Forsythe Wildlife Refuges to the Piping Plover and criticized studies for not showing how the proposed project would affect these refuges.[120]

O.4.6.2 Impacts on Birds

A few commenters expressed general concern for negative impacts on birds, especially migratory species, from wind energy development in the NY Bight area. One commenter asserted that the geographic location and important water resources of the Raritan and Sandy Hook Bays make those areas an important "migratory staging area" for birds on the Atlantic Flyway. The same commenter added that habitats in the Fire Island National Seashore and Jamaica Bay are important resting and feeding areas for migratory birds, especially the Piping Plover. [121] A couple of commenters asked that cumulative impacts on bird wildlife and their habitats from wind energy development be reviewed and investigated in the PEIS.[122]

A few commenters expressed concern about mortality risks to birds from collision with turbine blades, disorientation and displacement risk from the lighting of turbines and wind energy stations, and noise disruption from turbines and their blades/general operation.[123] One commenter asserted that the PEIS

---

[121] National Park Service.
[122] Borough of Seaside Park; National Wildlife Federation et al.
[123] Clean Ocean Action; New York State; Save Long Beach Island, Inc.

must identify and review these numerous impacts on birds, as well as identify ways to mitigate and minimize those impacts to the greatest extent possible.[124] Another commenter asked that BOEM consider information from the Block Island Wind Farm post-construction surveys in order to better assess impacts on bird species from wind energy development.[125] One commenter asked about results from studies regarding the environmental impact on birds from proposed development.[126]

One commenter expressed concern about a number of other wind energy development risks to birds, including upticks in prey resources around the turbines, which could lead to more collisions, potential oil and lubricant spills in the ocean, and destruction of habitat in order to make way for onshore substations and port facilities.[127]

One commenter criticized BOEM's use of a 98 percent turbine avoidance rate, asserting that referenced studies supporting that number are not representative of the scale of the Proposed Action in the NY Bight area and that uses of the 98 percent avoidance rate are not supported well enough. They also urged BOEM to do a current assessment of collision and fatality risks and asserted that such a cumulative risk analysis would require the inclusion of the New Jersey wind area in the PEIS.[128]

One commenter asked that BOEM identify "seasonal distribution, aggregation, abundance and migration routes" for birds in the area, specifying sea duck abundance as an important consideration.[129] Another commenter asked that BOEM generally protect avian species in its development of offshore wind.[130]

O.4.7 Climate Change

Approximately 10 commenters provided feedback on climate change as it relates to the NY Bight PEIS.

Some commenters generally addressed the global threat of climate change and how offshore wind development might fit into the process of combating climate change. Specifically, a couple of commenters asserted that the swift development of offshore wind projects is needed to address the climate crisis/emergency.[131] One commenter asserted that offshore wind development is "a critical strategy…at the State and federal levels" to counteract reliance on fossil fuel generation,[132] while another called it "one significant part of the antidote" for fighting climate change.[133] Another

[124] Clean Ocean Action.
[125] New York State.
[126] Twin Lights Historical Society.
[127] Clean Ocean Action.
[128] Save Long Beach Island, Inc.
[129] New York State.
[130] New York Offshore Wind Alliance.
[131] Atlantic Shores Offshore Wind, LLC; Attentive Energy LLC.
[132] New York Offshore Wind Alliance.
[133] Citizens Campaign for the Environment.

commenter asserted that wind energy installations would need to be quadrupled by 2030 in order to avoid climate change's worst effects.[134]

One commenter addressed climate change impacts specific to New York, including sea level rise and flooding, damages from major storms like Superstorm Sandy, warmer winters and hotter summers, air and ocean pollution from fossil fuels, and the destruction of certain ecosystems and species, like the 90 percent decline of the lobster species from warmer waters.[135]

A few commenters approached the idea of using offshore wind development to combat climate change with more caution. One commenter professed general support for offshore wind development to combat climate change but cautioned against developing these projects without a greater understanding of their impact on Atlantic coast resources and waters elsewhere.[136] One commenter asserted that, due to expanded use of fossil fuels overseas, the Proposed Action is unlikely to have a large impact on climate change, and that this use of fossil fuels should be considered as "part of Foreseeable Impacts" for each of the environmental issues and scenarios analyzed in the Draft PEIS for the Proposed Action and No Action Alternative. The same commenter also asserted that offshore wind may not be the best way to combat climate change and criticized BOEM's "silo" approach of limiting offshore wind as the only future clean energy projects, stating instead that BOEM should consider more clean onshore development projects and include the evaluation of those projects in the PEIS.[137]

One of the commenters that supported more offshore wind projects cautioned that they have a reciprocal relationship to climate change, meaning that they help to mitigate it but are nonetheless affected by it as well. They criticized BOEM's lack of climate change–related information in its evaluation process and urged BOEM to undergo a systematic process for "a holistic understanding science-based understanding of climate change and how offshore wind energy exists within it."[138] Another commenter that professed their support for offshore wind urged BOEM to weigh the environmental benefits to combat climate change with any negative impacts of offshore wind construction.[139]

A couple of commenters asserted that assessments of the climate change benefits from offshore wind should be a key part of the PEIS.[140]

One commenter asked that BOEM assess the Proposed Action's alignment with climate change policies like the Climate Act, consider environmental impacts and habitat changes from the Proposed Action in concert with current and future climate change impacts, and ultimately "evaluate the Net Carbon

[134] R. Griffin.
[135] Citizens Campaign for the Environment.
[136] American Saltwater Guides Association.
[137] J. Binder.
[138] R. Griffin.
[139] Citizens Campaign for the Environment.
[140] OW Ocean Winds East, LLC; American Clean Power Association.

Footprint" of its Proposed Action. They also urged BOEM to evaluate climate mitigation measures that would help reduce possible climate impacts.[141]

One commenter recommended that the PEIS identify and quantify greenhouse gas emissions associated with the Proposed Action, incorporate an energy substitution analysis, include a discussion on how reductions in greenhouse gas emissions would meet climate goals/commitments, and include as part of the NEPA analysis a discussion of foreseeable effects of future climate change on the Proposed Action and its surrounding area. They also requested that BOEM ensure that offshore wind development does not intrude on the achievement of Comprehensive Conservation and Management Plan goals, especially when considering the impacts of climate change.[142]

O.4.8 Coastal Habitat and Fauna

Two commenters provided feedback on coastal habitat and fauna issues related to the NY Bight PEIS.

One commenter asserted that the PEIS should analyze impacts on a number of listed protected species from offshore wind development affecting coastal habitats and fauna, adding that the cumulative impacts are likely to be significant and that any efforts to minimize and mitigate them should be taken. They also stated that the PEIS should discuss impacts on coastal habitat and fauna from the installation, presence, and eventual decommissioning of transmission cables, something that the Draft EIS did not do.[143]

Another commenter asked that the PEIS "identify Best Management Practices" to reduce impacts on vulnerable habitats, especially ones that may shift from the introduction of new structures and cable installation, evaluate the impacts on terrestrial vegetation, and consider "measures to prevent the spread of invasive species." They also asked that the PEIS evaluate impacts on vegetated dune/beach habitats, Coastal Erosion Hazard Areas (CEHA), and New York State (NYS) Significant Coastal Fish and Wildlife Habitats (SCFWF), providing a link to a list of the latter.[144]

O.4.9 Commercial and For-Hire Recreational Fishing

Approximately 15 commenters provided feedback on commercial and for-hire recreational fishing issues related to the NY Bight PEIS.

O.4.9.1 General Impacts

A few commenters addressed the extent to which commercial and recreational fishermen and fisheries operate in and around the NY Bight proposed lease areas and would be affected by the proposed rule. One commenter asserted that the PEIS should account for not only lease areas within NY Bight but also areas leased in the Southern New England area and all the way down to North Carolina, given that

[141] New York State.
[142] EPA.
[143] Clean Ocean Action.
[144] New York State.

commercial fishermen operate all throughout those areas.[145] Another commenter expressed concern about the effect of the construction, operation, and decommissioning of WEAs on Rhode Island commercial and charter fisheries.[146] Similarly, a commenter expressed concern about cumulative impacts on the Massachusetts fishing industry as more offshore wind projects are built on the coast.[147] One commenter asserted that the NY Bight is "one of the most important regions for both commercial and recreational fisheries on the East Coast" and referenced past comments they left on BOEM Calls for Interest and Proposed Sale Notices, asking BOEM to include any and all included fisheries information in the PEIS.[148] One commenter asserted that offshore wind development must "[safeguard] the abundance and diversity of the area's rich fisheries."[149]

One commenter referenced a number of figures showing overlap between the NY Bight leases and important fishing grounds and asked that BOEM consider their "Fisheries Mitigation Guidelines" in the PEIS in order to better develop impact minimization and mitigation standards.[150]

Some commenters echoed this concern about the impact of offshore wind development on the commercial and recreational fishing industries and generally urged BOEM to include an analysis and evaluation of cumulative impacts on fisheries and the fishing industry in its PEIS.[151] Specifically, one commenter recommended that the PEIS characterize the extent of Massachusetts fishing within the NY Bight area and evaluate potential impacts on key fishing species and thus the industry as a whole.[152] Another commenter asked that BOEM develop criteria for identifying "high-value fishing grounds" in order to better evaluate commercial fishing losses from offshore wind build-out.[153]

One commenter criticized BOEM for "deficient" previous actions on fisheries impacts and asserted that a cumulative analysis of impacts should be done on a fishery-by-fishery basis all down the coast, not simply in the NY Bight area.[154]

O.4.9.2 Specific Impacts

A few commenters stressed the importance of assessing cumulative economic impacts on the commercial fishing industry from offshore wind development, given the family-owned, community-dependent basis of many of those industries.[155] The latter commenter also stated the importance of including impacts on the recreational fishing industry, given the interconnected nature of the fishing

[155] Long Island Commercial Fishing Association; Clean Ocean Action; New York State.

economy off the Atlantic coast. They went on to discuss methods of analyzing economic impacts on the fishing industry, asserting that Vessel Monitoring Systems (VMS) and National Marine Fisheries Service (NMFS) data on fishing boat tracking and fish returns could best approximate catch rates and could then be used to track economic impacts of offshore wind development on the fishing industry.[156]

Similarly, one commenter stated that "spatially explicit catch and effort information" is severely lacking for the recreational fishing sector and thus is a data gap the PEIS needs to consider. They referenced survey and data mining work done by the New England Aquarium's Anderson-Cabot Center for Ocean Life as a possible blueprint for gathering future data for the PEIS.[157]

One commenter asked that BOEM "separate the analysis of commercial and recreational fisheries."[158]

One commenter expressed concern about commercial fishing losses as a result of changes in primary productivity from offshore wind development and added that the PEIS should incorporate these impacts into environmental and socioeconomic analysis, as well as the overall cumulative impacts analysis.[159]

One commenter discussed a number of impacts on commercial and recreational fishing, including displacement from typical fishing areas due to offshore wind development, potential gear loss, increased navigation time to avoid offshore wind infrastructure, and general safety concerns, asking BOEM to evaluate all of these potential impacts in the PEIS.[160]

O.4.9.3 AMMM Measures/Compensation

A few commenters generally asked that the PEIS identify AMMM measures for impacts to the commercial and recreational fishing industries.[161]

Another commenter cautioned about conflicts with fishing gear as a result of offshore wind development and stated that cable burial depth should be evaluated as a potential mitigation technique.[162]

One commenter listed a number of mitigation and compensation measures for BOEM's consideration, including measures to offset costs of supporting infrastructure, a standardized process for gear loss claims, and a "full, transparent, equitable, and science-based compensation program." They also recommended the establishment of a federal fisheries working group to manage and produce mitigation

[156] Clean Ocean Action.

[162] New York State.

frameworks.[163] Another commenter added that part of the cumulative analysis should include financial mitigation to fishermen who were not included in the federal review process.[164]

Refer to Section O.4.3, *Avoidance, Minimization, Mitigation, and Monitoring (AMMM) Measures (including stipulations),* for more details on specific AMMM measures.

O.4.9.4 Collaboration

A commenter professed support for a PEIS, asserting that it would help streamline consistency between different offshore wind projects and could allow cumulative impacts to be evaluated early in the process.[165]

One commenter asked that the PEIS outline a fisheries research plan to improve coordination between developers and stakeholders.[166] Another commenter asked that BOEM require developers to “co-develop cooperative monitoring and research plans” with the fishing industry and themselves partner with the fishing industry to provide a centralized “information depository” accessible to fishermen.[167] One commenter encouraged BOEM to continue conversations with the fishing industry about gear adaptations so that they can continue fishing throughout certain times of the year.[168]

O.4.10 Cultural Resources

Four commenters provided feedback on cultural resources issues related to the NY Bight PEIS.

A commenter warned that the anchoring, cabling, and use of chains involved in offshore wind energy development could substantially impact cultural resources in the NY Bight such as submerged shipwrecks. This commenter further recommended that BOEM’s PEIS analyze these resources, the potential impacts of offshore wind development on them, and potential mitigation measures, adding that Indian Tribes should be involved in the identification of cultural resources.[169] Similarly, another commenter suggested that offshore wind development be planned with sensitivity to historic and cultural heritage of northeastern Tribal Nations.[170]

A commenter suggested an alternative to BOEM’s current guidelines for geophysical surveys with respect to potential impacts on marine archeological resources, arguing that allowing lessees to first conduct surveys at wider intervals to identify larger shipwrecks and submerged landscape features, with closer interval surveys to be conducted later within the final project footprint to identify smaller, buried

[167] Responsible Offshore Development Alliance.
[168] New York State.
[169] Clean Ocean Action.
[170] New York Offshore Wind Alliance.

marine cultural resources. The commenter further recommended that BOEM analyze approaches to avoid, minimize, and mitigate impacts on these resources.[171]

A commenter said that there are ongoing conservation initiatives in the NY Bight, including the designation process for the Hudson Canyon National Marine Sanctuary to protect cultural resources.[172]

O.4.11 Cumulative Impacts

Approximately 15 commenters provided feedback on cumulative impacts relevant to the NY Bight PEIS.

O.4.11.1 General Comments on Cumulative Impacts

A commenter warned that the cumulative impacts of offshore wind energy development in the NY Bight would be substantial.[173] Another commenter said that BOEM's PEIS should include a fair and full consideration of potential cumulative impacts of offshore wind development in the NY Bight.[174]

A commenter said that BOEM should ensure that efforts are made to avoid, minimize, and mitigate potential cumulative impacts.[175] Similarly, another commenter recommended that where potential cumulative impacts are identified, BOEM should clarify which parties should be responsible for avoiding, minimizing, and mitigating those impacts.[176]

A commenter argued that by assessing cumulative impacts and mitigation measures, BOEM may be able to identify preferrable alternative actions.[177]

O.4.11.2 Cumulative Impacts on Fisheries and Fishing

A commenter expressed support for BOEM's plan to include a PEIS in its rulemaking process, which the commenter claimed appears to be in response to the fishing industry's requests to better assess the cumulative effects of offshore wind development on fisheries.[178] Similarly, another commenter expressed support for BOEM's proposed programmatic approach, claiming that the need for cumulative impacts analyses has been posited by fishery stakeholders and scientists, and that such an approach facilitates stakeholders, such as for-hire captains and private anglers, sharing their input.[179]

[177] National Wildlife Federation et al.
[178] Responsible Offshore Development Alliance.
[179] American Saltwater Guides Association.

A commenter recommended that BOEM's PEIS articulate how cumulative impacts are considered and incorporated on a project-by-project basis and on an industry-wide scale, identify funding mechanisms and interagency collaborations, and describe mechanisms for mitigating potential fishery collapse.[180]

A couple of commenters recommended that BOEM's PEIS include an analysis of cumulative impacts on fishing operations, such as changes to time and area fished, displaced fishing effort, gear used, stresses on fisheries, and landing ports.[181]

A commenter recommended that BOEM's cumulative analysis assess economic impacts on fishermen from New York who suffered because the State did not file for federal consistency review, as well as include a revamping of NOAA's regional geographic location definition process so that all qualified regional coastal states could automatically qualify if they can prove income from relevant landings. This commenter additionally recommended that the cumulative analysis consider financial mitigation schemes that could be designed for fishermen who were not included during the federal consistency review process.[182]

Multiple commenters recommended that BOEM's cumulative analysis, with respect to impacts on fisheries, be conducted coastwide and fishery-by-fishery and take into account the impacts of existing and foreseeable future offshore wind leases, rather than only on a project-by-project basis.[183] Another commenter echoed this argument and further suggested that in its analysis, BOEM include a description of the potentially impacted resources, current trends regarding the resources, and a discussion of likely future conditions of the resources based on current conditions, trends, and foreseeable projects.[184]

O.4.11.3 Cumulative Impacts on Wildlife

A commenter said that assessing cumulative impacts, through BOEM's PEIS, is essential to understanding the overall impacts of offshore wind development on species and ecosystems, including the effects of noise and the timing of construction.[185]

Multiple commenters recommended that BOEM's PEIS include an analysis of cumulative impacts on endangered species, particularly the effects of noise. [186] Another commenter specified their concern for cumulative impacts on the North Atlantic right whale and key benthic species, claiming that there is insufficient scientific understanding of offshore wind energy development's effects on these species. [187]

[184] Environmental Protection Agency.
[185] National Wildlife Federation et al.
[186] Environmental Protection Agency; Rhode Island Coastal Resources Management Council.
[187] Clean Ocean Action.

A commenter recommended that BOEM's cumulative impacts analysis consider effects on habitats, avian and marine mammal migratory pathways, and other ecological processes.[188]

O.4.11.4 Geophysical and Hydrodynamic Cumulative Impacts

A commenter expressed support for BOEM conducting cumulative impact analyses for the rule, particularly with regard to major oceanographic features such as the Mid-Atlantic Bight Cold Pool, which the commenter claimed is especially important for the regional benthic ecosystem and may be particularly susceptible to changes in hydrodynamics caused by wind farm structures.[189]

A commenter also suggested that the PEIS include an analysis of the potential cumulative impacts on sediment biogeochemistry from the increased volume of fecal pellets from fouling fauna and biomass falling from turbine reef structures, which lead to increases in mineralization activity, sedimentary oxygen consumption, and consequently carbon dioxide levels.[190]

Another commenter recommended that BOEM require permits for geological and geophysical surveys and conduct cumulative analyses for such permits.[191]

O.4.11.5 Other Comments on Cumulative Impacts

A commenter recommended that BOEM's PEIS include an analysis of offshore wind development's potential cumulative impacts on marine commerce.[192]

A commenter recommended that BOEM's PEIS include an analysis of the potential cumulative impacts of noise on residential and commercial buildings near port facilities.[193]

A couple of commenters recommended that BOEM consider increased vessel traffic and consequent navigational hazards in its cumulative impacts analysis.[194]

A commenter warned that offshore wind development would have cumulative adverse visual impacts on historic properties, sites, and districts listed or eligible for listing in the National Register of Historic Places, adding that because of the historic integrity of properties within the project area, and the precedent set by this rulemaking for future offshore wind development, it is important that the PEIS is complete and thorough.[195]

---

[188] New York State.

[192] Environmental Protection Agency.
[193] Environmental Protection Agency.
[194] Rhode Island Coastal Resources Management Council; New York State.
[195] Cape May County, NJ; Point O'Woods Association, Fire Island, NY.

A commenter recommended that BOEM's PEIS identify the temporal and spatial criteria necessary for its regional cumulative analysis.[196]

A commenter argued that BOEM's interpretation and tiering of the NEPA review process, as well as the bifurcation of nearby projects like Ocean Wind, Atlantic Shores, and Empire Wind, has obscured the cumulative impacts of offshore wind development. The commenter further requested clarification of the notice's claim that the PEIS will allow BOEM to address "tiering of project-specific environmental analyses."[197]

A commenter recommended that BOEM's cumulative impacts analysis consider effects on sand mining and planned resilience projects.[198]

Refer to the relevant resource sections throughout this appendix for more expansive summaries of the above topics not relating to cumulative impacts.

O.4.12 Demographics, Employment, and Economics

Approximately 10 commenters provided feedback on demographics, employment, and economics issues related to the NY Bight PEIS.

O.4.12.1 Positive Impacts on Demographics, Employment, and Economics

A commenter claimed that this initiative would help meet the Administration's, New Jersey's, and New York's clean energy goals while creating economic opportunity and tens of thousands of jobs.[199] Similarly, another commenter estimated that the development and construction of 16.5 GW of offshore wind energy off the coasts of New York and New Jersey could directly or indirectly support approximately 50,000 jobs, and that nationally reaching 30 GW by 2030 would create 83,000 jobs. This commenter further argued that BOEM has underestimated the economic benefits of offshore wind development in its past NEPA analyses by focusing on the effects on the local area and not including regional and national supply chain and economic effects, adding that project approvals in a young industry can have ripple growth effects across that industry's supply chain. Finally, the commenter said that to deny the project would have the opposite effect, disrupting supply chain investments in the wind energy industry.[200]

A commenter cited a study to claim that requiring developers to use 100 percent domestic content inputs versus 25 percent domestic content could result in a difference of 30,000–40,000 jobs created from 2023–2030.[201]

---

[196] Clean Ocean Action.
[197] Clean Ocean Action.
[198] New York State.
[199] OW Ocean Winds East, LLC.
[200] American Clean Power Association.
[201] Bluegreen Alliance.

A commenter said that this initiative would help reduce greenhouse gas emissions and create a robust domestic offshore wind manufacturing sector.[202]

O.4.12.2 Negative Impacts on Demographics, Employment, and Economics

A commenter argued that given the size and visibility of the proposed project, it could cause losses of tourism revenue of up to $300 million per year, nearby property value losses ranging from $1 million to $189,000 per home, an approximately 55 percent reduction in area vacation rentals, and job losses in the hospitality sector.[203]

A commenter claimed that based on figures published by the New Jersey Board of Public Utilities, the planned developments would cause electric rates to increase in the State, with residential rates increasing 10 percent, commercial rates 15 percent, and industrial sector rates 18 eighteen, which could cause job losses. This commenter further claimed that many of the jobs the projects would create are temporary and that it is unclear how many would be held by U.S. workers.[204] Similarly, another commenter claimed that wind turbines are largely manufactured outside of the United States, which does not benefit U.S. employment.[205]

O.4.12.3 Recommendations with Respect to Demographics, Employment, and Economics

A commenter recommended that BOEM require developers to report investments in workforce training and supply chain development.[206]

A commenter suggested that BOEM consider changes that have occurred since it issued its Programmatic EIS for Alternative Energy Development in 2007 with respect to the economics of offshore wind, including: the automation of the operation and maintenance of offshore wind energy systems, which reduces potential for job creation; the relative costs of offshore wind energy and other clean energy technologies; and the reliability of wind energy in general.[207]

A commenter recommended that BOEM's PEIS include a socioeconomic impact analysis that considers electric rates and lost tourism and the offsetting benefits in terms of reduced emissions.[208]

A couple of commenters recommended that BOEM consider impacts on regional fisheries, potential lost jobs and income among commercial fishermen and recreational for-hire fishing, and higher costs to the seafood industry in general.[209]

---

[202] New York Offshore Wind Alliance.
[203] K. Dreher.
[204] Save Long Beach Island, Inc.
[205] J. Binder.
[206] Aspen Institute.
[207] J. Binder.
[208] Save Long Beach Island, Inc.
[209] Responsible Offshore Development Alliance; Clean Ocean Action.

A commenter made numerous recommendations with respect to the rule's potential economic effects, including that BOEM:

- Require compensatory mitigation for fishermen for the life of the project and establish adequate reserve funds for that purpose by establishing a compensation program paid into by lessees.
- Honor compensation claims for up to 3 years after income loss, per review by fisheries experts.
- Conduct transparent impact analyses with respect to energy, economics, employment, and greenhouse gas emissions for regions and specific projects.[210]

Another commenter also made numerous recommendations with respect to the rule's potential economic effects, including that BOEM:

- Assess potentially higher costs for offshore wind energy.
- Present comprehensive mitigation and compensatory measures for unavoidable impacts.
- Clearly communicate the costs of development including siting, preconstruction, construction, operations, maintenance, and decommissioning.
- Provide information about cost protections to electricity ratepayers for potentially higher energy costs.[211]

Another commenter also made numerous recommendations with respect to the rule's potential economic effects, including that BOEM:

- Identify potential impacts on shore-based and water-dependent industries and potentially restricted port access due to increased vessel traffic and construction.
- Assess impacts on public services, populations, economy, employment, housing and property values, the reliability of electric facilities, and public safety.
- Evaluate conformity with United States Coast Guard (USCG) Marine Planning Guidelines.[212]

In order to maximize union job creation and comply with NEPA, a commenter recommended that BOEM's PEIS consider and evaluate: domestic content commitments; project labor, labor peace, and community benefits agreements; utilization of registered apprentices; protections against worker misclassification and wage theft; impacts on fisheries, in consultation with industry stakeholders; equitable access to benefits for historically underserved communities; quantity and quality of jobs created; plans to support the growth of a domestic supply chain to maximize U.S. employment; and programs necessary for expanding the domestic workforce with an emphasis on ensuring opportunities

---

[210] Responsible Offshore Development Alliance.
[211] Clean Ocean Action.
[212] New York State.

for displaced energy workers. This commenter further argued that using PLAs can help avoid labor disputes, increase project efficiency, improve safety, and create opportunities for historically marginalized communities.[213]

Refer to Section O.4.9 for additional comments on commercial and for-hire recreational fishing, Section O.4.19 for additional comments on navigation and vessel traffic, and Section O.4.23 for additional comments on recreation and tourism not relating to demographics, employment, and economics.

O.4.13 Environmental Justice

Nine commenters provided feedback on environmental justice issues related to the NY Bight PEIS.

O.4.13.1 Environmental Justice Benefits

A commenter stated that offshore wind development could create environmental justice benefits.[214] Another commenter concurred and specified that these benefits could include reducing the environmental and public health burden of fossil fuel generation on frontline communities.[215]

O.4.13.2 Environmental Justice Concerns

A commenter claimed that the impacts of offshore wind development they foresee, including noise, light pollution, air emissions from vessels, reduced access to coastal areas, loss of wetlands, loss of employment in marine industries, and increased stormwater runoff from new parking lots and roads, would be amplified for environmental justice communities.[216]

A commenter warned that people who live and invest in nearby ocean communities would be negatively impacted by this rule, with the quality of the ocean degrading, European developers earning money at their expense, and local livelihoods declining.[217]

O.4.13.3 Process Recommendations for Achieving Environmental Justice

Several commenters recommended that BOEM consider issues of environmental justice in this rulemaking process.[218] More specifically, a commenter recommended that BOEM incorporate environmental justice concerns raised in New York's Climate Act, consider impacts on disadvantaged communities (DACs) and potential mitigation measures for those impacts, and analyze increased air emissions and other impacts in Potential Environmental Justice Areas.[219] Another commenter recommended that BOEM use EPA's Environmental Justice Screening and Mapping Tool to consider

---

213 Bluegreen Alliance.
214 American Clean Power Association.
215 New York Offshore Wind Alliance.
216 Clean Ocean Action.
217 Wallace & Associates.
218 Mayor John A Peterson, Jr.; OW Ocean Winds East, LLC.
219 New York State.

possible impacts on vulnerable adjacent communities; and noise, air, lighting, and traffic impacts from construction and project operations on populations surrounding facilities.[220]

A commenter claimed that they identified DAC representatives from New York and New Jersey who desired earlier engagement in the present rulemaking process, in addition to increased transparency and accountability. By engaging these stakeholders later in the process, this commenter reasoned, their ability to provide valuable feedback is limited because they have had limited exposure to the process. This commenter further recommended that BOEM hold at least one roundtable with DAC stakeholders during the preparation of the PEIS; use these meetings as opportunities to educate DACs on the leasing process, explain the role of the PEIS in the process, identify key concerns and recommendations from DACs, and help build the capacity of DACs to engage overall; share these meetings' agendas, attendance rosters, and summaries of recommendations; and require developers to track and report percentage of the benefits of investments in workforce training and supply chain development going to DACs, which would facilitate understanding how offshore wind development affects DACs and encourage developers to more intentionally consider how DACs are affected by development. Finally, this commenter suggested that BOEM can find sample guidance for such investment monitoring benchmarks from New York State Energy Research & Development Authority's (NYSERDA) 2022 Offshore Wind Solicitation, under which bidders must present their own monitoring framework and ensure that it is verified by a third party. [221]

A commenter requested that if BOEM believes that the closure or displacement of fossil fuel facilities is beneficial for nearby communities and that this will occur if offshore wind energy is developed in the area, that the PEIS present evidence supporting these positions.[222]

O.4.14 ESA-Listed Species

Five commenters provided feedback on the NY Bight PEIS related to ESA-listed species.

O.4.14.1 Potential Impacts on Endangered Species and Mitigation Measures

A commenter stated that the NY Bight is used by a number of species listed under the ESA, including fish, sea turtles, and marine mammals.[223] This commenter further recommended that BOEM monitor protected species during wind farm construction and analyze and develop approaches to construction that will minimize impacts on protected species, particularly with regard to reducing noise from pile-driving, dealing with unexploded ordinances, managing vessel traffic at night and in low visibility conditions, avoiding construction during sensitive times of the year, requiring practices to minimize entanglement, mandating routine cleanups, and choosing cable installation methods that minimize impacts. The commenter also recommended that BOEM require adherence to best management practices to limit capture, entanglement, injury, and mortality of protected species in biological surveys

[220] Environmental Protection Agency.
[221] Aspen Institute.
[222] Clean Ocean Action.
[223] National Marine Fisheries Services.

and that protected species do not interact with gear such as anchor and buoy lines. Additionally, the commenter recommended that dredging activities be subject to seasonal restrictions based on dredge types and possible risks to listed species.[224]

A commenter warned that increased vessel activity and noise from offshore wind development in the NY Bight would be an existential threat to the endangered North Atlantic right whale, of which the commenter claimed only 336 remain. This commenter further recommended that no construction or other offshore wind activity be allowed in the NY Bight during the whale's most sensitive times of the year, including migration periods.[225] Another commenter similarly expressed concern for the project's potential impacts on North Atlantic right whales, adding that they are a particularly valuable and beautiful species.[226] Refer to Section O.4.18 for additional comments on marine mammals.

A commenter recommended that BOEM evaluate year-round northern long-eared bat activity in the vicinity of the proposed action and potential impacts on the species, including tree clearing during construction.[227]

O.4.14.2 Other Process Recommendations with Respect to Endangered Species

A commenter recommended that BOEM identify surveys for rare, threatened, and endangered species along all considered project routes; assess potential impacts on those species along those routes; and consider avoidance, minimization, and mitigation measures with respect to those potential impacts.[228]

A commenter recommended that BOEM consult with the United States Fish and Wildlife Service (USFWS) on potential impacts on aquatic and terrestrial species, in accordance with Section 7 of the ESA.[229]

O.4.15 Finfish, Invertebrates, and Essential Fish Habitat

Eight commenters provided feedback on finish, invertebrates, and essential fish habitat issues related to the NY Bight PEIS.

A commenter requested that BOEM include a consideration of fish habitats as part of its rulemaking process and warned that effects on them from offshore wind development in the NY Bight could be significant.[230] Another commenter requested information about studies of offshore wind development's

[224] National Marine Fisheries Services.
[225] Clean Ocean Action.
[226] Mayor John A Peterson, Jr.
[227] New York State.
[228] New York State.
[229] Environmental Protection Agency.
[230] Mayor John A Peterson, Jr.

effects on fish.[231] Another commenter argued that not enough data is available to fully understand the effects of offshore wind development on finfish and invertebrates.[232]

A commenter claimed that areas of the NY Bight are designated as essential fish habitat for nearly every life-stage of every species managed by the New England and Mid-Atlantic Fishery Management Councils and NMFS, as well as many managed by the South Atlantic Fishery Management Council.[233]

A commenter recommended that BOEM identify current stock status for different species of fish and invertebrates, as well as migration routes, life history stages, and egg and larval seasonality and abundance. This commenter further recommended that BOEM identify essential fish habitat, including spawning, recruitment, and nursery areas, as well as food web interactions. [234]

A commenter claimed that the NY Bight is home to and essential habitat for numerous species, including sea scallops, Atlantic surf clams, ocean quahogs, longfin squid, Atlantic cod, black sea bass, blue fish, and summer flounder.[235] Similarly, another commenter expressed particular concern for sea scallop, surf clam, and ocean quahog populations in and around the NY Bight, which the commenter claimed are particularly important for the seafood industry, and suggested that BOEM designate additional funding for research on potential mitigation measures to protect these species from any possible impacts from offshore wind development.[236]

Several commenters warned that many features or potential accidents arising from offshore wind development could impact finfish, invertebrates, and essential fish habitat, including mid-water structures, noise, EMFs, construction, pile-driving, vessel traffic, foundation lighting, thermal discharges, and oil or other lubricants spills, and that BOEM should analyze the potential impacts of these factors. [237] One of these commenters further warned that such factors could cause changes in migration routes and migratory behavior of migratory fish species, as well as potentially altering local and regional hydrodynamics, which could impact fish and invertebrate settlement, recruitment, and connectivity.[238]

A commenter recommended that BOEM expand NMFS's role in project monitoring and essential fish habitat consultations, as well as giving greater deference to its expertise in these areas.[239] Another commenter recommended that BOEM work with NOAA, State governments, and Tribal Nations to designate marine sanctuaries in the NY Bight.[240]

[240] National Wildlife Federation et al.

O.4.16 Geological, Geophysical, and Biological Bathymetric Conditions

One commenter provided several recommendations for BOEM regarding geological, geophysical, and biological bathymetric conditions, including that BOEM should:

- Identify sediment quality, type and chemistry within lease areas and along potential cable corridors.
- Evaluate micro-gyres and circulation changes around structures to evaluate scouring and sedimentation from turbine bases and cables and effects on cable burial from coastal processes and storms.
- Evaluate air circulation changes from turbines and sea surface temperature impacts to assess seafloor disturbances from turbine structures and cables.
- Assess seafloor disturbances from construction methodologies such as anchoring, dredging, and seafloor leveling.
- Evaluate cable burial depths necessary to avoid EMF impacts, conflicts with fishing gear, and anchor strikes.
- Evaluate habitat changes from turbine and cable installation, including boulder relocation and seafloor leveling.[241]

O.4.17 Land Use and Coastal Infrastructure

Four commenters provided feedback on land use and coastal infrastructure issues related to the NY Bight PEIS.

A commenter claimed that there is insufficient scientific data on the effects of the construction of the necessary supporting infrastructure for offshore wind energy development.[242]

A commenter warned that this initiative could cause substantial onshore land use impacts from land disturbance, port utilization, cabling routes, and transmission infrastructure, as well as new port areas, parking lots, and structures. This commenter further recommended that BOEM's PEIS estimate the total onshore acreage required for construction, manufacturing, assembly, transportation, operations, and maintenance, as well as disclose rezoning and reclassification and requirements. This commenter added that onshore land disturbance could have effects on stormwater collection and management, and consequently the PEIS should consider this effect in flood-prone areas. Additionally, the commenter recommended that the PEIS evaluate impacts from the use of pesticides, herbicides, and other chemicals in onshore project areas, and that BOEM should require green infrastructure methods in

[241] New York State.
[242] Mayor John A Peterson, Jr.

project development. Finally, the commenter warned that the developments could impact wetlands in the region.[243]

A commenter provided several recommendations for BOEM regarding land use and coastal infrastructure, including that BOEM:

- Evaluate potential temporary and permanent impacts on land use from siting new infrastructure, including docks, piers, and shoreline stabilization.
- Evaluate potential impacts on vegetated dune and beach habitats; consider impacts on CEHA.
- Avoid disturbing sand borrow areas and beach nourishment activities.
- Provide details on how environmental impacts from operational, maintenance, and port facilities will be analyzed.
- Consider the existing capacity or need for additional capacity of onshore cable for accepting additional power.[244]

A commenter suggested that BOEM adopt as a goal the improvement land use planning to protect soil function, water quality, water supply, and living resources.[245]

O.4.18 Marine Mammals

Approximately 10 commenters provided feedback on issues related to marine mammals in the NY Bight PEIS.

A couple of commenters claimed that the NY Bight is home to numerous species of marine mammals, some of which are endangered, including: sei, blue, fin, humpback, sperm, and northern right whales; harbor porpoises; bottlenose dolphins; harbor seals; and West Indian manatees.[246] Several commenters warned the offshore wind development could impact such marine mammals in the NY Bight and that BOEM should consider these impacts.[247] One of these commenters added that there has been insufficient research to date on these impacts.[248]

Many commenters warned of the potential effects that features and accidents arising from offshore wind energy development could have on marine mammals and requested that BOEM analyze these impacts and consider potential mitigation measures; these factors included: noise, vessel traffic and strikes, EMFs, in-water structures, sedimentation from land and seabed disturbances, trash, oil spills, pile-driving, dredging, cable laying, drilling, turbine operation, intakes and discharges related to cooling

[243] Clean Ocean Action.
[244] New York State.
[245] Environmental Protection Agency.

[247] Mayor John A Peterson, Jr.; New York Offshore Wind Alliance; National Park Service; Clean Ocean Action.
[248] Clean Ocean Action.

offshore wind conversion stations, altered micro-climates, altered hydrodynamics, and prey entrainment.[249]

A commenter requested that BOEM identify seasonal distribution, abundance, and migration routes for marine mammals.[250] Another commenter recommended that the PEIS report the results of recent and ongoing marine mammal surveys in the NY Bight and report how developers will work together and with the research community to improve understandings of mitigation measures.[251]

Several commenters suggested BOEM devote particular attention to the endangered North Atlantic right whale and potential impacts to the species.[252] Another commenter echoed this concern, additionally claiming that fewer than 340 of the whales remain, with the NY Bight being part of their migratory corridor. This commenter argued that vessel traffic and noise exacerbate pressures on this population and that the PEIS should account for potential impacts on the species. This commenter further recommended that no construction or other offshore wind activity be allowed in the NY Bight during the whale's most sensitive times of the year, including migration periods.[253] Similarly, another commenter recommended that noisy construction activities only occur during the day and good weather conditions to maximize visual detection probability for the whales; this commenter further argued that even a single vessel strike on a North Atlantic right whale is an unacceptable risk given their status.[254]

Another commenter suggested considering no-build migratory routing measures for protected species like the North Atlantic right whale.[255] Similarly, another commenter expressed concern for potential impacts on the North Atlantic right whale's migration corridors from noise from turbines, including preventing migration and causing injury or death by interfering with the whales' ability to communicate. Furthermore, the commenter claimed that one possible reaction of whales to such a disturbance is to swim just beneath the surface, which increases the likelihood of vessel strikes.[256] Refer to Section O.4.14 for additional comments on ESA-listed species.

O.4.19 Navigation and Vessel Traffic

Approximately 10 commenters provided feedback on navigation and vessel traffic issues related to the NY Bight PEIS.

[254] National Wildlife Federation et al.
[255] Responsible Offshore Development Alliance.
[256] Save Long Beach Island, Inc.

O.4.19.1 General Comments on Navigation and Vessel Traffic

Multiple commenters warned that offshore wind energy development in the NY Bight could increase vessel traffic. [257] One of these commenters added that this could impact marine mammals and sea turtles.[258] Another commenter warned that offshore wind development in the NY Bight would pose a threat to navigational safety for all commercial vessel traffic in the area.[259]

O.4.19.2 Specific Comments on Risks Posed by Increased Vessel Traffic

A commenter warned that offshore wind development in the NY Bight could interfere with marine radar, causing navigational safety risks, and cited a study to dispute BOEM's position that solid state and Doppler-based radars are adequate solutions to these impacts.[260] A couple of other commenters similarly expressed concern for the potential effects on marine radar.[261]

A commenter warned that wind farm construction could cause traffic impacts from construction vessels transporting turbine parts, from vessels exporting cable and upland infrastructure, and from the use of ports and operations and maintenance facilities.[262]

Another commenter expressed additional concerns about the effects of wind energy leasing in the NY Bight on navigation and vessel traffic, including:

- The scour protection employed by the developments could cause vessels' anchors to fail to hold and that interactions between anchors and cables could damage either.
- Turbines could increase collision risks with slow-moving maintenance vessels and by creating reefs that attract fishermen.
- Increased congestion and navigational complexity would increase crew fatigue, damage to vessels, injuries to crews, fuel spills, and engagement of USCG rescue teams.
- The development would significantly impact port utilization, increasing competition for berthing space and port services in the area and potentially further complicating national supply chain issues.[263]

A commenter warned that large vessel collisions in or around the lease areas could cause substantial environmental damage, and the emergency response and clean-up could severely restrict shipping lanes, causing significant economic impacts.[264]

O.4.19.3 Recommendations with Respect to Navigation and Vessel Traffic

Turbine Spacing and Lane Markings

A commenter recommended that BOEM require that wind farms be organized in straight rows and columns, in a grid pattern, to facilitate navigation safety, consistent marking and lighting, search and rescue, and safe commercial fishing. The commenter further recommended that when multiple wind projects share a border, lessees be required to adopt the same spacing and layout across borders to present a single wind farm with consistent straight-line routes. If this is not possible, the commenter recommended that space be left between borders to provide a clear delineation, or that clear markings be applied to warn mariners of changes in spacing or orientation. Finally, the commenter said that all mooring systems and ancillary equipment should be confined to the lease areas.[265]

Similarly, another commenter recommended that transit corridors be established through proposed wind farms and turbine arrays, and that the PEIS consider alternative layouts and provide information on navigational risks and mitigation measures.[266] Another commenter similarly suggested that BOEM analyze spacing patterns between turbines and other infrastructure that could either allow fishing to continue or preserve more structure-free areas.[267]

Buffer Zones

Several commenters argued that around offshore wind energy development near port approaches, there should exist a minimum buffer zone of 2 nautical miles from the parallel outer or seaward boundary of a traffic lane and of 5 nautical miles from the entry or exit of traffic separation schemes.[268] One of these commenters argued that such a buffer zone is necessary for vessels to detect each other visually and by radar, to allow large vessels to maneuver during an emergencies, and to accommodate the “swing circles” of large anchored vessels. These commenters found that lease blocks included in the proposal fall within this such appropriate buffer zones around nearby port approaches.[269]

Accommodating United States Coast Guard Designations

A commenter suggested that BOEM consider referencing port access route studies to mitigate navigation safety risks from offshore wind energy installations. This commenter also suggested that BOEM consider the future uses of the “Ambrose anchorage,” an offshore area used by ships awaiting inshore anchorages or berths, located 3 nautical miles south of Long Beach, New York, which is the subject of a USCG Notification of Inquiry and is under consideration for the establishment of an anchorage ground. Furthermore, this commenter suggested that BOEM adopt the Marine Planning

[265] US Coast Guard.
[266] Massachusetts Office of Coastal Zone Management.
[267] Responsible Offshore Development Alliance.
[268] World Shipping Council; The American Waterways Operators.
[269] World Shipping Council.

Guidelines detailed in the Navigation and Vessel Inspection Circular 01-19 with respect to AMMM measures.[270]

Multiple commenters said that one of the proposed lease areas, assigned to Mid-Atlantic Offshore Wind LLC, conflicts with USCG's proposed NY Bight cut-across fairway, which, if developed, would create navigation hazards in the NY Bight; consequently, the commenters argued that this area should not be developed or that BOEM should comprehensively analyze the associated vessel traffic impacts.[271]

Marine Radar

Multiple commenters recommended that BOEM's PEIS include an analysis of potential impacts on marine radar, impacts that could interfere with search and rescue capabilities, and further suggested that USCG be given a role in assessing this risk and considering potential mitigation measures.[272] Another commenter echoed this concern about impacts on marine radar and the need for mitigation measures.[273]

Liability

A commenter questioned how BOEM intends to manage allision and height hazards, if BOEM plans to include safety zones, and if BOEM plans to hold vessels liable for collisions. This commenter further recommended that BOEM analyze the potential economic impacts of marine insurance companies raising premiums or denying coverage to operators in the area in response to increased vessel navigation risks.[274] Another commenter echoed the importance of BOEM addressing operator liability.[275]

Other Recommendations

A commenter provided several recommendations for BOEM regarding navigation impacts, including that BOEM:

- Evaluate risk from vessel allisions, collisions, and groundings.
- Assess impacts from displacement of traffic.
- Analyze risk to smaller vessels during construction.
- Assess conflicts with concrete mattresses and scour protection measures.
- Assess impacts of cable exposures.

[270] US Coast Guard.
[271] The American Waterways Operators; Clean Ocean Action.
[272] Seafreeze Shoreside, Seafreeze Ltd.; Responsible Offshore Development Alliance.
[273] New York State.
[274] Seafreeze Shoreside, Seafreeze Ltd.
[275] New York State.

- Develop a plan for mariner communications and conduct routine check-ins with the New York/New Jersey Harbor Safety, Navigation, and Operations Committee to promote mariner safety.
- Identify best practices to minimize disruption to fishing from boulder relocation.
- Explore adapting mobile gears to navigate tighter corridors and continue engaging stakeholders regarding such equipment. [276]

A commenter recommended that BOEM study navigation with NMFS and USCG, work closely with USCG and relevant experts to improve safety in the area, develop safety mitigation measures, and include stakeholders in developing navigational aids such as lighting and markings.[277]

A commenter recommended that BOEM consider safety measures for vessel operations at night and in other low visibility conditions, consider approaches to minimize daily vessel traffic, and chart and communicate the placement of equipment and relocation of boulders to reduce the potential for allisions and gear damage. The commenter also recommended that the PEIS provide for communication and engagement with fishing industry members regarding the timing and duration of survey and construction activities before they commence.[278]

O.4.20 Noise

Six commenters provided feedback on noise as it relates to the NY Bight PEIS.

Some commenters discussed noise-related issues in their submissions, mostly regarding how noise from offshore wind projects might impact marine species. One commenter expressed concern regarding the impact of noise on marine life and fisheries.[279] Another commenter requested the region-wide examination of underwater noise on wildlife populations.[280] One commenter requested the provision of ambient noise levels for the Proposed Action, evaluation of potential sound penalties for onshore tonal noise impacts, assessment of the adequacy of proposed mitigation measures, evaluation of the impacts of offshore wind activities on marine mammals, and consideration of vibration-related impacts.[281] One commenter said that the PEIS should fully evaluate the consequences of pile-driving activities on marine mammal species, specifically stating that the PEIS should address the research gap on baleen whales and pile-driving; consider mysticetes and odontocetes in the PEIS; assess the impact of acoustic masking on marine mammal reproduction; and assess the impacts of persistent noise on marine mammals.[282]

One commenter stated that the scope of the PEIS should be expanded to include the New Jersey Wind Energy Area to account for cumulative impacts from turbine operational noise, citing concerns about

---

[276] New York State.
[277] Responsible Offshore Development Alliance.
[278] National Marine Fisheries Services.
[279] Mayor John A Peterson, Jr.
[280] New Jersey Offshore Wind Coalition.
[281] New York State.
[282] Clean Ocean Action.

impacts on North Atlantic right whale.[283] This commenter reviewed and cited research and submitted detailed analyses to support their position. The commenter suggested that the PEIS should contain estimates of elevated underwater noise levels based on studies they referenced and criticized BOEM for not including noise estimates from larger turbines. The commenter requested that the PEIS disclose the drive type of the turbines to be used for the projects and discussed their own analysis of research and its implications for expected turbine noise levels on masking North Atlantic right whale communication. They suggested that the PEIS should address how this masking from cumulative turbine operational noise could impact their migration capabilities.

Citing research on the adverse effects on marine wildlife from pile-driving noise, another commenter stated that “the installation of gravity-based or suction bucket (or ‘caisson’) foundations represents a ‘best practice’ in the context of the mitigation hierarchy.” [284] The commenter suggested that BOEM should coordinate with NMFS to characterize source noise levels during installation of foundations and use this information to ensure that installation mitigation and monitoring protocols are maximally protective. The commenter also urged BOEM to couple their foundation choice with a long-term monitoring program. The commenter suggested that BOEM design monitoring requirements to evaluate noise propagated through substrate during pile-driving by Rayleigh waves and their impacts on benthic invertebrates and demersal fish. The commenter also expressed concern about the impact of pile-driven bases of wind turbines impacting benthic creatures and suggested that mitigating this impact “would require acoustically decoupling the mast from the pile-driven base, or if the mast is below the waterline, acoustically decoupling the turbine from the mast.” They recommended BOEM include monitoring measures and adaptive management considerations for these issues in the PEIS.

This same commenter recommended using scientific information on the presence of marine mammals, especially the North Atlantic right whale, along with monitoring and mitigation systems to minimize impacts on these species. The commenter stated that no marine mammal species should be present in the Clearance Zone and that developers should only undertake pile-driving activities during times of good visibility or while using infrared technologies for visual monitoring. They also stated that pile-driving activities “should be commenced at least 1.5 hours before civil sunset” and that “lessees should not employ 24-hour pile driving.” The commenter discussed research and made specific recommendations about minimizing noise impacts, including requiring developers to use “the best commercially available combined NAS technology” and recommended soft-start procedures for pile-driving. The commenter cited research and commented on the impacts of vessel-related noise during wind farm construction, specifically noise produced by dynamic positioning systems, stating that BOEM should analyze these effects for individual projects and cumulatively. The commenter also recommended the use of “direct-drive turbines as opposed to turbines with a gear box” to minimize operational noise and impacts to marine species.

283 Save Long Beach Island, Inc.

284 National Wildlife Federation et al.

O.4.21 Oceanography

Seven commenters discussed issues related to oceanography in the NY Bight PEIS.

Several commenters expressed concern specifically about the impact that wind farms might have on the Mid-Atlantic Cold Pool.[285] Once commenter called for considering the impacts on the Mid-Atlantic Cold Pool cumulatively by accounting for the impacts of nearby wind farms and cited research suggesting that it was particularly vulnerable to hydrodynamic changes from wind farm structures.[286] Citing research, another commenter expressed concern about the cumulative impacts of wind turbines on the Cold Pool and subsequent effects on scallops, surf clams, the ocean food web, marine habitats, and migratory patterns on the mid-Atlantic Shelf.[287]

Other commenters discussed various other topics related to ocean ecology. One commenter stated the need to consider and evaluate currents, bathymetry, microclimates, and MetOcean data.[288] Additionally, the commenter called for the evaluation of micro-gyres; circulation changes around structures; scouring and sedimentation from turbine bases, cables, and scour protection; air circulation changes and sea surface temperature impacts; and assessment of seafloor and land disturbances from various wind farm construction and operation activities. This commenter also called for the evaluation of impacts on a variety of biological resources related to ocean and coastal habitats including identifying best management practices to reduce risks to the oceanic environment. Another commenter stated that the sea surface microlayer may be compromised due to wind farm activities.[289] This commenter also expressed concern about the impact of wind turbines on wakes, stating that the PEIS should include analyses of how the wake effect would be avoided at the six lease sites. The commenter listed several concerns they suggested should be included in the PEIS including microclimate effects of turbines such as turbulence, impacts on water temperature, and impacts on the sea surface microlayer. Additionally, the commenter stated that cooling offshore wind conversion stations could impact marine mammals through their intakes and discharges and suggested that the PEIS should prioritize the analysis of this issue.

Some commenters discussed impacts on marine life due to oceanographic changes. Citing research, a couple of commenters expressed concern about the impact that wind farms might have on the ecology of the area and commercial fishing and wakes.[290] One commenter expressed concern about the impact of large turbine arrays on wind and ocean current patterns and the resulting impacts on scallops.[291] The commenter stated that wind farms will alter patterns of scallop larval settlement and generally degrade the seabed environment.

---

[286] Fisheries Survival Fund.
[287] Save Long Beach Island, Inc.
[288] New York State.
[289] Clean Ocean Action.
[290] Wallace & Associates; Seafreeze Shoreside, Seafreeze Ltd.
[291] Fisheries Survival Fund.

One commenter stated that relying on historical data for future "blue economy" planning is no longer reasonable given the rapidly changing nature of the ocean and that planning should therefore be based on future ocean conditions.[292]

O.4.22 Other Uses

Three commenters provided feedback on other uses relevant in the NY Bight PEIS.

One commenter called for an analysis of preconstruction surveys, suggesting that this would "facilitate the National Oceanic and Atmospheric Association's (NOAA) review, improve permitting efficiencies and consistency across projects, and ensure projects have sufficient time to collect at least two (2) years of baseline data."[293] The commenter also urged BOEM to minimize disruptions to State and federal fisheries surveys through coordination with NOAA NMFS. They further called for the identification of U.S. Military training and exercises. Another commenter encouraged BOEM and developers to consider engaging with the fishing community during surveys as part of safety planning and risk identification.[294]

O.4.23 Recreation and Tourism

Seven commenters provided comments on recreation and tourism issues relevant to the NY Bight PEIS.

Some commenters expressed general concerns about the negative impacts that offshore wind projects may have on tourism economies, including lost revenue for businesses and jobs, and impacts on recreation.[295] One commenter asked if studies had been conducted investigating the impact on tourism and local economies due to turbines being visible from the shoreline.[296] Another commenter discussed the importance of tourism to the Fire Island National Seashore and Gateway National Recreation Areas.[297] A commenter also recommended evaluating measures to maintain public access and coastal use, tourism and recreational activities, and avoiding construction during peak tourism periods.[298] The commenter also mentioned that their respective Department of State had developed datasets for offshore diving and surfing areas important to their State and provided links to the datasets.

O.4.24 Scenic and Visual Resources

Approximately 10 commenters provided comments on scenic and visual resources.

Several commenters mentioned scenic and visual resources. Some commenters expressed general concern about and called for consideration regarding the visibility of wind turbines.[299] One commenter called for the elimination of visual assessments, stating that with the exception of Lease Area 544, the

[297] National Park Service.
[298] New York State.
[299] New York State; Twin Lights Historical Society; Kimberly Dreher; James Binder.

NY Bight lease areas are more than 40 miles from the nearest shoreline.[300] A commenter stated that the PEIS should address the visual impacts of turbines, such as which communities or parks they would be visible from, the extent to which turbines would be visible, the weather conditions in which they would be visible, and how often the turbines would be visible throughout the year.[301]

Some commenters discussed how wind turbines might impact historic sites. One commenter stated that the PEIS should evaluate the cumulative impacts of new leasing areas and the Empire Wind Projects on "the uninterrupted sea view from the seven ocean-front historic districts and 31 miles of ocean beaches, dunes and water" and specified key observation points from the Gateway National Recreation Area to be included in the assessment.[302] The commenter recommended the same for visual impacts at Fire Island, similarly including key observation points for analysis and suggesting that their staff can assist with more detailed discussions on these topics. The commenter further recommended the inclusion of the Empire State Building, Green-Wood Cemetery, and Twin Lights Historic Site as National Historic Landmarks in the PEIS along with assessment of potential visual impacts.

One commenter recommended that BOEM "further define the 'historic maritime setting' in the PA or in subsequent guidance."[303] Additionally, the commenter encouraged BOEM to "ensure that the PA recognize that impacts from NYB projects on historic properties will vary significantly and are dependent on location of the turbines and export cables" and further recommended the development of a "consistent metric by which NHPA [National Historic Preservation Act] effects determinations are made across all NYB [NY Bight] projects." Another commenter suggested that they did not understand how BOEM would model visual assessment in the Cape May County and Point O'Woods areas.[304] The commenter stated that all historic districts, National Historic Landmarks, and properties listed or eligible for inclusion in the National Register of Historic Places should be included in vantage point simulations and specifically requested the inclusion of the Cape May Historic District and Point O'Woods. They also called for the consideration of lighting impacts on the night sky. Another commenter suggested that a turbine exclusion zone of at least 17.2 miles should be established in the Beach Haven Historic District to minimize adverse visual impacts on historic resources.[305]

O.4.25 Sea Turtles

Three commenters provided comments on sea turtles.

A few commenters mentioned sea turtles. One commenter recommended that the PEIS include a threat analysis matrix for endangered sea turtles living in the NY Bight area and cumulative impacts.[306] The commenter further recommended prioritizing "research to fill gaps in baseline data on sea turtle distributions, abundance, habitat use, and movements above stressor-specific investigations of effect to

[304] Cape May County, NJ; Point O'Woods Association, Fire Island, NY.
[305] Borough of Beach Haven.
[306] Clean Ocean Action.

turtles, such as artificial reef effects, entanglements, vessel strike, or EMF." The commenter additionally stated there is no empirical data on noise threshold levels that would impact sea turtles and that the PEIS should consider the impacts on threshold shift and suggested that the PEIS should require the development of best practices by developers to minimize impacts on sea turtles. Another commenter called for consideration of the cumulative impact of wind project construction and operations on sea turtles, including noise, vessel traffic, EMF, and recommended visual and acoustic monitoring to detect sea turtles so construction can be avoided when they are present.[307] One commenter requested the identification of seasonal distribution, abundance, and migration routes of sea turtles and the evaluation of behavior and physiological impacts from vessel traffic, noise, foundation lighting, and EMF.[308]

O.4.26 Water Quality

Four commenters provided comments on water quality.

One commenter called for a review of the impacts of offshore wind on water quality.[309] Another commenter called for the evaluation of several factors related to sediment and deposition effects caused by offshore wind activities in the NY Bight area.[310] This commenter called for consideration of water quality impacts including considering New York State Water Quality Standards, modeling of the extent and duration of turbidity impacts, evaluation of changes to dissolved oxygen or nutrients in the overlying water column, and evaluation of cooling water intake structures on circulation and temperatures. The commenter further called for assessing the impacts of inadvertent spills, evaluation of methods for managing debris and waste, and considering impacts from cable heat transfer.

One commenter suggested that if vessels originating in foreign ports will be used during construction or maintenance of the wind farm projects, the PEIS should explain how they will prevent the discharge of ballast water to prevent the introduction of nonnative marine organisms.[311] The commenter expressed concern that discharge of pollutants may require National Pollutant Discharge Elimination System authorization and further recommended that the PEIS address whether the project will result in the discharge of pollutants into the water. This commenter also requested that BOEM consider the goals of the Comprehensive Conservation and Management Plan for the Barnegat Bay-Little Egg Harbor Estuary (e.g., water quality, water supply, living resources, and land use), which the Clean Water Act has designated an estuary of national significance.

A commenter called for the PEIS to fully investigate potential impacts of wind farm activities on ecologically important waterways and coastal habitats, drawing special attention to the New York/New Jersey Harbor Estuary, Peconic Bay Estuary, Barnegat Bay Estuary, Hudson Bay Estuary Program, Long Island South Shore Estuary Reserve, Hudson River National Estuarine Research Reserve, and Jacques

307 National Wildlife Federation et al.
308 New York State.
309 Mayor John A Peterson, Jr.
310 New York State.
311 EPA.

Cousteau National Estuarine Research Reserve.[312] The commenter also stated that the PEIS should "evaluate worst case scenarios to determine impacts and assure emergency response capabilities will be available to ensure water quality" should vessel collisions cause a spill. The commenter suggested that the PEIS evaluate all risks and mitigation plans to account for the possibility of oil spills due to collisions. The commenter stated that it is likely the case that current design specifications (e.g., related to corrosion, corrosion protection) may not "capture the corrosivity of the environment, likely rendering impacts far different from any kind of assessments," and that industry codes for wind energy are not yet fully developed.

O.4.27 Wetlands and Other Waters of the United States

Three commenters provided comments on wetlands and other water resources in the United States.

A few commenters mentioned wetland and other water topics. One commenter stated that Executive Order 11990 Protection of Wetlands requires federal agencies to minimize degradation of wetlands and recommended the implementation of best management practices to comply with this directive.[313] They further suggested that the PEIS should assess impacts "that could result in a change (either permanent or temporary) of cover type within a wetland." This commenter additionally stated that impacts on streams and wetlands should be avoided or minimized in accordance with Section 404 of the Clean Water Act, that aquatic resources in the area should be delineated according to the 1987 Corps of Engineers Wetlands Delineation Manual and Regional Supplement. and that an evaluation of "cumulative effects of onshore activities at a watershed scale (i.e., hydrologic unit code 12) be provided to ensure that measures are undertaken to avoid and minimize the potential of cumulative impacts."

Citing research and discussing the importance of wetlands, another commenter called for the PEIS to identify and evaluate the potential impacts on wetlands due to wind energy development in the NY Bight and consider how impacts could be avoided and minimized.[314] The commenter also mentioned Executive Order 11990 and Section 404 of the Clean Water Act and stated that the PEIS must go beyond acknowledging the importance of wetlands and identify mitigation measures. The commenter suggested a testing a pilot project to improve data on wind energy development before undertaking industrial-scale development. Another commenter called for evaluating potential impacts of transmission installations on wetlands, inland waters, and their species; evaluating the impacts of clearing vegetation near "designated Wild, Scenic, & Recreational Rivers (WSR) and NYS Significant Coastal Fish and Wildlife Habitats (SCFWF)"; and evaluating impacts on freshwater and tidal wetlands in the area.[315] This commenter also called for evaluating impacts on saltmarshes and identifying protective measures, stating the significance of saltmarshes to New York State's marine district.

---

[312] Clean Ocean Action.
[313] EPA.
[314] Clean Ocean Action.
[315] New York State.

O.4.28 Comments on Other Resource or Stressor Topics

Nine commenters provided comments on other resource or stressor topics.

Several commenters discussed various other issues related to resources or stressor topics. A couple of commenters mentioned using wind turbines to facilitate aquaculture or biodiversity. One commenter asked whether the government had considered establishing oyster beds or artificial reefs for wildlife at wind turbine bases.[316] Another commenter asked whether there were plans to employ aquaculture structures at the base of wind turbine foundations to "create habitats for mussels, oysters, sea weed and other sea life," suggesting that such structures could improve water quality and reduce reliance on sea food imports.[317] The commenter also asked how private companies could obtain permits to create, manage, and monetize such aquacultures. This commenter also asked how much energy would be generated for the NY Bight area and Monmouth County specifically and whether this proposal would eliminate fossil fuel use in the area. One commenter that BOEM adopt "net positive" biodiversity goals to guide the maintenance and enhancement of species and habitats impacted by offshore wind development.[318]

A couple of commenters mentioned security issues. One commenter recommended identifying emergency preparedness measures for severe storm events.[319] Another commenter expressed concern about offshore wind turbines' vulnerability to war time or terrorist attacks and stated that the issue should be addressed in the PEIS.[320]

One commenter stated that offshore wind energy is not emissions-free and argued that the "emissions from the activities necessary to prepare, build, operate, maintain, and decommission offshore wind energy facilities" should be included in the PEIS.[321] The commenter called for BOEM to address issues related to the amount of fossil fuel displacement that would occur due to offshore wind energy production. The commenter stated that it was unclear which State will receive the energy from the leases. The commenter additionally stated that the PEIS "must include all areas from where materials will be sourced for offshore wind project components in the environmental review," along with emissions data from turbine infrastructure production. The commenter called for the PEIS to evaluate secondary impacts related to onshore development needed to support the lease sales, management of dredged material, turbine malfunction, and security issues. This commenter expressed concern that wind energy development in the NY Bight requires the mining of rare earth elements with environmental consequences and suggested that the PEIS should consider these.

One commenter suggested requiring real-time cable monitoring technology for rapid identification of hazards, performing "micro siting" of wind energy infrastructure with fishermen familiar with the

[318] The Nature Conservancy.
[319] New York State.
[320] James Binder.
[321] Clean Ocean Action.

ecosystem, and coordinating transmission to minimize infrastructure in the water and seabed.[322] This commenter also suggested defining thresholds to determine when environmental impacts are unacceptable and establishing adaptive management procedures. Another commenter discussed the importance of night skies and recommended the following: requiring an Aircraft Detection Lighting System to turn aviation obstruction lights on and off in response to detection of aircraft, shielding and directing security lighting downward, keeping lights off when they are not needed, using the minimum necessary brightness, using warm color-temperature lights, and requiring lighting plans in project-specific EISs.[323]

One commenter submitted comments on several various resource topics.[324] The commenter requested that BOEM consider changes that they would like acknowledged in the Draft PEIS including the impact of automation on the potential for job creation; the reliability and storage capabilities of wind energy systems; advancements in other types of renewable energy technologies; and the cost of offshore wind alternatives, among other issues. The commenter stated that the cost of offshore wind power is high, even after subsidies, suggested that those who use electricity derived from wind energy will have to pay more than they would for natural gas, and questioned how power grid transmission needs would be financed. The commenter questioned whether there was a federal agency that would be performing an analysis, comparing the cost reliability of wind energy to other clean technology alternatives, and requested that BOEM identify and assess backup technologies needs and plans if offshore wind output is rendered insufficient due to storms or low wind. The commenter stated onshore alternatives to offshore wind were available that could meet clean energy needs and questioned why they were not being considered. The commenter mentioned as an alternative the upgrading of "natural gas power plants to include combined cycles power generation." The commenter requested that BOEM "present a numeric analysis of impacts on greenhouse gas emissions of the Proposed Action and compare those emissions reductions to the increases in global greenhouse gas emissions." The commenter requested an analysis of the benefits of onshore clean technology.

O.5 National Historic Preservation Act/Section 106 and Programmatic Agreement

Comments associated with the National Historic Preservation Act (NHPA)/Section 106 process are discussed in this section.

O.5.1 Programmatic Agreement

Four commenters provided comments on the NHPA Programmatic Agreement.

A commenter supported BOEM's intention to develop an NHPA Section 106 Programmatic Agreement (PA) and recommended including, as consulting parties, the New York and New Jersey State Historic

---

[322] Responsible Offshore Development Alliance.
[323] National Park Service.
[324] James Binder.

Preservation Officers (SHPOs). The commenter also recommended including in the consulting parties from the Empire Wind development, the Advisory Council on Historic Preservation, and Native American Tribes. They cited 36 Code of Federal Regulations (CFR) 800.4(a)(2) as the engagement of the New York and New Jersey SHPOs as PA consulting parties.[325] Another commenter agreed that BOEM should coordinate with New York State's Office of Parks, Recreation and Historic Preservation (NYS OPRHP), which houses the State's SHPO.[326]

Another commenter recommended that BOEM develop a system to streamline Section 106 PAs for individual COPs by tiering them off the PA. The commenter added that impacts on historic resources will vary widely depending on the location of turbines and export cables, reasoning that, for instance, turbines located more than 23 miles from the shore may not be visible. The commenter recommended that BOEM develop consistent metrics to apply for NHPA determinations across the NY Bight COPs.[327]

The commenter also requested that BOEM provide more information as to when Section 106 consultations for the NY Bight will take place and conclude; they stated that geophysical surveys for windfarm development will need to take place soon and that the PA could impact the scale and scope of geophysical surveys to identify marine archaeological resources. Thus, the commenter wrote, information from BOEM as to when the PA will be available will help in the geophysical survey planning process.[328]

Another commenter stated that it accepted BOEM's invitation to become an NHPA Section 106 consulting party.[329]

O.5.2 Impacts on Historic Properties

Three commenters provided comments on impacts on historic properties.

A commenter cited Section 106 as requiring that federal agencies consider the impacts of their actions on historic properties. The commenter stated that, during recent virtual public meetings, consulting parties raised concerns about BOEM's process for identifying historic properties, addressing adverse impacts, and creating a framework to mitigate adverse impacts in a manner proportionate to their threat.[330] Another commenter generally requested that BOEM consider impacts on historic resources, including "submerged landforms."[331]

A commenter anticipated that the projects would have no impact on the visual character of onshore resources because the projects would be 42 and 54 miles offshore. The commenter further stated that BOEM has previously found wind turbines to cause adverse impacts on "historic maritime settings." The

[325] National Park Service.
[326] New York State.
[327] Attentive Energy LLC.
[328] Attentive Energy LLC.
[329] Invenergy Wind Offshore LLC.
[330] Cape May County, NJ; Point O'Woods Association, Fire Island, NY.
[331] New York State.

commenter requested that BOEM provide a definition of this term in the PA or other guidance. The commenter added that current conditions, such as vessel traffic, aircraft, modern structures, nighttime lighting, and other modern elements already compromise the “historic maritime settings” from the view of historic properties.[332]

O.5.3 Identification of Historic Properties Under NHPA

Three commenters provided comments on the identification of historic properties under NHPA.

A commenter provided several comments regarding the identification of historic properties under NHPA. The commenter provided an overview of National Historic Landmarks and the procedural safeguards afforded to the properties by NHPA Sections 106 and 110(f). The commenter stated that it has statutory responsibility for two National Parks and several National Historic Landmarks in the NY Bight and provided information in its comment to respond to BOEM’s request for feedback regarding the identification of historic properties in the area. It described the Carrington Estate, several structures at Fire Island National Seashore, and locations at the Gateway National Recreation Area as historic properties that could be impacted by NY Bight development. The commenter requested that these National Parks and National Historic Landmarks be included in BOEM maps illustrating the NY Bight, offering to assist in this request by providing location data.[333] Also providing information on nearby historic properties, another commenter wrote that, pursuant to responsibility delegated to it by the New Jersey State Legislature, it has designated a historic district in Beach Haven that could be impacted by NY Bight development.[334]

A commenter recommended that BOEM design a phased identification process for marine archaeological resources within the NY Bight. The commenter suggested using, per 36 CFR 800.4(b)(2), phased identification efforts in progressively narrower surveys rather than implementing 30-meter survey intervals at the outset. The commenter reasoned that using 30-meter survey intervals results in overly detailed surveys of areas that development, because of preferred alternative selection or project design, ultimately would not affect. The commenter stated that using survey intervals of this precision increases costs and impacts on marine life. Application of a 30-meter survey interval to identify smaller, buried marine cultural resources could be done within the project footprint, the commenter suggested, following the issuance of a Record of Decision.[335]

O.6 Consultations

Comments associated with the various consultations are discussed in this section.

[332] Attentive Energy LLC.
[333] National Park Service.
[334] Borough of Beach Haven.
[335] Attentive Energy LLC.

O.6.1 ESA

Three commenters provided comments on ESA consultations.

A commenter emphasized that the ESA and Essential Fish Habitat (EFH) consultations are complementary and should be treated as such. The commenter reasoned that ESA and EFH consultations rely on standard project design criteria to avoid, minimize, and monitor impacts on ESA-listed species, designated critical habitats, and EFH.[336] A commenter recommended that BOEM integrate a framework for the ESA and EFH compliance, arrived at through coordination with NMFS and USFWS, into the purpose and need, alternative analysis, and effects analysis portions of the PEIS.[337]

Another commenter recommended that BOEM implement a programmatic process to facilitate interagency coordination itself and NOAA/NMFS in their ESA consultations for specific COPs.[338]

O.6.2 EFH

A commenter emphasized that the ESA and EFH consultations are complementary and should be treated as such. The commenter reasoned that ESA and EFH consultations rely on standard project design criteria to avoid, minimize, and monitor impacts on ESA-listed species, designated critical habitats, and EFH.[339]

O.6.3 Other (e.g., Marine Mammal Protection Act, Coastal Zone Management Act)

Five commenters provided general comments on other consultations, such as the Marine Mammal Protection Act (MMPA) and Coastal Zone Management Act (CZMA).

O.6.3.1 MMPA and CZMA

A commenter recommended a programmatic process be used to facilitate interagency coordination between BOEM and NOAA/NMFS in their MMPA consultations for specific COPs.[340] A commenter wrote that it may issue an incidental take authorization under MMPA for wind project development but that such an authorization would likely require further NEPA documentation. The commenter stated that, properly developed, a PEIS could support the issuance of a letter of authorization covering all COPs.[341]

A commenter stated that it is important to align the timing of CZMA reviews with New York Department of State (NYSDOS) Coastal Management Programs.[342]

[336] National Marine Fisheries Services.
[337] Invenergy Wind Offshore LLC.
[338] American Clean Power Association.
[339] National Marine Fisheries Services.
[340] American Clean Power Association.
[341] National Marine Fisheries Services.
[342] New York State.

O.6.3.2 General Comments on Governmental Consultations

A few commenters generally recommended that BOEM coordinate with other federal agencies at the PEIS stage rather than only for specific projects.[343] One of the commenters reasoned that early coordination would help in cumulative analyses and in designing mitigation strategies, but also suggested that BOEM consider lessons learned in other OCS regions and avoid "artificial restrictions" that could prevent full utilization of the NY Bight.[344]

A commenter stated that BOEM should, under 43 United States Code 1337(p)(7), consider affected States' offshore wind procurement goals in evaluating NY Bight projects under NEPA and the Outer Continental Shelf Lands Act (OCSLA), reasoning that these goals are vital to the States' interest in the permitting process.[345] A commenter requested that BOEM continue to coordinate with New York through the PEIS and COPs processes, stating that New York State agencies will have statutory obligations to approve offshore wind transmission projects as well as transmission line siting. The commenter attached a document detailing the NYDOT's legal authorities relevant to NY Bight developments. Overall, the commenter recommended that BOEM coordinate with NYSDPS, NYSDOT, OPRHP, NYSDEC, and NYSDOS, with NYSDOS formally requesting to be a NEPA cooperating agency. The commenter also requested that BOEM confirm that the PEIS will not authorize development activities and that BOEM would not initiate federal consistency reviews at the PEIS stage.[346]

O.7 Comments on the Scoping Process

Three commenters provided comments on the scoping process.

A commenter recommended that BOEM use the scoping process to clarify a compensatory mitigation approach based on the best available science and designed to maximum ecological benefits, especially with respect to protecting biological diversity. The commenter recommended mitigation efforts such as acquiring critical coastal land or using management strategies to abate threats, and added that targeted properties for mitigation and monitoring may be outside the footprint of the projects themselves.[347]

Another commenter stated that the PEIS should consider impacts related to decommissioning, reasoning that such impacts are foreseeable and thus required under NEPA. Additionally, the commenter stated that decommissioning would be a major regional impact, and thus appropriate to analyze in the PEIS. The commenter added that decommissioning efforts can be expensive, describing one project in which decommissioning accounted for 20 percent of project costs.[348] Also addressing decommissioning, a commenter requested information on anticipated decommissioning of cable protection and scour protection areas. The commenter supported BOEM requiring the removal of

[343] The Nature Conservancy, Atlantic Shores Offshore Wind, LLC.
[344] Atlantic Shores Offshore Wind, LLC.
[345] American Clean Power Association.
[346] New York State.
[347] The Nature Conservancy.
[348] Save Long Beach Island, Inc.

generation and transmission infrastructure during decommissioning, as long as such efforts would be accompanied by monitoring and contamination control measures.[349]

O.8 Other Comments

This section discusses comments that generally fell into miscellaneous categories.

O.8.1 Comments on NEPA Cooperating Tribal Government and Cooperating or Participating Agencies

Approximately 10 commenters provided comments on NEPA Cooperating Tribal Government and cooperating or participating agencies consultations.

O.8.1.1 Tribal Consultations

A commenter recommended that, to the extent federally recognized Tribes are impacted by activities described in the PEIS, the PEIS include a description of the processes and outcomes of consultations with Tribal Nations.[350] Another commenter stated that "the Delaware Nation; the Delaware Tribe; Cayuga; Mohican; Shinnecock; and Stockbridge-Munsee Community, Wisconsin; and one State recognized Tribe, the Unkechaug" have interests in the south shore of Long Island, urging BOEM to consult with these Tribes throughout the NY Bight OCS process.[351] Another commenter recommended that BOEM take a lead role in organizing tribal outreach for the NY Bight for both Section 106 consultations and NEPA cooperation; the commenter reasoned that doing so would promote efficiency and, consistent with an August 1, 2022, BOEM letter, reduce stakeholder burdens.[352]

O.8.1.2 Interagency Coordination

A commenter recommended that BOEM coordinate with NOAA, the United States Army Corps of Engineers (USACE), and the Advisory Council on Historic Preservation to ensure that the agencies conduct programmatic analyses in parallel with the PEIS, agree on AMMM measures, and commit to similar timelines.[353] Another commenter agreed, stating that a standalone PEIS from BOEM, without interagency consultation, would be inefficient.[354]

A commenter stated that it would, in a separate letter, accept cooperating agency status under NEPA for the PEIS and consulting party status under NHPA.[355]

---

[349] New York State.
[350] EPA.
[351] New York State.
[352] Invenergy Wind Offshore LLC.
[353] American Clean Power Association.
[354] Invenergy Wind Offshore LLC.
[355] National Park Service.

A commenter stated that, given the scope of the PEIS, BOEM should collaborate with "NMFS, state fishery agencies, fishery management councils and commissions, ocean data experts including the Regional Ocean Partnerships, United States Integrated Ocean Observing System (IOOS), [and the] NOAA National Centers for Coastal Ocean Science (NCCOS)," and should also consider fishing industry-held data and "fishermens' [sic] ecological knowledge."[356] Another commenter stated that the New Jersey Research and Monitoring Initiative (RMI) studies marine and coastal resources concerns related to New Jersey offshore wind development and has partnered with NYSERDA, the Regional Wildlife Science Collaborative, and the Responsible Offshore Science Alliance. The commenter supported BOEM coordinating research and monitoring efforts.[357] A commenter stated that input from other agencies is still needed, providing as an example a take request from NMFS for North American right whales.[358]

Another commenter agreed, reasoning that consulting agencies may have focuses other than energy development and thus that BOEM should insist on relevant statutory deadlines—in particular, the commenter emphasized the importance of close coordination between BOEM and NOAA, USACE, USFWS, and the Advisory Council on Historic Preservation to ensure an efficient review process.[359]

A commenter stated that, in previous offshore wind leasing projects, there has been insufficient coordination with local governments; the commenter raised the "Rhode Island SAMP [Special Area Management Plan] process" and Vineyard Wind as examples in which New York fisherman had too little representation.[360]

O.8.2 Comments on Potential Authorizations

No comments are associated with this issue.

O.8.3 Comments on the Timeline for the Notice of Availability of the Draft PEIS

Eight commenters provided comments on the timeline for the Notice of Availability (NOA) of the Draft PEIS.

Several commenters supported the programmatic approach, emphasizing its importance in expediting reviews and ultimately the authorization of COPs.[361] A couple of commenters also recommended that BOEM should take an active role to ensure that environmental reviews remain on schedule.[362] A commenter emphasized the importance of timeliness in environmental reviews for the NY Bight and recommended that BOEM impose a firm schedule for its consultations with NOAA, USACE, and other agencies.[363]

---

[356] Responsible Offshore Development Alliance.
[357] NJDEP.
[358] J. Binder.
[359] Community Offshore Wind.
[360] Long Island Commercial Fishing Association.
[361] Invenergy Wind Offshore LLC, Community Offshore Wind.
[362] Community Offshore Wind, OW Ocean Winds East, LLC.
[363] Atlantic Shores Offshore Wind, LLC.

To facilitate the PEIS's role in expediting the NY Bight environmental reviews, a commenter recommended that drafts for specific COPs be initiated before the finalization of the PEIS; the commenter reasoned that doing so would provide flexibility for different tiering approaches and ensure the PEIS does not inhibit project-specific reviews.[364] Another commenter also emphasized that the PEIS process should be concluded within 2 years. As part of that process, the commenter stated that the representative project design envelope (RPDE) should be defined and the AMMM measures selected in a manner consistent with leaseholder needs; in particular, the commenter stated that AMMM measures should include reasonably foreseeable options. The commenter stated that, to facilitate timeliness, the scope of the PEIS should include all issues common across the NY Bight.[365]

Conversely, another commenter questioned the role of a PEIS in expediting the leasing process, stating that, in the August 2 meeting, BOEM statements on PEIS efficiency failed to recognize the capacity for developers to quickly collect field data and prepare for COPs. The commenter also stated that New York and New Jersey appear prepared to move forward with leasing, stating that "NYSERDA has teed up RFP3S, (2,000 MW minimum) while NJ BPU has teed up RFP 3 for Q1, 2023 (1,200 MW minimum)." The commenter questioned if developers, New York, and New Jersey agreed with the PEIS approach. In considering impacts on timeliness, the commenter stated that BOEM should consider the impact of delays on carbon dioxide emissions.[366] Another commenter expressed concern that the PEIS could impose delays because the process for offshore wind development is untested.[367]

Another commenter expressed concern for an expedited NY Bight PEIS timetable. The commenter stated that ongoing litigation involving wind turbines could impact developer permitting goals.[368] Another commenter stated that the "Fast 41" initiative, and the fast-tracking of development, serves private developers' interests at the expense of BOEM's duty to hold offshore resources in the public trust. The commenter expressed concern for the impacts of NY Bight development to marine life and stated that 60 days for review should be provided for the environmental review documents relevant to the project.[369]

O.8.4 Comments on Public Comment Process/Engagement

Approximately 10 commenters provided comments on the public comment process or engagement.

O.8.4.1 Public Outreach

A commenter recommended that BOEM develop a Community Outreach Plan to include in NEPA documentation and ensure that documentation is available to linguistically isolated communities.[370] Another commenter generally agreed that the BOEM should make efforts towards public participation

[364] Attentive Energy LLC.
[365] Community Offshore Wind.
[366] T. Barten.
[367] OW Ocean Winds East, LLC.
[368] Cape May County, NJ; Point O'Woods Association, Fire Island, NY.
[369] Clean Ocean Action.
[370] EPA.

and consultation with local communities.[371] A commenter stated that BOEM should continue to engage with the public and stakeholders in the scoping process for NY Bight environmental reviews.[372]

A commenter provided a citation in recommending that BOEM convene a roundtable with DAC stakeholders as part of PEIS development. The commenter recommended identifying DACs by coordinating with the Intergovernmental Renewable Energy Task Force and by using a Climate and Economic Justice Screening Tool. The commenter attached a sample agenda for such a roundtable. The commenter also recommended that BOEM post documentation and notes relevant to DAC outreach and engagement to the BOEM website, similar to BOEM practices for the Intergovernmental Renewable Energy Task Force.[373] Another commenter stated that BOEM should consider implementing an adaptive management plan to address the possibility of environmental impacts that become more significant than initially anticipated. The commenter stated that this plan may include roles for non-fishing stakeholders or community liaisons. In addition, the commenter recommended that BOEM develop a mariner communication plan.[374]

A commenter stated that some of the benefits of the PEIS approach could be realized by coordinating with developers, citing the 1- by 1-nautical mile east–west/north–south grid agreed upon by developers in the Massachusetts WEA.

O.8.4.2 Public Comment Process

A commenter suggested that 45-day comment periods be provided for NY Bight environmental reviews and added that commenters should, because of the tiering approach to reviews, have the right to revisit and comment further on COP-specific NEPA analyses beyond this period.[375] Another commenter requested that all future environmental review documents, including environmental assessments, be available in draft form for public comment.[376]

A commenter expressed concern that the NY Bight environmental review processes have not been concluded before leases are awarded to developers. The commenter stated that the public comment period for the NY Bight has been too short and that public hearings should be held. Furthermore, the commenter stated that BOEM has privileged the importance of New York's interests, rather than those of New Jersey, in the NY Bight project.[377] Another commenter stated that BOEM has recently entered into several "fast-tracked" memoranda of understanding and PAs relevant to offshore wind; the commenter stated that BOEM should clarify how these fast-tracked documents are being implemented for NY Bight lease developments and environmental reviews.[378]

[371] New York State.
[372] Invenergy Wind Offshore LLC.
[373] Aspen Institute.
[374] New York State.
[375] US Coast Guard.
[376] New England and Mid-Atlantic Fishery Management Councils.
[377] Borough of Seaside Park.
[378] Clean Ocean Action.

A commenter recommended that lessees in contiguous areas consolidate their public outreach processes for the fishing industry, reasoning that, for instance, there are similar interests for scallop fishers across all six lease areas.[379]

O.8.4.3 Transparency and Information Availability

A commenter stated that good governance requires public trust in project development and transparency.[380] Additionally, the commenter stated that research on wind farm impacts is disparate and that creating a centralized portal for this research would be useful. The commenter emphasized the importance of the PEIS using the best available science and dynamic modeling based on multiple scenarios. The commenter stated that, in evaluating research, BOEM should consider whether research comes from disinterested parties or researchers with conflicting financial motivations.[381] Another commenter also recommended that BOEM support a centralized data portal for information on the environmental impacts of offshore wind development.[382]

O.8.5 Request to Extend Public Comment Period

Two commenters provided comments about extending the public comment period.

A commenter recommended that the comment period for the programmatic DEIS "be extended by a minimum of 3 months" from the 45-day norm, and that BOEM issue a supplemental EIS if more information or inputs become available later.[383]

A commenter recommended that the comment period for the PEIS scoping be extended.[384] Another commenter stated that the public comment period for NY Bight development was too short.[385]

O.8.6 Comments on the Programmatic Approach

Approximately 10 commenters provided comments on the programmatic approach.

O.8.6.1 Support for the Programmatic Approach

A commenter supported the use of a PEIS in the NY Bight as the best way to assess impacts and examine alternatives. The commenter also stated that the PEIS standpoint will allow BOEM to examine potential export cable connection points and identify AMMM measures. However, the commenter questioned how the proposed framework would parse negligible, minor, moderate, and major impacts. The commenter recommended that the PEIS compare alternative, full build-outs for the NY Bight—rather than a representative project—and consider requiring a suite of AMMM measures as conditions of COP

[379] Fisheries Survival Fund.
[380] Clean Ocean Action.
[381] Clean Ocean Action.
[382] R. Griffin.
[383] J. Binder.
[384] J. Binder.
[385] Borough of Seaside Park.

approval. The commenter recommended that BOEM utilize representative projects for each lease as appropriate for a basic review of protected species, habitat, fisheries overlaps, and navigational conflicts for a full build-out analysis.[386] Another commenter also expressed support for the programmatic approach, anticipating that the PEIS would include planning for offshore wind infrastructure to minimize impacts on natural resources. The commenter also emphasized the importance of, within the PEIS, standardizing data collection for research and monitoring of impacts on wildlife and fisheries.[387] Another commenter urged BOEM to coordinate planning with the Department of Energy while also facilitating preconstruction surveys.[388] A commenter supported the PEIS as a way to discuss cumulative impacts and facilitate captains', anglers', and other stakeholders' input.[389]

Another commenter stated that the programmatic approach could improve the efficiency of the permitting process while programmatic AMMM measures could make impacts more predictable.[390] A commenter stated that PEIS can help mitigate environmental impacts by improving project citing. The commenter supported using a PEIS overall but stated that specific COPs should be assessed by a full EIS rather than an environmental assessment.[391]

O.8.6.2 Criticism of the Programmatic Approach

Conversely, a commenter opposed the PEIS approach as "bifurcating" reviews and threatening historic properties. The commenter stated that a better approach would "take into account all the interrelated historical, cultural, scientific and economic impacts and threats" associated with NY Bight wind power development. The commenter added that there have been insufficient pilot projects and scientific review to support NY Bight development. The commenter also stated that BOEM failed to follow its own regulations by issuing a proposed sale notice before an environmental review. The commenter stated that BOEM's process violates NEPA by providing too little scientific basis for a proposed action.[392] Another commenter stated that impacts, such as impacts on fisheries, should be evaluated on a project-specific level.[393]

Another commenter questioned whether a PEIS is appropriate, stating that a prior EIS for an offshore windfarm minimized impacts on sea turtles as "minor."[394] Also discussing minor impacts, another commenter hoped that BOEM will be able to identify minor environmental impacts, such as EMFs around transmission cables, at the PEIS stage.[395]

[392] Borough of Seaside Park.
[393] Fisheries Survival Fund.
[394] Clean Ocean Action.
[395] American Clean Power Association.

O.8.6.3 Other Comments on the Programmatic Approach

A commenter stated that BOEM should disclose all important information relevant to the PEIS and state when information is unavailable or incomplete, providing a citation. The commenter emphasized the importance of accurate, up-to-date information to inform its environmental reviews and its characterization of impacts as minor or major. The commenter recommended that, in situations where the predictive certainty of possible impacts is low, BOEM require monitoring and provide adaptive management recommendations.[396] Another commenter stated that the PEIS should be based on sound science according to "standards for which scientific validation will be used." The commenter said the PEIS should provide a framework for incorporating new science and "benchmarks" that BOEM would use to assess the project's impacts.[397]

A commenter recommended that BOEM describe standardized processes and metrics to evaluate deviations from the PEIS.[398] Another commenter requested that the Draft PEIS include an explanation of changes since BOEM efforts to develop a PEIS in 2007. The commenter also requested that the PEIS include a quantified cost-benefit analysis that includes impacts on electric ratepayers.[399]

A commenter stated that the PEIS for the NY Bight should not be applied to other regions as the PEIS will be based on region-specific data.[400]

A commenter stated that they recognize the benefits inherent in a programmatic approach to assessing the common impacts of offshore wind development and measures to mitigate those impacts. However, the commenter appreciated that BOEM has been clear that individual projects may submit a COP in a timeline that best suits their needs.[401]

O.8.7 Comments on the RPDE (Including Cable Routes, Landfalls, etc.)

Approximately 17 commenters provided comments on the RPDE.

O.8.7.1 Need for Flexibility in RPDE Analysis or Design Parameters

A commenter expressed concern with respect to the RPDE, stating that developers are likely to change the scope of their COPs after the PEIS is finalized and that it could be difficult to adjust environmental reviews to these changes while adhering to project timelines. The commenter provided an example of this from the Vineyard Wind offshore wind project.[402]

A commenter urged BOEM to examine a variety of representative models using different technologies, and, in particular, models using "quiet technology fixed-foundations" and floating wind technology. The

[396] National Wildlife Federation et al.
[397] Clean Ocean Action.
[398] New York State.
[399] J. Binder.
[400] American Clean Power Association.
[401] Attentive Energy LLC.
[402] Seafreeze Shoreside, Seafreeze Ltd.

commenter recommended that BOEM's analysis consider impacts on waves based on differing foundations, providing citations. The commenter stated that quiet technologies may cause less harm to marine mammals and thus expedite MMPA reviews.[403] Another commenter agreed that the RPDE should evaluate several representative projects and consider technologies to avoid and minimize environmental impacts. The commenter provided a list of its own priorities in RPDE design, including evaluating gravity-based and suction bucket alternatives, using vibro pile versus impact piling, and factors relevant to scour protection and timing of activities.[404] Another commenter also provided numerous recommendations for project planning, siting, and design to minimize environmental impacts.[405]

Other commenters stated that, because the PEIS process may take years and offshore wind technology is advancing, the RPDE should not prescribe the use of certain technologies[406] or should anticipate the development of technological advances.[407] A few commenters said that BOEM should design its RPDE around a set of principles and outcomes rather than means of achieving those outcomes.[408] One of the commenters said that, in addition to technology, the RPDE should not specify project layout or siting within the lease area.[409] Another commenter said that, under a "maximum-case scenario," specifying project parameters such as foundation type does not assist project design. The commenter recommended that project parameters should instead focus on environmental impacts.[410] A commenter provided citations to recent redesigns in the Vineyard Wind project, arguing that these indicate that even an RPDE designed to accommodate changing wind turbine technologies may be unable to anticipate changing developer preferences over 2 years.[411] A couple of other commenters stated that BOEM should consult with turbine manufacturers and other equipment providers to develop the RPDE.[412] One of the commenters stated that, once BOEM has done so and produced an RPDE, it should present the RPDE to leaseholders for comment.[413] A comment stated that it is difficult for developers to provide locations for landing sites and onshore facilities at the PEIS stage because these decisions rely on State permitting. The commenter recommended that BOEM assess categories of landing sites and onshore facilities, arguing that such an approach is appropriate under OCSLA and would allow evaluation of various impact-producing factors.[414]

414 Attentive Energy LLC.

A commenter said that BOEM should base its RPDE on public information for similar projects and should consult with DOE on the reasonably foreseeable limits of technical and economic feasibility.[415] Another commenter agreed that BOEM should rely on information from other projects to characterize "minor" impacts or to inform analysis.[416] With respect to economic feasibility, a commenter also recommended that BOEM consider supply chain issues and tax credit availability under the Inflation Reduction Act in its RPDE.[417]

O.8.7.2 Power Transmission

Several commenters addressed wind power transmission. One urged BOEM to consider a backbone transmission effort and comparative cable corridor development impacts as part of the PEIS.[418] A commenter stated that BOEM should consider Wind Turbine Generator (WTG) layout and spacing to accommodate fishing and transit needs. The commenter stated that the layout should maximize efficiency for cable layouts to serve neighboring projects—such as Ocean Wind and Atlantic Shores—and minimize turbulent flow and wake effects.[419] Another commenter agreed that BOEM should consider backbone transmission designs and coordinating power transmission among multiple projects.[420]

Another commenter stated that BOEM should require the use of jet plows to bury inter-array cables, providing citations and stating that this method causes the fewest adverse environmental impacts. The commenter added that BOEM should consider implementing seasonal restrictions on cable burial to protect wildlife. Additionally, the commenter stated that BOEM should take into account how cable burial increases turbidity and how developers can minimize these impacts. Finally, the commenter asserted that open loop cooling systems for direct current transmission would not be appropriate in the NY Bight, citing the impacts of such systems from another EIS.[421]

Another commenter recommended that BOEM, as ways to minimize mobilization of the seabed from burying cables, consider requiring that developers:

- Include a robust siting analysis to avoid dynamic areas with known high seabed mobility.
- Include mariner notifications of shallow-buried and exposed cables and cable protection measures.
- Include methods to monitor and maintain target burial depth for the maximum possible distance and expeditiously repair/rebury cable(s).
- Evaluate adaptive management if repeated cable exposures occur.

415 Invenergy Wind Offshore LLC.
416 T. Barten.
417 American Clean Power Association.
418 National Wildlife Federation et al.
419 EPA.
420 New England and Mid-Atlantic Fishery Management Councils.
421 National Wildlife Federation et al.

With respect to submarine cable system burial and risk assessment, the commenter recommended that BOEM:

- Include draft assessment in the COP and BOEM's COP-specific NEPA analysis.
- Evaluate existing and emerging cable installation techniques to achieve target burial depth for the maximum possible distance.
- Evaluate secondary cable protection measures and include how impacts have been avoided and minimized to the greatest extent possible.[422]

Another commenter recommended that, with respect to power transmission RPDE concerns, BOEM consider:

- Potential incorporation of meshed or shared offshore transmission.
- Closed vs open-loop cooling of offshore AC/DC conversion stations.
- Operational noise profiles among alternative turbine options.
- Cable route options (particularly focusing on conflict avoidance and improved energy delivery opportunities).[423]

Another commenter recommended that BOEM require submission of as-built surveys to identify cable protection areas and extant cables in a project area.[424]

O.8.8 Comments on the Proposed Tiered Review Process

Six commenters provided comments on the proposed tiered review process.

A commenter supported a tiered review process for NY Bight development and expressed optimism that leaseholders, regulators, and stakeholders can collaborate for an efficient environmental review process.[425] A commenter also supported the approach and recommended that BOEM provide sufficient detail in the PEIS to "support impact assessment at a landscape level" and prevent the duplication of analyses at the COP level.[426] Another commenter supported the tiered approach, stating that the approach should avoid the repeated discussion of similar issues for multiple projects. The commenter added that the tiered approach should facilitate the adoption of programmatic AMMM measures where appropriate while preserving flexibility for AMMM measures to address site-specific needs.[427]

[422] New York State.
[423] The Nature Conservancy.
[424] New York State.
[425] Vineyard Offshore LLC.
[426] Atlantic Shores Offshore Wind, LLC.
[427] New York Offshore Wind Alliance.

A commenter expressed concern that, if the PEIS is implemented, there will not be enough time to conduct thorough environmental analyses for specific COPs.[428]

A commenter wrote that adopting a tiered approach for windfarm development artificially bifurcates environmental review and prevents effective analysis of cumulative impacts. [429] Several commenters stated that more detail as to the tiered review process is needed.[430] The commenters asked, in particular, how "minor" environmental impacts will be handled at the project-specific tier of review.[431] Another stated that pre-approving AMMM measures has not previously been done in BOEM offshore wind leasing.[432]

O.8.9 Other Comments

Eight commenters provided other general comments on the PEIS, including comments specific to a lease area.

A commenter asserted that areas already leased at auction should be considered for the PEIS, not only those within NY Bight.[433] Another commenter added that the New Jersey lease area should be included in the scope of the PEIS.[434]

A commenter stated that BOEM should consider how recent commitments from New York and New Jersey to wind energy development demonstrate support for a local supply chain and how stakeholder engagement requirements affect the development of AMMM measures.[435]

A commenter wrote in support of green construction methods, including recycling materials and using energy-efficient technologies.[436]

A commenter stated that offshore wind development will be vital to meeting clean energy goals in the Northeast and mid-Atlantic, stating that it is currently impracticable to transmit energy from the "wind-belt" states.[437]

A commenter stated that it has performed research relevant to NY Bight development, providing citations. The commenter wrote that BOEM should reach out to its studies' authors to integrate their findings into BOEM's analyses.[438]

[437] T. Barten.
[438] Responsible Offshore Development Alliance.

A commenter listed lease blocks that fall into buffer zones identified by the Mid-Atlantic Marine Portal and cited a visual depiction to that end.[439]

A commenter asserted that, because leaseholders will develop COPs in parallel with the PEIS process, BOEM must coordinate with leaseholders up to the September 2023 Draft EIS to minimize delays.[440]

O.9 Out of Scope

A commenter provided comments on BOEM's "Process for Identifying Alternatives for Environmental Reviews of Offshore Wind COPs pursuant to the National Environmental Policy Act (NEPA)," stating that this document was never open for public comment and inaccurately reflects BOEM processes.[441]

P.1 Introduction

On January 12, 2024, the U.S. Department of the Interior (DOI) Bureau of Ocean Energy Management (BOEM) published a Notice of Availability (NOA) for the New York Bight (NY Bight) Draft Programmatic Environmental Impact Statement (PEIS), consistent with the regulations implementing the National Environmental Policy Act (NEPA) (42 United States Code [USC] 4321 et seq.), to assess the potential impacts of the Proposed Action and alternatives. The Draft PEIS was made available in electronic form for public viewing at https://www.boem.gov/renewable-energy/state-activities/new-york-bight, and hard copies or electronic copies were delivered to other entities as specified in Appendix N, *Distribution List*, of the Draft PEIS. The NEPA review process requires agencies to allow the public the opportunity to comment on a Draft PEIS. The NOA initiated a 45-day public comment period for the Draft PEIS. BOEM extended the comment period in response to requests from Tribal Nations and stakeholders. The extended comment period closed on March 13, 2024. This appendix describes the Draft PEIS public comment processing methodology and definitions, includes responses to comments received on the Draft PEIS, and describes where specific updates to the Final PEIS can be found in the document.

P.2 Objective

BOEM reviewed and considered all written and oral public submissions received during the Draft PEIS public review and comment period. BOEM's goal was to identify comments to be addressed in this Final PEIS and to categorize those comments based on the applicable resource areas or NEPA topics. This categorization scheme allowed subject matter experts to review comments directly related to their areas of expertise and allowed BOEM to generate statistics based on the resource areas or NEPA topics addressed in each of the comments. All public comment submissions received can be viewed online at http://www.regulations.gov by typing "BOEM-2024-0001" in the search field.

P.3 Methodology

P.3.1 Terminology

The following terminology is used throughout this appendix:

- Submission: The entire content submitted by a single person or group at a single time. For example, a 10-page letter from a citizen, an email with a portable document format (PDF) attachment, and a transcript of an oral comment given at a public hearing meeting were each considered to be a submission.
- Comment: A specific statement within a submission that expresses a sender's specific point of view, concern, question, or suggestion. A comment can consist of more than one sentence, as long as those grouped sentences express a single idea. One submission may contain many comments.

- Substantive Comment: Draft PEIS submissions were reviewed to identify and categorize "substantive" comments. To be substantive, a comment must relate to the reasonably foreseeable impacts of the Proposed Action, alternatives, or cumulative actions and do one or more of the following:
  - Question (with supporting rationale) the accuracy of information in the Draft PEIS.
  - Question (with supporting rationale) the adequacy of, methodology for, or assumptions used for the environmental analysis.
  - Present new information relevant to the analysis.
  - Present reasonable alternatives or mitigation measures other than those analyzed in the Draft PEIS.
  - Present or cause modifications to alternatives or mitigation measures analyzed in the Draft PEIS.
  - Correct factual errors in the content of the Draft PEIS.
- General Comment: General comments are comments other than substantive comments. General comments may: (1) express interest or concern regarding an impact topic without providing specific comments on the information, methods, or findings presented in the Draft PEIS; (2) express general support for or opposition to the Proposed Action or alternatives; or (3) comment on a topic unrelated to the Proposed Action or alternatives.

P.3.2 Comment Submittals

Tribal governments, federal agencies, state/local governments, and the general public had the opportunity to provide comments on the Draft PEIS via the following mechanisms:

- Electronic submissions via www.regulations.gov on docket number BOEM-2024-0001;
- Hard-copy comment letters submitted to BOEM via traditional mail; and
- Written or oral comments submitted at each of the public meetings.

BOEM held three in-person and two virtual public meetings via Zoom to solicit written and verbal comments to inform preparation of the Final PEIS. The meetings were free and open to the public. Locations and dates of these meetings are outlined in Table P.3-1.

Table P.3-1. Public Meetings

Date	Time	Location
January 31, 2024	5:00 p.m. Eastern Time	Zoom Webinar: https://kearnswest.zoom.us/webinar/register/WN_81Ha7GyxSXG-aNgk9EBajA
February 5, 2024	4:00 p.m. Eastern Time	UMass Dartmouth, The Marketplace, MacLean Campus Center, 285 Old Westport Rd, North Dartmouth, MA 02747
February 7, 2024	4:00 p.m. Eastern Time	Stony Brook University, Bauman Center for Leadership and Service, Benedict D013 Room C029, 200 Circle Rd, Stony Brook, NY 11790
February 8, 2024	4:00 p.m. Eastern Time	Clarion Hotel, 815 Route 37 West, Toms River, NJ 08755
February 13, 2024	1:00 p.m. Eastern Time	Zoom Webinar: https://kearnswest.zoom.us/webinar/register/WN__Bci_zhgRACj26jYkqrGlA

All submissions initially provided by methods other than www.regulations.gov, including the transcripts of comments recorded at each public meeting listed in Table P.3-1, were uploaded to the docket. Each submission, including testimony by individual speakers at the public meetings listed in Table P.3-1, was assigned a unique identification number. That unique Submission ID was retained throughout the comment management process, for both submissions and the individual comments within those submissions.

P.3.3 Comment Processing

BOEM downloaded and reviewed all submissions from regulations.gov. These submissions were provided in Hypertext Markup Language (html) format, while attachments provided by stakeholders as part of their regulations.gov submission were typically provided in PDF or Microsoft Word format. Text from all formats was parsed, coded, and exported into a single Microsoft Excel file that served as the primary submission database. In cases where an attachment did not contain comments specific to the docket for the NY Bight Draft PEIS, the attachment was retained separately for BOEM reference as applicable, linked to the main body of the submission through the unique Submission ID. Examples of this type of attachment include copies of comment letters that were originally submitted during the scoping period, copies of comment letters that were originally submitted on another docket, or attached photos, published reports, news articles, or other secondary material. The submission database also included information about each submission, including the submitter's contact information, submission date, and whether the submitter was a government entity or agency.

Each submission and all oral testimony were read to identify individual substantive and general comments (as defined under Section P.3.1, *Terminology*). Each comment was parsed, coded, and exported to a spreadsheet that served as the master comment database. Each comment then received a unique comment ID number, tied to the Submission ID. For example, the third comment identified in regulations.gov submission 0007 was identified as BOEM-2024-0001-0007-0003.

Substantive comments from cooperating agencies were organized by agency and are presented verbatim in Section P.4, *Responses to Cooperating and Participating Agency Comments on the Draft PEIS*. Other agency, stakeholder, and public comments were each assigned to one section of the Draft PEIS, based on the document's table of contents, or to a general topic such as "NEPA/Public Involvement Process." Substantive comments are presented verbatim in Section P.5, *Responses to Other Agency, Stakeholder, and Public Comments on the Draft PEIS*. General comments are summarized in Section P.6, *General Comment Summaries and Responses*, and the specific submissions that contributed to a comment summary are identified by submission number. Tables P.4-1 through P.8-1 include 1,507 of the 1,568 total comments submitted during the Draft PEIS comment period.[1]

[1] Additional comments from one cooperating agency and two tribes were submitted to BOEM internally and are not reflected in Appendix P per their request. However, their comments have been addressed in the Final PEIS, as appropriate.

P.4 Responses to Cooperating and Participating Agency Comments on the Draft PEIS

P.4.1 Cooperating and Participating Federal Agencies

P.4.1.1 National Park Service

Table P.4-1. Responses to Comments from the National Park Service (BOEM-2024-0001-0471)

Comment No.	Comment	Response
BOEM-2024-0001-0471-0001	Agency: NPS Commenter: NPS Section Title: Purpose of and Need for the Proposed Action Section #: 1.3 Page # 1-4 NPS is among the cooperating agencies participating in the PDEIS development process; would NPS continue to be engaged by BOEM on COP-specific NEPA reviews? NPS, as a bureau within DOI and cooperating Federal agency for the preparation of this EIS, has special expertise regarding the regulation of uses on NPS units and management of park system resources that includes compliance with the Park System Resource Protection Act (Public Law 113287, December 2014). NPS intends to support the decision to authorize mitigation and monitoring activities that are associated with park resources and their enjoyment on NPS lands and waters. Mitigation and monitoring activities on NPS lands and waters would include, but not be limited to, mitigation of impacts on National Historic properties, response activities should marine mammal strandings and/or disposals (burials) on NPS lands and waters increase, dark night skies, visitor experience, and economic impacts on lesees and other park partners operating within the park as a result of implementing the proposed plan.	BOEM will continue to engage with the U.S. Department of Interior National Park Service (NPS) for project-specific Construction and Operations Plan (COP) NEPA reviews.
BOEM-2024-0001-0471-0002	Agency: NPS Commenter: NPS Section Title: Purpose of and Need for the Proposed Action Section #: 1.3 Page #: 1-4 The Final Guidance for Effective Use of Programmatic NEPA Reviews (https://ceq.doe.gov/docs/ceq-regulations-and-guidance/Effective_Use_of_Programmatic_NEPA_Reviews_Final_Dec2014_searchable.pdf) for makes it clear that the Federal agency	Comment noted. BOEM appropriately describes, in Chapter 1, *Introduction,* why BOEM is preparing a programmatic analysis of the six NY Bight lease areas and the objectives for the programmatic review.

Comment No.	Comment	Response
	program responsible for complying with NEPA has the discretion to determine whether a programmatic NEPA review is appropriate (79 FR 76986). Discussion of why a PDEIS was identified by BOEM is appropriate, but it is not a distinguishing characteristic among the alternatives presented.	
BOEM-2024-0001-0471-0003	Agency: NPS Commenter: NPS Section Title: Purpose of and Need for the Proposed Action Section #: 1.3 Page #: 1-6 Line #: 5 Section 108 of the Fiscal Responsibility Act of 2023 (42 USC 4336b) provides time limits for PCEs, as allowing the programmatic environmental review document as being able to be relied on for 5 years as long unless there are substantial new circumstances or information about the significance of adverse effects that bear on the analysis. The question then becomes: How would post-construction monitoring be evaluated in a timely manner to verify that it either supports continued use of the PDEIS evaluation or provides the foundation for re-evaluating the underlying assumptions of the original analysis?	Prior to initiating NEPA review for each COP in the NY Bight, BOEM will review the COP and the PEIS to determine if the proposed project is within the general parameters of analysis included in the PEIS. BOEM will also evaluate whether the information analyzed in the PEIS is sufficient, considering factors such as age of data and availability of site-specific information, to incorporate by reference the analysis from the PEIS. If necessary, BOEM will engage in further analysis at the COP NEPA stage.
BOEM-2024-0001-0471-0004	Agency: NPS Commenter: NPS Section Title: Relevant Existing NEPA and Consulting Documents Section #: 1.5 Page #: 1-7 If the decision to lease for exclusive right to submit COPs for WTG construction has already been made, then including any characterization of the existing conditions (i.e., no WTGs) would have already been described in the associated NEPA analysis for the selected action. Since that analysis was completed and alternative selected, have there been substantive changes in the baseline condition that need to be captured in the PDEIS?	The PEIS used the most relevant and current information available regarding baseline conditions, and any information in the existing NEPA and consultation documents that were incorporated by reference was used, as appropriate.
BOEM-2024-0001-0471-0005	Agency: NPS Commenter: NPS Section Title: Alternatives Analyzed in Detail Section #: 2.1 Page #: 2-1 The decision to lease for exclusive right to submit COPs for WTG construction has already been made and the lease stipulations dictate options for consolidating equipment alignment and other features of any WTG (https://www.boem.gov/sites/default/files/documents/renewable-energy/state-activities/ATLW-8-NY-Bight-Final-Lease-Sale-Decision-Memorandum.pdf), so Alternative A: No Action Alternative in this	The No Action Alternative does not represent the minimum legal requirements for avoidance, minimization, mitigation, and monitoring (AMMM) measures and lease stipulations. As stated in PEIS Section 2.1.1, *Alternative A – No Action Alternative*, the No Action Alternative assumes that no offshore wind development occurs on any of the six NY Bight lease areas. The current resource conditions, trends, and impacts from ongoing and planned non-offshore wind and offshore wind activities under the No Action

Comment No.	Comment	Response
	PDEIS should describe how the minimum legal requirements for AMMMs would be met to meet the terms and conditions of that leasing decision. At this point in the decisionmaking process for the NY Bight lease and construction, it is disingenuous to represent not issuing the WTG leases and construction as the No Action Alternative. The content currently described under Alternative A would be more appropriate to describe the existing conditon that would be altered to the extent previously characterized in the EIS for the lease issuance decision and supplemented with new or additional information to document a change in baseline condition.	Alternative serve as the baseline against which the direct and indirect impacts of all action alternatives are evaluated.
BOEM-2024-0001-0471-0006	Agency: NPS Commenter: NPS Section Title: Alternatives Analyzed in Detail Section #: 2.1 Page #: 2-1 On what basis would any COP for WTG construction be rejected?	The purpose of this PEIS is not to approve any projects; the decision to approve, approve with modifications, or disapprove a COP will not occur until after COPs are submitted and another level of NEPA analysis is completed. Any decision to disapprove a COP would be made at that time, and BOEM cannot speculate on what that might be based on.
BOEM-2024-0001-0471-0007	Agency: NPS Commenter: NPS Section Title: Alternatives Analyzed in Detail Section #: 2.1 Page #: 2-1 Figure/Table #: 2-1 Alternative B is not within the range of reasonable alternatives because it does not characterize the minimum legally required AMMMs for leasing and construction of wind farms in the NY Bight. As described in this table, "full build-out of six NY Bight projects without the application of any AMMM measures" should be among the alternatives considered but dismissed if any one AMMM is legally required.	Refer to response to comment BOEM-2024-0001-0371-0004. Alternative B considers the potential impacts of future offshore wind development for the NY Bight area without the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts. However, the analysis in Alternative B assumes that development of the NY Bight projects would be required to comply with federal and international requirements.
BOEM-2024-0001-0471-0008	Section Title: Alternatives Analyzed in Detail Section #: 2.1 Page #: 2-1 If a revised Alternative A: No Action Alternative is to represent the minimum legal requirements for AMMMs and any lease stipulations, then revised Action Alternatives could consider any AMMMs that are above and beyond the minimum legally required AMMMs that would further reduce adverse impacts on resources or values at a programmatic level.	BOEM declines to modify the No Action Alternative. As stated in PEIS Section 2.1.1, the No Action Alternative assumes that no offshore wind development occurs on any of the six NY Bight lease areas. The current resource conditions, trends, and impacts from ongoing and planned non-offshore wind and offshore wind activities under the No Action Alternative serve as the baseline against which the direct and indirect impacts of all action alternatives are evaluated. Refer to response to comment BOEM-2024-0001-0371-0004 for additional clarification on Alternative B and Alternative C.

Comment No.	Comment	Response
BOEM-2024-0001-0471-0009	Section Title: Alternatives Analyzed in Detail Section #: 2.1.2.1.1 Page #: 2-5 If BOEM's authority under OCSLA extends only to activities conducted on the OCS, then who would have enforcement responsibilities for the AMMMs to be implemented outside the OCS? How do the cost recovery terms included in the leases reimburse agencies with jurisdiction for enforcement of the AMMMs that are to be implemented outside the OCS	As stated in PEIS Appendix G, not all AMMM measures are within BOEM's statutory and regulatory authority, and those that are not may still be imposed by other governmental agencies. Table G-1 in Appendix G indicates who has the enforcement responsibilities for AMMM measures in the "Anticipated Enforcing Agency" column. Mitigation measures that entail actions outside the Outer Continental Shelf (OCS) have been identified as recommended practices (RPs) and have been moved to Table G-2. If state or other entities choose to enforce these RPs through their respective permitting processes, those agencies would be responsible for the cost of enforcement.
BOEM-2024-0001-0471-0010	Agency: NPS Commenter: NPS Section Title: Transition Interconnection Configurations Section #: 2.1.2.1.1 Page #: 2-13 Line #: 3-8 As stated in this section, there are differing levels of environmental impacts that would result from the various combinations of transmission interconnection configurations. These would have meaningful differences that would provide the foundation for conducting impact analyses. These differences would be more meaningful than the current range of alternatives, where Alternative A has already been dismissed, Alternative B does not account for any legally required AMMMs, and Alternative C simply states that a wide range of AMMMs could become programmatic and applicable to all six leases.	As stated in PEIS Section 1.3, *Purpose of and Need for the Proposed Action*, BOEM's Proposed Action in the Final PEIS is to identify AMMM measures that could avoid, minimize, mitigate, and monitor impacts on resources in the six NY Bight lease areas. At this programmatic stage, the PEIS does not approve any projects, and BOEM is not considering project-level details or individual alternatives or AMMM measures that are project-specific. Project-specific alternatives will be considered by BOEM and cooperating agencies at the COP NEPA stage. RP MUL-18 encourages lessees to coordinate their transmission infrastructure among their projects. Also, refer to response to comment BOEM-2024-0001-0371-0004 for additional clarification on Alternative B and revisions made to Alternative C regarding AMMM measures. Alternative B considers the potential impacts of future offshore wind development for the NY Bight area without the AMMM measures identified in Appendix G that could avoid, minimize, mitigate, and monitor those impacts. However, the analysis in Alternative B assumes that development of the NY Bight projects would be required to comply with federal and international requirements.
BOEM-2024-0001-0471-0011	Agency: NPS Commenter: NPS Section Title: Alternatives Considered but Not Analyzed in Detail Section #: 2.2 Page #: 2-19 Line#: Rows 2-3 Figure/Table#: 2-3	Refer to response to comment BOEM-2024-0001-0471-0010. BOEM does not consider co-location or sharing of corridors as an enforceable AMMM measure. BOEM considers co-locating or sharing of corridors to be an RP and encourages lessees to

Comment No.	Comment	Response
	As stated in this section, there are differing levels of environmental impacts that would result from the various combinations of transmission interconnection configurations. These would have meaningful differences that would provide the foundation for conducting impact analyses. If co-location is to be promoted as a AMMM, then it needs to be analyzed for its benefit relative to not co-locating. As it stands now, this PDEIS dismisses the value of considering if and when co-locating cables or other wind farm-related features would actually result in more significant impacts to the human or natural environments. For example, to what extent would co-locating nearshore cables result in impacts that differ from not co-locating those cables? This analysis would be meaningful to any landowner in the vicinity of proposed cable crossings.	consider RPs in addition to the AMMM measures to further reduce impacts (see PEIS Appendix G, COMFIS-4, MUL-18, and MUL-23). Regarding landowners in the vicinity of cables onshore, as stated in PEIS Section 2.1.2.1.1, because the analysis in the PEIS was prepared before any of the NY Bight COPs were submitted by lessees, actual locations of landfall locations and onshore facilities are unknown at this time. Because the locations of cables on the OCS and those of landfalls and onshore facilities are unknown, the PEIS describes the types of impacts from construction and operation of transmission components generally, and largely defers the more specific analysis of these components and their locations to the COP-specific NEPA documents.
BOEM-2024-0001-0471-0012	Agency: NPS Commenter: NPS Section Title: Alternatives Considered but Not Analyzed in Detail Section #: 2.2 Page #: 2-19 Line #: Rows 2-6 Figure/Table #: 2-3 The rationale for dismissing these alternatives refers the reader back to Alternative C, relying very heavily on the idea that this alternative includes enough AMMMs to avoid speculative and unnecessary analysis. This conclusion can not be made from the range of alternatives presented in the PDEIS. The PDEIS provides no identification of thresholds or considerations for determining when co-locating any element of the wind farm would result in a quantifiable difference in conditions (e.g., temperature increase due to co-locating HVDC converters or not co-locating them). The matrix of AMMMs could be meaningfully different should the transmission interconnection configurations be different.	Refer to response to comments BOEM-2024-0001-0471-0010 and BOEM-2024-0001-0471-0011.
BOEM-2024-0001-0471-0013	Agency: NPS Commenter: NPS Section Title: Non-Routine Activities and Events Section #: 2.3 Page #: 2-21 Although non-routine activities and events are not possible to predict with certainty, are there aspects of how such events would be coordinated among agencies with jurisdiction that should be described in this section as common to all alternatives or aspects that would potentially differentiate the action alternatives?	Non-routine activities and events are analyzed in the PEIS for the resources and impact producing factors (IPF) where they apply and at a level consistent with a programmatic analysis. These activities and events would also be addressed in project-specific COP NEPA documents and may include more detailed information and analysis based on project-specific information. Information on coordination with agencies on these activities and events would be addressed in more detail in project-specific COP NEPA

Comment No.	Comment	Response
		documents when more detail on the offshore and onshore components, including specific locations of project components, is known.
BOEM-2024-0001-0471-0014	Agency: NPS Commenter: NPS Section Title: Summary and Comparison of Impacts by Alternative Section #: 2.4 The purpose of this section is to explain the impacts resulting from implementation of any alternative, summarizing conclusions that can only result after review of Chapters 3 and 4. This summary table could be appropriate to include at the end of Chapter 4 or a new Chapter 5. For Chapter 2: Alternatives, a summary of similarities and differences among the elements of alternatives that are currently detailed in Appendix G would be more informative, particularly because the current range of alternatives relies heavily on illustrating how Alternative C would offset impacts via inclusion of AMMMs programmatically.	Council on Environmental Quality (CEQ) NEPA implementing regulations at 40 Code of Federal Regulations (CFR) 1502.14 requires EISs to present the environmental impacts of the proposed action and alternatives in comparative form in the proposed action and alternatives section of the environmental impact statement (EIS) (PEIS Chapter 2). The impact conclusions presented in Chapter 2, Table 2-4, account for the implementation of AMMM measures under Alternative C. Also, refer to response to comment BOEM-2024-0001-0371-0004 for additional clarification on Alternative B and revisions made to Alternative C regarding AMMM measures.
BOEM-2024-0001-0471-0015	Agency: NPS Commenter: NPS Section Title: Summary and Comparison of Impacts by Alternative Section #: 2.4 Figure/Table #: 2-4 The relative value of implementing any AMMMs under Alternative C is not noticeably different when compared to impacts under Alternative B. Therefore, the basis for which BOEM identified the proposed action is Alternative C remains unclear as it relates to the purpose and need, as other questions listed on page 2-17.	The overall impact rating conclusions (as shown in PEIS Table 2-4 and Executive Summary Table ES-2) may not always be different under Alternative C when compared to Alternative B, while impacts for specific individual IPFs may be different. Depending on the specific IPF and the resource analyzed, there can be notable differences that change the impact determination for a specific IPF under Alternative C (see Lighting IPF in PEIS Section 3.5.3, *Birds*, under Alternative B and Alternative C). However, the overall impact rating conclusions for the resource encompasses all IPF impact conclusions. The details of the analysis for each IPF and the justification for the overall impact conclusion for a resource is found in the Chapter 3, *Affected Environment and Environmental Consequences,* resource sections. The Proposed Action for the Final PEIS is the identification of AMMM measures at the programmatic stage that could avoid, minimize, mitigate, and monitor impacts on resources in the six NY Bight lease areas. Refer to response to comment BOEM-2024-0001-0371-0004 for additional clarification on revisions made to Alternative C regarding AMMM measures.

Comment No.	Comment	Response
BOEM-2024-0001-0471-0016	Agency: NPS Commenter: NPS Section Title: Primary IPFs Discharge/Intakes Section #: 3.1 Page #: 3.1-2 Figure/Table #: 3.1-1 Types of discharges from the HVDC converter cooling system should include warmer water and associated thermal effects (according to chapter 2, page 2-8).	Additional analysis has been added to Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative*; *Discharges/intakes,* to further describe the warm water discharges.
BOEM-2024-0001-0471-0017	Section Title: Primary IPFs – Noise Section #: 3.1 Page #:3.1-4 Figure/Table #: 3.1-1 Does noise include broad range of sensitive receptors (e.g., more than human) and in all media (e.g., air, water)?	As described in Table 3.1-1, the Noise IPF captures impacts from both offshore and onshore activities and therefore describes impacts both in the air and water. Potential noise impacts are described for both human and animal receptors in various Chapter 3 resource sections.
BOEM-2024-0001-0471-0018	Agency: NPS Commenter: NPS Section Title: Impact Terminology Section #: 3.3.2 Page #: 3.3-3 Line #: 2 & Footnote Short-term effects are characterized as 3 years in the main text parenthetically and supplemented with a footnote that says 3 to 5 years. Clarification is needed to assist the reader to understand whether impacts that could occur during years 4 and 5 have been described as either short- or long-term effects.	BOEM has revised the parenthetical to include a 3–5 year range based on the footnote.
BOEM-2024-0001-0471-0019	Agency: NPS Commenter: NPS Section Title: Impact Analyses Section #: 3.4 In addition to its land base, NPS has jurisdiction over the water column on the intercoastal waterway side north of Fire Island National Seashore (NS) and jurisdiction from mean high tide to 1000 feet out, including the ocean bottom on the ocean side south of Fire Island. Gateway National Recreation Area (NRA) also includes ocean waters within its boundaries. The potential impacts within the boundaries of Fire Island NS and Gateway NRA from accidental discharges of fuel, trash, debris from construction/operation/ decommissioning, discharge of bilge water and associated invasive species should be addressed. Notification and coordination with Fire Island and Gateway should be included in any proposed mitigation plans (e.g. spill response plans). This should be addressed throughout the DEIS as there are accidental release sections in all Affected Environment sections.	Comment noted. The "Accidental releases" IPF considers the impacts of accidental discharges of fuel, trash, and other debris. This IPF is included in Proposed Action (Alternative C) and alternatives analysis for resources where such impacts would be applicable. In addition, a project-specific COP NEPA review would revisit all potential impacts on land and water areas under NPS jurisdiction should the details in a project-specific COP indicate potential direct or indirect effect on these areas.

Comment No.	Comment	Response
BOEM-2024-0001-0471-0020	Agency: NPS Commenter: NPS Section Title: Impacts of Six Projects Section #: 3.4.1.4.2 Page #: 3.4.1-20 Line #: 4 To what extent would activation of the WTGs likely result in reduction in emission generation by fossil-fuel plants? Does lease, construction, and operation of the WTGs require a reduction in fossil-fuel plant operations? What evidence is used to support statements in this paragraph about electricity pricing, power plant dependence, and decisions to alter existing output or taking plants offline? If no mandate or evidence can support the conclusion that activating WTGs would actually result in a reduction of dependence on fossil-fuel plant operations, then the analysis must focus on how much additional impact would result if WTGs are activated and there is no change in fossil-fuel plant operations. There is too much uncertainty and speculation included in the current analysis to conclude that either Alternative B or C is preferrable to Alternative A.	Leasing, construction, and operation of the wind turbine generators (WTG) do not require a reduction in fossil-fuel plant operations. However, the response of the grid to the introduction of wind energy is market-based: wind energy would displace fossil fuel energy to the extent that it is offered to the grid at a lower price than the bids from fossil-fueled energy sources. BOEM expects that wind energy would be bid at a lower price and consequently would be substituted for and not add to energy from fossil-fueled energy sources. If there were no reduction of fossil-fuel plant operations, then there would be no avoided emissions, and the project emissions would be as shown in Final PEIS Table 3.4.1-6 (*Operations and maintenance emissions from a single NY Bight project*).
BOEM-2024-0001-0471-0021	Agency: NPS Commenter: NPS Section Title: Impacts of Alt C Water Quality Discharges/Intakes Section #: 3.4.2.5.1 Page #: 3.4.2-23 As described on pages 2-7 and 2-8, different equipment would be required on each OSS depending on whether HVAC or HVDC technology is used and HVDC cooling systems may employ an open loop system that discharges warmer water back into the ocean. Although MUL-21 requires the use of the best available technology, it does not exclude the potential use of open loop systems that would have thermal impacts on ocean water quality. These thermal impacts are not quantifiably characterized or analyzed in the PDEIS. The conclusion that measurable impacts are expected to be minimal is unsupported, as no measurements or reference to supporting research has been cited to provide a foundation for this impact analysis. Furthermore, other similar conclusions related to potential discharge impacts (e.g., benthic habitat, sea turtles) are also unsubstantiated.	MUL-21 is now included as an RP in Section 3.4.2.6 (see PEIS Appendix G for descriptions of RPs), but BOEM does encourage lessees to analyze and consider implementing all RPs to reduce impacts on environmental resources. Clean Water Act (CWA) Section 316(b) requires National Pollutant Discharge Elimination System (NPDES) permits to ensure that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available to minimize adverse environmental impacts. The project-specific, COP-level NEPA analysis will provide further details.
BOEM-2024-0001-0471-0022	Agency: NPS Commenter: NPS Section Title: Benthic resources geographic analysis area Section #: 3.5.2-2 Figure/Table #: 3.5.2-1	Figure 3.5.2-1 was developed to display the geographic analysis area for benthic resources. Consistent with other figures in the

Comment No.	Comment	Response
	The boundary for Gateway National Recreation Area and Fire Island National Seashore (including waters) should be delineated on this map so proximity to the submarine export cable can be seen; the same is true for other maps that include NPS lands in these documents.	PEIS displaying the geographic analysis area, it does not display site-specific features as that information is not needed and would distract from the purpose of the figure. In addition, as described in Chapter 2, the location of offshore export cables are not known so geographic features potentially affected by the cables cannot be depicted on figures. Future project-specific COP NEPA EIS documents will identify cable corridors and analyze their effects on environmental resources.
BOEM-2024-0001-0471-0023	Agency: NPS Commenter: NPS Section Title: Recreation and Tourism Section #: 3.6.8.1.2 Page #: 3.6.8-3 Line #: 2 Expectations of experiences in National Parks differ from other shoreline areas; therefore, the Peregrine Energy Group Inc (2008) report and other references may not adequately evaluate impacts of visible WTGs on beach use and the visitor experience of cultural landscapes, bathing beaches, night skies, and natural areas within the National Park properties that would be impacted by the proposed project. Gateway National Recreation Area's 2014 General Management Plan (https://www.nps.gov/gate/learn/management/gmp-2012.htm) identifies management zones that provide a spectrum of visitor experiences from developed areas to remote natural areas. Evaluation of the proposed project impacts on recreation and tourism should account for the unique experiences that visitors expect at a coastal National Park and the management zones and range of visitor experiences identified in the Park's 2014 General Management Plan. The General Management Plan identifies darkness and night sky, feelings associated with open space in a high-density area, views of the New York Outer Harbor, contemplation of the physical environment, astronomy, and the beach experience as fundamental resources and values. The same considerations apply at Fire Island National Seashore, including in evaluating the impacts of the project on the Otis Pike Fire Island High Dunes Wilderness.	Refer to response to comment BOEM-2024-0001-0466-0012 concerning visual resources.
BOEM-2024-0001-0471-0024	Agency: NPS Commenter: NPS Section Title: Recreation and Tourism Section #: 3.6.8.1.2 Page #: 3.6.8-4 Line #: 1	Refer to response to comment BOEM-2024-0001-0355-0020.

Comment No.	Comment	Response
	Gateway National Recreation Area's 2014 General Management Plan (https://www.nps.gov/gate/learn/management/gmp-2012.htm) identifies leasing as a primary tool for long-term rehabilitation and preservation of the Park's historic structures. The Park has executed 5 long-term leases for rehabilitation and adaptive re-use of historic structures within the Fort Hancock and Sandy Hook Proving Ground National Historic Landmark District. The Park is currently in negotiations and planning for leasing of more than 20 additional historic structures at Sandy Hook. The Park has issued a long-term lease for the rehabilitation and adaptive re-use of the historic bathhouse at Jacob Riis Park. Several years ago, the Park released a request for interest for leasing historic structures in the Fort Tilden Historic District and the USCG Station Far Rockaway Historic District and plans to move ahead with leasing in those areas of the Park in the future. Preservation of the leased historic structures is dependent upon the economic viability of the leasee. Impacts of the proposed project on recreation and tourism that support the leased facilities will impact the long-term viability of the leased properties and subsequently the capacity of the Park to maintain and preserve the historic structures. Impacts of the proposed project on historic structures within the existing and proposed leasing program should be evaluated in the PEIS.	
BOEM-2024-0001-0471-0025	Agency: NPS Commenter: NPS Section Title: Recreation and Tourism Section #: 3.6.8.1.2 Page #: 3.6.8-4 Line #: 1 Although the New York and New Jersey shores in general have been extensively developed, the shores within National Park Service Units within the project area have not been extensively developed. Visitors come to these National Parks to experience more natural and undeveloped shorelines within the broader more highly developed landscape. Thus the impact of the proposed project on National Park Service Recreation and Tourism cannot be treated the same as the highly developed shoreline areas within the affected environment for recreation and tourism.	Refer to response to comment BOEM-2024-0001-0355-0020.
BOEM-2024-0001-0471-0026	Agency: NPS Commenter: NPS Section Title: Impacts of Alts B and C Recreation and Tourism Section #: 3.6.8.4 and 3.6.8.5	Thank you for the comment. Helicopters, when used, would leave existing airports and follow all transportation/flight path

Comment No.	Comment	Response
	Would use of helicopters be anticipated to occur over NPS lands and waters? PEIS discusses use of helicopters during construction and O&M, which would be over 35 year lifespan of the project. PEIS does not provide characterization of potential noise impacts on NPS natural soundscape at Gateway National Recreation Area (a park fundamental resource) and human receptors enjoying the natural habitats and environments at Gateway National Recreation Area (a park fundamental value). NPS Resource Brief that provides a baseline characterization of the acoustic environs at this park are available in Wood 2015, "Acoustic Environment and Soundscape Resource Summary, Gateway National Recreation Area," accessible at https://irma.nps.gov/DataStore/Reference/Profile/2225921. The park's fundamental resources and values are characterized here: http://npshistory.com/publications/foundation-documents/gate-fd-2017.pdf.	restrictions required by transportation agencies. Most crew transport is expected to occur by vessels. Project-specific NEPA EIS documents will address helicopter use and any potential noise impacts in greater detail.
BOEM-2024-0001-0471-0027	Agency: NPS Commenter: NPS Section Title: Scenic and Visual Resources SLIA Affected Environment Section #: 3.6.9.1.1 Page #: 3.6.9-9 Figure/Table #: Table Footnote Please correct the footnote to state that Gateway National Recreation Area is a unit of the National Park System.	Comment noted and revision has been made.
BOEM-2024-0001-0471-0028	Agency: NPS Commenter: NPS Section Title: Scenic and Visual Resources SLIA Affected Environment Section #: 3.6.9.1.2 Page #: 3.6.9-18 Figure/Table #: 3.6.9-11 The table does not specifically state that there is consideration of both daytime and nighttime experiences for receptors. With approximately 9 million visitors annually, Gateway National Recreation is the 4th most visited park within the National Park System. Evaluation of impacts of the proposed action on scenic and visual resources must recognize that visitors to National Parks expect an experience that is different from many developed shorelines. Gateway National Recreation Area's 2014 General Management Plan (https://www.nps.gov/gate/learn/management/gmp-2012.htm) identifies management zones that provide a spectrum of visitor experiences from developed areas to remote natural areas. Evaluation of the proposed project impacts on the scenic and visual	Thank you for your comment. Table 3.6.9-11 has been revised to recognize National Park visitor experiences and documented dark sky environments. The following language was added to High Sensitivity: “visitors to National Park System sites, where visitors expect a visual and sensory experience emphasizing a unique nature experience, protected views, and dark night skies. Dark sky environment is documented as high quality on the Bortel scale (Bortel 1-2).” The following language was added to Medium Sensitivity: “Dark sky environment is documented as moderate quality on the Bortel scale (Bortel 3-4).”

Comment No.	Comment	Response
	resources and visitor experience should account for the unique experiences that visitors expect at a coastal National Park and the management zones and range of visitor experiences identified in the Park's 2014 General Management Plan. The General Management Plan identifies darkness and night sky, feelings associated with open space in a high-density area, views of the New York Outer Harbor, contemplation of the physical environment, astronomy, and the beach experience as fundamental resources and values.	
BOEM-2024-0001-0471-0029	Agency: NPS Comment #: 27 Commenter: NPS Section Title: Description of the Affected Environment and Future Baseline Conditions Section #: 3.6.21 Page #: 3.6.2-6 When defining "cultural resource" the National Register of Historic Places should be identified as the regulatory basis for physical/tangible resources.	Thank you for this comment, but no changes were made for the following reasons: effects considered under NEPA include historic and cultural (40 C.F.R. § 1508.8); the term "cultural resources" covers a wider range of resources than "historic properties" as defined in 36 CFR 800.16(l)(1), such as sacred sites, archaeological sites not eligible for listing in the National Register of Historic Places, and archaeological collections; and Table 3.6.2-2 provides definitions for both "cultural resources" and "historic properties," with the latter referencing the aforementioned definition included in the Section 106 regulations.
BOEM-2024-0001-0471-0030	Agency: NPS Comment #: 28 Commenter: NPS Section Title: Description of the Affected Environment and Future Baseline Conditions Section #: 3.6.21 Page #: 3.6.2-6 Figure/Table #: 3.6.2-2 Again, when describing marine archeological resources the document is making a tangential reference to the National Register of Historic Places while avoiding any explicit reference. The 50-year time frame is based on the National Register of Historic Places and should be acknowledged.	Thank you for this comment, but no changes were made for the following reason: according to 30 CFR 585.113, "archaeological resource" means any material remains of human life or activities that are at least 50 years of age and are of archaeological interest (i.e., which are capable of providing scientific or humanistic understanding of past human behavior, cultural adaptation, and related topics through the application of scientific or scholarly techniques, such as controlled observation, contextual measurement, controlled collection, analysis, interpretation, and explanation). Please also refer to response BOEM-2024-0001-0471-0029.
BOEM-2024-0001-0471-0031	Agency: NPS Comment #: 29 Commenter: NPS Section Title: Description of the Affected Environment and Future Baseline Conditions Section #: 3.6.21 Page #: 3.6.2-8 Line #: 3 and 5 Potential historic properties should be characterized as "unidentified" or "unevaluated", aligning with verbiage used in federal regulations.	Thank you for this comment, but for the purposes of this programmatic NEPA document, the phrase "potential historic properties" in the context of "resources anticipated to be located in the Programmatic Visual APE" is appropriate (see page 3.6.2-8).

Comment No.	Comment	Response
BOEM-2024-0001-0471-0032	Agency: NPS Comment #: 30 Commenter: NPS Section Title: Description of the Affected Environment and Future Baseline Conditions Section #: 3.6.21 Page #: 3.6.2-8 Line #: 3 and 6 As defined by the National Register of Historic Places, property types include more than just buildings. This sentence is awkwardly phrased and does not align with the guidance provided in the NRHP.	Thank you for this comment, but no changes were made for the following reasons: effects considered under NEPA include historic and cultural (40 C.F.R. § 1508.8); the term “cultural resources” covers a wider range of resources than “historic properties” as defined in 36 CFR 800.16(l)(1); and the sentence already references non-building property types, including cultural landscapes and traditional cultural places.
BOEM-2024-0001-0471-0033	Agency: NPS Comment #: 31 Commenter: NPS Section Title: Description of the Affected Environment and Future Baseline Conditions Section #: 3.6.21 Using this document to tier the identification and analysis of impacts to cultural resources is negated by the fact that we lack sufficient information to allow for any of the prescribed process to occur at this early stage.	The programmatic approach is not intended to analyze impacts on specific cultural resources. The identification and specific analysis of effects on cultural resources will be required as part of each developer’s COP submission. The programmatic effort establishes a prescribed process to be applied to the analysis that will be required as part of that later stage of COP environmental review. BOEM is meeting the reasonable, good faith effort standard.
BOEM-2024-0001-0471-0034	Agency: NPS Comment #: 32 Commenter: NPS Section Title: Impact Level Definitions to Cultural Resources Section #: 3.6.22 Page #: 3.6.2-9 Figure/Table #: 3.6.2-3 The impact levels as correlated to an adverse effect versus a no adverse effect finding is narrowly defined and the framework is flawed. These categories don't translate to how impact assessments are made in real-world scenarios and are weighted towards a no adverse effect determination.	BOEM applies the National Historic Preservation Act (NHPA) Section 106 definition (36 CFR 800.5(a)(1)) of an adverse effect. Each undertaking has one effect finding. Through this analysis, individual properties are evaluated in the areas of potential effects (APEs) to make this one finding for the undertaking. Therefore, BOEM will make a finding of adverse effect for the undertaking even when some historic properties are not adversely affected but one or more historic properties are adversely affected. Procedurally, BOEM needs to provide this step in the event that there is a no adverse effect finding for the undertaking; however, none of the previous COP reviews to date have resulted in a finding of no adverse effect for the undertaking.
BOEM-2024-0001-0471-0035	Agency: NPS Comment #: 33 Commenter: NPS Section Title: Impact Level Definitions to Cultural Resources Figure/Table #: 3.6.2-3 The definition and criteria used for major impacts to cultural resources that “could” result in an adverse effect determination misrepresents the definition as stated in the federal regulations. Major impacts would result in an adverse effect and don’t have to impact all seven aspects of integrity, as noted in the table, to result in an adverse effect finding. The level of impacts presented in the table	BOEM would like to clarify that Table 3.6.2-3 reads “could occur,” not “could result in an adverse effect determination.” If there is a potential for an adverse effect, then the lead federal agency can make a finding of an adverse effect. This table defines the levels of potential impacts on cultural resources and is intended to cross-walk the potential scenarios resulting in findings between NEPA and NHPA. Furthermore, the description of major impacts as applied to historic properties under Section 106 of the NHPA does

Comment No.	Comment	Response
	provides a level of latitude that does not align with codified federal regulations.	not require all seven aspects of integrity to be diminished to result in an adverse effect finding, as the comment states.
BOEM-2024-0001-0471-0036	Agency: NPS Comment #: 34Commenter: NPS Section Title: Cumulative Impacts of the No Action Alternative Section #: 3.6.2.3.2 Page #: 3.6.2-13 Line #: 3 and 9 The National Historic Preservation Act was enacted in 1966 and subsequently amended four times: 1976 (Pub. L. No. 94-422, 90 Stat. 1320), 1980 (Pub. L. No. 96-515, 94 Stat. 2987), 1992 (Pub. L. 102-575, 106 Stat. 4753), and 2016 (Pub. L. No. 96-515).	Thank you for the information about the NHPA.
BOEM-2024-0001-0471-0037	Agency: NPS Comment #: 35 Commenter: NPS Section Title: Cumulative Impacts of the No Action Alternative Section #: 3.6.2.3.2 Page #: 3.6.2-13 Line #: 3 and 7 If submerged maritime archeological resources at Gateway National Recreation Area waters were to be adversely impacted by activities, mitigative measures could be applied to other GATE resources if mitigating impacts to a particular maritime archeological resource is truly undoable, and as determined through consultation.	Thank you for this comment. BOEM will consult with NPS if there are any impacts on individual NPS units at the COP NEPA stage. As appropriate, BOEM will consider creative mitigation measures through consultation with the NPS for any historic properties that are adversely affected in NPS units.
BOEM-2024-0001-0471-0038	Agency: NPS Comment #: 36 Commenter: NPS Section Title: Socioeconomic Conditions and Cultural Resources Section #: 3.6.8.1.1 Page #: 3.6.8-2 Figure/Table #: 3.6.8-1 The delineated boundary excludes the bay abutting Staten Island and potentially impacted recreational areas in the vicinity, specifically those associated with Gateway National Recreaton Area. It's not clear why Staten Island is included but not associated waters.	Thank you for your comment. The waters of the Gateway National Recreation Area are not included because BOEM does not anticipate that the offshore wind activities would impact the recreation and tourism quality of those waters. The waters of that area are included in other resource assessments.
BOEM-2024-0001-0471-0039	Agency: NPS Comment #: 37 Commenter: NPS Section Title: Socioeconomic Conditions and Cultural Resources Section #: 3.6.9.1 Page #: 3.6.9-7 Figure/Table #: 3.6.9-4 Fort Tilden Historic District and the Floyd Bennet Field are both missing from the map. Ensure that all Gateway NRA historic districts are reflected on the map.	Thank you for your comment. These sites have been added to Figure 3.6.9-7 and the more detailed maps in Appendix H, specifically Figures H-2, H-7, H-8, and H-13. Figure 3.6.9-7 shows the entire geographic analysis area; therefore, some of these smaller NPS sites are not visible at this scale.
BOEM-2024-0001-0471-0040	Agency: NPS Comment #: 38 Commenter: NPS Section Title: Socioeconomic Conditions and Cultural Resources Section #: 3.6.2 Page #: 3.6.2-1 Consider a heavy rewrite of this section in general. There are	Thank you for your comment. The commenter does not pose a question or raise specific issues with the environmental analysis.

Comment No.	Comment	Response
	recurring issues with basic concepts regarding cultural resource management and historic preservation that are not accurately presented in the narrative.	
BOEM-2024-0001-0471-0041	Agency: NPS Commenter: NPS Section Title: Socioeconomic Conditions and Cultural Resources Section #: 3.6.2 Page #: 3.6.2-2 If "BOEM expects each lessee to complete the requisite cultural resource technical studies" National Criteria for Evaluation should be used. Maintaining consistency across individual evaluations will be key. preliminary APE (PAPE) per the COP PDE, completion of associated cultural resource and historic property identification efforts, assessment of potential effects, and development of potential AMMM measures for identified historic properties.	As stated in the *Draft Programmatic Agreement Among The U.S. Department of the Interior, Bureau of Ocean Energy Management; The State Historic Preservation Officers of New York and New Jersey; and The Advisory Council on Historic Preservation Regarding Six Renewable Energy Projects (Leases OCS-A 0537, 0538, 0539, 0541, 0542, and 0544) Offshore New York and New Jersey Under Section 106 of the National Historic Preservation Act* (hereafter, the Draft Programmatic Agreement for the NY Bight), and consistent with all other offshore wind COP approval requirements, lessees are required to identify historic properties in the marine, terrestrial, and visual APEs; assess potential effects; and propose AMMM measures. These reports are then consulted upon during the Section 106 consultation. The cultural resource technical studies are required to meet the "reasonable and good faith effort" described in 800.4(b)(1) and to follow BOEM's "Guidelines for Providing Archaeological and Historic Property Information" as well as all applicable state guidelines and requirements. Additional information can be found in Stipulation I.B of the Draft Programmatic Agreement for the NY Bight.
BOEM-2024-0001-0471-0042	Agency: NPS Commenter: NPS Section Title: Socioeconomic Conditions and Cultural Resources Section #: 3.6.2 Page #: 3.6.2-3 The primary objective of the programmatic Section 106 review is to provide an opportunity for Section 106 consulting parties to identify historic properties early in project planning that could be avoided and/or minimized from project impacts and consult on and identify a consistent Section 106 consultation process that will allow Tribal Nations and consulting parties to consult as early as possible for each of the six project-level reviews.	Thank you for the comment. The commenter does not pose a question or raise issues with the environmental analysis. While the Section 106 Programmatic Agreement provides for a consistent review and consultation process for each of the six COP NEPA reviews, BOEM does not intend to identify any specific historic properties through this programmatic evaluation. Developers of individual leases will be required to undertake comprehensive identification of historic properties within the marine, terrestrial, and visual APEs, and BOEM will assess the effects of each project on those identified historic properties during the COP NEPA reviews and related consultations.
BOEM-2024-0001-0471-0043	Agency: NPS Commenter: NPS Section Title: Socioeconomic Conditions and Cultural Resources Section #: 3.6.2 Page #: 3.6.2-3	Thank you for your comment. Please refer to Stipulation I.B.2 through I.B.5 in the Draft Programmatic Agreement for the NY

Comment No.	Comment	Response
	In order to execute the PA and potential future MOA(s), APEs must be firmly established in order to identify all possibly impacted cultural resources. Please clarify.	Bight for the details of how the APEs for each project will be delineated during the COP stage reviews.
BOEM-2024-0001-0471-0044	Agency: NPS Commenter: NPS Section Title: Impact Level Definitions to Cultural Resources Section #: 3.6.2.2 Page #: 3.6.2-10 Figure/Table #: Table 3.6.2-4 Issue of what is later described as "accidental releases" such as unanticipated disturbance from fuel spills and associated cleanup activities should be added to this table.	Table 3.6.2-4 summarizes high-level disturbances. Accidental releases are classified under IPFs and are included in offshore seabed disturbance later in the text of Section 3.6.2.3 for Alternative A, Section 3.6.2.4.1 and 3.6.2.4.3 for Alternative B, and Section 3.6.2.5.1 for Alternative C (Proposed Action).
BOEM-2024-0001-0471-0045	Agency: NPS Commenter: NPS Section Title: Cumulative Impacts of the No Action Alternative Section #: 3.6.2.3.2 Page #: 3.6.2-17 Under 'Presence of Structures,' could they also be characterized as permanent intrusive visual elements to the viewsheds of cultural resources? Or is there a plan to remove them after their life cycle? Please clarify.	There is an expected lifecycle of these projects; see Decommissioning in Chapters 2 and 3. These are not considered permanent structures for the purposes of this PEIS. Lessees can request that facilities remain in place in the decommissioning application submitted to the U.S. Department of the Interior Bureau of Safety and Environmental Enforcement (BSEE (30 CFR 285.900-285.913), but BOEM approves or does not approve the request (30 CFR 585.434). Unless otherwise determined during the decommissioning application review, NY Bight lessees would be required to remove or decommission all facilities, projects, cables, pipelines, and obstructions and clear the seabed of all obstructions created. Conceptual decommissioning would typically follow a “reverse installation” process, with turbine components or the offshore substation (OSS) topside structure removed prior to foundation removal.
BOEM-2024-0001-0471-0046	Agency: NPS Commenter: NPS Section Title: Cultural Resources Section #: 3.6.2 Page #: 3.6.2-16 Document states: "The impacts of construction and operational lighting would be limited to cultural resources subject to visual impacts and for which a dark nighttime sky is a contributing element to historical integrity." NPS disagree. We have raised this general issue with BOEM before on various wind project. Please consult with NPS Cultural Resource Specialists. NPS suggested rewording statements about night sky quality and protection being limited only to those cultural resources where was called out in the national register listing of the property. The night sky as an integral part of the	BOEM is demonstrating a reasonable and good faith effort with identifying and evaluating potential historic properties pursuant to the Section 106 regulations and is not required to evaluate if a dark night sky is a character-defining feature of each individual resource at this programmatic stage. BOEM will continue to consult with NPS cultural resource specialists regarding any potential concerns regarding nighttime operational lighting. The use of the term "cultural resources" was chosen by BOEM to reflect a broader range of resources than would be suggested by the use of the term historic properties and because it is a term used in NEPA. Please refer to the CEQ Advisory Council on Historic

Comment No.	Comment	Response
	cultural landscape and its importance was not acknowledged back when many historic properties were evaluated for the National Register. Now we know that the night sky resource is an integral component of the overall setting and feel of a historic property and/or cultural landscape, and can be of ethnographic importance and value to indigenous peoples. Dark skies / cultural landscapes are important to all historic sites, whether or not dark skies were recognized independently during designation of historic sites.	Preservation (ACHP) handbook, which defines key terms in NEPA and Section 106 reviews [https://www.achp.gov/integrating_nepa_106]. BOEM notes that it agrees with the NPS characterization of earlier National Register of Historic Places (NRHP) nominations as not being the only source of information for evaluating historic properties. BOEM does not solely rely on the character-defining features identified in NRHP nominations to determine whether a project would have an adverse effect on a particular historic property.
BOEM-2024-0001-0471-0047	Agency: NPS Commenter: NPS Section Title: Cultural Resources Section #: 3.6.3 Page #: 3.6.2-17 It's great to see that benefits of using ADLS are mentioned here. NPS would like to see the developer is committed in using ADLS.	Thank you for this comment. The Draft Programmatic Agreement for the NY Bight Appendix IV includes Aircraft Detection Lighting Systems (ADLS) as a standard minimization measure. At this programmatic evaluation stage, there are no COPs under review. ADLS will continue to be a standard minimization measure at the COP-level review stage.
BOEM-2024-0001-0471-0048	Agency: NPS Commenter: NPS Section Title: Scenic and Visual Resources Section #: 3.6.9 Include nighttime simulations for Fire Island or Sandy Hook, as the current PEIS does not. As those two units/locations are the most likely to be impacted, those visuals would be crucial for informing a decision. Moreover, the Wilderness area is one of the key resources at Fire Island likely to be impacted, yet there are no visual simulations from within the wilderness itself.	Nighttime simulations were created for Key Observation Point (KOP)-38 Robert Moses Field 5, which is less than a mile from Fire Island Lighthouse. Although 14.5 miles south of more sensitive wilderness environments on Fire Island, KOP-38 is 2 and 7 miles closer to lease area OCS-A 0544 and Empire Wind (OCS-A 0512), respectively, making it a more conservative point for comparison. KOP-38 is comparable to Sandy Hook for understanding nighttime impacts from Empire Wind but is 45 miles from NY Bight lease area OCS-A 0544. For the COP-level NEPA stage, additional analysis and KOPs will be considered.
BOEM-2024-0001-0471-0049	Agency: NPS Commenter: NPS Section Title: Scenic and Visual Resources Section #: 3.6.9 The potential cumulative impacts of all 6 areas within the Bight being developed seems significant, even with mitigation measures. Do they have a procedure for addressing cumulative effects, as individual development plans are proposed and, especially, if approved?	Cumulative impacts are analyzed for each alternative in Chapter 3.6.9 and in Appendix H.4. Table 3.6.9-27 and 3.6.9-28 show the additive changes as other leases areas are constructed for each NY Bight WTG height. To consider the six NY Bight projects from a cumulative perspective for Alternative B, please see Section 3.6.9.4.2, Impact of Six Projects. Because the NY Bight leases are far from shore (the closest distance is 20 nautical miles [37 kilometers] and the average distance is 32 nautical miles [59 kilometers]), their individual and collective visibility is greatly reduced. See Table 3.6.9-16, Magnitude of View Summary.

Comment No.	Comment	Response
BOEM-2024-0001-0471-0050	Agency: NPS Commenter: NPS Section Title: Scenic and Visual Resources Section #: 3.6.9 Please provide an ADLS efficacy analysis so that the impact from the flashing red lights can be quantified for the cases with and without ADLS.	Thank you for your comment. An efficacy analysis on an ADLS was not completed specifically for the programmatic evaluation of NY Bight. Nighttime visual impact is based on visual simulations and analysis of ADLS effectiveness conducted for Atlantic Shores South and Empire Wind (See Section 3.6.9.5, Impacts of Alternative C – Lighting). Impacts are based on 2018–2019 air traffic over the nearby Atlantic Shores South (OCS-A 0499) and Empire Wind (OCS-A 0512) lease areas, which are representative of New Jersey and New York, respectively, and hours of sunlight and darkness. The Atlantic Shores South (OCS-A 0499) ADLS-controlled obstruction lights would be activated for 9 hours over a 1-year period, 1 percent of the normal operating time that would occur without ADLS (Atlantic Shores 2022). The Empire Wind (OCS-A 0512) ADLS-controlled obstruction lights would be activated for 357 hours, 46 minutes, and 45 seconds over a 1-year period, 7.5 percent of the normal operating time that would occur without ADLS (Equinor 2022). A single NY Bight project is estimated to have similar or fewer shorter-duration synchronized flashing of ADLS, as compared to the standard continuous, medium-intensity red strobe U.S. Department of Transportation Federal Aviation Administration (FAA) warning system. The ADLS aviation hazard lighting would be in use for the duration of operations and maintenance (O&M) of any of the NY Bight projects. VIS-7 would establish monitoring requirements for ADLS to determine the frequency of use and effectiveness of the ADLS system. The potential visibility of aviation lights is documented in Table H-42 and H-43 at Key Observation Points for each lease area and for each WTG height. In addition, the photo simulations available on the BOEM website (https://www.boem.gov/renewable-energy/state-activities/new-york-bight) quantify the number of WTG hubs (where the aviation light is located) visible for each KOP by lease area. An analysis of lighting effects will be conducted at the project-level NEPA stage and would include an analysis of ADLS lighting, if such lighting is part of the COP.

BOEM-2024-0001-0471-0051	Agency: NPS Commenter: NPS Viewshed impacts to FIIS Visual impacts were identified from the Fire Island Lighthouse and it is also stated that the structures would be visible from Watch Hill. This means that there will also be viewshed impacts to the Carrington Estate (NHPA listed) and the Fire Island Otis Pike wilderness area. BOEM is encouraged to use the visual impact analysis for Fire Island from Empire Wind 1 and 2 for the NY Bight Draft Programmatic EIS and to incorporate this analysis into an updated impact analysis for NHPA-listed properties.	Please see response to comment BOEM-2024-0001-0466-0011. At this programmatic stage, BOEM is not making any findings of effect on historic properties, including Fire Island Lighthouse. Findings of effect will occur during COP-level NEPA and NHPA Section 106 review.
BOEM-2024-0001-0471-0052	Agency: NPS Commenter: NPS Onshore cable impacts onshore cable locations are not discussed in this document. Given the potential impact that these connected onshore activities could have, we request that any landfall connections and related activities be explicitly excluded from NPS administered lands and existing or proposed designated wilderness areas to preserve the integrity of these protected lands and the purposes of the parks.	Thank you for the comment. Landfall locations for cables will be addressed in project-specific NEPA EIS documents. The PEIS does not have these locations to evaluate them.
BOEM-2024-0001-0471-0053	App D Planned Activities Agency: NPS Commenter: NPS Section #: D.2.9 Page #: D-14 Given the anticipated take of marine mammals resulting from implementation of the proposed action, the NPS and BOEM would need to establish an agreement or understanding to coordinate marine mammal stranding response activities (e.g., biological sample collection, euthanization, carcass burial, Tribal government consultations, cost recovery) that may occur on NPS lands and waters.	BOEM encourages NPS to reach out directly to the National Marine Fisheries Service (NMFS) regarding marine mammal stranding response on NPS properties. BOEM proposed activities are not anticipated to result in any stranding of marine mammals.
BOEM-2024-0001-0471-0054	App G Mitigation and Monitoring Agency: NPS Commenter: NPS Section #: 1 Page #: G-1 The assemblage of AMMMs presented is diverse, comprising at least four distinct categories: 1. Within a Federal agency's statutory and regulatory authority; 2. Mitigations required under NHPA Section 106; 3. Enforceable under state permitting requirements; 4. Voluntary. This paragraph explains that at some future time, BOEM may determine that any or all AMMMs might not be included in leases if a COP-analysis finds that implementation of such measure is not warranted or effective. Thus, it becomes very difficult (if not	BOEM has reviewed and considered public comments on AMMM measures and revised the measures as presented in Appendix G. In an effort to create a more efficient process, the PEIS analyzes AMMM measures that are commonly applied through the COP NEPA stage process. The Final PEIS would signal to lessees which AMMM measures would apply to one or more of the NY Bight projects. Refer to response to comment BOEM-2024-0001-0406-0004 regarding the revision of the purpose and need in the Final PEIS.

Comment No.	Comment	Response
	impossible) to understand how analysis of these AMMMs as part of Alternative C is meaningfully different from Alternative B.	
BOEM-2024-0001-0471-0055	Agency: NPS Commenter: NPS Section #: 3 Page #: G-1 How are the "Previously Applied as a COP Term and Condition" AMMMs relevant to the current PDEIS and/or leases issued for the NY Bight? These are terms and conditions of leases beyond the scope of this PDEIS, and the basis for their inclusion in any other BOEM-issued leases or relevance to any current/future leases in the NY Bight is not obvious or explained. Are these the lease stipulations (section 6 of https://www.boem.gov/sites/default/files/documents/renewable-energy/state-activities/ATLW-8-NY-Bight-Final-Lease-Sale-Decision-Memorandum.pdf)? If so, they should be used to provide the foundation upon which the No Action Alternative is developed.	Refer to responses to comments BOEM-2024-0001-0317-0016 and BOEM-2024-0001-0331-0012.
BOEM-2024-0001-0471-0056	Agency: NPS Commenter: NPS Section #: 4 Page #: G-1 Line #: 3 What monitoring duration would be required to determine that any single AMMM could or should be excluded from the AMMMs as not warranted or ineffective, and therefore excluded from COP-specific NEPA analysis? How would potentially lengthy transient dynamics be considered in the decisionmaking process of determining which AMMMs are deemed unwarranted or ineffective? What qualitative and quantitative thresholds, or metrics, would be used to conclude any particular AMMM would be unwarranted or ineffective?	In an effort to create a more efficient process, the PEIS analyzes AMMM measures that are commonly applied through the COP NEPA process. The Final PEIS would signal to lessees which AMMM measures would apply to one or more of the NY Bight projects. Refer to response to comment BOEM-2024-0001-0406-0004 regarding the revision of the purpose and need in the Final PEIS.
BOEM-2024-0001-0471-0057	Agency: NPS Commenter: NPS Page #: G-3 Line #: BB-3 Listed mitigation does not include painting one rotor black to enhance rotor visibility to birds, which has been shown to decrease collisions by 70%. 	yellow (2700K or warmer); shielding to direct light downward; lowest lumens possible; and fixtures with adaptive technology controls such as timers, motion detectors, hue adapters, and dimmers.	
BOEM-2024-0001-0471-0059	Agency: NPS Commenter: NPS How would new AMMMs be incorporated programmatically to the NY Bight leases?	As noted in Section 1.3, *Purpose and Need for the Proposed Action*, BOEM is evaluating as part of the PEIS AMMM measures that BOEM may require as conditions of approval for activities proposed by lessees in COPs submitted for the NY Bight lease areas. Refer to response to comment BOEM-2024-0001-0406-0004 regarding the revision of the purpose and need in the Final PEIS.
BOEM-2024-0001-0471-0060	AppH SLVIA Agency: NPS Commenter: NPS Section Title: Visual Impact Assessment Section #: H.3.2.1 Page #: H-78 Figure/Table #: H-33 The Sandy Hook Light is missing from the table. Please add. Agency: NPS Commenter: NPS Section Title: Magnitude Section #: H.3.2.2 Page #: H-80-81 Figure/Table #: H-34 and H-35 The Sandy Hook Light is missing from the table. Please add.	Forty KOPs were initially identified for analysis during scoping. Following the analysis, eight of these KOPs appeared outside of the affected viewshed and have been removed from the impact analysis. KOP-20 Sandy Hook Beach and KOP-34 Sandy Hook Observatory were two of the eight removed.
BOEM-2024-0001-0471-0061	Appl NHPA Summary Agency: NPS Commenter: NPS Section Title: NY Bright Programmatic Visual Impact Analysis Key Observation Points Section #: I.2.4.1 Page #: I-18 Figure/Table #: Table I-4 KOP No. 20 Sandy Hook Lighthouse NHL needs a simulation both during clear and cloudy days and nights.	The visual simulations presented in the Programmatic Visual Impact Analysis are examples and are not fully representative of all affected resources. Individual COP-level analysis will provide additional visual assessments, which may include daytime and nighttime simulations.
BOEM-2024-0001-0471-0062	Agency: NPS Commenter: NPS Section Title: Background Section #: I.1.1 Page #: I-1 Baseline data is information often employed to compare other data acquired afterward. It serves as a foundation of projects. Since "BOEM will not have the results of archaeological surveys prior to the issuance of leases or grants and, as such, will be conducting historic property identification and evaluation efforts in phases" the information gathered is unlikely to serve as a true baseline.	Appendix I, Section I.1.1 states that the current programmatic review of the six New York Bight leases “seeks to compile baseline information, where feasible,” which does not indicate the intention to compile a comprehensive and final baseline as that is not feasible at this programmatic stage.
BOEM-2024-0001-0471-0063	Agency: NPS Commenter: NPS Section Title: Programmatic Area of Potential Effect Section #: I.1.3 Page #: I-4	Thank you for this comment, but it is not clear which part of the text is of concern. As a result, no changes were made.

Comment No.	Comment	Response
	National Criteria for Evaluation as described by the National Register of Historic Places should prevail when lessees complete the requisite cultural resource technical studies.	
BOEM-2024-0001-0471-0064	Agency: NPS Commenter: NPS Section Title: Marine Portion of the Programmatic APE Section #: I.1.3.1 Page #: I-7 Basing adverse effects on typical hypothetical activities cannot accurately reflect impacts.	Thank you for this comment, but BOEM does not intend to identify any specific impacts through this programmatic evaluation, as this evaluation does not yet include individual COPs. Developers of individual leases will be required to thoroughly propose processes, locations, schedules, and other pertinent data, and BOEM will assess the impacts of project activities at that time.
BOEM-2024-0001-0471-0065	Agency: NPS Commenter: NPS Section Title: Terrestrial Portion of Programmatic APE Section #: I.1.3.2 Page #: I-7 The terrestrial portion discussion fails to account for impacts other than ground disturbing activities, whereas elsewhere mitigations are discussed for "screening" of above ground components. Please resolve this issue in the document.	The Terrestrial APE only considers terrestrial ground disturbance with the potential to disturb archaeological historic properties. It is unclear from this comment how "screening" aboveground resources is relevant to protecting archaeological historic properties; therefore, no changes were made.
BOEM-2024-0001-0471-0066	Agency: NPS Commenter: NPS Section Title: Historic Aboveground Resources Section #: I.3.4 Page #: I-15 Under point no. 2 please make edits to "views and vistas" to more precisely define the differences between these two features.	Appendix I Section I.3.4 was revised to remove the word "vistas."
BOEM-2024-0001-0471-0067	Agency: NPS Commenter: NPS Section Title: Historic Aboveground Resources Section #: I.3.4 Page #: I-15 Under no. 5 add design to the aspects of integrity that could be impacted since a "vista" is a deliberate and controlled via design elements.	Please refer to the response to comment BOEM-2024-0001-0471-0066.
BOEM-2024-0001-0471-0068	Agency: NPS Commenter: NPS Section Title: NY Bright Programmatic Visual Impact Analysis Key Observation Points Section #: I.3.4.1 Page #: I-18Figure/Table #: I-4 The correct name of the NHL is the "Sandy Hook Light". Please make this correction.	Thank you for this comment. The name for Sandy Hook Light was revised.
BOEM-2024-0001-0471-0069	Agency: NPS Commenter: NPS Please include Sandy Hook Proving Ground NHL district.	Thank you for this comment. Sandy Hook Proving Ground Historic District is noted to be a National Historic Landmark (NHL); however, Table I-4 only includes NHLs that are also KOPs. At this time, Sandy Hook Proving Ground Historic District is not a KOP due to the close proximity of Sandy Hook Light, which is a KOP.

Comment No.	Comment	Response

Table P.4-2. Responses to Comments from the National Park Service (BOEM-2024-0001-0466)

Comment No.	Comment	Response
BOEM-2024-0001-0466-0001	[Bold: Comments] We are concerned that the DPEIS may be fatally flawed because it does not provide a range of reasonable alternatives. Alternative A (No Action Alternative) does not align with existing condition characterized in the EIS for the lease issuance decision. Alternative B does not characterize the minimum legally required AMMMs for leasing and construction of wind farms in the NY Bight and Alternative C is not noticeably different in impacts (when compared to Alternative B) so basis for selection of that alternative as proposed action is unclear. More specific comments are provided on the DPEIS tab of the excel file. If the DPEIS alternatives are flawed then tiered compliance would also be flawed. In addition, if the DPEIS is flawed NPS would not be able to adopt BOEM compliance if authorization of project elements on NPS lands is necessary. Related to the above paragraph and detailed in our comments in the spreadsheet the DPEIS is not well grounded in law and does not identify minimal legal requirements.	The analysis in the PEIS is not flawed. The No Action Alternative presents the potential impacts associated with ongoing and future activities absent the development of offshore wind in the NY Bight lease area. This has been updated to reflect the most current information going into the Final PEIS. BOEM has provided additional clarification on the purpose of Alternative B (see PEIS Chapter 2). Alternative B serves to compare how impacts would change with AMMM measures analyzed in Alternative C. Alternative B considers the potential impacts of future offshore wind development for the NY Bight area without the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts. However, the analysis in Alternative B assumes that development of the NY Bight projects would be required to comply with federal and international requirements. The PEIS will not result in the approval of any activities. As detailed in the PEIS, Alternative C may or may not be noticeably different than Alternative B. Depending on the specific IPF and the resource analyzed, there can be notable differences that can change the impact determination for an IPF under Alternative C (see Lighting IPF in PEIS Section 3.5.3, *Birds*, under Alternative B and Sub-alternative C1).

Comment No.	Comment	Response
		Regarding the potential effects on National Park Service Lands and adopting BOEM compliance, because details on locations of onshore project components are not known for this programmatic environmental review, details on resource impacts, including any on National Park Service lands, are also not known in detail. These specific impact details would be assessed in project-specific COP NEPA documents for NY Bight lease areas that might be developed in the future. The AMMM measures in Alternative C are considered programmatic insofar as they may be applied to COPS for the six NY Bight lease areas, not because they necessarily will apply to COPs under BOEM's renewable energy program outside of the NY Bight lease areas. BOEM has modified the PEIS language describing the Proposed Action and refined language throughout the PEIS to make clear that this PEIS is *not imposing* any AMMM measures—and therefore is not establishing a presumption at COP review that a lessee would need to rebut—but is identifying those AMMMs that BOEM may impose at the COP NEPA stage. By identifying and analyzing those AMMMs now, the expectation is that the analysis at the COP NEPA stage can be more streamlined and efficient.
BOEM-2024-0001-0466-0002	Given the potential impact that these connected onshore activities could have we request that any landfall connections and related activities be explicitly excluded from NPS administered lands and existing or proposed designated wilderness areas to preserve the integrity of these protected lands and the purposes of the parks.	Comment noted. Specific landfall connections will be determined at the COP NEPA stage and can be further discussed at that time.
BOEM-2024-0001-0466-0003	Visual impacts were identified from the Fire Island Lighthouse and it is also stated that the structures would be visible from Watch Hill. This means that there will also be viewshed impacts to the Carrington Estate (NHPA listed) and the Fire Island Otis Pike wilderness area. BOEM is encouraged to use the visual impact analysis for Fire Island from Empire Wind 1 and 2 for the NY Bight DPEIS and to incorporate this analysis into an updated impact analysis for NHPA-listed properties.	Thank you for your comment. For the COP-level NEPA stage, additional analysis will be considered. Visual impacts from the Carrington House can be correlated to KOP-37 Point O'Woods, which is approximately 2.88 miles southwest. At this programmatic stage, BOEM is not making any findings of effect on historic properties, including Fire Island Lighthouse. Findings of effect will occur during COP-level NEPA and NHPA Section 106 review.
BOEM-2024-0001-0466-0004	As requested in our previous letters Fire Island National Seashore and Gateway National Recreation Area should be identified on all the	Thank you for this suggestion, but BOEM does not intend to identify any specific historic properties through this programmatic

Comment No.	Comment	Response
	maps that show the NY Bight. The boundary of each park unit and its various districts should be outlined and labeled including boundaries as they extend into ocean and bayside waters. We also request that point locations are included for all National Historic Landmark (NHL) locations. We can assist in providing location data to fulfill this request.	evaluation. Developers of individual leases will be required to undertake comprehensive identification of historic properties within the marine, terrestrial, and visual APEs, and BOEM will assess the effects of each project on those identified historic properties during the COP-level reviews.
BOEM-2024-0001-0466-0005	[Bold: NPS Units and Program Lands in the NY Bight] NPS manages two National Parks in the NY Bight Fire Island National Seashore and Gateway National Recreation Area and has program responsibilities for numerous National Historic Landmarks (NHLs) in the NY Bight identified pursuant to the National Historic Preservation Act of 1966 (NHPA) (54 U.S.C. 300101 et seq.). NPS has provided information on each of these areas below to satisfy BOEM's request for information on the topics listed in the NOI including a) biological resources including bats birds coastal fauna finfish invertebrates essential fish habitat marine mammals and sea turtles; b) physical resources and conditions; and c) socioeconomic and cultural resources including land use and coastal infrastructure recreation and tourism and scenic and visual resources as applicable and would like this information added where appropriate to the DPEIS.	Thank you for your comment. BOEM recognizes that there are numerous recreation areas and historic landmarks throughout the geographic analysis area for this PEIS, too many to name and characterize them all. For this PEIS, BOEM did not list and assess each one individually to the level of detail as will be required in a project-specific COP NEPA analysis. At that stage, additional project specifics (e.g., locations, size, timing) will be known that will enable that level of analysis for each of the six NY Bight lease areas.
BOEM-2024-0001-0466-0006	[Bold: Overview of Fire Island National Seashore] Fire Island National Seashore (the Seashore) lies along the south shore of Long Island in Suffolk County New York. The Seashore encompasses 19580 acres of upland tidal and submerged lands along a 26- mile stretch of the 32-mile barrier island part of a much larger system of barrier islands and bluffs stretching from New York City to the very eastern end of Long Island at Montauk Point. Easily accessed on Fire Island are nearly 1400 acres of federally designated Wilderness (The Otis Pike Fire Island High Dune Wilderness) that include an extensive dune system centuries-old maritime forests and solitary beaches. On the western end of the Seashore is the Fire Island Lighthouse. Nearby on Long Island adjacent to the Village of Mastic Beach the 613-acre William Floyd Estate preserves more than 250 years of history. The park maintains the historic house cultural landscape and archival collection that includes items pertaining to both the estate and the Seashore.	Refer to response to comment BOEM-2024-0001-0466-0005.

Comment No.	Comment	Response
	Approximately 60 miles away from densely populated New York City lies the Fire Island Wilderness a landscape of wind-swept dunes and dynamic waves. The Fire Island Wilderness has been afforded the highest level of protection by Congress under the Wilderness Act of 1964 (16 U.S.C. 1131 et seq.) in order to preserve its unique and ever-changing ecosystems. In the Fire Island Wilderness forces of nature are allowed to take their course creating a refuge for wildlife and people alike. Interspersed among the federal lands within the Seashore on Fire Island are 17 residential communities that predate the Seashore's authorization. Resort development on Fire Island began as early as 1855 and a number of the island's communities were established prior to the 1930s. The Seashore's enabling legislation includes provisions for private land to be retained and developed if zoning requirements are met. No hard-surfaced roads connect the communities either to each other or to the mainland of Long Island. Communities are accessible mainly by passenger ferry or private boat. Vehicle use is restricted within the boundary of the Seashore. Without paved roads and with limited traffic the communities have retained much of their original character. Some of the communities have hotels or facilities for overnight guests while others are strictly residential. There are approximately 4200 developed properties on Fire Island with approximately 300 residents living on the island year-round. The number of year-round residents has slowly and steadily declined in recent years. Vehicle access is limited for year-round residents contractors and other service providers (telephone fuel garbage etc.) because all vehicles crossing federal lands must have a National Park Service driving permit. The population of Fire Island swells to approximately 30000 during the summer season with a total of two to three million visitors each year. In 2016 recreational visitation to sites and facilities owned or managed by the Seashore was 389075. The primary visitor facilities on Fire Island are the Fire Island Lighthouse Sailors Haven Watch Hill Talisman and the Wilderness Visitor Center. Fire Island Lighthouse is maintained and operated by the Fire Island Lighthouse Preservation Society an NPS cooperating association that offers tours and other visitor programming. Concessioners operate the marina at Sailors	

Comment No.	Comment	Response
	Haven as well as the marina and campground at Watch Hill. The Seashore offers lifeguard- protected swimming areas at Sailors Haven Talisman/Barrett Beach and Watch Hill. Also on Fire Island are ranger stations visitor contact facilities maintenance facilities and several units of park housing. At either end of Fire Island are major state and county beaches that receive sizable visitation and are accessible by vehicle. On Long Island the Seashore's headquarters are in Patchogue and include administrative offices a maintenance facility and a ferry terminal. The William Floyd Estate in Mastic includes the Old Mastic House several outbuildings and structures a cemetery curatorial storage facility preservation and maintenance shop and other natural and cultural resources.	
BOEM-2024-0001-0466-0007	[Bold: Wildlife at Fire Island National Seashore] Habitats within the Fire Island National Seashore are important refuge for a wide variety of migratory and resident birds. A total of 333 avian species have been observed within the Seashore; 67 have been documented to breed within the Seashore (Mitra and Putnam 1999 Trocki 2008). The Seashore is within the Atlantic Flyway a major North American migratory bird route that spans the northern habitats of the Arctic islands coastal Greenland and Canada to as far south as Jamaica and South America (Bird and Nature 2009). The Seashore provides a resting and feeding area for migratory birds traveling this route. Migrating and wintering birds of prey also are inhabitants of Fire Island National Seashore. The northern harrier (*Circus cyaneus*) and American osprey (Pandion haliaetus) may use marsh habitats on the island for nesting while short-eared owls (*Asio flammeus*) long-eared owls (*Asio otus*) and snowy owls (*Nyctea scandiaca*) are occasional winter inhabitants. Other birds of prey using the park may include the red-tailed hawk (*Buteo jamaicensis*) and the bald eagle (Haliaeetus leucocephalus) (Trocki 2008). Fire Island is one of the best-known hawk migration areas on the Eastern seaboard. Peregrine falcons (*Falco peregrinus*) merlins (*Falco coumbarius*) Cooper's hawks (*Accipiter cooperii*) sharpshinned hawks (*Accipiter striatus*) harriers (*Circus spp*.) and short-eared owls (*Asio flammeus*) also winter on Fire Island.	BOEM appreciates the NPS submitting detailed information for Fire Island National Seashore, which is within the birds geographic analysis area. Given that the onshore project components are generally unknown in this programmatic level analysis, BOEM intends to use this detailed information in any future COP-specific NEPA document developed for the NY Bight lease areas, as appropriate.

BOEM-2024-0001-0466-0008	Nineteen species of marine mammals have been recorded within the boundaries of the Seashore. Identified species include whales porpoises dolphins and seals. The harbor seal (*Phoca vitulina*) is a regular winter visitor at both the Fire Island and Moriches Inlets. Three species of endangered whales have been reported in the waters offshore of Fire Island: fin whale (*Balaenoptera physalus*) humpback whale (*Megaptera novaeangliae*) and northern right whale (*Eubalaena glacialis*) (Trocki 2008).	This information has been incorporated into Section 3.5.6.1.
BOEM-2024-0001-0466-0009	Fire Island National Seashore is used by an array of special-status species including migratory birds butterflies (migratory Monarch Butterflies) and bats including the federally listed Northern Long-Eared Bat [Italics: *Myotis septentrionalis*].	A sentence has been added to Section 3.5.4.1.1 highlighting Fire Island National Seashore.
BOEM-2024-0001-0466-0010	Federal- and state-listed species include the Piping Plover (*Charadrius melodus*) the roseate tern (*Sterna dougallii*) the least tern (*Sterna antillarum*) and the common tern (*Sterna hirundo*). All four are shorebirds that rely on maritime beach and dunes for nesting between March and July. Birds have been found to nest at differing locations from year to year but the Fire Island Wilderness and several of the bay islands appear to be the most popular nesting sites.	Refer to response to comment BOEM-2024-0001-0466-0007.
BOEM-2024-0001-0466-0011	[Bold: Visual Impacts at Fire Island] Visual impact assessments have been done in and around Fire Island for the Empire Wind 1 and 2 Projects. With this DPEIS there is an opportunity to provide a more comprehensive assessment of the cumulative visual impacts from development of the newly leased areas and Empire Wind. NPS recommends the following locations be included as Key Observation Points (KOPs) at the Seashore for this new analysis. Fire Island National Seashore: -Otis Pike Fire Island High Dune Wilderness: views to the southwest from the eastern and western areas of the Wilderness-Watch Hill: view from the ocean overlook-Sailors Haven: view from the ocean overlook-Fire Island Lighthouse Keepers Quarters: view from the Terrace area-Fire Island Lighthouse: view from the top of the lighthouse	Thank you for your comment. Several KOPs were selected for analysis within Fire Island National Seashore. Sailors Haven is approximately 1.4 miles northeast of KOP 37 Point O' Woods, and the Fire Island Lighthouse has two KOPs: KOP-32 Fire Island Lighthouse-top and KOP-33 Fire Island Lighthouse- bottom. Otis Peak High Dune Wilderness and Watch Hill are approximately 8 miles from KOP-37, which can be used as a proxy KOP for these locations. For the COP-level NEPA stage, additional analysis and KOPs will be considered.
BOEM-2024-0001-0466-0012	In regard to the Otis Pike Fire Island High Dune Wilderness protecting "wilderness character" is the bedrock of protecting Wilderness under	Thank you for your comment. The following paragraph has been added to the PEIS *Visual Resources* Section 3.6.9.1.1 *SLIA Affected*

Comment No.	Comment	Response
	the Wilderness Act of 1964 (16 U.S.C. 1131 et seq.). Monitoring and managing wilderness responsibly derives from a framework that uses the five qualities of wilderness character from the legislation: 1. [Underline: Untrammeled]: Wilderness is essentially unhindered and free from modern human control or manipulation.2. [Underline: Natural]: Wilderness maintains ecological systems that are substantially free from the effects of modern civilization.3. [Underline: Undeveloped]: Wilderness retains its primeval character and influence and is essentially without permanent improvements or modern human occupation.4. [Underline: Opportunities for Solitude or Primitive and Unconfined Recreation]: Wilderness provides outstanding opportunities for remoteness from sights and sounds of people and modified areas for self-reliant recreation and freedom from restrictions on visitor behavior.5. [Underline: Other Features of Value]: Wilderness may contain ecological geological or other features of scientific educational scenic or historical value. At Fire Island the night sky looking south from the park's wilderness has always been one of the more stunning and important aspects related to wilderness character and wind turbine generator (WTG) night lighting may have an impact on the Natural Undeveloped Solitude and Other Features wilderness characteristics of the Fire Island wilderness area. Analysis of dark night skies impacts should consider potential impacts under the Wilderness Act. To meet this responsibility and to ensure these unique Wilderness resources are protected necessary information should be gathered for the PEIS to allow NPS to analyze potential impacts to the Wilderness at Fire Island. NPS staff can assist in more detailed discussions on this topic.	*Environment*, to address potential night sky impacts at Fire Island during construction and O&M. Night skies and natural darkness are also components of seascape and landscape character. The numeric Bortel scale measures the night sky's brightness/darkness. Class 1 represents the darkest skies available on Earth, whereas Class 9 is an urban brilliantly lit sky. Dark sky areas along the coast of New England are uncommon because of the dense urban development and associated light domes. However, Fire Island is recognized as being good star-gazing location with Class 4 Bortle rating for "bright suburban" allowing the central galaxy to appear visible only at the zenith and light pollution up to 35° according to the U.S. Light Pollution Map (www.lightpollutionmap.info n.d.). Although Fire Island has decent stargazing as compared to Long Island and New York City, residents need to travel 100 miles the Catskills to experience Class 3 rating and nearly 200 miles to the Adirondacks to experience Class 2 average dark sky. Morristown NHP is the nearest location where the National Park Service (NPS) is collecting data on night skies brightness and Cape Cod National Seashore the nearest collection point with high-quality night sky viewing. (https://www.nps.gov/subjects/nightskies/datacollectionsites.htm) The location of the WTGs at the horizon and their associated, red-colored aviation hazard lighting will generally not be in the direction of stargazing and will not create a light dome like those created by urban area lighting.
BOEM-2024-0001-0466-0013	[Bold: Historic Properties at Fire Island National Seashore] Cultural landscapes that may be impacted at Fire Island include the most prominent of the Seashore's historic structures: the Fire Island Lighthouse and the Keepers Quarters which were completed in 1858 and 1859 respectively. These structures are built on a 15-foot-tall bluestone terrace whose materials were salvaged from the original 1825-1826 lighthouse and keeper's house which was demolished to build the current structures on the site. The extant Lighthouse is a 164-foot conical tower constructed of brick with a hyperbolic curved	Thank you for the information about historic properties present at NPS park units. The commenter does not pose a question or raise issues with the environmental analysis. BOEM does not intend to identify specific cultural resources through this programmatic evaluation. BOEM Subject Matter Experts will use the information in this comment and subsequent comments provided by the NPS concerning historic properties present at NPS park units to inform COP-level reviews. Developers of individual leases will be required to thoroughly identify cultural resources, and BOEM will assess the

Comment No.	Comment	Response
	profile and a cylindrical shape near its top. The upper portion features a granite cornice and an iron-railed projecting gallery. Since 1891 the tower has been painted with four alternating black and white bands which were kept in the same configuration when the tower was coated in reinforced concrete in 1912. The Keepers Quarters is a two-story rough-coursed granite building whose roof is a combination of a gable and a hip roof. There are 13 historic buildings or structures within two clusters (the Light Station and the Radio Compass Station) on the Light Station tract. Core buildings and structures for the Light Station cluster include the historic Lighthouse Keepers Quarters Terrace and Boat House (1939). Missing from the Light Station cluster are the coal/oil house wharf storehouse and power generation plant. The Radio Compass Station cluster is primarily comprised of the historic Lighthouse Annex Building (1906). This two-story structure with a hip roof (which has been enlarged twice) was originally built as a one-story dwelling. In addition to the Lighthouse Annex Building there are several contributing buildings and structures including the Lighthouse Annex Garage Tool House Oil House Store House the remains of the wireless station's Engine House and Battery House Foundation and several historic buildings and structures within the Radio Officer's residence. Visible concrete foundations and guy wire remnants mark the site of two large radio towers that were demolished in 1937. Another cultural landscape within the boundary of the Seashore is the Carrington Estate located off the Burma Road on federal lands to the west of the residential community of Fire Island Pines. The estate was the property of Broadway producer Frank Carrington who hosted a number of stage screen and literary celebrities during his period of residence and consists of two structures. The main house was constructed in 1909 by Mr. Carrington's father and was sold to the National Park Service by Mr. Carrington in 1969. The adjoining cottage was originally part of a lifesaving station and was moved near the main house in 1947 for use as a guest house. The property was listed on the National Register of Historic Places in 2014. The boardwalk to the beach at the estate provides views of the sea.	impacts of each project on those resources during the COP-level reviews.

BOEM-2024-0001-0466-0014	[Bold: Overview of Gateway National Recreation Area] Gateway National Recreation Area (Gateway) brings the National Park Service experience to more than nine million visitors each year. As the fourth most visited unit within the National Park System Gateway preserves a mosaic of coastal ecosystems and natural areas interwoven with historic coastal defense and maritime sites in the New York Metropolitan area. Spanning three New York City boroughs and the northernmost portion of the New Jersey shore Gateway's park lands stand in sharp contrast to the nearby metropolitan area and offer abundant opportunities for residents and visitors to recreate and experience nature and historic settings. The Park covers more than 40 square miles in New York and New Jersey with nearly 27000 acres of land and waters under NPS management. Natural areas; water beaches and coastal views; historic coastal defense and maritime structures; diverse recreation opportunities; and educational and interpretive programming combine to create rich and varied visitor experiences at Gateway. Views of the New York Outer Harbor the oldest operating lighthouse in the United States coastal defense resources at Fort Hancock Fort Tilden and Fort Wadsworth public access to bay and ocean shorelines and darkness and night sky are some of the resources that are fundamental to the park's purpose and significance [NPS Gateway National Recreation Area General Management Plan of 2014 (Gateway GMP 2014)]. Unimpeded views are integral to the visitor experience along the park's 31 miles of ocean beaches dunes and water (Gateway GMP 2014).	Refer to response to comment BOEM-2024-0001-0466-0005.
BOEM-2024-0001-0466-0015	The Fort Hancock and Sandy Hook Proving Ground National Historic Landmark District comprises the entirety of the park's Sandy Hook Unit. Fort Hancock and Sandy Hook Proving Ground was designated a National Historic Landmark in December 1982. The district includes the cantonment area of Fort Hancock numerous batteries and the Proving Ground. Sandy Hook is significant in American History as the site of the Federal Reservation that played dual roles in United States Military History. The Sandy Hook Defenses (Fort Hancock) were the key fortification guarding the approaches to New York Harbor through the Nike Era. While the entire District is a fundamental park resource the Endicott/Taft-era batteries Parade Ground (including	Thank you for the information about historic resources present at NPS park units. Comment No.	Comment	Response
	Officers' Row barracks and cultural landscape) and Nike Missile Launch and Radar Sites are individually identified as fundamental park resources within the Historic District (Gateway GMP 2014). The majority of the coastal fortifications found in the district face the ocean and/or New York Harbor and this association is important. The Sandy Hook Light was individually designated a National Historic Landmark in January 1964. Constructed in 1764 it is the oldest active lighthouse in the United States that is maintained today as an aid to navigation. The 1894 Spermaceti Cove Life Saving Station No. 2 is also located in the park's Sandy Hook Unit. The Life Saving Station was individually listed in the National Register in November 1981. The station which includes a watchtower and boat room was constructed as one of the earliest federally sponsored efforts to save life and property from shipwrecks.	
BOEM-2024-0001-0466-0016	The Fort Tilden Historic District is a fundamental park resource located in the Jamaica Bay Unit on the Rockaway Peninsula. Fort Tilden was listed in the National Register of Historic Places in April 1984 for its significance as a historic Army base commissioned in 1917 as part of the harbor defenses of New York. The original National Register boundary encompassed only the World War I and World War II gun emplacements and associated structures in the fortification area. In 2009 the Keeper of the National Register expanded the boundary to areas administered by the NPS including the fortification post and wharf areas in their entirety under National Register Criterion A for its significance in military history during the period 1916-1967 and is potentially eligible under Criterion D for archeological resources pending further archaeological study. The DOE found that Fort Tilden met Criterion Consideration G to address the Nike Hercules period and Cold War resources that were not yet 50 years old. Battery Harris Battery Kessler Construction Battery 220 and the Nike Missile Launch Site are individually recognized fundamental park resources within the Historic District (Gateway GMP 2014).	Thank you for the information about historic resources present at NPS park units. The commenter does not pose a question or raise issues with the environmental analysis. See response to comment BOEM-2024-0001-0466-0013 above.
BOEM-2024-0001-0466-0017	The Fort Wadsworth Historic District is a fundamental park resource located on the west side of the entrance to New York Harbor in the Staten Island Unit. 	Fresh water wetland and maritime forests provide critical foraging habitat and a resting place on the Atlantic migratory flyway. Three hundred twenty-six (326) species of birds including 62 breeding species have been documented using the habitats of the Jamaica Bay Wildlife Refuge (U.S. Fish and Wildlife Service 1997). Research using nano-tags is being conducted by USFWS and Audubon to identify migratory routes of the federally listed piping plover and other shorebirds within the proposed project area. Offshore of Staten Island lie Hoffman and Swinburne Islands which are important habitat for colonial nesting waterbirds wading birds and seabirds. One hundred forty (140) acres of airfield at Floyd Bennett Filed is managed as habitat for grassland birds.	components are generally unknown in this programmatic level analysis, BOEM intends to use this detailed information in any future COP-specific NEPA document developed for the NY Bight lease areas, as appropriate.
BOEM-2024-0001-0466-0024	Migratory bats found at Gateway include little brown myotis (*Myotis lucifugus*) silver-haired bat (*Lasionycteris noctivagans*) red bat (*Lasiurus borealis*) and hoary bat (*Lasiurus cinereus*).	These four bat species are identified as occurring in the bat geographic analysis area (see PEIS Table 3.5.1-1), which includes the Gateway National Recreation Area.
BOEM-2024-0001-0466-0025	Dolphins whales and seals sometimes travel in park-managed waters. Harbor seals are winter visitors to Sandy Hook Great Kills Harbor Hoffman and Swinburne Islands Jamaica Bay and the Rockaway Inlet area and use local docks the jetty at Breezy Point Tip and other locations as haul-out areas. Several marine mammals that use park-managed waters are listed species. These include sei (Balaenoptera borealis) blue (*Balaenoptera musculus*) fin (*Balaenoptera physalus*) humpback (*Megaptera novaeangliae*) and northern right whales (*Eubalaena glacialis*) as well as the state-listed harbor porpoise (*Phocoena phocoena*). All of the whale species are both state- and federally listed as endangered. Humpback whales occasionally feed in New York Bay adjacent to the Rockaway Inlet (USFWS 1997c) and sei humpback and sperm whales (*Physeter macrocephalus*) have been noted swimming in Raritan Bay. The endangered humpback whale occasionally feeds in New York Bay adjacent to the inlet and bottlenose dolphins and endangered sperm whales (*Physeter macrocephalus*) have been noted as strandings in the area.	This information has been incorporated into Section 3.5.6.1.
BOEM-2024-0001-0466-0026	The wildlife group for which the park is best known is birds particularly the waterbirds seabirds shorebirds and waterfowl that frequent its estuarine and coastal shorelines. The park is visited	Refer to response to comment BOEM-2024-0001-0466-0023.

Comment No.	Comment	Response
	annually by 34 species of migratory shorebirds (Harrington pers. comm. n.d.). Jamaica Bay for example averages mid-winter ground counts of birds at about 11000 with a peak (during the years from 1980 to 1992) of 36000 (USFWS 1997b). The migratory and mid-winter concentrations of waterfowl in the Raritan/Sandy Hook Bay complex (which includes both Sandy Hook and the park sites on the shore of Staten Island) average over 60000 birds (USFWS 1997c). Breezy Point and Sandy Hook support some of the highest concentrations of beach-nesting birds in the entire New York Bight coastal region including threatened piping plovers and other rare bird species such as least terns black skimmers and common terns. Other nesting waterbirds at Breezy Point include great black-backed gull herring gull and American oystercatcher. The gulls terns and oystercatchers nesting at these park sites feed throughout Rockaway Inlet and Jamaica Bay. Breezy Point and Sandy Hook are also concentration areas for other migratory shorebirds waterfowl and raptors and other landbirds especially during the summer and fall migrations. The raptor banding station at Breezy Point banded 2414 raptors during the period from 1978 to 1987 and sighted 15715 raptors. The most numerous species sighted were American kestrel (*Falco sparverius*) and sharp-shinned hawk (Accipiter striatus) with a total of 9244 and 4373 birds respectively sighted during that period (USFWS 1997b). Spring hawk counts at Fort Hancock on Sandy Hook average nearly 5000 birds with the same two species dominating (USFWS 1997c). Other species consistently sighted include Cooper's hawk (*Accipiter cooperii*) northern harrier (*Circus cyaneus*) osprey (Pandion haliaetus) peregrine falcon (Falco peregrinus) and merlin (Falco columbarius).	
BOEM-2024-0001-0466-0028	Jamaica Bay's islands because they are somewhat isolated from predation support large numbers of colonial-nesting waterbirds as well as a variety of migratory species. At least 326 species of birds have been sighted at Jamaica Bay on its islands and at the wildlife refuge including confirmed breeding by 62 of those species (USFWS 1997b). A mixed-breed heronry on Canarsie Pol includes a variety of nesting waders including glossy ibis great egret snowy egret cattle egret black-crowned night-heron and tricolored heron. Recent	Refer to response to comment BOEM-2024-0001-0466-0023.

Comment No.	Comment	Response
	information from the New York City Audubon (Phillips pers. comm. 2013) indicates herons and egrets also nest at Elder's Point Subway Island and Little Egg and that breeding at Canarsie Pol has declined from predation by raccoons and human disturbance in recent years. Although no wading birds nested here in recent years Canarsie Pol also has nesting by the state-listed threatened common tern as well as by great black-backed gull herring gull and American oystercatcher. Common terns occur on several other islands in the bay including Jo Co Marsh and Silver Hole Marsh with smaller numbers at Duck Creek Marsh East High Meadow Ruffle Bar and Subway Island. An average of about 1000 common terns and a maximum of 1630 common terns nested on the combined seven colonies in Jamaica Bay between 1984 and 1996 (USFWS 1997b). Laughing gulls (*Larus atricilla*) recolonized Jamaica Bay in 1979; over 99.9 percent of nesting by this species in the state of New York from 1979 to 2007 was associated with the colony at Joco Island in the park. As of 2008 an estimated 1280 nests were active at this site (Washburn Lowney and Gosser 2012). Ospreys also nest in the Jamaica Bay Unit and elsewhere in the Park. Approximately 18 osprey pairs nest in Jamaica Bay 14 pairs at Sandy Hook and 1 pair on Staten Island. Clapper rails (*Rallus longirostris*) and common moorhens (*Gallinula chloropus*) nest in the saltmarshes. American oystercatchers nest at several islands in Jamaica Bay; they also have nested along the airport shoreline. A variety of other birds breed on the islands and uplands in the bay including one of only two New York State sites for and the northernmost nesting extent of the boat-tailed grackle (*Quiscalus major*). Shorebirds known to breed in or around Jamaica Bay include killdeer (*Charadrius vociferus*) American oystercatcher willet spotted sandpiper (*Actitis macularia*) upland sandpiper and American woodcock (*Scolopax minor*). In addition to providing wintering and nesting habitat Jamaica Bay is one of the most important migratory shorebird stopover sites in the New York Bight region especially during fall migration (July to November). The shorebirds use much of the bay during the migration stopovers but tend to focus on the intertidal areas during low tide and move to East and West Ponds on Ruler's Bar Hassock during higher tides. The water in East Pond is artificially lowered after July 1 each year. From	

Comment No.	Comment	Response
	1981 to 1990 there was an average of 27 and a maximum of 36 shorebird species counted at the East and West Ponds in the Jamaica Bay Wildlife Refuge during the fall. The most abundant shorebirds during that period were black-bellied plover (*Pluvialis squatarola*) semipalmated plover (*Charadrius semipalmatus*) greater yellowlegs (*Tringa melanoleuca*) ruddy turnstone (*Arenaria interpres*) sanderling (*Calidris alba*) semipalmated sandpiper (*Calidris pusilla*) least sandpiper (*Calidris minutilla*) dunlin (*Calidris alpina*) and short-billed dowitcher (*Limnodromus griseus*). Jamaica Bay is also important during spring migration (March to June) on the ponds for several of these same species as well as red knot (*Calidris canutus*). Hunting is prohibited in the park by virtue of its New York City location which may contribute to the high numbers of individual ducks and duck species. In one year-round survey of birds at Jamaica Bay 263000 individuals of 32 species were recorded (USFWS 1997b).	
BOEM-2024-0001-0466-0029	The combination of geographic location and configuration coupled with productive bay wetlands flats and waters in Raritan and Sandy Hook Bays make this another important migratory staging area in the park for many species of waterfowl on the Atlantic Flyway. Peak migration occurs in late October but November aerial counts in New Jersey waters still average nearly 45000 birds (USFWS 1997c). The number of horned grebes (*Podiceps auritus*) as well as common and red-throated loons (*Gavia immer G. stellata*) during migration is regionally significant. Especially notable are the overwintering scaup concentrations primarily greater scaup which have increased in this area recently and are an important component of the Atlantic Flyway population. Other significant species populations include Canada geese in the Raritan River and the Navesink system American black ducks canvasbacks (*Aythya valisineria*) mallards (Anas platyrhynchos) and brant along with lesser numbers of bufflehead oldsquaw (*Clangula hyemalis*) mergansers (primarily red-breasted mergansers [*Mergus serrator*]) common goldeneye (*Bucephala clangula*) and American wigeons (*Anas americana*). These waterfowl are not evenly distributed but rather tend to concentrate along the southern Raritan Bay and Staten Island shorelines where moderate-sized flocks of scaup and American black ducks and smaller groups of brant occur.	Refer to response to comment BOEM-2024-0001-0466-0023.

Comment No.	Comment	Response
	Shrublands and woodlands can offer important feeding or resting habitat for songbirds (or "passerines") in the park such as sparrows warblers and other perching species. As noted above grasslands at Fort Hancock on Sandy Hook and open areas at Breezy Point support very large spring raptor migrations as well.	
BOEM-2024-0001-0466-0030	Grasslands at Floyd Bennett Field became habitat for certain open-country bird species after the airfield was decommissioned in 1950 and stayed that way until the last few decades when open areas began to transition into shrub and forest. In 1985 a portion of Floyd Bennett Field was cleared and mowed to create grasslands; about 140 acres are still maintained using these techniques. This area is unique in that it is a large grassland in the urban area of New York City supporting feeding and resting grassland species that are not seen elsewhere in the city. In addition several birds have or now use this habitat for nesting including grasshopper sparrow (*Ammodramus savannarum*) horned lark (*Eremophila alpestris*) eastern meadowlark (Sturnella magna) upland sandpiper savannah sparrow (*Passerculus sandwichensis)* northern harrier American kestrel and common barn owl (*Tyto alba*). Use of this area by grasshopper sparrows (a state-listed species) increased significantly in average abundance between 1984 and 1992.Since 1996 however there have been no grasshopper sparrows nesting at Floyd Bennett Field. Overwintering grassland birds at Floyd Bennett Field include northern harrier roughlegged hawk (Buteo lagopus) American kestrel common barn owl short-eared owl (*Asio flammeus*) horned lark eastern meadowlark and savannah sparrow. The bobolink (*Dolichonyx oryzivorus*) is a regular migrant visitor in the grasslands. Grassland birds especially upland sandpipers also use the grassland habitat along the runways at John F. Kennedy International Airport (USFWS 1997b). The combination of geographic location and configuration coupled with productive bay wetlands flats and waters in Raritan and Sandy Hook Bays make this another important migratory staging area in the park for many species of waterfowl on the Atlantic Flyway.	Refer to response to comment BOEM-2024-0001-0466-0023.
BOEM-2024-0001-0466-0031	[Bold: Visual Impacts at Gateway] The Gateway General Management Plan (GMP) of 2014 identifies views of the New York Harbor as a	Thank you for your comment. Five KOPs within the Gateway National Recreation Area were studied in the PEIS: KOP-26 Fort

Comment No.	Comment	Response
	fundamental park resource. The PEIS should evaluate the maximum cumulative impacts of the new leasing areas and the Empire Wind Projects on the uninterrupted sea view from the seven ocean-front historic districts and 31 miles of ocean beaches dunes and water. NPS recommends the following locations be included as Key Observation Points (KOPs). Gateway National Recreation Area: -Sandy Hook Light: View from the top of the lighthouse looking southeast.-Sandy Hook beaches: View from B beach cross-over looking southeast.-Sandy Hook Observation Deck at Lot M: View from top of observation deck looking southeast.-Riis Park boardwalk: View from boardwalk in front of bathhouse looking southeast.-Battery Harris Fort Tilden: View from viewing platform looking southeast.-Fort Wadsworth: View from overlook looking southeast. NPS staff can assist in providing access to these areas.	Tilden/Jacob Riis Park (nighttime simulation available here: https://www.boem.gov/renewable-energy/state-activities/new-york-bight), KOP-21 Great Kills, KOP-22 Roosevelt Pier, KOP-20 Sand Hook Beach, and KOP-34 Sandy Hook Observatory. It was determined that the NY Bight projects were not visible from the Staten Island Unit of the Gateway National Recreation Area; therefore, these KOPs were not included in the EIS analysis. The turbine blade tips of OCS-A 0544 are potentially visible from the Jamaica Bay Unit and the Sandy Hook Unit. KOP-20 Sandy Hook Beach and KOP-34 Sandy Hook Observatory were removed from the study because the project team was denied access to the outside viewing of the Sandy Hook Lighthouse to collect data and photography due to safety concerns. GIS viewshed analysis also determined that the NY Bight projects would have extremely low visibility from Sandy Hook. However, there are comparable views from other KOPs that were included in the analysis. Views from Sandy Hook Beach B (approximately 43.0 miles from OCS-A 0544) can be compared to KOP-19 Navasink Twin Lights Base and KOP-35 Twin Lights Light House, which, although 0.5 mile inland, has a 203-foot elevated view, creating similar viewing conditions with earth curvature. A visual simulation was created for KOP-35. The Gateway National Recreation Area does fall into cumulative impacts from the Empire Wind lease area OCS-A 0512, and KOP-26 Fort Tilden and KOP-35 Twin Lights Lighthouse are both analyzed for maximum cumulative impacts. For the COP-level NEPA stage, additional analysis and KOPs will be considered.
BOEM-2024-0001-0466-0032	[Bold: Historic Properties at Gateway National Recreation Area]Gateway possesses more than 800 historic buildings structures landscapes and archeological sites with hundreds of additional individual features that contribute to the character of these special places. Structures dedicated to ship navigation and lifesaving are well represented in the maritime cultural record of the area. The Sandy Hook Light a National Historic Landmark was first illuminated on June 11 1764 generated by 48 oil-fueled lamps. Today it is the oldest operating lighthouse in the United States and the only surviving one of the eleven lighthouse buildings dating to the colonial period. Comment No.	Comment	Response
	Elm Tree Light a contributing structure at Miller Army Airfield Historic District has undergone several transformations. The current Elm Tree Light was constructed by the U.S. Coast Guard in 1939 to replace an earlier tower that had served as a mark for sailing vessels in the late 18th century (Wren 1974; NPS 1979a). The first Fort Tompkins lighthouse was replaced in 1893 with a new light constructed on the top of Battery Weed to provide better protection of the shipping lane through the Narrows. The light was visible for 14 nautical miles. The light was decommissioned in 1965 (Olmsted Center for Landscape Preservation 2008). By the 19th century lifesaving stations were being constructed across the harbor area that would prove crucial for saving shipwreck victims. The extant Spermaceti Cove Life Saving Station (1894) was identified as Station No. 2 at the Sandy Hook Unit. The station was decommissioned in 1949 as an active U.S. Coast Guard Station. Additional lifesaving stations built in 1848 1855 1872 and 1891 on Sandy Hook no longer exist. The Far Rockaway Coast Guard Station complex served as an important lifesaving site for the numerous marine accidents and shipwrecks on the Rockaway Peninsula during the 19th and early 20th centuries. Seacoast fortifications along the New York Harbor area date to the early days of discovery and colonization of the New Jersey and New York coastlines. Since the Colonial period the defense of New York Harbor was considered critical for commerce and the defense of the United States. The fortifications included a variety of forts and batteries dating back to the late 18th century and continuing through the Cold War era. Technological advances in weaponry and construction techniques through time resulted in greatly improved fortifications some of which were built over earlier outdated structures. Both commercial and military aviation were quickly evolving after World War I. The early history of aviation in the United States is well represented in several Gateway facilities dating back to the early 20th century including Floyd Bennett Field Miller Army Airfield and the Rockaway Naval Air Station (now the site of Jacob Riis Park).	
BOEM-2024-0001-0466-0033	[Bold: Benthic Environment] Both Fire Island and Gateway have jurisdiction over activities occurring along the coastline and in their respective jurisdictional marine waters. NPS is responsible for the	Thank you for your comment. More detailed benthic mapping and descriptions would be addressed in project-specific COPs and

Comment No.	Comment	Response
	protection of resources in its jurisdictional waters including but not limited to biologic geologic historic and cultural resources. Of note the coastal and marine areas of both parks have known and unknown submerged archaeological resources related to historic activities and events of importance to area Federal Indian Tribes. From an ecological perspective the benthic environments within these coastal and marine jurisdictional areas include a variety of resources of concern to the NPS including physical benthic habitat characteristics as well as the biotic communities associated with them (e.g. aquatic vegetation and fauna living in and depending on these habitats) all of which affect and are affected by the water column. Limited information is available for the submerged benthic habitats; however seafloor habitat mapping projects were completed for both Fire Island National Seashore and the Sandy Hook unit of Gateway in response to Hurricane Sandy. Offshore wind development can impact benthic ecosystems in a variety of ways depending on the location and development phase. In addition to direct impacts such development may result in indirect impacts associated with artificial reef effects seafloor disturbance and the introduction of energy emissions (e.g. noise vibrations and electromagnetic fields) that could have long- term impacts on benthic ecosystem structure and function. Reports associated with the Empire Wind Projects include data such as bottom surface features sediment characteristics and vegetative and macrofaunal species distributions descriptions and management interest; results of these reports and other local benthic analyses including cumulative impacts to seagrass beds (and suitable habitat as indicated by historical seagrass distribution) and other declining benthic resources should be considered as part of the analysis of potential impacts to the benthic environment. If construction or operation activities would occur in or near the marine and coastal environments of Fire Island or Gateway additional collaboration would be required to ensure those activities do not disturb any sensitive park benthic resources. The NOI does not address the issue of potential landfall locations for power cables from the newly leased areas. This would seem to be a topic that should be addressed in the PEIS.	would include potential export cables and landfall locations for each of the lease areas.

Comment No.	Comment	Response
BOEM-2024-0001-0466-0034	[Bold: Marine Life Birds and Bats] A synopsis of wildlife resources of concern to the Parks is provided below and more detailed park-specific information is available for many resources. We request this information be considered in more detailed analyses and discussions with applicable agencies such as the U.S. Fish and Wildlife Service (USFWS) National Oceanic and Atmospheric Administration (NOAA) and its National Marine Fisheries Service (NMFS) regarding appropriate AMMM measures to avoid adverse impacts to these species. The New York State Energy Research and Development Authority (NYSERDA) State of the Science Workshops on Wildlife and Offshore Wind Energy reports also provide a good summary of questions related to potential offshore wind impacts to some of these resources of concern to the NPS and other groups (e.g. benthic habitat fish and invertebrates sea turtles marine mammals bats and birds). These resources could be affected by a range of stressors and environmental changes associated with various stages of project development (e.g. pre-construction construction operation decommissioning). We look forward to being able to review and comment in the future when more detailed information and analyses are provided in the PEIS. Overall as the marine environment is built out by the newly leased offshore wind project areas in the NY Bight as well as by the Empire Wind Projects the potential cumulative impacts to marine mammals and sea turtles will be of significant importance. The PEIS should serve to highlight these potential impacts and the AMMM measures that could be applied across the NY Bight. Many of the potentially affected species do not occur in areas where utility-scale offshore wind exists today (e.g. Europe) and so there is no parallel data from which to draw conclusions. Due to U.S. Coast Guard regulations the bases of the turbines will be lit and could become an attractant that alters current navigation patterns. Similarly the turbines may disrupt the marine acoustic environment for acoustic sensitive species such as whales which in turn may inhibit communication or change patterns of behavior; little is known about the potential impacts of other potential disruptions to the marine environment such as vibrations and electromagnetic fields associated with wind turbines and cables. These animals are already	AMMM measure BB-3 includes monitoring the potential impacts on birds and bats through the life of the New York Bight projects. More detailed and project-specific AMMM measures could be evaluated at the project-specific COP NEPA review stage to further address potential project-specific impacts on biological resources, including birds and bats.

Comment No.	Comment	Response
	experiencing changes in migratory patterns related to climate change (e.g. changes in water temperatures and food source availability) which have potentially led to stranding and cold stunning events occurring more regularly in the Atlantic and an expansion of turtle nesting north of previously recognized nesting sites. The NPS defers to USFWS NOAA and its NMFS for their expert opinions regarding permitting under the Endangered Species Act of 1973 (16 U.S.C. 1531 et seq.) Marine Mammal Protection Act of 1972 (16 U.S.C. 1361 et seq.) Migratory Bird Treaty Act of 1918 (16 U.S.C. 703 et seq.) and related laws and regulations. The NPS nonetheless has jurisdiction over those animals that occur within its boundaries and to the degree possible protects those individuals and populations. As such NPS has a strong interest in potential disruptions to those individuals and populations that frequent the Parks and recommends that the relevant agencies develop monitoring plans as a subset of the AMMM measures so that all can benefit from scientific data in this emerging area of study.	
BOEM-2024-0001-0466-0035	[Bold: Night Skies]Protecting the night sky is a critical role NPS pursues at Fire Island National Seashore and Gateway National Recreation Area. Despite the presence of the New York and New Jersey metropolitan areas both Parks provide some of the darkest nighttime skies available to visitors and residents alike and night skies are identified as a fundamental resource in the Gateway GMP of 2014. Night skies are an important resource for Fire Island Gateway and NHLs such as the lighthouses affecting aspects such as biological and cultural properties the wilderness and historic setting and the visitor experience and enjoyment. The opportunity to enjoy starry night skies and other nocturnal phenomenon as well as landscape features of the park under natural light from the night sky is an integral part of an overall visitor experience. Night skies are one of the many resources protected under the National Park Service Organic Act. The important role that natural cycles of light and dark play in natural resource processes and the evolution of species is well established and therefore the NPS protects natural darkness and other components of natural lightscapes in parks by minimizing light from park facilities and by educating and working cooperatively with	See response to comment BOEM-2024-0001-0466-0012.

Comment No.	Comment	Response
	neighboring communities local governments and the public to minimize the use of outdoor lighting wherever possible considering public safety and other park management objectives. NPS night skies and natural sounds experts can assist BOEM in addressing these topics in the PEIS.	
BOEM-2024-0001-0466-0036	NPS recommends the following potential AMMM measures: -Projects should be required where possible to implement an Aircraft Detection Lighting System (ADLS; or a similar system) to turn the aviation obstruction lights on and off in response to detection of nearby aircraft.-ADLS efficacy analysis should be conducted so that the impact from the aviation warning lights can be quantified for the cases with and without ADLS.-Security lighting should be directed downward and shielded. Some lights could have motion sensors added.-Lighting principles: a. Control -- lights should be off when not needed. This applies to both construction and operations phases. b. Brightness the minimum lumen output needed should be used c. Warm color-temperature light -- use amber lights when possible instead of white light.-Lighting plans for both construction and operations should be required in project specific EISs.-Visual simulations should be required using both static images and light-flashing animation at night from multiple KOPs for offshore wind projects as they are developed.	AMMM measure MUL-37 requires lessees to use ADLS. Additionally, AMMM measure VIS-7 addresses ADLS efficacy through monitoring the frequency that ADLS is operative during the project's operations. Lessees are required to implement BOEM lighting and marking guidelines, and U.S. Coast Guard (USCG) and FAA lighting and marking requirements. Project-specific lighting will be analyzed during COP NEPA reviews. The visual simulations necessary for COP NEPA review are decided on a project-by-project basis depending on if the project is concealed below the visible horizon.
BOEM-2024-0001-0466-0037	[Bold: Visual Impacts to NHLs] There are numerous NHLs in the New York and New Jersey area that could be visually impacted by the wind turbine generators and/or by offshore substations or by onshore infrastructure as the new lease areas and Empire Wind 1 and 2 are developed. We recommend the following NHLs be included in the PEIS including the assessment of potential visual impacts. -Empire State Building NHL: View from iconic Observation Deck on 86th floor with sweeping 360-degree views on Manhattan including NY Harbor.-Green-Wood Cemetery NHL: Located on the highest elevation in Brooklyn-Twin Lights Historic Site NHL: Highlands NJ 246 above sea level on the headlands of Navesink Highlands and directly overlooking Sandy Hook Bay the entrance to New York Harbor	Thank you for your comment. KOP-19 Navasink Twin Lights Base, KOP-35 Twin Lights Light House, and KOP-39 Empire State Building Observation Deck were all evaluated as part of the PEIS. Both KOP-35 and KOP-39 are included in the cumulative impact evaluation. For the COP-level NEPA stage, additional analysis and KOPs will be considered.

Comment No.	Comment	Response
BOEM-2024-0001-0466-0038	[Bold: Overview of Area National Historic Landmarks and the NY Bight PDEIS]National Historic Landmarks are historic properties that illustrate the heritage of the United States. The NPS has specific responsibilities with regards to administration of the NHL Program. The over 2600 NHLs found in the U.S. today come in many forms: historic buildings sites structures objects and districts. Each NHL represents an outstanding aspect of American history and culture. Of note federal funding or licensing of activities that affect historic properties are regulated principally by Section 106 and Section 110(f) of the NHPA. Other federal effects are listed in 36 CFR 65.2. Under Sections 106 and 110(f) of the Act federal agencies must "take into account" the effects of their undertakings on historic properties and afford the Advisory Council on Historic Preservation (ACHP) an opportunity to comment on the undertaking and its effects. Implementing regulations of the ACHP may be found in 36 CFR 800 "Protection of Historic Properties" which establishes a process of consultation with the SHPO and the ACHP leading in most instances to agreement on how the undertaking will proceed. Steps in the process include identification and evaluation of historic properties that may be affected assessment of the effects of the federal action and resolution of any adverse effects that would occur. If a federal activity will "directly and adversely affect" a Landmark Section 110(f) of the Act also calls for federal agencies to undertake "such planning and actions as may be necessary to minimize harm to such Landmark." As with Section 106 the agency must provide the Advisory Council with a reasonable opportunity to comment.	Thank you for the information about the NHL program. BOEM has complied and will continue to comply with all requirements under Section 106 and 110(f) regarding NHLs. The commenter does not pose a question or raise issues with the environmental analysis. See response to comment BOEM-2024-0001-0466-0013 above.

P.4.1.2 U.S. Fish and Wildlife Service

Table P.4-3. Responses to Comments from the U.S. Fish and Wildlife Service (BOEM-2024-0001-0400)

Comment No.	Comment	Response
BOEM-2024-0001-0400-0001	BOEM is preparing a Programmatic Biological Assessment (BA) that the Service will review pursuant to Section 7(a)(2) of the ESA. The Service has been consulting with BOEM regarding the BA which (among others) includes the six New York Bight lease areas. The Service will continue coordinating with BOEM as additional information is received. Impact determinations to federally listed species that the Service has jurisdiction over should not be included within future NEPA documentation without concurrence from the Service or an explanation that BOEM is still seeking our concurrence.	On June 20, 2024, BOEM initiated consultation with the USFWS on a Programmatic Framework ESA Section 7 consultation, and the PEIS has been edited to reflect this.
BOEM-2024-0001-0400-0002	The Service continues to maintain the position that insufficient evidence exists to demonstrate that the wider spacing of offshore wind turbines and intermittence/patchiness of projects will result in negligible impacts to bats. We also continue to maintain the position that there is currently a large amount of uncertainty regarding bat activity in offshore environments during any climatic conditions that overall makes it difficult to support the conclusion of negligible impacts reached in Chapter 3.5.1 of the DPEIS. BOEM continues to state that the cumulative impacts of the no action alternative (which considers other offshore wind projects) would be negligible to bats. However due to the reasons stated throughout Service comments on the preliminary Draft PEIS and our continuing comments in Enclosure A the Service continues to disagree with negligible impact determinations. Additionally it is unclear why the cumulative impacts of the no action alternative (which considers the construction of 2252 wind turbine generators and associated structures with planned offshore wind projects) was explained to have negligible impacts to bats but the impacts of the proposed New York Bight alternatives are expected to have negligible to minor impacts to bats. The Service recommends that all impact determinations to bats are listed as minor or greater.	BOEM acknowledges that there is no study that looked at offshore wind turbine spacing and bat migration. However, unless new information becomes available on this matter, BOEM maintains that this is a reasonable hypothesis: that wider spacing of offshore wind turbines and intermittence/patchiness of projects will result in negligible impacts on bats. But more importantly, the literature, studies, and offshore bat surveys documented and described in PEIS Section 3.5.1, *Bats,* show that bat presence in the offshore environment is low and represents a very small percentage of total populations onshore. As such, BOEM anticipates the risk to bats from any offshore IPF is low (regardless of weather conditions). Therefore, BOEM maintains the negligible determination for potential impacts on bats in the offshore environment. Regarding the "negligible" impact determination for cumulative impacts under the No Action Alternative – the impact determination should have been "negligible to minor." The negligible determination is more applicable to impacts in the offshore environment (see paragraph above) while the minor impact determination is applicable to the onshore environment where there is more uncertainty on project locations and amount/quality of habitat removal. This is the same reasoning for both Alternatives B and C, and should also have been included

Comment No.	Comment	Response
		under cumulative impacts for the No Action Alternative. The PEIS has been revised to include "minor" for cumulative impacts under the No Action Alternative.
BOEM-2024-0001-0400-0003	The Service continues to recommend that disclaimers of information gaps are clearly articulated throughout the birds section (Chapter 3.5.3) of the DPEIS. Also due to the reasons previously stated in our preliminary DPEIS review letter and our additional comments from the Service's Migratory Birds Team in Enclosure A the Service continues to disagree with BOEM's "moderate beneficial impacts" determination. As such we continue to recommend that this determination is removed from the DPEIS.	Regarding data gaps, BOEM cites original works in Section 3.5.3, and those works disclose the data gaps and uncertainties that may exist. Identifying every data gap or uncertainty throughout the resource section would be redundant and affect flow of writing/reading; and would pose issues regarding page length, which is already constrained due to NEPA regulatory requirements (40 CFR 1502.7 *Page Limits*). BOEM also notes that the PEIS does not ignore uncertainties and data gaps, as there is an entire PEIS appendix (Appendix E, *Analysis of Incomplete and Unavailable Information*) that addresses incomplete and unavailable information for every resource analyzed in the PEIS, as required by NEPA regulations. In accordance with 40 CFR 1502.21, when an agency is evaluating reasonably foreseeable significant adverse effects on the human environment in an EIS and when information is incomplete or unavailable, the agency must make clear that such information is lacking; BOEM has done so in PEIS Appendix E, and the discussion for birds is in Section E.1.5, *Birds*. As BOEM states in Section E.1.5, there will always be some level of incomplete information on the distribution and habitat use of birds in the offshore portions of the geographic analysis area, as well as for the potential for collision risk and avoidance behaviors for some of the bird species. However, BOEM concludes the PEIS is sufficient to support sound scientific judgments and informed decision-making related to bird distribution and use of the offshore portions of the geographic analysis area as well as to the potential for collision risk and avoidance behaviors, and does not believe that there is incomplete or unavailable information on birds that is essential to making a reasoned choice among alternatives. Furthermore, BOEM continues to collect information on bird presence in the offshore environment to help inform the assessment of potential impacts on birds from construction and operation of offshore wind farms. In addition, COP-specific NEPA documents for NY Bight lease areas that might be developed in

Comment No.	Comment	Response
		the future would include project-specific bird information based on the most current and relevant bird information available at that time. Regarding the “moderate beneficial” impact determination, to ensure a complete analysis of the presence of structures IPF, BOEM is retaining the beneficial effects discussion and determination of “moderate beneficial” related to derelict fishing gear and the creation of habitat for structure-oriented or hard-bottom species (typically referred to as “reef effect”). These beneficial effects have been observed and are documented with citations in the PEIS. BOEM understands that there could be a potential relationship between bird attraction to these areas and adverse effects related to interactions with WTGs (e.g., collisions), which is why BOEM included statements of this related risk immediately after the discussion of the beneficial effects (see PEIS page 3.5.3-17, where BOEM states “*Conversely, increased foraging opportunities could attract marine birds, potentially exposing those individuals to increased collision risk associated with operating WTGs*” and “*In contrast, the presence of structures may also increase recreational fishing and, thus, expose individual birds to harm from fishing line and hooks*”). Therefore, BOEM discloses the full potential impact and believes it is reasonable to state that there could be potential beneficial effects on birds because it is possible that a bird could be attracted to these areas near WTGs to utilize the habitat and never collide with any part of the structure.
BOEM-2024-0001-0400-0004	USFWS Draft Programmatic Environmental Impact Statement Comments: The Service continues to support our position that there is not enough evidence to support that the wider spacing of offshore wind turbines and intermittence/patchiness of projects will result in negligible impacts to bats. The Madsen et al. (2012) study that was added in to support BOEM's position is about bird movement not bats. Given the biological differences between birds and bats the study does not appear applicable to analyzing impacts to bats. Additionally the Madsen et al. (2012) study analyzed movements of common eider (Somateria mollissima) in the Western Baltic Sea	Refer to response to comment BOEM-2024-0001-0400-0002.

Comment No.	Comment	Response
	located south of Denmark. While the information from Madsen et al. (2012) is potentially useful for heavy-bodied waterfowl it inadequately (or does not at all for bats) addresses behavioral responses of other species within the proposed lease areas. Due to the lack of evidence the Service recommends that BOEM removes their assumptions that wider spacing and intermittence of projects will result in negligible impacts to bats. The Service recommends that BOEM explains that there is currently not enough information to determine how spacing and intermittence of projects will impact bats (e.g. likelihood of collision or injury rates increased usage of energy expenditures etc.) and edits the remaining portions of the Draft PEIS as necessary to reflect that.	
BOEM-2024-0001-0400-0005	USFWS Draft Programmatic Environmental Impact Statement Comments: The Service appreciates the inclusion of potential impacts to bats due to roosting on wind turbine generators. However the Service continues to support the position that there is currently a large amount of uncertainty regarding bat activity in offshore environments during any climatic conditions that overall makes it difficult to support the conclusion of negligible impacts reached in this section of the Draft PEIS. As previously explained if bats were to experience adverse conditions over the ocean barring returning to land there are likely no suitable locations for them to roost or to wait out the weather. It is not clear how BOEM is suggesting that bats will reduce their activity offshore during these conditions. If the bats reduce their activities during adverse weather conditions and attempt to roost on the wind turbine generators they may collide with the blades and be injured or die. It is unclear how this is supportive of BOEM's position that there will be negligible impact to bats. If there is evidence to support that bats migrating in offshore environments fly to terrestrial environments to reduce their activities during adverse climatic conditions that would be helpful to include in BOEM's analysis. The Service recommends that BOEM provides clarity on how bats flying over the proposed offshore wind areas will reduce their activity during adverse climatic conditions. This should include an explanation as to whether bats are expected to fly towards terrestrial	Impacts on bats in the offshore environment should be viewed in the context of bat presence in the offshore environment. Based on best-available information, including literature, studies, and offshore bat surveys documented and described in PEIS Section 3.5.1, bat presence in the offshore environment is low and represents a very small percentage of total populations onshore. As such, BOEM anticipates the risk to bat species from offshore IPFs is low (regardless of weather conditions). Regarding adverse weather conditions, the PEIS is simply stating that bats are found in lower numbers when winds are higher, temperatures are colder, and during rain (including in the offshore environment), which is based on the cited literature (Arnett et al. 2008; Erickson et al. 2002; Sjollema et al. 2014; Dominion Energy 2022). In a scenario where a bat along the coastline intended on migrating out from the coastline to offshore waters, any high winds, cooler temperatures, and rain along the near coastal area would likely deter the bat from migrating offshore, thus avoiding exposure to turbines should turbines be present in the intended migration path. If a bat is already migrating far offshore and encounters weather conditions that include higher winds, lower temperatures, and rain, it is unknown what that bat would do. They tend to avoid these climatic conditions, so they could attempt to fly back to shore or look for a structure to seek shelter and rest (e.g., buoy, ship). Ultimately, the fate of a bat cannot be

Comment No.	Comment	Response
	environments and seek shelter rest on the proposed offshore wind structures (which could increase collision risk) fly away from those conditions or do something else. If there is no evidence to support what bats flying over the ocean will do during adverse climatic conditions BOEM should explain that uncertainty within the PEIS and analyze the possibility of those conditions being adverse to bats.	predicted in this situation because it depends on the location offshore where the climatic conditions are encountered, how far the individual is from shore, and the type of structure they might land on, if a structure is even present. If the structure is a wind turbine, then the bat would be at risk because, as documented in PEIS Section 3.5.1.3.3, bats have been found to use offshore structures to provide shelter from adverse weather or to rest after a long flight (see Solick and Newman 2021), and have been found to roost in the nacelles of turbines, albeit closer to shore than the locations considered in the PEIS (see Ahlen et al. 2009). However, because bat presence in the offshore environment is low and represents a very small percentage of populations onshore, the risk would be low and no population effects would be anticipated. BOEM will continue to collect information on bat presence in the offshore environment to help inform the assessment of potential impacts on bats from construction and operation of offshore wind farms.
BOEM-2024-0001-0400-0006	USFWS Draft Programmatic Environmental Impact Statement Comments: The Service appreciates the inclusion of the bird and bat post- construction monitoring plan in BB-3. BOEM continues to state that the cumulative impacts of the no action alternative (which considers other offshore wind projects) would be negligible to bats. However due to the reasons stated throughout Service comments on the preliminary Draft PEIS and our continuing comments above the Service continues to disagree with negligible impact determinations. Additionally it is unclear why the cumulative impacts of the no action alternative (which considers the construction of 2252 wind turbine generators and associated structures with planned offshore wind projects) was explained to have negligible impacts to bats but the impacts of the proposed New York Bight alternatives are expected to have negligible to minor impacts to bats. The Service recommends that all impact determinations to bats are listed as minor or greater.	Refer to response to comment BOEM-2024-0001-0400-0002.
BOEM-2024-0001-0400-0007	USFWS Draft Programmatic Environmental Impact Statement Comments: For BB-1: We recommend the usage of the Injury and	BOEM has revised BB-1 to include usage of the IMR system for reporting.

Comment No.	Comment	Response
	Mortality Reporting (IMR) System to report all occurrences of all species of bird and bat carcasses.	
BOEM-2024-0001-0400-0008	USFWS Draft Programmatic Environmental Impact Statement Comments: The Service continues to recommend that disclaimers of information gaps are clearly articulated throughout the birds section of the Draft PEIS. For example BOEM is still stating the following in Chapter 3.5.3.3.3 that we expressed concerns about in our original comment: "Generally only a small percentage of a species' seasonal population would potentially encounter operating WTGs during annual migration Table 3.5.3-1)." We appreciate the inclusion to note that the data is referring to seabird populations but that is not clear while reading that sentence. The Service recommends adding in the following sentence (or something like it) after the sentence of concern mentioned above "However the 47 species listed in Table 3.5.3-1 do not account for the songbirds shorebirds raptors and other species that are known to migrate across the Atlantic Outer Continental Shelf. Particularly this likely excludes species that migrate nocturnally and that have not been detected during boat-based or aerial surveys. Additional studies are required to fill in these data gaps."	Refer to response to comment BOEM-2024-0001-0400-0003 regarding articulating data gaps throughout the PEIS bird section. In response to previous USFWS comments, BOEM clarified in the PEIS that Table 3.5.3-1 is specific to seabirds (including the title of the table). As stated in PEIS Table 3.5.3-2, other non-sea birds, such as songbirds, almost exclusively use terrestrial, freshwater, and coastal habitats and do not use the offshore marine system except during migration. Further, the PEIS states that within the Atlantic Flyway, much of the bird activity is concentrated along the coastline (Watts 2010). Waterbirds use a corridor between the coast and several kilometers out onto the OCS, whereas land birds tend to use a wider corridor extending from the coastline to tens of kilometers inland (Watts 2010). Although both groups may occur over land or water within the flyway and may extend considerable distances from shore, the highest diversity and density are centered on the shoreline. Overall, and as described in the PEIS, current information indicates an overall low abundance of all bird types on the OCS, with much higher abundances along the nearshore areas of the coastline.
BOEM-2024-0001-0400-0009	USFWS Draft Programmatic Environmental Impact Statement Comments: The Service continues to support our position that BOEM elaborates on this section to clarify the claim that multiple course corrections or an altered route for avoidance will not result in significant effects. As previously mentioned it does not appear that this subject has been studied enough to support BOEM's statement. Additional Comments from Region 5 Migratory Birds Team: Even if it is the best available science it is still insufficient for making definitive statements about the broader community such as the last two sentences: "As such adverse impacts of additional energy expenditure due to minor course corrections or complete avoidance of the lease areas would not be expected to be biologically significant. Any additional flight distances would likely be small for most migrating birds when compared with the overall distances traveled and no	Refer to response to comment BOEM-2024-0001-0400-0003 regarding articulating data gaps throughout the PEIS bird section.

Comment No.	Comment	Response
	individual fitness or population-level effects would be anticipated." As suggested in the original comment these statements should be reworded to better reflect that lack of data and thus uncertainty related to the subject.	
BOEM-2024-0001-0400-0010	USFWS Draft Programmatic Environmental Impact Statement Comments: The Service appreciates the inclusion of AMMM Measure BB-3. However the Service continues to support our recommendation that a disclaimer is included as mentioned in our original comment.	Refer to response to comment BOEM-2024-0001-0400-0003 for a discussion on data gaps, uncertainties, and incomplete and unavailable information. BOEM notes that BB-3 is an AMMM measure that has been previously applied on other offshore wind approvals and has been updated to align with the most current agreed-upon language with USFWS.
BOEM-2024-0001-0400-0011	Section #: 3.5.3 USFWS Draft Programmatic Environmental Impact Statement Comments: Due to reasons previously stated and our additional comments from the Migratory Birds Team below the Service continues to disagree with BOEM's "moderate beneficial impacts" determination. As such we continue to recommend that it is removed from the Draft PEIS.	Refer to the second paragraph of response to comment BOEM-2024-0001-0400-0003.
BOEM-2024-0001-0400-0012	The Service is still concerned that derelict fishing gear is anticipated to get tangled and gather around WTG turbines but simultaneously foraging opportunities around the WTG are supposed to increase for marine birds. If the foraging opportunities at WTGs are better than surrounding areas then birds will be attracted to the turbines and have an increased risk 1) of direct collision with turbines and/or 2) have increased risk of entanglement with debris while foraging around turbine bases especially for deep diving species.	Refer to the second paragraph of response to comment BOEM-2024-0001-0400-0003.
BOEM-2024-0001-0400-0013	USFWS Draft Programmatic Environmental Impact Statement Comments: Within the presence of structures section of Chapter 3.5.3.3.3 BOEM explains that "Potential annual bird kills from WTG collisions would be relatively low compared to other causes of migratory bird deaths throughout the United States. For instance feral cats are the primary cause of migratory bird deaths in the United States (2.4 billion per year) followed by collisions with building glass (599 million per year) collisions with vehicles (214.5 million per year) poison (72 million per year) collisions with electrical lines (25.5 million	BOEM included the USFWS bird mortality data in the PEIS to provide context for potential bird mortality that could occur from offshore wind. BOEM notes that the PEIS paragraph before the one cited by the commenter (page 3.5.3-16) states that the USFWS estimates an average of 320,000 birds killed annually in the United States from onshore wind farms (totaling 49,000 turbines); this is approximately 0.001 percent of all bird mortality from all causes (based on mortality data provided by USFWS at https://www.fws.gov/library/collections/threats-birds). With the

Comment No.	Comment	Response
	per year) collisions with communication towers (6.6 million per year) and electrocutions (5.6 million per year) (USFWS 2021)."Please consider take from wind turbines in an additive context to other sources of anthropogenic bird mortality. Many of the species harmed by the other factors listed here are declining and adding additional mortality to these populations may cause steeper declines and/or prevent populations from recovery. This sort of justification for acceptable take for wind development should be reconsidered.	current understanding that bird presence in the offshore environment is low compared to onshore/nearshore, and knowing that onshore wind turbines cause a fraction of a percent of all bird deaths annually and the total number of anticipated offshore WTGs on the OCS is much smaller than the number onshore, BOEM does not think it is unreasonable to consider this information as a factor in concluding that offshore WTGs are unlikely to have a measurable effects on bird populations (even in an additive context). BOEM understands that bird species protected under the Endangered Species Act (ESA) are more sensitive to potential impacts, and BOEM is addressing those concerns in more detail as part of their consultation with the USFWS on a Programmatic Framework ESA Section 7 consultation, which was initiated on June 20, 2024.
BOEM-2024-0001-0400-0014	Section #: 3.5.3.1 USFWS Draft Programmatic Environmental Impact Statement Comments: For Paragraph 1 on this page: Please provide an explanation of how the analysis in Table 3.5.3-1 was conducted. Without an explanation it is not possible to interpret the importance of the values in the table.	The detailed description/explanation of the methods and results that generated the information in PEIS Table 3.5.3-1 can be found in Winship et al. (2018), which is the reference for Table 3.5.3-1. The body of the Winship et al. (2018) report can be accessed at BOEM's website at https://espis.boem.gov/final%20reports/BOEM_2018-010.pdf. The data in Table 3.5.3-1 was taken directly from the 47 pages of tables in Appendix D of the Winship et al. (2018) report, which can be accessed on BOEM's website at https://www.boem.gov/sites/default/files/environmental-stewardship/Environmental-Studies/Renewable-Energy/AppendixD.pdf. However, BOEM notes that the Winship et al. 2018 report has been updated with new data (see Winship et al. 2023 in the PEIS) that has replaced the Winship et al. 2018 data in the PEIS. Therefore, Table 3.5.3-1 has been updated with this new information. Winship et al. 2023 can be found at https://espis.boem.gov/Final%20Reports/BOEM_2023-060.pdf; the data shown in PEIS Table 3.5.3-1 can be found in Appendix H.

Comment No.	Comment	Response
BOEM-2024-0001-0400-0015	Section #: 3.5.3.1 USFWS Draft Programmatic Environmental Impact Statement Comments: How did this table contribute to the impact determinations? If it was used for more than background information there is a need to explain how these percentages of the "population" would be used to support negligible minor moderate major impact determinations.	The bird population data in PEIS Table 3.5.3-1 is used to show the estimated bird presence in all anticipated offshore wind energy development on the OCS. As shown in the table, the population percentage of each bird species that overlaps with these areas is very low, ranging from 0 to 4.1 percent, with most species' populations below 1 percent. With such low percentages of bird populations potentially exposed to all anticipated offshore wind development on the OCS, BOEM believes it is reasonable to conclude that the impact or risk would be low for these bird populations. If the potential impacts are put into the context of the impact definitions defined in PEIS Table 3.5.3-3, it is reasonable to conclude that bird impacts are unlikely to be measurable or would be so small that they would be extremely difficult or impossible to discern or measure, and would never reach the level of affecting populations.
BOEM-2024-0001-0400-0016	Section #: 3.5.3.1 USFWS Draft Programmatic Environmental Impact Statement Comments: For Paragraph 2 on this page: These datasets and UDs are from a small sample size of birds captured from the mid-Atlantic and therefore are not representative of the entire Atlantic populations and should not be used to determine absence from a given location.	Based on the full context of the comment in the original comment table submitted, it is unclear what specific page is being referenced in the comment, but it appears to be PEIS page 3.5.3-7. The second paragraph on this page discusses satellite telemetry information for the surf scooter, red-throated loon, and northern gannet. This data is only one piece of information/data presented in PEIS Section 3.5.3.1 regarding bird use of the offshore environment. In this section, BOEM has presented all relevant and best available information/data on bird use in the geographic analysis area of the offshore environment. BOEM understands there are data gaps, uncertainties, and incomplete and unavailable information (refer to response to comment BOEM-2024-0001-0400-0003 on this matter).
BOEM-2024-0001-0400-0017	Section #: 3.5.3.1 USFWS Draft Programmatic Environmental Impact Statement Comments: For the "Petrel Group" in this table: Leach's storm-petrels breed in the northern hemisphere and winter in the southern hemisphere Wilson's storm-petrels are the opposite as described in this table.	BOEM has deleted leach's storm-petrel as an example of a petrel that breeds in the southern hemisphere from PEIS Table 3.5.3-2.

Comment No.	Comment	Response
BOEM-2024-0001-0400-0018	Section #: 3.5.3.1 USFWS Draft Programmatic Environmental Impact Statement Comments: For paragraph 1 on this page: Many species take a transoceanic route during migration (La Sorte at al. 2016 Stabile et al 2017). For example Blackpoll warblers make extended flights from the US East coast south across large expanses of the Atlantic Ocean to South America (DeLuca et al 2019). More data is needed to understand land bird migration patterns in offshore areas.	Refer to response to comment BOEM-2024-0001-0400-0003 for a discussion on data gaps, uncertainties, and incomplete and unavailable information.
BOEM-2024-0001-0400-0019	Section #: 3.5.3.1 USFWS Draft Programmatic Environmental Impact Statement Comments: For Paragraph 3 on this page: Morphology alone should not be used to make such a broad statement about flight patterns in a specific area. There is evidence from eBird (see: https://ebird.org/map/baleag?neg=true&env.mi nX=&env.minY=&env.maxX=&env.maxY=&zh=false&gp=false&ev=Z& excludeExX=false&ex cludeExAll=false&mr=1-12&bmo=1&emo=12&yr=all&byr=1900&eyr=2 024) that suggest bald eagles make flights over ocean including one record in the NY Bight and several in the Gulf of Maine. We would like to see this sentence revised to suggest the potential for bald eagles to be offshore.	BOEM has revised the text on bald eagles and included eBird bald eagle observations along the New Jersey and New York coastlines, and the single observation about 40 miles (64 kilometers) offshore New Jersey in the New York Bight area.
BOEM-2024-0001-0400-0020	USFWS Draft Programmatic Environmental Impact Statement Comments: For table 3.5.3-3: It is challenging to assess the accuracy of impact determinations when there is a lack of definitions associated with these benchmarks. For example there should be a clear definition or understanding of the "population" "population-level effects" and different effect types (i.e . "severe" "long- term" or "population-level").	For more information on impact terminology used in PEIS Chapter 3, see PEIS Section 3.3.2, *Impact Terminology*.
BOEM-2024-0001-0400-0021	Section #: 3.5.3.3.3 USFWS Draft Programmatic Environmental Impact Statement Comments: For paragraph 2 on this page regarding "Lighting": Why would this not be expected to increase collision risk? Avian vessel strikes largely occur during the night or twilight hours when visibility is reduced and birds are exposed to artificial lighting (Black 2005 Merkel 2010). Many bird species are known to be attracted to artificial lighting at night including many seabird and landbird species (Hppop et al. 2016 Rodriguez et al. 2017). Poor weather conditions increase the risk of avian collision (Black 2005 Merkel 2010 Ronconi et al. 2015).	BOEM has revised the text to clearly indicate the collision risk from construction vessel lighting.

Comment No.	Comment	Response
BOEM-2024-0001-0400-0022	Section #: 3.5.3.3.3 USFWS Draft Programmatic Environmental Impact Statement Comments: For paragraph 1 on this page: This study focuses on a single species and relies heavily on simulation not empirical data and therefore should not be used to make definitive statements about the entire community.	BOEM acknowledges the study focuses on a single species and relies on simulation (refer to response to comment BOEM-2024-0001-0400-0003 for a discussion on data gaps, uncertainties, and incomplete and unavailable information). However, additional studies are referenced later in the section, including the Vattenfall (2023) study on page 3.5.3-21. Vattenfall recently studied bird movements within an offshore wind farm. The purpose of the study was to improve the understanding of seabird flight behavior inside an offshore wind farm with a focus on the bird-breeding period and post-breeding period when densities are highest. The study was robust in that seabirds were tracked inside the array with video cameras and radar tracks, which allowed for measuring avoidance movements with high confidence and at the species level. Detailed statistical analyses of the seabird flight data were enabled both by the large sample sizes and by the high temporal resolution in the combined radar track and video camera data. Meso-avoidance behavior showed that species avoided the rotor-swept zone (RSZ) by flying in between the turbines, with very few avoiding the RSZ by changing their flight altitude to fly either below or above the rotors. The most frequently recorded adjustment under micro-avoidance behavior was birds flying along the plane of the rotor; other adjustments included crossing the rotor either obliquely or perpendicularly, with some birds crossing the rotor swept area without making any adjustments to the spinning rotors. The study concluded that, together with the recorded high levels of micro-avoidance in all species (>0.96), seabirds would be exposed to very low risks of collision in offshore wind farms during daylight hours. This was substantiated by the fact that no collisions or even narrow escapes were recorded in over 10,000 bird videos during the 2 years of monitoring covering the April–October period. The study's calculated micro-avoidance rate (>0.96) is similar to Skov et al. (2018) (also cited in the PEIS).
BOEM-2024-0001-0400-0023	Section #: 3.5.3.3.3 USFWS Draft Programmatic Environmental Impact Statement Comments: For Paragraph 2 on this page: Currently there is no evidence to suggest offshore mortality rates will be similar to onshore rates because the conditions are extremely different (e.g. it	BOEM has revised the presence of structures IPF section in PEIS Section 3.5.3.3.3, which resulted in this removal of the paragraph. Refer to response to comment BOEM-2024-0001-0400-0013 on

Comment No.	Comment	Response
	is an entirely different ecosystem with different bird behaviors and movement patterns there is a very different species composition and the wind turbines are much larger). Therefore we feel it is inappropriate to definitively state that this is a worst-case scenario and recommend the removal of this statement.	why BOEM believes the USFWS turbine mortality data is a reasonable factor to consider for offshore wind.
BOEM-2024-0001-0400-0024	Section #: 3.5.3.3.3 USFWS Draft Programmatic Environmental Impact Statement Comments: For Paragraph 4 on this page: Migrating birds typically fly at altitudes above the rotor swept zone; however they will gradually descend or climb at the beginning or end of each migration bout exposing them to lower altitudes or fly at lower altitudes during inclement weather (Lao et al. 2020 Elmore et al. 2021).	BOEM has revised the presence of structures IPF section in PEIS Section 3.5.3.3.3, which resulted in this removal of the paragraph.
BOEM-2024-0001-0400-0025	Section #: 3.5.3.3.3 USFWS Draft Programmatic Environmental Impact Statement Comments: For Paragraphs 3 to 4 on this page: The entanglement of derelict fishing gear around wind energy related structures may not be a benefit for marine birds as stated. If the foraging opportunities at WTGs are better than surrounding areas due to a reef effect then birds will be attracted to the turbines and have an increased risk 1) of direct collision with turbines and/or 2) have increased risk of entanglement with debris while foraging around turbine bases. Many marine birds dive deep and hunting prey in a mass of derelict fishing gear increases the chance of entanglement.	Refer to the second paragraph of response to comment BOEM-2024-0001-0400-0003.
BOEM-2024-0001-0400-0026	Section #: 3.5.3.4.1 USFWS Draft Programmatic Environmental Impact Statement Comments: For Paragraph 2 on this page regarding Lighting: Avian mortality has been reported on offshore energy platforms and structures from a variety of species including landbirds shorebirds rails Procellariids and Larids due to collision with structures while flying towards artificial lighting (Ronconi et al. 2015 Hppop et al. 2016 Gjerdrum et al. 2021). Poor weather conditions increase the risk of avian collision (Black 2005 Merkel 2010 Ronconi et al. 2015). Developers should be aware of strategies to reduce collisions of birds during inclement weather at night as well as inclement weather conditions which may increase collisions.	AMMM measure BIR-2 (see PEIS Appendix G) would require lessees to incorporate light reduction measures to avoid and minimize light attraction and bird collision impacts. Additional measures may be required as part of BOEM's terms and conditions for approvals of COPs for specific NY Bight lease areas that might be developed in the future, should BOEM decide to approve a COP.

Comment No.	Comment	Response
BOEM-2024-0001-0400-0027	Section #: 3.5.3.4.1 USFWS Draft Programmatic Environmental Impact Statement Comments: For Paragraph 3 on this page: How is it known that "impacts from suspended sediments would be short term and localized"? Please provide a citation. Otherwise this sentence should be changed to be less definitive.	Sediment disturbed by construction activities in water settle once the construction is complete. Therefore, the sediment is suspended for a short period of time and in the general area of disturbance, which means potential impacts on foraging birds that happen to be in the area during construction could be affected during that short period of time. There is a more detailed analysis on the suspension of sediment and recovery of benthic assemblages in PEIS Section 3.4.2, *Water Quality*, and Section 3.5.2, *Benthic Resources*.
BOEM-2024-0001-0400-0028	Section #: 3.5.3.4.1USFWS Draft Programmatic Environmental Impact Statement Comments: For Paragraph 3 on this page: This is based off of information derived when Wind turbine generators (WTG) were not offshore. We don't know if WTGs may attract birds through perching or foraging opportunities. More information from multi-sensor systems is needed to validate attraction as well as avoidance after construction.	Attraction to WTGs is mentioned in PEIS Section 3.5.3, Birds. BOEM recognizes that monitoring after construction may be necessary. Based on COP approvals to date, BOEM anticipates monitoring may be part of the terms and conditions of a future COP approval for any of the NY Bight lease areas, and adaptive management may be required if impacts deviate substantially from the impact analysis in the PEIS.
BOEM-2024-0001-0400-0029	Section Title: Table G-1. Adaptive mitigation for birds and bats. Section #: BB-3USFWS Draft Programmatic Environmental Impact Statement Comments: For clarification our original recommendation was to "Either work with the Service to develop a metric or remove the word substantially from the sentence. That word can be interpreted differently depending on the resource being impacted."	Thank you for your comment. BB-3 has been revised.
BOEM-2024-0001-0400-0030	Section #: Appendix G USFWS Draft Programmatic Environmental Impact Statement Comments: For Measure ID BB-1: Given their status under the Bald and Golden Eagle Protection Act bald and golden eagles should be included as species with immediate reporting requirements.	BOEM has revised BB-1 to include mention of eagles protected under the Bald and Golden Eagle Protection Act.
BOEM-2024-0001-0400-0031	Section #: Appendix G USFWS Draft Programmatic Environmental Impact Statement Comments: For Measure ID BB-2: Developers should also report any other form of tag such as MOTUS or satellite	BOEM has revised BB-2 to include reporting of any other form of tag such as MOTUS or satellite.
BOEM-2024-0001-0400-0032	Section #: Appendix G USFWS Draft Programmatic Environmental Impact Statement Comments: For Measure ID BB-2: Post-construction data (both survey and tracking data) will be of significantly lower value without pre-construction monitoring data.	Available preconstruction data could be incorporated in future COPs and analyzed at the project-level COP NEPA review and consultation stage.

Comment No.	Comment	Response
	Obtaining both pre- and post-construction data is particularly critical for understanding displacement one of the three main "issues" impacting birds outlined in Table 3.5.3-4 of the DPEIS. Therefore we strongly recommend that all post-construction monitoring is coupled with pre- construction data collection.	
BOEM-2024-0001-0400-0033	Section #: Appendix G USFWS Draft Programmatic Environmental Impact Statement Comments: For Measure ID BB-3: Since displacement (I.e. functional habitat loss) is one of the two primary negative effects of offshore wind we feel that the list of goals for the BBPCMP should include an additional goal that explicitly addresses displacement (e.g. "(4) to understand the magnitude and variation in potential displacement effects for the resident avian community").	Habitat displacement is project-specific and would be determined at the project-specific COP NEPA and consultations stage.
BOEM-2024-0001-0400-0034	Section #: Appendix G USFWS Draft Programmatic Environmental Impact Statement Comments: For Measure ID BB-3: We recommend incorporating non-listed species into tagging efforts along with listed species. Many non-listed species are of conservation concern and lacking movement information. We recommend coordinating tracking projects with the RWSC (Regional Wildlife Science Collaborative).	Thank you for your comment. BOEM has revised BB-3 to include "other species of concern".
BOEM-2024-0001-0400-0035	Section #: Appendix G USFWS Draft Programmatic Environmental Impact Statement Comments: For Measure ID BB-3: In order to detect displacement effects it is important to survey an additional buffer around lease areas. Please include the need to survey a 4-20 km buffer for digital aerial surveys	Buffers for digital aerial survey are project-specific and would be determined at the project-specific COP NEPA and consultations stage.
BOEM-2024-0001-0400-0036	Section #: Appendix G USFWS Draft Programmatic Environmental Impact Statement Comments: For Measure ID BB-3: Please consider non-listed species in addition to listed species.	Thank you for your comment. BOEM has revised BB-3 to include "other species of concern".
BOEM-2024-0001-0400-0037	Section #: Appendix G USFWS Draft Programmatic Environmental Impact Statement Comments: Please ensure that "Nbat" is corrected to "North American Bat Monitoring Program (NABat).	Appendix G has been revised to replace Nbat with North American Bat Monitoring Program (NABat).
BOEM-2024-0001-0400-0038	USFWS Draft Programmatic Environmental Impact Statement Comments: BOEM did not respond to this comment. However a response was not necessary. The Services comment is applicable to the Draft Programmatic Environmental Impact Statement and ESA Section 7(a)(2) consultation.	Comment noted.

P.4.1.3 U.S. Environmental Protection Agency

Table P.4-4. Responses to Comments from the U.S. Environmental Protection Agency (BOEM-2024-0001-0435)

Comment No.	Comment	Response
BOEM-2024-0001-0435-0001	EPA acknowledges the purpose of the Draft Programmatic Environmental Impact Statement (PEIS) is to allow for tiering and reduce the need for redundant analyses for the six offshore lease areas. As such the Draft PEIS does not include the same level of detail as a project-specific environmental review. However EPA suggests that the Final PEIS clarify in the executive summary section the intended distinctions in the type of information to be provided in future NEPA documents. Although this is provided in Appendix C it would be helpful to include a brief description within the body of the PEIS. Additionally we recommend that the executive summary section also address what the public review process will entail for the subsequent construction and operations plan (COP)-specific NEPA documents.	Appendix C is referenced in the Executive Summary, Chapter 1, and in each Chapter 3 resource section, and it effectively points readers to the detailed recommendations by resource topic regarding how the PEIS may be incorporated by reference in the future COP-specific NEPA documents. Each individual COP submitted by a developer to BOEM will be separately analyzed as required under NEPA and will disclose the full impacts of the construction and installation, O&M, and conceptual decommissioning of the project. BOEM will conduct project-specific NEPA analysis of the COP for each lease area, which will consider the best available data and information that reflect the state of the science at the time of publication. The COP-specific NEPA process will follow BOEM's public involvement process, which will include holding a public comment period at the start of the NEPA process (scoping) and following the release of the Draft NEPA document whereby members of the public and agencies can provide input to help inform the NEPA process. Additionally, throughout the NEPA process, BOEM works closely with cooperating state and federal agencies and tribal governments to assist with assessing impacts and identifying mitigation measures.
BOEM-2024-0001-0435-0002	The Draft PEIS makes impact determinations for resource categories (ex. Air Quality Environmental Justice Wetlands Benthic etc.) where site-specific information and evidence (including modeling) is necessary in order to support that determination. Given the limited information available it is unclear how such impact determinations can be reasonably made. We are concerned that future tiered documents will rely on unsubstantiated impacts determinations presented in the Draft PEIS. We recommend that the Final PEIS clarify that COP-specific NEPA documents will not just adopt the impacts determinations from the Draft PEIS. Rather we expect that the future COP-specific NEPA documents will evaluate these resource areas	Each individual COP submitted by a developer to BOEM will be separately analyzed as required under NEPA and will disclose the full impacts of the construction and installation, O&M, and conceptual decommissioning of the project. BOEM will conduct project-specific NEPA analysis of the COP for each lease area, which will consider the best available data and information that reflect the state of the science at the time of publication. At the time of the COP-level NEPA analysis, BOEM will determine to what extent information in the PEIS can be incorporated by reference into the COP-level NEPA document.

Comment No.	Comment	Response
	based on an appropriate level of analysis informed by site-specific data to arrive at an impact determination. EPA recommends that BOEM make it clear that this additional information be presented for public review at the project specific level.	For each resource area, Appendix C, *Tiering Guidance*, summarizes the affected environment, impact analysis, and AMMM measures discussed in this PEIS and identifies additional analysis that BOEM anticipates may be included in the COP-specific NEPA analysis for each lease area.
BOEM-2024-0001-0435-0003	Further EPA suggests that COP-specific NEPA documents provide a detailed discussion of impact determinations before and after the implementation of AMMMs. Given the broad and vague nature of the proposed AMMMs it is not clear how BOEM is able to substantiate impact level comparisons between the deferment of AMMMs (Alternative B) and the adoption of AMMMs (Alternative C) as it is expected that even if deferred many of the AMMMs would be applied on a lease-by-lease basis.	Refer to response to comment BOEM-2024-0001-0371-0004. The analyses in the PEIS do discuss impacts after implementation of AMMM measures. Depending on the specific IPF and the resource analyzed, there can be notable differences that change the impact determination for an IPF with implementation of AMMM measures under Alternative C. For example, see the Lighting IPF analysis for birds (PEIS Section 3.5.3) under Alternative B and Alternative C, where the impact was reduced from moderate to minor with implementation of an AMMM measure under Sub-alternative C. Future COP-specific NEPA documents for NY Bight lease areas would assess impacts in the context of any AMMM measures that would be implemented.
BOEM-2024-0001-0435-0004	As is stated in the Draft PEIS alternatives should "avoid or substantially lessen one or more significant socioeconomic or environmental effects." Although Alternative B is helpful for comparison of impacts between the full build with and without AMMMs it is not clear that Alternative B is an alternative that would meaningfully reduce impacts of the project. This is displayed in Table ES-2 as there are only 5 resource areas where the impact rating differs between Alternative B and Alternative C. EPA suggests that BOEM reframe the alternatives to better align with CEQ regulations at 40 CFR 1502.14(a) and DOI regulations at 43 CFR 46.420(b-c).	Refer to response to comment BOEM-2024-0001-0371-0004. The overall impact rating conclusions (as shown in PEIS Table 2-4 and *Executive Summary* Table ES-2) may not always be different under Alternative C when compared to Alternative B, while impacts for specific individual IPFs may be different. Depending on the specific IPF and the resource analyzed, there can be notable differences that change the impact determination for a specific IPF under Alternative C (see the Lighting IPF in PEIS Section 3.5.3, *Birds*, under Alternative B and Sub-alternative C1). However, the overall impact rating conclusions for the resource encompasses all IPF impact conclusions. The details of the analysis for each IPF and the justification for the overall impact conclusion for a resource is found in the Chapter 3 resource sections.
BOEM-2024-0001-0435-0005	Appendix C provides a description of how this PEIS will vary with tiered COP-specific NEPA documents. We encourage BOEM to provide a summary of resource areas where the adoption of AMMMs will mostly be based on information determined in COP-specific NEPA documents and those resource areas where AMMMs will include	Refer to response to comment BOEM-2024-0001-0371-0004 regarding revisions made to Alternative C and AMMM measures. Sub-alternative C1 analyzes the AMMM measures that BOEM has required as conditions of approval for previous activities proposed by lessees in COPs submitted for the Atlantic OCS or through

Comment No.	Comment	Response
	regulatory requirements such as Section 7 National Marine Fisheries Service (NMFS) Consultation requirements. Additionally EPA suggests that a complete list of Plans to be required as part of the AMMMs be included in the PEIS.	related consultations. The applicability of these AMMM measures will depend on the project-specific COP submittals for the NY Bight, and BOEM cannot speculate how a future COP will fit within the PEIS. For special purpose statutes (e.g., ESA), the list of AMMM measures in PEIS Appendix G, Table G-1, does include AMMM measures that BOEM has proposed or that have been required by resource agencies to address impacts. Project-specific COP NEPA documents may also include additional AMMM measures beyond the AMMM measures in this PEIS to address project-specific impacts. The plans that are part of AMMM measures can be found in the AMMM measures listed in PEIS Appendix G, Table G-1.
BOEM-2024-0001-0435-0006	Appendix E provides an explanation of incomplete or unavailable information for each resource area. A statement similar to "Therefore BOEM believes that the analysis provided in the Draft PEIS is sufficient to make a reasoned choice among the alternatives in terms of coastal habitat and fauna" is made for each resource area. This is a confusing statement as it's not clear if further information will be needed to decide between alternatives in COP-specific NEPA documents. As much of the impact analysis for each resource area is being pushed to COP-specific NEPA documents this should be clarified.	Appendix E is applicable to the analysis detailed in the PEIS for the six NY Bight lease areas. Site-specific impacts associated with the construction and installation, O&M, and conceptual decommissioning of these facilities that deviate from the broad-scale analysis presented in the PEIS will be analyzed in subsequent COP NEPA EIS documents. Each COP NEPA EIS will consider the best available data and information that reflect the state of the science at the time of publication.
BOEM-2024-0001-0435-0007	The PEIS should include clarification on the timing of the Draft PEIS in relation to the issuance of COPs for each lease areas. It is EPA's understanding that COPs for the NY Bight lease areas have begun being submitted in early 2024.	BOEM's authority under the Outer Continental Shelf Lands Act (OCSLA) requires BOEM to review COPs once they are submitted by a developer. The timeline for COP submittal by the developer and the timing of the COP-level NEPA analysis varies depending on the lease area.
BOEM-2024-0001-0435-0008	Glauconite can create significant issues for offshore wind development. It is currently unclear whether geotechnical studies have been conducted to determine the presence of glauconite sands. We recommend conducting such studies as early as possible to inform the viable alternatives and potential impacts.	The PEIS acknowledges the possibility for glauconite soils to be present in the NY Bight lease areas and identifies potential impacts associated with glauconite. Thank you for your comment. These details will be addressed at the COP-specific level.
BOEM-2024-0001-0435-0009	COP-specific NEPA documents should provide additional information on the Unexploded ordnance (UXO) mitigation activities especially related to remediation for agency review. This should include but is	Appendix C, *Tiering Guidance*, summarizes the affected environment, impact analysis, and AMMM measures discussed in this PEIS and identifies additional analysis that will be included in

Comment No.	Comment	Response
	not limited to siting criteria mapping identification/classification of UXO type and discussion of whether/how each UXO will be monitored once relocated.	the NEPA EIS analysis for each resource area, including Other Uses. Each lease area will undergo project-specific environmental analyses through the development and submittal of a Site Assessment Plan (SAP) and a COP. BOEM will conduct project-specific NEPA analysis of the COP for each lease area, which will include detailed evaluation of impacts and will consider the best available data and information that reflect the state of the science at the time of publication.
BOEM-2024-0001-0435-0010	There are inconsistencies within the Draft PEIS with respect to the specified time for construction. For example, Figure 1-2 indicates that construction for projects typically occurs between 0-2 years as has been the documented constructed period in prior EISs issued by BOEM for offshore wind projects. However in 2.1.2.1.1 the Draft PEIS states that construction for offshore wind projects can take on average 3 to 5 years. We recommend these discrepancies in the timeframe for construction be clarified in the Final PEIS.	BOEM revised Figure 1-2 to show that construction could take up to 5 years. Construction timelines for each NY Bight project is expected to vary and could be more or less than the schedule estimates provided in the Draft PEIS. The project-level NEPA reviews will analyze construction impacts based on the schedules provided in each COP.
BOEM-2024-0001-0435-0011	Alternatives Since all projects will be required to implement avoidance minimization and mitigation measures (either as required by this PEIS or COP-specific NEPA documents) it is unclear how there are differences in the impacts between Alternative B and Alternative C.	Refer to response to comment BOEM-2024-0001-0371-0004.
BOEM-2024-0001-0435-0012	EPA recommends that BOEM consider additional alternatives (some of which were dismissed from consideration) that would allow for a more meaningful comparison of impact minimization efforts.	Refer to response to comment BOEM-2024-0001-0371-0004.
BOEM-2024-0001-0435-0013	The PEIS should make clear if there may be differences in the efficacy of AMMMs between the alternatives.	Refer to responses to comments BOEM-2024-0001-0371-0004 and BOEM-2024-0001-0435-0003.
BOEM-2024-0001-0435-0014	The No Action alternative is intended to serve as a baseline for comparison to alternatives and evaluation of impacts. It's not clear how a No Action of not building the NY Bight Projects corresponds to an action alternative of the adoption of AMMMs. EPA recommends that future NEPA analyses include action alternatives that clearly address the purpose and need of the project as well as a No Action alternative that allows for meaningful evaluation of impacts.	As stated in PEIS Section 2.1, *Alternatives Analyzed in Detail*, the No Action Alternative analyzes the potential impacts from ongoing and planned non-offshore wind and offshore wind activities without development in the six NY Bight lease areas. Any potential environmental and socioeconomic impacts, including benefits, associated with offshore wind development of the six NY Bight lease areas as described under Alternative B or the AMMM

Comment No.	Comment	Response
		measures as described under the Proposed Action, would not occur. As clarified in PEIS Chapter 2, Alternative B serves to compare how impacts would change with AMMM measures analyzed in Sub-alternatives C1 and C2. BOEM will not approve any projects at the COP-NEPA stage without AMMM measures. Project-specific COP NEPA documents would also address the No Action Alternative, which will serve as the baseline against which the direct and indirect impacts of all action alternatives are evaluated for that specific project.
BOEM-2024-0001-0435-0015	Air Quality EPA recommends encouraging lessees to require the best available technology for marine vessels and non-road equipment. Many of the AMMMs for air quality seek to address this. It could be strengthened by broadening AQ-7 (Onshore measures: diesel engine emissions standards) to apply to marine vessel engines in addition to onshore equipment. If zero-emissions options are not available non-road equipment should meet "Tier 4 Final" standards rather than simply "Tier 4." This is relevant for some non-road equipment and is distinct from Tier 4 interim standards which allow for higher emissions of nitrogen oxides. For marine engines the highest tier may be Tier 4 or Tier 3 depending on the engine size.	BOEM has revised AQ-7 and included the CFR language for marine engine standards and the distinction between Tier 4 Final and Tier 4 Interim standards for non-road equipment.
BOEM-2024-0001-0435-0016	Page 3.4.1-9 states that "Construction activity would occur at different locations and could overlap temporally with activities at other locations including operational activities at previously constructed projects. As a result air quality impacts would be minor shifting spatially and temporally across the air quality geographic analysis area." The geographic or temporal variability does not necessarily result in only minor air quality impacts. The impact of other ongoing offshore wind activities included in the No Action Alternative have not been fully assessed.	The commenter is correct that geographic or temporal variability does not necessarily result in only minor air quality impacts. However, such variability can decrease the likelihood of impacts due to multiple emission sources operating at the same location for an extended time. Data are not available to evaluate impacts quantitatively from multiple projects across the air quality analysis area.
BOEM-2024-0001-0435-0017	Page 3.4.1-14 states that "A NY Bight project must demonstrate compliance with the NAAQS and must demonstrate no adverse impact on air quality related values (AQRV). The Outer Continental Shelf (OCS) air permitting process includes air dispersion modeling of emissions to demonstrate compliance with the NAAQS. As part of the AQRV analysis a NY Bight project must demonstrate that significant	For each project proposed for the NY Bight, the applicant will be responsible for performing the air quality analysis in accordance with BOEM and U.S. Environmental Protection Agency (USEPA) requirements and guidance.

Comment No.	Comment	Response
	visibility degradation at a Class I area would not occur as a result of increased haze or plumes." EPA reminds BOEM that the OCS air permitting process does not necessarily cover all air emissions associated with the project. NY Bight projects must conduct full analyses of all direct and indirect air emissions in order to determine the severity of the air quality impacts.	
BOEM-2024-0001-0435-0018	Additionally please note for future COP-specific NEPA documents that the AQRVs includes visibility and acid deposition at the Class I area and are regulated by the Federal Land Manager (FLM) of that Class I area. In this case the Brigantine Wildlife Refuge is nearby. The FLM for Brigantine Wildlife Refuge is the US Fish and Wildlife Service (USFWS). o Additionally the visibility impairment is not limited to the Class I area but could also include other scenic vistas such as the Statue of Liberty. The scenic vista depends on the location of the source.	For each project proposed for the NY Bight, the applicant will be responsible for evaluating impacts on AQRVs at applicable Class I areas and at Class II areas designated by the FLM.
BOEM-2024-0001-0435-0019	BOEM anticipates that the air quality impacts associated with the project would be minor. However this remains largely unsubstantiated based on the information presented in the Draft PEIS. As currently written it is not clear whether a NAAQS violation may occur. Specifically Table 3.4.1-6. includes an estimate of criteria pollutant emissions from construction which are not annualized but total. Overall the analysis should ensure that any of the NY projects will not cause or contribute to a violation of any applicable NAAQS Prevention of Significant Deterioration (PSD) increment state air quality standards or other relevant standard during construction as well as determine if emissions would adversely impact air quality. We recommend the PEIS include a table with emissions of criteria pollutants in comparison with the NAAQS to clearly demonstrate whether a violation of NAAQS may occur.	For each project proposed for the NY Bight, the applicant will be responsible for performing the air quality analysis to demonstrate compliance with the National Ambient Air Quality Standards (NAAQS). The requested table is not included in the Final PEIS because emissions are expressed in units of mass per time (e.g., tons per year) and cannot be compared to the NAAQS, which are in units of mass per unit volume (e.g., micrograms per cubic meter [$\mu g/m^3$]) or volume per unit volume (e.g., parts per billion).
BOEM-2024-0001-0435-0020	Additionally although any given NY Bight project would have lower emissions than otherwise might be generated from another fossil fuel source there are still sizable emissions that are not negligible. This is further supported by BOEM's claims that it would take nearly the entire lifetime of the project (28 years of operation) to offset NOx emissions resulting from construction operations and	A determination of “minor” (as well as the distinction between "minor" and "moderate") is a qualitative evaluation. Because emissions levels alone do not determine concentrations, setting an impact level based on emissions is subjective.

Comment No.	Comment	Response
	decommissioning. In light of this statement it is unclear how a minor impacts determination may be made.	
BOEM-2024-0001-0435-0021	We recommend separating the greenhouse gas (GHG) and climate change section from the Air Quality section. This would aid in making relevant information regarding avoided and offset GHG emissions more readily accessible as GHG emissions are discussed throughout the Air Quality Section but the impact level definitions do not incorporate parameters to evaluate the significance of GHG reductions. We recommend evaluating GHG separately from NAAQs pollutants and developing impact level definitions specific to GHGs.	Because no project has greenhouse gas (GHG) emissions large enough to make a measurable difference to climate impacts, BOEM does not assign impact ratings specifically to GHG emissions.
BOEM-2024-0001-0435-0022	Table 3.4.1-9 presents the net emissions of CO2 for a single NY Bight project. EPA recommends that BOEM specify whether this refers to CO2eq. Additionally the Draft PEIS could benefit from a clarifying statement on how the total lifetime net emissions for the no action (emissions from the grid in absence of one NY bight project) was calculated.	The emissions in Table 3.4.1-9 are carbon dioxide (CO_2) not CO_2 equivalent. The table data are labeled properly as CO_2. The lifetime net emissions for the No Action Alternative (which has no avoided emissions) represents the amount of emissions that would occur from the grid (as configured in 2018) to produce the same quantity of electrical energy as would have been produced by one NY Bight project. This information has been added to Final PEIS Section 3.4.1, *Air Quality and Greenhouse Gas Emissions*, as well.
BOEM-2024-0001-0435-0023	The Draft PEIS concludes that air quality impacts due to a single NY Bight project within the air quality geographic analysis area are anticipated to be small relative to larger emission sources such as fossil-fuel power plants. In support of this claim footnote 5 provides the annual operational emissions from a single NY Bight project expressed as a percentage of the emissions from fossil-fuel power plants in New Jersey based on the USEPA 2020 National Emissions Inventory (USEPA 2023). As stated in CEQ's interim National Environmental Policy Act Guidance on Consideration of Greenhouse Gas Emissions and Climate Change "NEPA requires more than a statement that emissions from a proposed Federal action or its alternatives represent only a small fraction of global or domestic emissions. Such a statement merely notes the nature of the climate change challenge and is not a useful basis for deciding whether or to what extent to consider climate change effects under NEPA this approach does not reveal anything beyond the nature of the climate	The comparisons in footnote 5 apply to criteria pollutants, not GHGs, and are included to provide perspective on emissions from one NY Bight project relative to regional emissions from the fossil-fuel power plant sector. The CEQ guidance quoted by the commenter applies to GHGs, does not apply to criteria pollutants, and is not relevant to criteria pollutants outside the climate change context.

Comment No.	Comment	Response
	change challenge itself the fact that diverse individual sources of emissions each make a relatively small addition to global atmospheric GHG concentrations that collectively have a large effect."	
BOEM-2024-0001-0435-0024	Additionally the manufacturing of components and transit of vessels from other locations may contribute to emissions including global GHG emissions. It is not clear whether these emissions are currently included in the assessment. Where emissions cannot be reasonably estimated information such as lifecycle information may be useful (e.g. https://www.nrel.gov/analysis/life-cycle-assessment.html.) EPA suggests including a full accounting of direct and indirect emissions including upstream emissions that may result from the proposed action.	As stated in Final PEIS Section 3.4.1.4.1, emissions from manufacturing and other "upstream" sources are not included in the analysis. However, life cycle considerations are discussed in Section 3.4.1.4.1. As indicated in Section 3.4.1.4.1, although wind energy has higher upstream emissions than many other generation methods, its life-cycle GHG emissions are orders of magnitude lower than from other generation methods.
BOEM-2024-0001-0435-0025	EPA also recommends that GHG emissions for each alternative be provided to form a basis for comparison across alternatives.	Final PEIS Section 3.4.1.4.1 provides emissions for Alternative B. Section 3.4.1.5 discusses emissions for Alternative C and states that the estimated emissions with Sub-alternatives C1 and C2 would be the same as for Alternative B.
BOEM-2024-0001-0435-0026	Although at this time there is limited information on the potential ports to be utilized by each of the lease areas we recommend that future COP-specific NEPA documents carefully consider how impacts to port communities areas with pre-existing air quality impairments and low income and disadvantaged communities will be addressed as the projects proceed. We also note that while operation and maintenance facilities at or near some or all of the identified ports would be used for multiple offshore wind projects and have utility that is independent of any single project the impacts associated with the development or expansion of these facilities should be considered. To facilitate a clear analysis of air quality impacts we again recommend showing maximum modeled concentrations or emissions estimates from construction and operations and maintenance activities in comparison with NAAQS or other standards. This information should be provided in subsequent COP-specific NEPA documents.	Future COP-specific NEPA documents will consider air quality impacts on the relevant port areas and environmental justice communities.
BOEM-2024-0001-0435-0027	Section 3.4.1.4.3 states: "BOEM is considering conducting or participating in a regional modeling study that would assess	This study has not received financial support and will not commence prior to the issuance of the Final PEIS. BOEM intends

Comment No.	Comment	Response
	development impacts of six NY Bight projects along with other planned and reasonably foreseeable projects." EPA encourages BOEM to perform the study as the quantitative results would be a critical piece of evidence in the cumulative impacts section of the Final PEIS.	to revisit the matter of conducting a regional modeling study at a subsequent time.
BOEM-2024-0001-0435-0028	Climate change can make ecosystems resources and communities more susceptible as well as lessen resilience to other environmental impacts apart from climate change. In some instances this may exacerbate the environmental effects of the proposed action. We recommend that the climate change section in future COP-specific NEPA documents include consideration of climate resiliency measures particularly for infrastructure that may be vulnerable to the impacts associated with climate change (such as sea level rise more frequent storms etc.). This discussion would provide additional details regarding the durability of the proposed infrastructure (including wind turbine generators and buried cables at all locations) in the face of more severe weather and more severe sea states.	Future COP-specific NEPA documents will consider climate resiliency measures and the durability of the proposed infrastructure.
BOEM-2024-0001-0435-0029	Water and Natural Resources. The COP-specific NEPA documents should describe how AMMMs and any additional mitigation will be coordinated with current efforts to preserve the quality of water resources (for example the Barnegat Bay Comprehensive Conservation and Management Plan.)	Thank you for your comment. This coordination would be included in the COP-specific NEPA documents.
BOEM-2024-0001-0435-0030	The National Pollutant Discharge Elimination System (NPDES) permit program under the Clean Water Act (CWA) addresses water pollution by regulating point sources that discharge pollutants to waters of the United States. EPA recommends that BOEM and the lessees coordinate with EPA as project design progresses in order to determine the necessity of a NPDES permit. COP-specific NEPA documents should address any potential discharges from onshore or offshore project components (including wind turbine generators or offshore substations) and indicating whether they may be subject to NPDES permits.	Thank you for your comment. Section 3.4.2.3.2 provides a discussion of circumstances and activities that would require an NPDES permit. CWA Section 316(b) requires NPDES permits to ensure that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available to minimize adverse environmental impacts. More specific information would be included in the project-specific COP-level NEPA analysis.
BOEM-2024-0001-0435-0031	In the discussion of water quality impacts associated with cable emplacement and maintenance the Draft PEIS applies the findings of the sediment transport model for Empire Wind in assessing the	A statement has been added to the Final PEIS Section, 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative,* to make clear to the reader that a project-specific, COP-level NEPA analysis will

Comment No.	Comment	Response
	implications of sediment suspension. The Draft PEIS should articulate the assumptions made in applying these results to the New York Bight lease areas and should disclose potentially different existing conditions that may make the findings of this model inapplicable to the sites being evaluated. Additionally EPA would look to future COP-specific NEPA documents to evaluate whether there may be regions within each lease area or corresponding near and on-shore components that may be more sensitive to sediment deposition or suspended sediment (such as tidal wetlands along the shoreline and shellfish harvesting areas). Subsequent COP-Specific NEPA documents should carefully assess potential impacts to these sensitive resources. Additionally EPA recommends a pre-and post- construction bathymetric survey be provided to ensure the sediment resettles over the proposed cables rather than disturb nearby benthic habitat.	provide greater details of the specific New York Bight lease areas and the possible impacts on resources from sediment resuspension and transport. Through the application of RP MUL-27, BOEM encourages lessees to explore ways to minimize potential impacts related to sediment disturbance.
BOEM-2024-0001-0435-0032	Furthermore the EPA recommends that subsequent COP-specific NEPA documents consider the following components related to water quality: o Port expansion could include dredging deepening and construction of new berths resulting in impacts on water quality through accidental spills leaks or discharges or sedimentation during port use. Any potential increases in erosion related to dredging should be addressed. EPA encourages BOEM to consider beneficial use of dredged material to the extent practicable. The PEIS should also include a discussion of potential disposal sites if known as each disposal alternative may have different requirements and/or result in potentially different impacts Waters of the U.S. and water quality. Specific information about cable corridors is not yet known. While EPA is generally supportive of the concept of shared or common cable corridors to reduce potential impacts to benthic resources and wetlands given the cable ranges included within the representative project design envelope we are not able to meaningfully assess the extent of impacts to arrive at a conclusion. Subsequent analyses should quantitatively evaluate the acreage of benthic habitats wetlands submerged aquatic vegetation and other sensitive resources/areas associated with various potential cable corridors routes to inform a determination of impacts. A map showing the coinciding resource areas intersected by cable corridors would also be	Thank you for your comment. Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative*; *Port Utilization*, provides an assessment of the impacts on water quality from port utilization and possible port improvements. Port improvement projects are described in Appendix D, Section D.2.5. If the individual projects include other port improvement activities or components, the project-specific, COP-level NEPA analysis will provide further details. Analysis of impacts on benthic resources is provided in Section 3.5.2. The analysis of wetland impacts are provided in Section 3.5.8. Text has been added to Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative*, *Presence of Structures* IPF regarding emissions from anodes. Additionally, AMMM measure WQ-1 requires lessees to avoid using zinc sacrificial anodes on external components of WTG and OSS foundations to reduce the release of metal contaminants in the water column.

Comment No.	Comment	Response
	informative in demonstrating the potential scale of impacts associated with cable emplacement. o No consideration for impacts of turbine port infrastructure on wetlands is included in the analysis. Furthermore given the broad scope of the wetland impacts there is no consideration for the cumulative effects of the wetland impacts region wide. It is recommended that there be additional consideration of the cumulative impacts on wetlands including any impacts to wetlands' ability for natural inland migration as a consequence of project impacts. o Protective measures for corrosion of offshore wind structures have different potentials for emissions (e.g. galvanic anodes emitting metals such as aluminum zinc and indium; organic coatings releasing organic compounds due to weathering or leaching). While the current understanding is that chemical emissions from offshore wind structures is likely low the effects of multiple projects is not known. We recommend that BOEM consider commitments to water quality monitoring to better understand potential impacts and how they can be avoided or managed if necessary.	
BOEM-2024-0001-0435-0033	In future COP-specific NEPA documents EPA recommends that BOEM provide additional information documenting the anticipated location and type of scour protection to be used throughout the project area. Additionally if the scour systems are to be removed EPA recommends including this removal in a management plan that includes measures to avoid impacts to the seafloor bed as well as indicating where the material will be placed.	Thank you for the comment. The project-specific, COP-level NEPA analysis will provide greater details regarding location and type of scour protection. Additionally, any decommissioning activities, including the removal of scour protection, would be included in the decommissioning application required by BSEE.
BOEM-2024-0001-0435-0034	Additionally the COP-specific NEPA document should include sufficient information on how the selected project alternative is consistent with the CWA Section 404(b)(1) Guidelines to support permitting by the U.S. Army Corps of Engineers. Such a discussion would demonstrate how the proposed/selected alternative qualifies as the least environmentally damaging practicable alternative.	Thank you for the comment. The project-specific COP-level NEPA analysis will provide greater details on CWA Section 404(b)(1) guidelines for project alternatives.
BOEM-2024-0001-0435-0035	Land Use and Coastal Infrastructure The PEIS states that Port Utilization will result in minor beneficial impacts to land use and coastal infrastructure through economic activity and increased employment opportunities. EPA urges BOEM to consider impacts	The specific ports that the NY Bight projects will utilize are not yet known, nor are potential port upgrades that might be required. The PEIS analyzes representative ports to describe the types of impacts that could result from port utilization. Ongoing and

Comment No.	Comment	Response
	related to port upgrades and construction that will be required to facilitate their use as part of the NY Bight full build.	planned port upgrades within the geographic analysis are identified in Appendix D, *Planned Activities Scenario*, and are evaluated as part of the cumulative impact analysis. Specific port-related impacts will be analyzed at the COP NEPA stage when specific ports are chosen for each individual project.
BOEM-2024-0001-0435-0036	Indian Nation Coordination In the COP-specific NEPA documents EPA recommends including any lease area specific coordination with Indian Nations such as information received in public meetings or information received after the PEIS is finalized.	BOEM will continue to consult with Tribal Nations through the COP-specific environmental review process and will include summaries of Tribal coordination efforts and formal government-to-government consultation conducted for each COP in the respective NEPA documents.
BOEM-2024-0001-0435-0037	Environmental Justice (EJ) and Impacted Communities EPA recommends making the “Environmental Justice Community Mitigation Resources Plan” and the “Environmental Justice Communications Plan” available for federal cooperating agency and public review.	BOEM is exploring mechanisms to ensure plans and reports submitted under EJ-1 (now EJ-1a in the Final PEIS) will be made publicly available with a point of contact for the lessees.
BOEM-2024-0001-0435-0038	Additionally several of the AMMMs require substantial involvement from communities impacted by NY Bight projects. The document or the plans developed as per the AMMMs should make clear how public participate will be encouraged and what will happen if the public does not provide substantial feedback in the required AMMMs.	Refer to response to comment BOEM-2024-0001-0406-0021-c. EJ-1 (now EJ-1a in the Final PEIS), and EJ-3 have been revised to reflect community-based organization comments and now better reflect requirements to coordinate with residents and organizations in the creation of the plans. BOEM expects lessees to utilize best practices for meaningful engagement, and reporting requirements of the AMMM measures can still be submitted explaining what engagement activities occurred to seek coordination with EJ communities. Note that EJ-2 has been revised to be an RP as an "Environmental Justice Impact Mitigation Resources Plan" and includes language recommending coordination with residents and organizations in the development of the plan.
BOEM-2024-0001-0435-0039	EPA recommends that the final PEIS should be adjusted to reflect guidance from the Executive Order 14096 Revitalizing Our Nation's Commitment to Environmental Justice for All (April 21 2023) Section 3 (i) each agency shall "identify analyze and address disproportionate and adverse human health and environmental effects (including risks) and hazards of Federal activities on communities with environmental	BOEM agrees with EPA’s comment. The draft was written prior to the Executive Order. The Final PEIS reflects guidance from EO 14096. Resource areas found to have minor and moderate impacts should be included in COP NEPA analysis of disproportionate and adverse effects.

Comment No.	Comment	Response
	justice concerns." EPA encourages BOEM to revise the analysis of disproportionate and adverse effects to include consideration of resource areas found to have minor and moderate impacts. It is possible that minor or moderate impacts could constitute a disproportionate and adverse impact.	
BOEM-2024-0001-0435-0040	With respect to EJ-4 EPA recommends that BOEM provide additional justification for the derivation of the specified financial contribution to the compensatory mitigation fund. The timeframe for the funding coverage should also be clarified to address how construction and decommissioning periods (which may result in some of the largest impacts) may be included. Additionally it would be helpful to provide further information on the proposed allocation methodology and measures being considered to ensure equitable distribution of funds.	Refer to response to comment BOEM-2024-0001-0319-0004.
BOEM-2024-0001-0435-0041	Furthermore we strongly encourage BOEM to revise the current narrow criteria when defining "eligible impacts" for this mitigation measure. In particular we urge BOEM to include minor and moderate impacts when defining "eligible impacts" as these may still constitute a disproportionate and adverse impact to communities with EJ concerns. We would also suggest that BOEM further clarify what is meant by "direct" and "not otherwise mitigated." It's not clear if for example traffic related to port activity for a NY Bight lease area project would be considered direct as this is something that would make sense to include in such a mitigation measure. Additionally it is not clear what level of mitigation would constitute an impact being "otherwise mitigated" and therefore preclude it from being further mitigated through EJ-4. EPA suggests that BOEM more clearly identify how BOEM will decide what impacts will be considered for mitigation under EJ-4.	Refer to response to comment BOEM-2024-0001-0319-0004.
BOEM-2024-0001-0435-0042	The PEIS should clearly and effectively define the "reference community" and the "affected community" used in the environmental justice analysis. These definitions are used to determine whether there are disproportionate and adverse impacts by comparing the impacts to the affected community with the impacts to the reference community. A well-defined affected community will accurately reflect the demographic characteristics of the populations likely to be	BOEM acknowledges that the PEIS does not provide the specificity needed to determine whether there are disproportionate and adverse impacts or conduct a site-specific cumulative impact assessment (see section 3.6.4.2 on Scope of the Environmental Justice Analysis). The project-specific COP NEPA documents should include more detailed information that can better assess potentially affected communities and compare them with the

Comment No.	Comment	Response
	adversely impacted by the proposed project. A well-defined reference community will reflect the characteristics of the general population (e.g. municipal regional state).	appropriate level of demographic characteristics to determine whether there are disproportionate and adverse impacts from one project, or if there are cumulative impacts from multiple projects. The project-specific NEPA documents will also be subject to public comment.
BOEM-2024-0001-0435-0043	Additionally the PEIS would benefit from a baseline description of current existing stressors/pollution burden within these communities to better assess cumulative effects.	Thank you for your comment. Section B.5 of Appendix B, *Supplemental Information and Additional Figures and Tables,* has been revised to include baseline environmental conditions for each of the counties in the geographic analysis area exceeding environmental justice thresholds as identified in Section 3.6.4, *Environmental Justice*. BOEM acknowledges that the PEIS does not provide the specificity needed to determine whether there are disproportionate and adverse cumulative impacts for potentially affected communities with environmental justice concerns (see Section 3.6.4.2 on Scope of the Environmental Justice Analysis). The project-specific COP NEPA documents should include more localized baseline assessments of existing stressors/pollution burden in the proposed locations for the permit activities.
BOEM-2024-0001-0435-0044	The PEIS states in several locations that "A single NY Bight project could benefit environmental justice populations by displacing fossil fuel power-generating capacity within or near the geographic analysis area including at port locations." This statement is potentially misleading as it is not clear how BOEM and the leases would ensure that those fossil fuel power generating locations near environmental justice populations would be the ones displaced.	Thank you for your comment. The Final PEIS has been revised to communicate the conditions necessary for site-specific displacement of fossil fuel power-generating capacity. To the extent possible at the time of the COP NEPA documents, the COP NEPA documents should address how potential benefits may be felt by the population in and around the geographic analysis area.
BOEM-2024-0001-0435-0045	The COP-specific NEPA documents should provide an analysis of increased traffic around ports for both the construction and operation and maintenance phase of the project. As is stated in the PEIS this analysis will be specific to the ports selected for use and it is premature to state that impacts will be short-term.	BOEM agrees that the COP NEPA documents should provide an analysis of impacts of increased traffic around relevant ports throughout the project phases. Port vehicular traffic will be analyzed as a part of each project-specific COP NEPA document, including the cumulative impact of each project. Due to lack of location-specific information at this stage, the Final PEIS has been amended, and determination of short-term impacts related to air emissions and port traffic have been removed (Section 3.6, *Environmental Justice,* subsections 3.6.4.5.2 and 3.6.5.4.3). Increases in construction emissions will be short-term.

Comment No.	Comment	Response
BOEM-2024-0001-0435-0046	The PEIS states several benefits that can be expected as a result of the development of the NY Bight Offshore Wind Projects. It is helpful to include these benefits in the PEIS as part of the analysis but EPA would like to state that benefits to the project cannot be used to offset impacts. A full analysis of impacts should be included in the COP specific NEPA documents.	BOEM acknowledges that project benefits cannot be used to offset project impacts. Each individual COP submitted by a developer to BOEM will be separately analyzed as required under NEPA and will disclose the full impacts of the construction and installation, O&M, and conceptual decommissioning of the project.
BOEM-2024-0001-0435-0047	Additionally per Executive Order 13045 on Children's Health EPA recommends that BOEM consider impacts to places where children live learn and play such as homes schools and playgrounds. Future COP-specific NEPA documents should identify proximity to sensitive receptors and should implement AMMMs near these locations in order to be protective of children's health.	BOEM agrees that children’s health and other sensitive populations should be addressed in future COP-specific NEPA documents.
BOEM-2024-0001-0435-0048	Further the EJ analysis seems to compare county demographic data to state demographic data a broad scope that may not be an appropriate geographic comparison as it may dilute the presence of low-income communities that would be directly impacted by the project. The PEIS includes figures that represent more granular scales and text indicating that more community-based analysis will be conducted when the project scope is more fully defined but it is not clear how this will be incorporated into the EJ analysis. EPA recommends that BOEM consider census block groups or another appropriate geographic unit to capture localized impacts and most accurately reflect the potential presence of low-income communities and communities of color as is suggested in the Promising Practices For EJ Methodologies In NEPA Reviews (2016) report.	BOEM agrees that the PEIS does not include the specificity needed to make determinations regarding disproportionate and adverse effects at the community level (see Section 3.6.4.2 on Scope of the Environmental Justice Analysis). COP NEPA documents should include location specific demographic data on a more granular scale once the project scope is clearly defined. The COP NEPA documents should consider examining the smallest geography, census block groups, to capture localized impacts and ensure that siting decisions will not cause disproportionate and adverse impacts on the basis of demographic characteristics.
BOEM-2024-0001-0435-0049	There are several locations within the draft PEIS that broadly discuss dredged material disposal (2-12 3.1-2 3.4.2-8 3.5.2-22 D-12 and several locations within D1). Ocean disposal of dredged material excavated from the navigable waters of the United States requires an MPRSA permit (issued by USACE but reviewed and concurred by the EPA). We therefore recommend including a brief description of the MPRSA potentially under section 1.4 Regulatory Overview. Including brief information about the MPRSA in the Regulatory Overview will help any parties involved in offshore wind development determine	BOEM has added text to the Final PEIS and determined that the most appropriate place for this information is the discharges discussion in Table 3.1-1. Lessees would need to comply with all permitting requirements during the project-specific environmental review.

Comment No.	Comment	Response
	applicable laws and regulations and coordinate with USACE and/or EPA as necessary.	
BOEM-2024-0001-0435-0050	Table 3.1-1: Primary IPFs lists "dredged material ocean disposal" as one of the Sources or Activities that could produce an impact associated with offshore wind development. The MPRSA's applicability to dredged material disposal should be included in the description similar to the descriptions provided regarding NPDES permit requirements.	Text in Table 3.1-1 has been revised to include the Marine Protection, Research and Sanctuaries Act (MPRSA).
BOEM-2024-0001-0435-0051	The PEIS refers to unexploded ordinances in several locations however there is no mention of the National Guidance for Industry on Responding to Munitions and Explosives of Concern in U.S. Federal Waters developed by the U.S. Committee on the Marine Transportation System. After inviting public comment in the Federal Register the comment period on the National Guidance has now closed and it should be issued imminently. The National Guidance is intended to identify and help to coordinate federal statutory and regulatory authorities that approve regulate or permit the detonation removal or mitigation of munitions and explosives of concern (MEC) on the outer continental shelf. The EPA recommends that the final version of this PEIS refer to if not include text from the National Guidance.	Discussion of the National Guidance for Industry on Responding to Munitions and Explosives of Concern in the U.S. Federal Waters has been added to Section 3.6.7.1.2.
BOEM-2024-0001-0435-0052	There are several mentions in the document that refer to managing and/or modifying sand waves occurring on the seafloor (e.g. 2-12 3.5.2-22 3.5.5-21 3.5.5-36 and D1-17). In one example page 3.5.5-21 the document states that "[s]and waves that are dredged would likely be redeposited in areas containing similar sediments." The Final EIS should note that this type of activity may fall under the purview of the MPRSA if material is dredged or excavated from sand waves in the navigable waters of the United States. Project proponent should coordinate with USACE and/or EPA as necessary.	Text modifications were made within Section 3.5.2.4. “This type of activity may fall under the purview of the MPRSA if the material is dredged or excavated from sand waves in the navigable waters of the United States, lessees would coordinate with USACE and/or EPA as needed.”
BOEM-2024-0001-0435-0053	The potential for adverse marine impacts of the given alternatives primarily focus on impacts to marine mammals and ESA listed species. EPA recommends that the document expand consideration to and discuss the potential for adverse impacts to the marine environment	Analysis of potential impacts from the Proposed Action (Alternative C) and alternatives on the broader marine environment and other marine uses are found throughout the PEIS in the various resource topics that include the marine

Comment No.	Comment	Response
	generally and other uses of the ocean. The sections describing the cumulative impacts of the alternatives would be appropriate places to discuss these broader considerations.	environment (e.g., PEIS Section 3.4.2, *Water Quality*, Section 3.5.2, *Benthic Resources*). In addition, PEIS Section 3.6.7, *Other Uses*, discusses potential impacts on other uses not addressed in other sections of the PEIS, including marine minerals, national security and military use, aviation and air traffic, cables and pipelines, radar systems, and scientific research and surveys.

P.4.1.4 U.S. Coast Guard

Table P.4-5. Responses to Comments from the U.S. Coast Guard (BOEM-2024-0001-0370)

Comment No.	Comment	Response
BOEM-2024-0001-0370-0001	The USCG does not oppose the Proposed Action Alternative and recommends all Proposed Action avoidance minimization mitigation and monitoring (AMMM) measures pertaining to Navigation and Vessel Traffic be made mandatory. Additionally the USCG offers the following recommendations. Turbine Layout Proposed Action AMMM measures for consistent turbine layout marking and lighting incorrectly states turbines should have [Underline: one of the two lines] of orientation per lease area spaced at least 1 nautical mile (nm) apart to support navigation safety and Search and Rescue (SAR). Per Navigation and Vessel Inspection Circular (NVIC) 02-23 the Coast Guard recommends each windfarm be organized in straight rows and. columns creating a grid pattern consisting of two lines of orientation with at least 1 nm between turbines. Each windfarm's bathymetric circumstances are different and spacing of less than 1 nm may be unavoidable but programmatic AMMM measures applied throughout the NYB should align with NVIC 02-23. Deviations from this guidance should be assessed during project-specific environmental impact assessments and Navigation Safety Risk Assessments (NSRA) on a case-by-case basis for each lease area.	MUL-25 is now an RP. Refer to response to comment BOEM-2024-0001-0371-0004 for additional information on Alternative C, the updating of AMMM measures, and RPs. MUL-25 has been revised to be in alignment with Navigation and Vessel Inspection Circular 02-23, in which the Coast Guard recommends "each windfarm be organized in straight rows and columns, creating a grid pattern consisting of two lines of orientation." NVIC 02-23 does not create a requirement for 1 nm spacing between turbines.
BOEM-2024-0001-0370-0002	Marine Casualty Data In its assessment of affected environment and environmental consequences BOEM claimed to review pollution search and rescue and vessel incident data from 2017 to 2018. NVIC 02-23 recommends 20 years of marine casualty data in the study area	Search and rescue (SAR) incident data for 20 years has been incorporated in Table 3.6.6-3 to meet the requirements of Navigation and Vessel Inspection Circular (NVIC) 02-23. Navigation Safety Risk Assessments (NSRA) for each individual COP will still be

Comment No.	Comment	Response
	to provide an incident change analysis resulting from project development. One year of data is insufficient. If BOEM does not assess 20 years of data in the PEIS this assessment should not be tiered to or incorporated by reference and it is critical all future projects within the NYB study area carry out NSRAs in accordance with NVIC 02-23.	required, and project-specific NEPA analysis will be conducted for each COP.
BOEM-2024-0001-0370-0003	Project-specific NSRAs The USCG acknowledges National Environment Policy Act analysis for individual Construction and Operation Plans will tier to or incorporate by reference the NYB PEIS. However the assessment of potential increases in the likelihood for vessels to be involved in a collision or allision must be determined through project specific NSRAs. The NYB Draft PEIS uses NSRA data from ongoing projects in the vicinity of the NYB which is not an accurate assessment of impacts from future projects to be located within the NYB. All six NYB lease areas will have unique vessel traffic characteristics which must be assessed independently through project specific NSRAs as agreed upon by the USCG and BOEM (see Memorandum of Agreement OCS-06).	BOEM developed the PEIS prior to the issuance of any COPs and therefore relied on existing information, including COPs and NSRAs of nearby lease areas, to inform its analysis in the PEIS. As noted in Chapter 1, *Introduction,* the PEIS will not approve any projects, and all projects will be subject to additional project-specific NEPA analysis. The project-specific NSRAs will be developed in accordance with the current guidance, which includes future vessel traffic assessments. The project-specific NSRAs will be used to inform the COP-specific NEPA analysis.

P.4.1.5 National Marine Fisheries Service

Table P.4-6. Responses to Comments from the National Marine Fisheries Service (BOEM-2024-0001-0371)

Comment No.	Comment	Response
BOEM-2024-0001-0371-0001	[Bold: Analysis Structure and the Representative Project Design Envelope] The structure of the PEIS creates challenges for meeting BOEM's stated objectives for the document and for accurately characterizing potential resource impacts. The representative project design envelope (RPDE) approach does not provide a realistic estimate of actual build out in each lease area. Instead it considers a design envelope for one project and applies that to the six lease areas to assess the theoretical impacts of full build out rather than considering the lease-specific footprint and unique characteristics of each lease area. The analysis does not consider individual resources or habitats present among the leases nor does it include a detailed	The purpose of the PEIS is to present a programmatic analysis of the six NY Bight lease areas to characterize the types of impacts that could occur and mitigation measures that could minimize those effects. A detailed area-specific analysis that considers all potential impacts of development is more appropriate at the COP-specific stage when project details are known and site-specific survey data is available. Where information was available, impacts unique to each lease area were analyzed. Because project-specific details nor surveys have been prepared for each lease area, the level of information requested in the comment is limited. Regarding the Representative Project Design Envelope (RPDE) not

Comment No.	Comment	Response
	analysis of cumulative impacts resulting from a representative full build-out of all six leases. Where a cumulative analysis of impacts is provided it does not include further discussion of the effects and presents a limited assessment of the implications of the impacts. A detailed area- specific analysis that considers all potential impacts of development in the NYB would allow for a comprehensive evaluation of potential cumulative effects and the identification of specific AMMMMs to reduce those effects. We recommend BOEM update the PEIS to highlight and assess whenever possible resources and impacts that are unique to each of the existing NYB leases based on information currently available for these lease areas. This would allow for a full review of anticipated effects to protected species habitat fisheries and navigational conflicts across all lease areas to support the identification of appropriate AMMMMs. Such an approach would also provide a robust baseline to facilitate tiering of this analysis for project-specific decisions consistent with BOEM's intent and guidance for programmatic analyses.	being realistic, as stated in Section 2.1.2.1, the RPDE is not associated with any particular lease area and is instead representative of development that could occur associated with any of the six NY Bight lease areas. The RPDE was developed with input from the six NY Bight lessees, American Clean Power, National Renewable Energy Laboratory, and the States of New York and New Jersey.
BOEM-2024-0001-0371-0002	[Bold: AMMMMs Analysis] The structure of action alternatives is a critical element of the document because it drives the comparative analysis of potential impacts to NOAA trust resources discloses trade-offs and supports development of effective mitigation measures. We support BOEM's description of Alternative A the No Action Alternative as a "true no action" under which no development would occur. This alternative will establish a baseline against which the action alternatives can be evaluated and is consistent with the approach that we have developed in coordination with BOEM in which the existing baseline for the No Action Alternative will only include past and ongoing activities and their effects.	Comment noted.
BOEM-2024-0001-0371-0003	We continue to support the inclusion, analysis, and use of a full build-out scenario without AMMMMs at the PEIS stage for analysis and discussion of potential impacts of development in the lease areas without the AMMMMs. Alternative B is intended to allow for a comparison to the impacts that could result from the programmatic adoption of AMMMMs under Alternative C. However, as written Alternative B assumes deferred adoption of AMMMMs to the COP	Refer to response to comment BOEM-2024-0001-0371-0004.

Comment No.	Comment	Response
	stage functionally equivalent to current practices for project reviews. This leaves Alternative B essentially functioning as a second No Action Alternative. While this has the potential to be useful for the purposes of comparison it leaves the document with a very limited range of action alternatives realistically capable of selection. The PEIS should clarify the distinction between adopting a suite of AMMMMs at this stage in the process versus at the project-specific COP stage. Below we suggest a path for expanding the range of reasonable alternatives and for providing more meaningful comparisons between alternatives.	
BOEM-2024-0001-0371-0004	To allow for a more meaningful comparative analysis we continue to recommend expanding the range of alternatives by updating Alternative C to include sub-alternatives with different combinations of AMMMMs to expand the range of action alternatives that could be selected. Individual projects will still be required to implement a host of AMMMMs through compliance with applicable statutes (e.g. the Endangered Species Act (ESA) the Marine Mammal Protection Act (MMPA) the Magnuson-Stevens Fishery Conservation and Management Act (MSA) and the Outer Continental Shelf Lands Act (OCSLA)). Many standard measures associated with these statutes are fairly predictable based on our experience with offshore wind projects that have undergone review. Most of the AMMMMs included in the PEIS fall into the more standard AMMMMs category in contrast to a more programmatic approach to reducing impacts. This approach along with the design of Alternative B make it difficult to identify the potential effectiveness of adopting programmatic AMMMMs under Alternative C. Sub- alternatives under Alternative C could evaluate sets of AMMMMs ranging from minimum standard measures to levels of mitigation that may have more profound effects at the programmatic level. This approach would allow for consideration of measures that may reduce effects of construction (e.g. time of year restrictions for pile installation) alone and in combination with measures that may reduce effects of project operations (e.g. limiting locations of turbine foundations). However regardless of whether additional sub-alternatives are added we	BOEM has provided additional clarification on the purpose of Alternative B and has revised Alternative C to group AMMM measures into sub-alternatives (see Final PEIS Chapter 2). Alternative B serves to compare how impacts would change with the AMMM measures analyzed in Alternative C. Selection of Alternative B in the Record of Decision (ROD) would defer identification of AMMM measures to the COP-specific NEPA stage. The PEIS would not result in the approval of any activities, and BOEM would not approve any COP without implementation of mitigation measures. Alternative C has been divided into two sub-alternatives: Sub-alternative C1 and Sub-alternative C2. Sub-alternative C1 analyzes the AMMM measures that BOEM has required as conditions of approval for previous activities proposed by lessees in COPs submitted for the Atlantic OCS or through related consultations. Sub-alternative C2 analyzes the AMMM measures under Sub-alternative C1 plus the AMMM measures that have not previously been applied. These AMMM measures that have not been previously applied may be less familiar to the offshore wind industry but could further avoid and minimize impacts on resources if applied. In addition, BOEM has reviewed all AMMM measures in Appendix G and identified measures that are RPs for the offshore wind industry. Any previously identified AMMM measure that is an RP has been removed from Alternative C. BOEM encourages lessees to analyze and consider implementing these RPs as they may further avoid and minimize impacts on resources but will not require them as a condition of

Comment No.	Comment	Response
	recommend that BOEM ensure the PEIS includes a more complete analysis of Alternative C as discussed further below. As currently written Alternative C is intended to cover all AMMMMs outlined in Appendix G. However in our view this list of AMMMMs should be expanded. Further the document as currently drafted does not address important aspects of the AMMMMs that are included in Appendix G. For example despite the overlap of projects with the Mid-Atlantic Cold Pool the PEIS does not consider or analyze effects to the Cold Pool from build out in the NYB and does not include any potential AMMMMs that may minimize adverse effects. Additionally while each section of the PEIS includes a suite of mitigation measures under each resource area those sections do not examine how these measures will be applied nor their efficacy based upon the RPDE parameters summarized in the PEIS. We recommend that the analysis include a comparative description of when and how each AMMMM would be implemented and the expected change in impacts due to implementing each measure. This would help BOEM to make an informed decision when selecting which AMMMMs will and will not be adopted at the programmatic level.	COP approval. AMMM measures from Sub-alternative C1 or C2, or a combination of both, may be required as conditions of approval for activities proposed by lessees in COPs submitted for the six NY Bight lease areas. BOEM may also require additional or different measures based on future, site-specific NEPA analysis of project-specific COPs. The PEIS addressed cold pools in Section 3.5.4, *Benthic Resources*; Section 3.5.5, *Finfish, Invertebrates, and Essential Fish Habitat*; and Section 3.5.6, *Marine Mammals*.
BOEM-2024-0001-0371-0005	Many of the current AMMMMs are vague which makes it difficult to understand how they would result in meaningful reductions of adverse impacts from a project. Others are composed well but do not provide a clear linkage between the AMMMM and an avoidance minimization or monitoring of a particular impact. For example for BEN-2 (scour protection inspection) there is no clear linkage between the requirement to routinely inspect scour protection features (e.g. concrete mattresses rock etc.) and a reduction of adverse impacts to benthic habitats or Essential Fish Habitat (EFH). The efficacy of a standardized set of AMMMMs will be limited if there is no clarity and specificity in the substance and timing of the measures and how they would be implemented to reduce adverse impacts. For example one measure listed in Appendix G proposes a monitoring plan to avoid or reduce impacts to scallop populations (COMFIS-3) but it is unclear if this would be required in advance of Lessee submission of COPs or associated evaluation of project-specific impacts. If not required prior to project planning this limits the likelihood of altering project	BOEM has reviewed all AMMM measures in Appendix G and identified measures that are RPs for the offshore wind industry. Any previously identified AMMM measure that is now an RP has been removed from Alternative C. BEN-2 was reclassified as MUL-41 because the measure does not directly mitigate impacts on benthic habitats or essential fish habitat (EFH). COMFIS-3 has also been updated for clarification. Refer to response to comment BOEM-2024-0001-0371-0004 for additional information on Alternative C and RPs. Project-specific NEPA analysis for individual COPs could apply revised, additional, or different AMMM measures as needed.

Comment No.	Comment	Response
	components in a timely manner to minimize impacts to scallop populations or associated fisheries. While we support AMMMMs that facilitate collection of additional data to assess and avoid impacts if this type of data collection requirement is not put in place until the COP approval this and similar AMMMMs would be more likely to avoid and mitigate impacts for future projects instead of the existing six leases several of which are in the advanced planning and COP submission stages and have already begun development of initial project plans. Providing a broader range of AMMMMs and clarifying which AMMMMs will be mandatory conditions for all COP approvals and which ones may be required based on the details of a specific COP will provide predictable parameters for developers to follow and allow for a more robust analysis of the effectiveness of the AMMMMs at a programmatic level. There are several AMMMMs identified that do not implement any requirements or identify specific parameters that dictate Lessee adoption but rather defer to the Lessee to consider how they may or may not be incorporated into project planning. This approach creates challenges for evaluating the effectiveness of these AMMMMs. This is particularly true for the analysis of impacts to EFH in which the PEIS concludes there is no difference in impacts to EFH whether or not AMMMMs are adopted (Alternative B vs. C). This may be due to the fact that many of the AMMMMs aimed at minimizing habitat impacts do not include specific actions but defer to the Lessee to consider how to implement such AMMMMs (e.g. BEN-1 boulder avoidance/relocation; MUL-23). While we certainly support the consideration of avoiding sensitive habitats in project planning (as described in AMMMM MUL-23) the ultimate effectiveness of this AMMMM and any potential reduction in impacts to sensitive habitats would not be determined until the COP review stage. Additionally the EFH analysis and impact determination is primarily driven by the presence of structures yet there are no specific AMMMMs identified in Appendix G that would require avoidance or minimization of impacts to EFH from the presence of structures. As a result this lack of specific required action for avoidance/minimization for some AMMMMs limits BOEM's ability to meet the objective to analyze programmatic AMMMMs for the six	

Comment No.	Comment	Response
	NYB lease areas. We note the AMMMMs identified do not appear to follow the standard stepwise approach for mitigation consistent with NOAA's 2022 Administrative Order on Mitigation Policy[Footnote 1: Available at https://www.noaa.gov/organization/administration/noaa-administrative-orders-chapter-216-program- management/nao-216-123-noaa-mitigation-policy-for-trust-resources]. Such an approach first focuses on avoiding adverse impacts to high value habitats and resources. Following avoidance this approach would then call for minimizing the impact of activities by limiting the degree or magnitude of the impact action or its implementation. Finally any remaining adverse impacts that cannot be avoided or minimized should be offset or compensated for by replacement/replication or providing equivalent substitute resources or environments. This approach is also described in the 2024 NMFS-BOEM Right Whale and Offshore Wind Strategy. Following this approach would provide more clarity on how the AMMMMs would be implemented and ultimately modify the level of project impacts. We note that offsets and compensation may not be legally possible for all impacts including for example potential impacts to endangered species such as the North Atlantic right whale. As such avoidance may be the only option for certain impacts.	
BOEM-2024-0001-0371-0006	[Bold: Relationship Between PEIS and COP-specific Analyses] We understand that BOEM intends to use the final PEIS as the basis for tiering individual COP- specific analyses and that it will be incorporated by reference into future NEPA documents. However we have concerns that the current approach and level of detail in the draft PEIS will create challenges for tiering and limit meaningful uses of the PEIS. Appendix C is intended to describe how BOEM will approach tiering off of the PEIS and incorporation by reference but this section and Table C-1 remain vague. The document is also inconsistent and unclear in descriptions of what it means for AMMMMs to be formally adopted how those measures will be applied and when those AMMMMs would be effective. We appreciate BOEM's explanation that "the Record of Decision (ROD) for the PEIS will state which of the AMMMMs analyzed in the PEIS BOEM	BOEM has revised Alternative C to group AMMM measures into sub-alternatives (see Final PEIS Chapter 2): Sub-alternative C1 and Sub-alternative C2. Sub-alternative C1 analyzes the AMMM measures that BOEM has required as conditions of approval for previous activities proposed by lessees in COPs submitted for the Atlantic OCS or through related consultations. Sub-alternative C2 analyzes the AMMM measures under Sub-alternative C1 plus AMMM measures that have not previously been applied. These AMMM measures that have not been previously applied may be less familiar to the offshore wind industry but could further avoid and minimize impacts on resources if applied. BOEM intends to use AMMM measures identified at the programmatic stage to inform the selection of appropriate AMMM measures at the COP decision stage. BOEM may require the

Comment No.	Comment	Response
	has committed to adopting and for those that are not adopted the reasons why." However the PEIS also describes adopted measures as those which BOEM "would require as conditions of approval for activities proposed by lessees unless future COP-specific NEPA analysis shows that implementation of such measures is not warranted or effective" while other sections note that "BOEM may require" the selected measures. Without a definition of "adoption" for the purposes of these measures as well as clarity on whether selected AMMMMs will be required or remain optional for BOEM to require of individual Lessees it is difficult to determine whether the document will provide value for tiering project-specific analyses. Expanding the scope of sub-alternatives to evaluate commitment to various types and "mixes" of AMMMMs at the programmatic stage would facilitate a meaningful comparative analysis. We also request the document clarify how BOEM intends to handle any AMMMMs not adopted in the PEIS. It is unclear if AMMMMs that are not adopted will still be considered at the COP-specific NEPA stage and how the PEIS may be considered in BOEM's decision to require certain AMMMMs in the project-specific regulatory process. We recommend BOEM incorporate more details in Appendix C and describe the AMMMM adoption process consistently throughout the document so it is clear what the PEIS may mean for future project-specific regulatory processes.	AMMM measures from Sub-alternatives C1 or C2, or a combination of both, at the COP decision stage. BOEM may also require additional or different measures based on future, site-specific NEPA analysis of specific COPs. BOEM reviewed all AMMM measures in Appendix G and identified some measures that are RPs for the offshore wind industry. BOEM encourages lessees to analyze and consider implementing these RPs as they may further avoid and minimize impacts on resources.
BOEM-2024-0001-0371-0007	Executive Summary Section: ES.6 PDF Page: 35 Comment: Cumulative impacts to NARW from the No Action Alternative are stated as negligible to major here but in Chapters 2 and 3 it is stated only as major. Impacts should be described uniformly throughout the document. Section: ES.7PDF Page: 35Comment: Alternative B: Impacts to non-NARW mysticetes are stated to be negligible to moderate here and in Chapters 2 and 3 is reads only minor to moderate. Impacts should be described uniformly throughout the document.	Section 3.5.6, *Marine Mammals*, as well as the Executive Summary have been reviewed to ensure consistency in the impact determinations provided.
BOEM-2024-0001-0371-0008	Section: ES.2PDF Page: 27Comment: The PEIS notes that "BOEM may require additional or different measures based on future site-specific NEPA analysis or the parameters of specific COPs." In the case that an	Refer to response to comment BOEM-2024-0001-0371-0006.

Comment No.	Comment	Response
	AMMMM is not appropriate for a specific lease area as this statement suggests the site-specific NEPA analyses can document and explain how a different AMMMM would be a better fit in that situation. It is reasonable to assume that the six NYB leases may have different characteristics which may affect applicable AMMMMs for that project. As we note in our comments elsewhere we recommend that all the AMMMMs under consideration in Alternative C be considered as mandatory for each lease area in order to ensure a meaningful analysis of the potential efficacy of the suite of AMMMMs that BOEM will adopt through the PEIS ROD. In addition this would also help achieve the goal of the PEIS to reduce redundancies across COP-specific NEPA analyses.	
BOEM-2024-0001-0371-0009	Section 1 Section: 1.9 PDF Page: 48 Comment: As described in more detail in our comment letter we recommend the AMMMs follow the standard stepwise approach for mitigation which first focuses on avoiding adverse impacts to high value habitats and resources. Following avoidance this approach would then call for minimizing the impact of activities by limiting the degree or magnitude of the impact action or its implementation. Finally any remaining adverse impacts that cannot be avoided or minimized should be offset or compensated for by replacement/replication or providing equivalent substitute resources or environments. This approach is also described in the 2024 NMFS-BOEM Right Whale and Offshore Wind Strategy. Avoidance measures should be required prior to project planning which would increase the likelihood of altering project components in a timely manner to minimize impacts to our trust resources.	BOEM agrees that compensatory mitigation is the last step in mitigation hierarchy and that the project-specific COP NEPA stage will evaluate site-specific avoidance and minimization measures.
BOEM-2024-0001-0371-0010	Section 2 Section: 2.4 PDF Page: 83 Comment: It is unclear to NMFS why the cumulative impacts to NARW are stated as major for the no action alternative but are stated as a range of impacts for the action alternatives. Please be consistent in the way impact determinations are made (i.e. singular versus range). It appears that the same IPFs apply to both the action and no action alternatives.	The marine mammal PEIS section as well as the Executive Summary have been reviewed to ensure consistency in the impact determinations provided.
BOEM-2024-0001-0371-0011	Section: 2.4 PDF Page: 83 Comment: Alternative C: NMFS is concerned with the impact determination for NARW as reduced from major from the No Action Alternative. Consistent with comments on	As described in Section 3.1, *Impact-Producing Factors*, the No Action Alternative and action alternatives analysis include the current conditions and future baseline conditions. The No Action

Comment No.	Comment	Response
	OSW EISs if the status quo is expected to be major impacts no AMMM measures would address the ongoing and planned actions of the status quo. Therefore NMFS requests this be changed to major impacts for NARW. Additionally this is a different conclusion from what is in Table ES-2 where it reads impacts would be moderate but matches the conclusions in Chapter 3. Section: 2.4PDF Page: 83Comment: Alternative C: NMFS requests this sentence clarify which marine mammals are anticipated to be impacted "Impacts resulting from pile-driving noise would be reduced to minor for one project and remain the same moderate for six projects under Alternative C."	Alternative and action alternatives *cumulative* analyses include ongoing and planned non-offshore wind and offshore wind activities. However, the action alternatives analysis does not include the ongoing and planned non-offshore and offshore wind activities. Therefore, the impact determinations for the action alternatives analysis can be less than the cumulative impacts of the No Action Alternative. The action alternatives cumulative analysis, on the other hand, would always have the same or greater impact determinations than the No Action Alternative cumulative analysis due to the inclusion of ongoing and planned non-offshore and offshore wind activities. Please refer to Figures 3-1 through 3-4. The marine mammal PEIS section as well as the Executive Summary have been reviewed to ensure consistency in the impact determinations provided. Additionally, the impacts for Alternative C were reduced from major because this includes the implementation of AMMM measures (including vessel strike avoidance measures) for all vessels associated with the representative offshore wind projects assessed in Alternative C, such that BOEM does not believe vessel strikes would occur for North Atlantic right whale (NARW). Because all six projects under Alternative C would follow these same AMMM measures, the risk is not expected to increase to major between one and six projects because the implementation of these AMMM measures for NARW vessel strike avoidance would continue to be effective such that vessel strike would not occur. The only scenarios in which BOEM considers vessel strike a major impact for NARW are Alternative A and cumulative impacts for Alternatives B and C because the non-offshore wind–related vessel traffic would not follow the same AMMM measure requirements as OSW vessels and ongoing Unusual Mortality Events (UME) for NARW suggest vessel strikes are occurring and therefore cannot be discounted. Text has been updated and clarified throughout all alternatives to clarify that the driver of the major impact determination is the non-offshore wind vessel traffic, and any alternatives considering ONLY offshore wind vessels would have reduced impacts with implementation of the AMMM measures.

Comment No.	Comment	Response
BOEM-2024-0001-0371-0012	Section 3.5.2 Benthic Resources Section: Global PDF Page: Comment: BOEM dismissed the Benthic Habitat Impact Minimization alternative NMFS suggested in our scoping comments due to the unknown location of cables at this stage. However including areas as off-limits to development as part of a potential AMMM would allow analysis of the benefits of avoiding these areas. This would add value to a programmatic analysis of benthic habitat impacts in the NYB overall. Below is detail about Prime Fishing Grounds and overlap of lease areas with the mid-shelf scarp (MSS):We recommend avoiding the Mid-Shelf Scarp (MSS) for development. The MSS is a regional-scale bathymetric feature of high slope (rapid change in depth) that bounds the eastern side of the Mid-Shelf Wedge. Bathymetric features such as the MSS act as congregation areas for many species of finfish shellfish and diverse invertebrate species that are essential to marine ecosystem functioning. Seafloor features like the MSS modify physical processes - such as hydrodynamic flow and nutrient concentration - and ecological patterns; commercial and recreational fishers often target these areas which can have high catch-per-unit-effort. It appears that eastern portions of Lease Area OCS-A 0538 and OCS-A 0539 overlap with the MSS. This area of overlap also includes a large designated Prime Fishing Ground known as "The Wall" which appears to be a reference to the rapid change in depth of the MSS. Avoiding development on the MSS is important because changes to the complex physical structure of this feature may lead to long- term or permanent adverse impacts on species use and productivity. Development should be avoided on the MSS and within 1600 meters on either side of the MSS (3200 meter bidirectional buffer of the centerline of the MSS).More specifically portions of Lease Area OCS-A 0538 primarily blocks/aliquots 6315 6316E 6316I 6316J 6316M 6316N 6366A 6366E 6365 6415D and 6415C overlap with the MSS. Additionally the southern tip of Lease Area OCS-A 0539 primarily blocks/aliquots 6611H 6611K and 6611J also appear to overlap with the MSS. Much of the MSS follows the -50 meter bathymetric contour but should be identified and mapped with high-resolution site-specific surveys for projects that may overlap with the feature. Development should be avoided on the MSS and within 1600 meters on either side	Thank you for your comment. The NY Bight lease areas were designed to avoid certain commercial fishing activity based on stakeholder inputs and task force meetings held from 2017 to 2021. The Final Lease Sale Decision Memorandum explains that areas were removed from the leases to avoid the MSS (https://www.boem.gov/sites/default/files/documents/renewable-energy/state-activities/ATLW-8-NY-Bight-Final-Lease-Sale-Decision-Memorandum.pdf). BOEM will evaluate project-specific impacts based on the project-specific COP before issuing an ROD. Benthic mapping and sampling will inform the project-specific details and design including the type of foundation proposed and how much scour would be required, as well as the bedforms present and any plans for disturbance of the bedforms. The project-specific COP NEPA EIS analyses will also address potential impacts in various habitats from the proposed project. The caveat stating that the characteristics of the NY and NJ Wind Energy Areas (WEA) may not be present in the six leases covered by this PEIS and new features may be in the NY Bight WEAs that are not already present in the NY and NJ WEAs, has been added. At the programmatic level, too many details about each potential project remain unknown to be able to provide a more robust impact analysis of the NY Bight projects. Refer to the response to comment BOEM-2024-0001-0346-0013 for a response to larval transport and hydrodynamic changes. Miles et al. 2021 studied the potential effects of offshore wind farms on the Mid-Atlantic Bight Cold Pool (Miles T., S. Murphy, J. Kohut, S. Borsetti, D. Munroe. 2021. Offshore Wind Energy and the Mid-Atlantic Cold Pool: A Review of Potential Interactions. Marine Technology Society Journal 55:72-87). See discussion in Section 3.5.6.3.3. The cumulative impacts analysis for the Proposed Action considers the full build out of the six New York Bight lease areas in combination with other reasonably foreseeable planned activities, including offshore wind activities, within the geographic analysis area for each Chapter 3 resource topic.

Comment No.	Comment	Response
	of the MSS (3200 meter bidirectional buffer of the centerline of the MSS). Section: Global PDF Page: Comment: This section would benefit from inclusion of more specific and quantitative analysis and direct discussion of effects. The addition of figures as visual aids is strongly recommended. At present the section provides an overly broad description of the activities with impacts and effects that appear to be understated or minimized. For example it would be helpful to show a summary of benthic habitat conversion from existing bottom to bottom occupied by WTG and OSS foundations and associated scour protection based upon type and size. Additionally there is little discussion of the effects and implications of mobile bedform removal during seabed preparation activities. Further it would be beneficial to provide a similar or greater level of description of the resources bedforms and characteristics of the 6 leases included in the PEIS consistent with what was provided in descriptions of the New York and New Jersey WEAs (see 3.5.2.1.1 pg 3.5.2-5). It is also recommended that the document more clearly state that the characteristics of the NY and NJ WEAs may not be present in the 6 leases covered by this PEIS and that in reverse the 6 leases may include benthic features and resources not present in the NY and NJ WEAs. Section: Global PDF Page: Comment: When discussing the impacts of one or all 6 projects it would be helpful to distinguish the geographic location of the impact(s) - the OCS nearshore estuarine or riverine areas. This reduces uncertainty in understanding the potential impacts and effects from a particular IPF where impacts and effects may differ from the same IPF by location and habitat type. For example cable preparation and installation in estuarine habitats with finer sediments seagrasses and shellfish reefs will be impacted differently (more severely) than non-vegetated mostly sandy habitats of the OCS. In estuaries sediment transport and disturbance of sensitive resources will not have the same recovery times (if recovery is possible) as the environments of the OCS and these differences are not clear from the current format of the document. We recommend	

Comment No.	Comment	Response
	the document more clearly provide separate discussions of IPFs and effects for the OCS nearshore estuarine and riverine environments. Section: Global PDF Page: Comment: A robust substantive discussion of the cumulative and synergistic regional impacts of IPFs from 6 projects is needed under Alt. B. This should be followed by a clearly defined relationship between specific AMMMs and cumulative regional impacts under Alt. C. Subsequent examples in this spreadsheet should be used as a reference for areas deficient in discussion and should be carried throughout. This includes but is not limited to: discussion of changing hydrodynamics and wake effects; regional cumulative impacts on larval transport; distribution formation and breakdown of bedforms; formation and breakdown of the mid-Atlantic Cold Pool (a model should be developed similar to the one described for Rhode Island and Massachusetts leases); cumulative regional effects from cable and converter station heat; and cable EMF. Although these IPFs were addressed there is little substantial supporting information for conclusions that on a single project or regional scale effects would be negligible or minor.	
BOEM-2024-0001-0371-0013	Section: 3.5.2 PDF Page: 174 Comment: Please provide a resource or other evidence to support the statement that sediment transport would likely be on a spatial scale of less than 10 miles. Section: 3.5.2.1 PDF Page: 176 Comment: Please provide clarity and consistency in describing the analysis area. For example are estuaries and rivers included? Section: 3.5.2.1 PDF Page: 176 Comment: Please elaborate on the importance of the Gulf Stream Labrador Current and the Mid-Atlantic Cold Pool as regional oceanographic features. This should include but is not limited to the importance of the Cold Pool's stratification on nutrients and primary production commercial and recreational species distribution and tempering the impacts of hurricanes. Please also include a clearer description of the geographic extent of the Cold Pool as it relates to the 6 leases in this PEIS. A more robust description of the regional oceanographic conditions is warranted. Section: 3.5.2.1 PDF Page: 177 Comment: NMFS recommends updating the figure to make leases transparent so that the underlying	As stated in Section 3.5.2, "Although sediment transport beyond 10 miles (16.1 kilometers) is possible, sediment transport related to the NY Bight project activities would likely be on a smaller spatial scale than 10 miles (16.1 kilometers); project-specific sediment transport modeling would be required to verify this." This is based on sediment transport modeling conducted for other proposed offshore wind farms, which found that sediment deposition from the seafloor disturbance during cable emplacement was estimated to fall very close to the disturbance. Empire Wind results found deposition of 0.004 inch (0.01 centimeter) within 246 feet (75 meters). Atlantic Shores found deposition of ≥ 0.04 inch (1 millimeters) in thickness would occur within 656 feet (200 meters) from the Monmouth ECC centerline, within 164 feet (50 meters) of the Atlantic ECC centerline, and within 361 feet (110 meters) of the centerline for jet trenching installation of the interarray cables. The geographic analysis area includes offshore waters from Montauk Point on Long Island, New York, southwest into the NY

Comment No.	Comment	Response
	seabed topography can be seen or providing a second figure with only lease area borders (thin black line). Section: 3.5.2.1.1 PDF Page: 178 Comment: Please provide a figure showing the mid-shelf scarp as it overlays with leases 0538 and 0539 and elaborate on the importance of the feature for species community composition and fishing grounds (see Global comment above). Section: 3.5.2.1.1 PDF Page: 179 Comment: BOEM states that winter storms can reshape the upper 20-39inches of sediments within a few hours. Please provide analysis on how this normal process may be altered by the introduction of structure to the OCS and the effects of the altered process on benthic bedforms benthic resources and Essential Fish Habitat. Section: 3.5.2.1.1 PDF Page: 179 Comment: Guida et al. 2017 should not be exclusively replied upon as a proxy to characterize the 6 leases in the PEIS. Instead a study similar to or exceeding in complexity should be conducted for the leases discussed in the PEIS. Additionally trawl and other survey data are available from NMFS state agencies and academic partners to provide insights on non-commercial species distribution (non-targeted but collected species). USGS and NOAA should be consulted for outer continental shelf bedform and benthic habitat characteristics. Publications such as Sylvia Nordfjord John A. Goff James A. Austin Laurie Schuur Duncan Shallow stratigraphy and complex transgressive ravinement on the New Jersey middle and outer continental shelf Marine Geology Volume 266 Issues 14 2009 Pages 232-243 is an excellent starting point that includes additional valuable references.	Bight, and west to Cape May, New Jersey, and includes both the offshore project areas and potential export cable corridors that may traverse inshore benthic habitats in coastal inlets, estuaries, and bays in state waters. Terrestrial resources in coastal areas are discussed in further detail in Section 3.5.4*, Coastal Habitat and Fauna*; tidal wetlands are discussed in Section 3.5.8, *Wetlands*. Text was added to address the Mid-Atlantic Bight Cold Pool in Section 3.5.2.1. Updated figures will occur within project-specific COPs, once benthic mapping and sampling have been conducted, and will be used to inform the project-specific details and design. Unfortunately, no studies exist to analyze what role offshore wind farm monopiles play in the alteration of the upper seafloor sediment during winter storms. Project-specific COPs will contain more details about the results of benthic surveys and sediment samples associated with that particular lease area. Nordfjord et al. 2009 is already cited within Section 3.5.2.1.
BOEM-2024-0001-0371-0014	Section: 3.5.2.1.2 PDF Page: 181 Comment: A minor point of clarification - although eelgrass is a dominant species in estuarine environments widgeon grass is increasingly prevalent in brackish and estuarine waters and in some cases is out-competing eelgrass. Additionally maps of SAV resources in New Jersey estuaries are available on the NJ Dept. of Environmental Protection website. Section: 3.5.2.1.2 PDF Page: 182 Comment: Please include a discussion of other prevalent commercial and recreational bivalves	Thank you for your comment. Widgeon grass is mentioned as being present within NY and NJ estuarine waters. Mapping of nearshore marine and estuarine habitats will occur in project-specific COPs, once export cable corridors and landfalls are proposed. Section 3.6.1 provides discussion of commercial and for-hire recreational bivalves.

Comment No.	Comment	Response
	including hard clams (*Mercenaria mercenaria*) soft clams (*Mya arenaria*) and bay scallops (*Argopecten irradians*) and their habitats.	
BOEM-2024-0001-0371-0015	Section: 3.5.2.3.2 PDF Page: 185 Comment: The determination that accidental releases of fuel fluids or hazardous materials would cause harm to benthic species is understated. Please elaborate by including additional discussion and analysis of direct indirect and cumulative impacts to a variety of species groups (bivalves crustaceans soft corals etc.) Please provide references to support the discussion. Section: 3.5.2.3.2 PDF Page: 186 & 187 Comment: Please elaborate on the implications of route clearance for removing debris and bedforms prior to cable placement and the effects on benthic habitats. Depending on the bedform the disturbance may be minor or significant (such as elimination of the bedform). Section: 3.5.2.3.2 PDF Page: 187 Comment: Please provide a description of articulated pipes as a cable protection measure - this appears to be a new measure. Section: 3.5.2.3.2 PDF Page: 187 Comment: The impacts of cable placement in sensitive habitats such as SAV and shellfish reefs appears to be understated and minimized. Please elaborate on these impacts and effects including typical timeframes for recovery habitat conversion and effects on Essential Fish Habitat or Habitat of Particular Concern status (may be cross-referenced with the section on Finfish & EFH). Section: 3.5.2.3.2 PDF Page: 188 Comment: Supporting evidence is needed for the assertion that disturbance of sand waves sand shoals ridge and trough formations would be a minor impact and of short duration. Although bedforms are naturally dynamic features the time scale for the formation or breakdown of larger scale features is significant sometimes on the scale of decades or more. For example ripples and mega ripple may form move degrade over periods of weeks to years whereas sand shoals and ridge and trough complexes are formed move and degrade over decades to centuries. Excavations of sand borrow pits for beach nourishment often do not regenerate short-term. Additionally analysis has not been provided to explore the hydrodynamic alterations from WTG and OSS foundations and those effects on mobile bedform reformation.	Text was added to Section 3.5.2.4.1 to include that the risk of a spill from an offshore structure would be low and collisions and allisions are anticipated to be unlikely based on prevention factors. Project-specific COPs will address any proposed seabed clearance activities. At the programmatic level this can only be handled in an abstract, general way. Altering large bedforms is likely to have a greater impact than altering minor bedforms. Cable protection approaches include rock placement, concrete mattresses, frond mattresses, rock bags, and seabed spacers, according to the RPDE parameters provided in Table 2-2. Text has been edited. Horizontal directional drilling (HDD) methods would likely be used to install offshore export cables and avoid affected sensitive nearshore and intertidal habitats or seagrass beds. Trenchless installation would likely occur from an offshore punch-out location from the cable landing. Shoal habitats occur in high-energy environments and migrate in a generally southwest direction within the NY Bight area (Rutecki et al. 2014). Field testing of the recovery from sand removal of a total of 4,610,00 cubic yards (3,525,000 cubic meters) from Sandbridge Shoal, Virginia, concluded that sand dredging had no or no long-term impact on macrofaunal abundance. They stated, “It is likely that a combination of storm events, which periodically completely rework surface sediments, and benthic recruitment events, which when large and successful can structure surface sediments, are constantly shaping and reshaping the substrate” (Hobbs C. H., III. 2006. Field Testing of a Physical/Biological Monitoring Methodology for Offshore Dredging and Mining Operations. Marine Minerals Branch, Herndon, VA. Report No. MMS 2005-056. p.). The proposed activities would not remove sediment from the shoal, but would rather disturb it for cable emplacement. There is an ongoing BOEM-funded study to investigate these potential

	Section: 3.5.2.3.2 PDF Page: 188 Comment: Please discuss the impact of DC cables on the natural geomagnetic field through resulting changes to EMF and the effects to benthic species. Section: 3.5.2.3.2 PDF Page: 189 Comment: Please provide examples of EMF impacts to invertebrate taxa rather than a generalization of negligible effects. Section: 3.5.2.3.2 PDF Page: 189 & 191 Comment: The section on Noise should be updated to include known values of noise production and sound dissemination from pile driving and other equipment. Section: 3.5.2.3.2 PDF Page: 190 Comment: The discussion on noise transmission and stress/behavior effects is broad and understated. Please elaborate further with a discussion of specific time scales definitions of 'proximity' and examples of stress-induced behavioral changes (bivalve opening/closure burial reduced feeding etc.). See for example Jzquel Y. Cones S. Jensen F.H. et al. Pile driving repeatedly impacts the giant scallop (Placopecten magellanicus). Sci Rep 12 15380 (2022). https://doi.org/10.1038/s41598-022-19838-6. Please elaborate on the anticipated differing effects if any based upon pile diameter hammer energy (especially in glauconite sands) and what 'local acoustic conditions' means. [Embedded Hyperlink: https://doi.org/10.1038/s41598-022-19838-6] Section: 3.5.2.3.2 PDF Page: 191 Comment: Please include a brief discussion of the current and proposed construction and/or expansion activities at ports referenced in this section. Section: 3.5.2.3.2 PDF Page: 192 Comment: Please provide a more thorough discussion of the anticipated hydrodynamic changes from the presence of structures and the effects on benthic resources. This should include a discussion on the consequences for benthic resources (larval transport effects food supply variability species distribution etc.). Please also provide evidence to support the statement that such disturbances are likely to be localized vary seasonally and have minor impacts as there appear to be numerous assumptions without support. Section: Global PDF Page: Comment: The above examples of improvements are also applicable to the subsequent sections on Alts	changes within the NY bight (https://www.boem.gov/sites/default/files/documents/environment/environmental-studies/MM-20-01_2.pdf). Electric and magnetic field (EMF) levels from direct current (DC) cables above 50 milligausses (5.0 microteslas) would result primarily from exposed cable, which is not expected for offshore wind projects, and would occur close to (i.e., within 25 feet [7.6 meters] of) the cable. High voltage direct current (HVDC) cables can produce higher EMF levels, up to 207 milligausses (20.7 microteslas); however, this level was associated with shallower cable burial depths, and cables buried deeper under the seafloor would produce EMF closer to 4 milligausses (0.4 microteslas) (Hutchison et al. 2018). EMFs are discussed in Section 3.5.2.3 under cumulative impacts as other offshore wind farms are planned within the NY Bight. Newer references of studies on DC cables emitting EMF have been added. As other ongoing and planned offshore wind projects are set to take place within the NY Bight, several ports plan to expand, such as South Brooklyn Marine Terminal where Empire Wind 1 plans to make landfall, and a new O&M facility is proposed in Atlantic City, New Jersey, to support Atlantic Shore. These are some examples of port expansion projects that are generally referred to in Section 3.5.2.3.2 of the NY Bight PEIS. Refer to response to comment BOEM-2024-0001-0331-0037 for hydrodynamic changes. Text has been added to Section 3.5.2.3.2 to help characterize impact pile-driving noise, though the reader is referred to Appendix J, *Introduction to Sound and Acoustic Assessment*, for a more comprehensive description. Additionally, information from Jézéquel et al. (2022) has been incorporated into this section.

Comment No.	Comment	Response
	B and C and should be carried through in the discussions of impacts from one project 6 projects cumulative impacts and cumulative impacts with AMMMs.	
BOEM-2024-0001-0371-0016	Section: 3.5.2.4.1 PDF Page: 197 Comment: In addition to the discussion of invertebrate taxa recovery rates from sand mining operations please also include information on the recovery rates of the borrow areas themselves and discuss how this relates to the anticipated recovery of bedforms eliminated through the pre-sweeping process. When discussing the recovery rates of bedforms please more clearly distinguish the anticipated recovery based upon bedform type and size - large regional features (eg. ridge and trough formations) will not rebuild/recover on the same spatial or temporal scale as smaller ripples or mega ripples. Section: 3.5.2.4.1 PDF Page: 199 Comment: An example of where detail is needed per the Global comment above: "The predicted thermal effect is a small rise in temperature within a few centimeters of the cable." Please provide the predicted temperature increase. Section: 3.5.2.4.1 PDF Page: 200 Comment: Please elaborate on the relationship between WTG foundation type and noise transfer from the nacelle to the seafloor. What foundation type transfers the least noise? Is this the foundation type anticipated for use in the NY Bight? Section: 3.5.2.4.1 PDF Page: 201 Comment: Please provide supporting evidence that port expansion and redevelopment is expected to have negligible effects on benthic resources despite the likelihood of dredging filling bulkhead installation etc. Section: 3.5.2.4.2 PDF Page: 204 Comment: Please provide supporting evidence for the determination that the impacts from EMF cable heat survey gear utilization and port development would be negligible from 6 projects. Without supporting evidence it appears unlikely that full build out of 6 offshore wind farms in the NY Bight would result in undetectable impacts and effects from those IPFs. A substantially more robust discussion with supporting evidence is needed for the regional cumulative impacts and effects of these IPFs on benthic resources (flora fauna and bedforms) in the OCS nearshore and estuarine environments.	Refer to response to comment BOEM-2024-0001-0371-0015 for discussion of sand mining activities. Ports are typically very disturbed habitats, given the presence and movements of vessels from within the port. Therefore, although port expansion projects are anticipated, the benthic species within the port are accustomed to the disturbances. Mobile organisms would likely move out of the port, while sessile organisms would likely recover once the turbidity and sediment deposition pass. Text has been added to Section 3.5.2.4.1 to address cable heat in more detail. Survey gear utilization is a minimal impact as sampling stations are spaced out and the size of the collected samples is very small relative to the size of the WEA. Project-specific COPs will address this in more detail, and include details on the nearshore and estuarine environments once the export cable routes and landfall is proposed. Port improvement and expansion projects take place on a routine basis within heavily trafficked ports of New York and New Jersey. As stated above, the species that inhabit port environments are accustomed to disturbance and are likely to fully recover or temporarily move out of the area before or as a result of the disturbance. Activities associated with the proposed NY Bight projects included in the PEIS do not increase port impacts appreciably compared to background levels. Based on data from Tougaard et al. (2020), concrete foundations would produce the lowest sound levels during turbine operations (compared to steel monopile and jacket foundations). However, concrete foundations are often using in very shallow waters and would not be applicable for the WTG proposed for the NY Bight projects. Therefore, for the purposes of the PEIS, it was assumed that steel foundations, similar to those described for other approved offshore wind projects in this region, would be used for these NY Bight projects. However, during the project-specific COP NEPA analysis, developers will identify the specifics of their

Comment No.	Comment	Response
	Section: 3.5.2.5 PDF Page: 206 Comment: Please update the table of AMMMs to include a clear linkage between the measure proposed and the anticipated benefit to benthic resources. For example in BEN-2 it is not clear how requiring regular scour protection inspection avoids minimizes mitigates or monitors adverse impacts and effects to benthic resources. It would helpful for the reader to be told that the measure is considered avoidance minimization mitigation or monitoring.	proposed foundations and re-assess if a different material is proposed.
BOEM-2024-0001-0371-0017	Section 3.5.5. Finfish Invertebrates and EFH Section: 3.5.5 PDF Page: Global Comment: This EIS repeatedly states (for example section 3.5.5.5.2) that AMMMs would generally reduce impacts on finfish inverts and EFH but the impact determinations remain unchanged. Further the impact determinations remain unchanged between 1 and 6 project build-outs. The EIS is concluding that regardless of AMMMs adopted and regardless of projects constructed impacts will remain unchanged if that is the case then the AMMMs are not functioning as intended. Section: 3.5.5PDF Page: Global Comment: Repeatedly (for example section 3.5.5.5.5) this EIS identifies the presence of structures as the primary driver of major impacts. As a result we recommend developing and incorporating additional AMMMs in regards to the presence of structures.	BOEM has considered all comments on AMMM measures and has made several changes to address potential impacts on resources as provided in Appendix G and analyzed in Alternative C. Alternative C describes how impacts would be reduced with application of AMMM measures, but overall impact levels may not be reduced for all IPFs as impacts would still result from construction and O&M phases of project facilities. During project-specific COP NEPA analyses, additional mitigation measures can be considered for inclusion to address project-specific impacts.
BOEM-2024-0001-0371-0018	Section: 3.5.5.1.2 PDF Page: 266 Comment: Hydrodynamic conditions are important in determining habitat suitability within the region. More discussion about how hydrodynamic regimes in particular in regards to the Mid-Atlantic Cold Pool determine habitat suitability and influence species abundance and distribution across the GAA should be included. Section: 3.5.5.2 PDF Page: 275 Comment: (Table 3.5.5-5) Please ensure that the impact conclusions throughout this section are in alignment with the definitions provided. By the definitions provided any impact to a HAPC SAV included or complex habitat could never be considered minor since that would equate to an impact on 'sensitive habitats'. Additionally any habitat impact that is longer than 'short-term' could not be considered anything less than 'moderate'.	Additional information about the Mid-Atlantic Bight Cold Pool has also been included in Final PEIS Sections 3.4.2.1, 3.4.2.3, 3.5.2.4, and 3.5.5. *Impacts of the Proposed Action on Benthic Resource*s, under the Presence of structures IPF. Changes in cold pool dynamics resulting from future activities, should they occur, could conceivably result in changes in habitat suitability and fish community structure, but the extent and significance of these potential effects are unknown. Any impact on sensitive habitats is moderate at a minimum. However, per definition, minor impacts could be short to long term as could moderate and major impacts. Habitat areas of particular concern (HAPCs) (including SAV and complex habitats) are defined as subsets of EFH that provide important ecological functions or are especially vulnerable to degradation. No

Comment No.	Comment	Response
	Section: 3.5.5.3.1 PDF Page: 277 Comment: Please provide a citation to references that support the assumption that long-range migratory finfish would be precluded from many of the temporary and short-term impacts associated with offshore impacts as this appears to be based on numerous assumptions that lack support. Section: 3.5.5.4.2 PDF Page: 302 Comment: The discussion on the impacts from pile driving and subsequent exposure to noise focuses exclusively on the magnitude of decibel exposure from pile driving activities while omitting all discussion on duration of exposure. The duration of noise exposure is critically important in understanding cumulative impacts from pile-driving activities. This is particularly important in areas such as the GAA with longfin squid EFH as squid have short life and reproductive cycles and repeated noise exposure from pile-driving activities over the course of multiple years (and spawning seasons) could significantly degrade the quality of squid EFH available for spawning. Section: 3.5.5.4.2 PDF Page: 302 Comment: In the discussion on impacts from the presence of structures please include discussion on how the six proposed projects will impact the hydrodynamic regimes within the GAA. Specifically include discussion about potential impacts on the Mid-Atlantic Cold Pool and associated dependent species. Additionally this discussion should include analysis on the cumulative impact of the six projects in concert with the other regionally approved and expected projects on regional hydrodynamic regimes. Section: 3.5.5.4.5 PDF Page: 304 Comment: In the discussion on cumulative impacts of Alternative B; the conclusion states that impact rating could be decreased if construction of the NY Bight projects is staggered. Additional analysis and discussion of impacts and anticipated minimization (via staggered construction) on specific species and habitats should be included.	designated HAPCs are located within the NY Bight lease areas; however, summer flounder and sandbar shark HAPCs (Figure 3.5.5-2) may overlap with potential NY Bight offshore export cable corridors and vessel routes to the identified representative ports (see Chapter 2). RP MUL-23 includes avoiding cable emplacement in sensitive areas such as SAV habitat, and AMMM measures MUL-2 and MUL-27 include avoiding bottom interactions by enacting anchoring plans or using dynamic positioning (DP) vessels Based on their status as migratory species, this species group is not expected to be in a sustained habitat or location for a prolonged period of time. Research specific to noise impacts on squid was reviewed during the preparation of the Draft PEIS, and the discussion is included in the cumulative impacts discussion in the Impact and Vibratory Pile Driving section (Section 3.5.6.4.1) (research by Stanley et al. 2023 and Cones et al. 2022). The Final PEIS considers the best available data and information that reflect the state of the science at the time of publication of the PEIS. A discussion of uncertainty about the impacts of underwater noise is included in Appendix E. Future research will be incorporated into subsequent COP NEPA analyses as information becomes available. Discussion related to the current research on the potential impacts of the NY Bight projects on the Mid-Atlantic Bight Cold Pool is included in Section 3.5.5.4.2. Future project-specific COP NEPA documents will focus on providing site- and project-specific analyses that were not already addressed by the PEIS. The timing of the construction of each of the six NY Bight projects is not known and depends on many factors outside the scope of the PEIS. As projects are developed, future project-specific COP NEPA documents may discuss potential overlaps in site development activity, if applicable.
BOEM-2024-0001-0371-0019	Section: 3.5.5.5.1 PDF Page: 307 Comment 1: Under the initial discussion on impacts from IPFs from Alternative C the text states that impacts would be reduced compared to Alternative B however the impact determinations (negligible to major) remains unchanged. Therefore either the text should be revised to say the impacts from	Through the utilization of the described AMMM measures, the quantity and extent of impacts related to the IPFs would be reduced; however, the identified AMMM measures would not completely remove or reduce these impact determinations.

Comment No.	Comment	Response
	the IPFs would not be reduced or further discussion must be provided on which impacts are being reduced and the impact determinations should be updated. Section: 3.5.5.5.1 PDF Page: 307 Comment 2: Under the initial discussion on impacts from IPFs from Alternative C the text identifies AMMMs BEN-1 MUL-4 MUL-12 and MUL-23 as the most effective at minimizing impacts on sensitive benthic and EFH resources however the AMMMs referenced lack any specific restrictions or parameters dictating the extent of adoption. Specific restrictions and parameters outlining the extent of adoption of each AMMM identified should be included to support this assertion. Section: 3.5.5.5.1 PDF Page: 309 Comment 3: Under noise - please include more discussion about the interaction between pile driving activities noise and presence of glauconite with each other. Section: 3.5.5.5.1 PDF Page: 310 Comment 5: Under Presence of Structures - The colonization of artificial hard bottom habitat created from project installation has the potential to be dominated by invasive species. This risk will be elevated in areas where Didendum vexillium is present and is fragmented across broad areas during sea bed prep activities (i.e. boulder relocation) for cable installation. Further the subsequent cable armoring will create novel hard bottom habitats for invasive species to spread and colonize along the cable corridors which may have been converted from unsuitable soft bottom habitat prior to installation. Cumulatively this could result in less resiliency to the spread of invasive species within the region. More discussion on the risks associated with habitat conversion fragmentation and invasive species spread should be included here. Section: 3.5.5.5.2 PDF Page: 310 Comment: This section describes the IPFs as being the same whether one or six projects are constructed however that fails to address how IPFs change and interact with each other cumulatively and introduce more regionally detectable impacts and mechanisms such as wind wake effects and the potential confounded associated ecological impacts. Further discussion and analysis should be added to describe these compounding IPFs and how they impact EFH finfish and inverts on a regional scale.	The measures are identified and described in Table 3.5.5-8. Details about the specific activities will be addressed during project-specific COP NEPA analysis. Text within Section 3.5.5.5.1 (page 3.5.5-42) has been enhanced to discuss the correlation between the presence of glauconite sand and the potential need to use increased level of hammer strike energy during pile-driving operation for WTG installation. Potential colonization by non-indigenous biota altering benthic or epipelagic communities is discussed in the *Presence of structures* subsection of 3.5.5.3.3. Thank you for your comment. Section 3.5.5.3.3 has been updated to include assessment of hydrodynamic effects of ongoing and planned offshore wind projects.

Comment No.	Comment	Response
BOEM-2024-0001-0371-0020	Section 3.5.6 Marine Mammals Section: 3.5.6 PDF Page: Comment: Note that due to workload this section did not receive a complete review by MMPA and ESA SMEs. Section: PDF Page: Comment: Please revisit all determinations for the NARW in each sub-section particularly Alternative C. The NARW has a small population size and therefore all impacts would be greater on this already at risk species. AMMMs decrease impact levels but in most cases cannot remove risk entirely so any negative impact to one individual may have population-level effects. This is not well represented throughout the section. Section: 3.5.6.1 PDF Page: 319 Comment: It is unclear how this list was made and how the species to include were decided upon. The paragraph states "species considered likely to occur in the NYB project area" however the previous table (3.5.6-1) lists relative occurrence in the offshore project area. The Sei Whale and the Atlantic White Sided Dolphin are included on the list but are both reported to be "Uncommon" in the project area by the table. Along the same lines the Short Finned Pilot Whale and Blue Whale are also reported as "Uncommon" are discussed later on in the section but are not included in the list. This is inconsistent and requires clarification. Section: 3.5.6.1 PDF Page: 320 Comment: Roberts revised the models in 2023 newer source now available; the most up to date version of the model should be used to inform the FEIS . Section: 3.5.6.1 PDF Page: 322Comment: Please add the BIAs identified by Van Parjis et al. 2015: BIAs for fin whale feeding have been identified off Rhode Island Sound between March and October and year-round for Georges Bank Cape Cod Bay and the Gulf of Maine BIAs for sei whale feeding have been identified from the Gulf of Maine to the continental shelf off Georges Bank between the months of March and November BIAs for minke whale feeding have been identified on Georges Bank in Cape Cod Bay and the Gulf of Maine between the months of Marchand November. Section: 3.5.6.1 PDF Page: 322 Comment: Please add that the NARW feeds primarily on Calanus spp. (Stone et al.1988; Kann and Wishner 1995; Woodley and Gaskin 1996). Also that Sei whales are often sighted in conjunction with right whales during the spring when they are both feeding on copepods. Section: 3.5.6.1 PDF Page: 325 Comment: Please add that	The sub-sections in Alternative C have been reviewed specifically for NARW, and based on available science BOEM concludes that no major effects on NARW would occur due to impacts of Alternative C. For additional information, please see response to comment BOEM-2024-0001-0371-0011. The species listed on page 3.5.6-7 are those likely to occur in the offshore project area defined in the first paragraph of Section 3.5.6, and text has been updated to denote: "The 14 species considered likely to occur in the offshore project area include" to be consistent with terminology. Additionally to maintain consistency, short-finned pilot whales and blue whales have been added to that list. Similarly, harp seals were added to the list. The newer information from Roberts et al. (2023) has been incorporated into the PEIS. Information about fin whale, sei whale, and minke whale Biologically Important Areas (BIA) has been added to Section 3.5.6.1.1 for ESA whales and 3.5.6.1.2 for non-ESA whales. Both the note about NARW preferred prey species and sei whales foraging in conjunction with NARW because they target the same zooplankton species has been added to Section 3.5.6.1.1. A note about the 2022 pinniped UME event in Maine between June and July 2022 based on the webpage last updated on April 23, 2024 (https://www.fisheries.noaa.gov/marine-life-distress/2022-pinniped-unusual-mortality-event-maine-closed) has been added to Section 3.5.6.1.2. The risk of GI tract injuries has been added to the discussion of potential non-auditory injuries in Section 3.5.6.1.3.

Comment No.	Comment	Response
	since June 2022 another UME for harbor and gray seals has been declared by NMFS off the southern and central coast of Maine with 322 seal strandings between June and December 18 2022 (NOAA Fisheries 2023). Preliminary testing has found some of the harbor and gray seals affected by the June 2022 UME to be positive for highly pathogenic avian influenza H5N1. Section: 3.5.6.1.3 PDF Page: 327 Comment: Please add that gastrointestinal injuries are also possible from explosive sources. (Reference: Criteria and Thresholds for U.S. Navy Acoustic and Explosive Effects Analysis (Phase III) (2017)- "The gas-containing organs (lungs and gastrointestinal tract) are most vulnerable to primary blast injury. ")	
BOEM-2024-0001-0371-0021	Section: 3.5.6.2 PDF Page: 334 Comment: The purpose of this table is unclear. Are these issues that are currently affecting marine mammals based on current trends? Please provide additional detail. In addition some impact indicators provide a level of impact for an issue while others describe how the issue is assessed. Water quality impact indicator for example lists how the issue is assessed. It seems that this is the more appropriate type of information to be stored in this table than what for example is provided for underwater noise. Please consider having each impact indicator in the same format. Also please define how seabed and water column alteration is different from habitat alteration. Section: 3.5.6.2PDF Page: 334Comment: The source provided for this table links to the recommendation for project pile driving sound exposure. That document does not discuss all issues provided in this table. Please update or provide additional sources.	The issues and indicators table in Section 3.5.6.2 has been revised in response to this comment. The footnote on the table is connected to the noise impact indicator source, not the source for the entire table.
BOEM-2024-0001-0371-0022	Section: 3.5.6.3.1 PDF Page: 335 Comment: It would be beneficial to include a more thorough analysis of each IPF relative to the No Action Alternative. Section: 3.5.6.3.3 PDF Page: 341 Comment: It would be beneficial to include more detail on intake/entrainment impact on plankton as it is a prey source for many marine mammals including the NARW. Section: 3.5.6.3.3 PDF Page: 341 Comment: More detail should be provided on EMF for HVDC cables as some are proposed in the GAA and (as stated) they emit 10 times more magnetic field than HVAC. Section: 3.5.6.3.3 PDF Page: 343 Comment: Entanglements can	Impacts of the No Action Alternative would be comparable to those discussed in Section 3.5.6.3.3 for the cumulative impacts, which provide a detailed discussion of each IPF. Additional information on intake effects for prey species for NARW has been added to Section 3.5.6.3.3 on page 3.5.6-30. Text in the discussion of survey gear utilization in Section 3.5.6.3.3 on page 3.5.6-32 has been updated to include the statement about any body parts/multiple body parts being affected.

Comment No.	Comment	Response
	occur on any body part as well as multiple body parts. Section: 3.5.6.3.3 PDF Page: 344 Comment: Please include that gear utilization from planned non-offshore wind activities could result in major long-term impacts for NARW if a NARW is entangled because impacts on individual NARWs could have severe population-level effects and compromise the viability of the species. Section: 3.5.6.3.3 PDF Page: 356 Comment: Please note that sound levels from wind turbine operations are likely to increase somewhat with increasing generator size and power ratings while the newer use of direct-drive technology is expected to lower underwater noise levels substantially. Section: 3.5.6.3.3 PDF Page: 356 Comment: Please provide sources for "researchers" as well as additional detail. Masking effects for what species? More information is necessary here. Section: 3.5.6.3.3 PDF Page: 359 Comment: Ocean Wind 1 has determined the cumulative impact of port utilization for the no action alternative is major for the NARW and moderate for other species. Ports discussed are very similar so it is unclear why NYB has determined the impact to be so much lower (minor for all species including the NARW). Please provide more detail or re-consider the impact determination. This also applies to subsequent Port Utilization sections. Section: 3.5.6.3.3 PDF Page: 359 Comment: Please review recent information/comments provided by NMFS on other OSW EISs and in Biological Opinions regarding effects of presence of structures and operations of WTGs. We consider this section to require updates to ensure that it reflects the best available scientific information (note that this comment is relevant to fish and sea turtles as well as marine mammal chapter) Section: 3.5.6.3.3 PDF Page: 359 Comment: Please add that an increase in offshore wind farms may weaken the regional thermocline and affect heat storage atmospheric CO_2 uptake and benthic resupply of oxygen gas (Dorrell et al. 2022). Section: 3.5.6.3.3 PDF Page: 360 Comment: "Tall vertical structures" are not the primary reason for the reduction of wind-driven mixing of surface waters. That would be energy extraction from the turbines. Section: 3.5.6.3.3 PDF Page: 361 Comment: Please provide a source that supports the claim that hydrodynamic effects will be limited to within 600 to 1300 feet down current of each monopile.	The discussion for gear utilization in Section 3.5.6.3.3 has been updated as requested to discuss non-offshore wind activities that would have major effects on NARW. Text in Alternatives B and C has also been checked to be consistent with this determination. The note about use of direct drive technology reducing sound levels even for larger turbine sizes has been added to the WTG noise discussion on page 3.5.6-48. This information comes from Lucke et al. (2007), and text has been updated to clarify that these are the researchers being referred to in the WTG operational noise masking discussion. The presence of structures discussion in Section 3.5.6.3.3 has been updated to include additional sources such as Jonhson et al. (2021), Floeter et al. (2022), Raghukumar et al. (2023), and NASEM (2023), and subsequent text has been updated to expand discussions as needed. The conclusion about thermoclines and heat storage from Dorrell et al. (2022) has been added to the discussion of the presence of structures in Section 3.5.6.3.3. Text in Section 3.5.6.3.3 referring to tall vertical structures has been updated as follows: "Human-made structures, such as bottom-founded foundations and operational WTG associated with offshore wind projects, alter local water flow…" The section has been updated with additional/newer references to clarify this range so this statement has been removed/replaced with results from Johnson et al. (2021) and Schultze et al. (2020).

Comment No.	Comment	Response
BOEM-2024-0001-0371-0023	Section: 3.5.6.4.1 PDF Page: 372 Comment: Please add that marine mammal species that are more likely to forage near the benthic organisms such as certain delphinids have more potential to experience EMF above baseline levels (Tricas and Gill 2011). Section: 3.5.6.4.1 PDF Page: 376 Comment: Please provide information on the possible behavioral responses from vessel noise such as the onset of avoidance behavior changes in acoustic behavior diving and subsurface interval behavior and changes in vocal rates (Southall et al. 2021). Section: 3.5.6.4.1 PDF Page: 376 Comment: The impact determined for G&G Survey Noise for Ocean Wind 1 with/including mitigation measures is minor. Please provide more detail as to how one NY Bight project without mitigation measures has a lower impact determination. Please apply this comment to all subsequent G&G Survey Noise sections as masking and behavioral responses are possible for all species as a result of this noise LFCs in particular. Section: 3.5.6.4.2 PDF Page: 382 Comment: Some of the IPFs included in this list as "expected to be minor" were determined to have a negligible impact not minor. Also not all of the IPFs had the same impact determination for each species/group such as the NARW. For example survey gear utilization while minor for other species was higher for the NARW. This summary is misleading.	The risk of EMF exposure increasing for benthic foraging marine mammals has been added as requested to Section 3.5.6.4.1. A full discussion of the potential behavioral responses to vessel noise is provided in Section 3.5.6.3.3 and referenced in Section 3.5.6.4.1 to reduce redundancy in the document. BOEM agrees with the point raised by this comment regarding impacts from geophysical and geotechnical (G&G) noise in Alternative B and has changed this to minor for all marine mammals. Masking and behavioral effects are discussed in detail in Section 3.5.6.3.3. Section 3.5.6.4.2 has been cross checked against Section 3.5.6.4.1 to ensure consistency with determinations.
BOEM-2024-0001-0371-0024	Section: 3.5.6.5PDF Page: 389Comment: (3.5.6-11) The first entry in the table for measure COMFIS-5 does not incorporate the redline edit reflected in the October 18 2023 DPEIS. It's missing the word "requiring." It should read "This measure proposes requiring during- and post-construction fisheries monitoring survey plan design follows the BOEM Fisheries Survey Guidelines." Section: 3.5.6.5.5PDF Page: 404 -405Comment: Here it reads impacts from one or six projects to mysticetes (including NARW) are expected to be "moderate for mysticetes (including the NARW) mainly resulting from UXO detonations and pile-driving noise because impacts would be noticeable and measurable and could result in population-level effects for some species;..." but it also reads that "For pile-driving BOEM expects impacts to be minor for non-NARW mysticetes..." Please verify the impacts from pile driving to mysticetes. Section: 3.5.6.5.5PDF Page: 404Comment: Alternative C: NMFS is concerned	COMFIS-5 has been reclassified as an RP. The cumulative impacts of Sub-alternatives C1 and C2 for NARW are expected to be major because serious injury or loss of an individual would result in population-level impacts that threaten the viability of the species if a vessel strike or entanglement were to occur. The proposed mitigation measures under Sub-alternatives C1 and C2 will eliminate the risk of Permanent Threshold Shift (PTS) for NARW due to UXO and impact pile-driving and will reduce the risk of vessel strikes such that the likelihood of one occurring is negligible. Because no PTS or vessel strike injuries are anticipated for NARW, no population-level effects are anticipated, and impacts were reduced from major to moderate.

Comment No.	Comment	Response
	with the impact determination for NARW as reduced from major from the No Action Alternative. Consistent with comments on OSW EISs if the status quo is expected to be major impacts for ongoing and planned activities no AMMM measures would reduce those impacts since they are tied to this proposed action. Therefore NMFS requests this be changed to major impacts for NARW. Additionally this is a different conclusion from what is in Table ES-2 and Chapter 2.	
BOEM-2024-0001-0371-0025	Section 3.5.7 Sea Turtles Section: 3.5.7 PDF Page: Global Comment: Note that due to workload this section did not receive a complete review by MMPA and ESA SMEs. Section: 3.5.7.1 PDF Page: 406 Comment: NMFS and USFWS have not designated DPSs for leatherback sea turtles because the species is listed as endangered throughout its global range (85 Federal Register 48332). 'Leatherback sea turtle Northwest Atlantic subpopulation' is more appropriate. Please also incorporate this change into table 3.5.7-1. Section: 3.5.7.1 PDF Page: 409 Comment: More recent AMAPPS survey data is available than 2017; please update the data and references in the FEIS. Section: 3.5.7.1 PDF Page: 410 Comment: Please add that visual sighting data may be limited because this small species is difficult to observe using typical aerial survey methods (Kraus et al. 2016) Section: 3.5.7.1 PDF Page: 410 Comment: Please add that Leatherback sea turtles dive the deepest of all sea turtles to forage and are more tolerant of cooler oceanic temperatures. In addition Please add that Bailey et al. 2012 found that oceanographic features such as mesoscale eddies convergence zones and areas of upwelling attracted foraging leatherbacks as these features are often associated with aggregations of jellyfish. Section: 3.5.7.1 PDF Page: 412 Comment: Please add that studies have indicated that the Mid-Atlantic Bight of the Atlantic OCS is an important a seasonal foraging ground for approximately 40000 to 60000 juvenile and adult loggerheads during summer months (NEFSC and SEFSC 2011). Section: 3.5.7.1 PDF Page: 412 Comment: Please add that sea turtles are wide-ranging and long-lived making population estimates difficult and survey methods vary depending on species (TEWG 200 NMFS and USFWS 2015). Because they have large ranges and highly migratory behaviors these factors can have impacts on individuals over broad	Text regarding the leatherback sea turtle population in Section 3.5.7.1 on page 3.5.7-1 has been updated to include the suggested recommendation, and Table 3.5.7-1 has been similarly revised as requested. The most recent Atlantic Marine Assessment Program for Protected Species (AMAPPS) reports have been reviewed and incorporated into this section where appropriate. A statement regarding difficulty in detection of Kemp's ridley sea turtles due to their size has been incorporated into Section 3.5.7.1. The requested leatherback information has been incorporated in Section 3.5.7.1. Loggerhead foraging information has been incorporated into Section 3.5.7.1. The following text has been added to the beginning of Section 3.5.7.3.1: "Because sea turtles have large ranges and highly migratory behaviors, these IPFs can have impacts on individuals over broad geographical scales. Therefore, in addition to the current conditions and trend of sea turtles in the geographic analysis area, these populations are also affected by factors beyond the geographic analysis area. However, the assessment in this PEIS focuses on those stressors currently present within the geographic analysis area, and any effects on the populations outside this region are considered as part of the species ongoing vulnerability affecting the species risk."

Comment No.	Comment	Response
	geographical scales. In addition the current condition and trend of sea turtles are also affected by factors beyond the geographic analysis area.	
BOEM-2024-0001-0371-0026	Section: 3.5.7.3.3 PDF Page: 424 Comment: It would be beneficial to include the estimated distances of planned export and inter array cables. Section: 3.5.7.3.3 PDF Page: 429 Comment: Please remove the phrase "dredging impacts on sea turtles are relatively uncommon" and begin the sentence after the semicolon. This statement is not descriptive and is misleading as written. Section: 3.5.7.3.3 PDF Page: 431 Comment: Please add that project decommissioning such as the removal of the monopile foundations and scour and cable protection would reverse the artificial reef effect provided by these structures and remove or disperse the associated biological community. Section: 3.5.7.3.3 PDF Page: 433 Comment: Please add that while sea turtles are capable of remaining submerged for long periods they appear to rapidly consume oxygen stores when entangled and forcibly submerged in fishing gear (Lutcavage and Lutz 1997).	The estimated areas for the planned export and interarray cables are provided in Appendix D, Table D2-2. The dredging statement for sea turtles was removed as requested. A statement about decommissioning effects reversing potential benefits has been added to Sections 3.5.7.3.3 and 3.5.7.4. A statement about sea turtles consuming oxygen stores when entangled was added to Section 3.5.7.3.3.
BOEM-2024-0001-0371-0027	Section: 3.5.7.4.1 PDF Page: 435 Comment: Please add that even though the impact of one NY Bight project "would be of low intensity short term and localized" ingestion of debris by a sea turtle can be fatal for the individual. Section: 3.5.7.4.1 PDF Page: 435 Comment: Please add that dredging could contribute additional impacts on sea turtles related to impingement entrainment and capture associated with mechanical and hydraulic dredging techniques. It would also be beneficial to discuss the different types of dredging that have the potential to be utilized for one project. Section: 3.5.7.4.1 PDF Page: 436 Comment: Please provide additional detail for explaining the negligible determination. Ocean Wind 1 determined the impact of EMF to be minor and that project proposed only HVAC. One NYB project has the potential to use HVDC which have considerably higher potential to adversely impact sea turtles than HVAC as stated. Section: 3.5.7.4.1 PDF Page: 442 Comment: Please add that periods of poor visibility or inclement weather would increase the collision risk for turtles because both turbid water and darkness would impede turtles' visual detection of approaching boats. Section: 3.5.7.4.1 PDF	Potential for fatal injuries due to ingestion of debris was added to the discussion in Section 3.5.7.4.1. Risk of impingement and entrainment due to mechanical dredging techniques was added in Section 3.5.7.4.1, as well as a summary of potential cable emplacement methods considered in this PEIS. Though EMF from HVDC is likely to be higher than high voltage alternating current (HVAC) cables, the potential impacts on sea turtles would still be limited to behavioral disturbances within a few feet from the cables due to the expected burial depth and more recent studies looking at HVDC effects on marine life. This negligible determination for one project in Alternative B is consistent with other recently published EISs, including Sunrise Wind and Empire Wind. A statement regarding increased vessel collision risk during poor visibility conditions for sea turtles has been added to Section 3.5.7.4.1. Requested information from the U.S. Navy Undersea Warfare Center has been incorporated into Section 3.5.7.4.1.

Comment No.	Comment	Response
	Page: 442 Comment: Please add surface information provided by the U.S. Navy Undersea Warfare Center's dive distribution and group size parameter reports (Watwood and Buonantony 2012; Borcuk et al. 2017). These data suggest that loggerhead and green sea turtles spend 60 to 75 percent of the time within 32 feet (10 meters) of the surface leatherback sea turtles spend about 20 percent of the time within 32 feet (10 meters) of the water surface and there are insufficient data to quantify Kemp's ridley sea turtle activity. Any sea turtle found in the geographic analysis area could thus occur at or near the surface whether resting feeding or periodically surfacing to breathe which is where they are at risk of vessel strike. Section: 3.5.7.4.2 PDF Page: 443 Comment: While the impact determination may not change it is inaccurate to equate the chance of accidental release for one project with that of six projects. Bejarano et al. 2013 modeled that a release of 2000 gallons or less is likely to occur every 5 to 20 years. The more turbines that are in the water the more fluid there is in each turbine and thus the higher the opportunity there is for a potential spill. Section: 3.5.7.4.2 PDF Page: 443 Comment: The statement that the likelihood of impacts are so low to be discountable contradicts the preceding section which describes impacts for each IPF not all of which were determined to be negligible. Section: 3.5.7.5.4 PDF Page: 458 Comment: AMMMs are implemented to mitigate adverse impacts. Therefore they lessen adverse impacts and do not create "greater beneficial impacts" as stated. Please fix.	The introduction to Section 3.5.7.4.2 states: "There would be more potential for impacts for these IPFs due to the greater amount of offshore and onshore development under six NY Bight projects. Impacts for accidental releases, discharges/intakes, EMFs and cable heat, survey gear utilization, and lighting are expected to be the same as those discussed above for one NY Bight project." Therefore, BOEM acknowledges an increased risk of oil spills due to the increased number of project infrastructure in the water column; however, the likelihood is still low, and BOEM does not anticipate that effects would combine such that the overall impact determination would increase from one project to six. The statement has been updated to clarify as follows: "…the overall likelihood of impacts resulting from these IPFs for any one project remains the same as described in Section 3.5.7.4.2 regardless of the number of NY Bight projects considered." The statement has been updated as follows: "Impacts on sea turtles are anticipated to be similar as described under Alternative B. While the application of not previously applied AMMM measures for six NY Bight projects can reduce potential adverse impacts, the impact level determination is not expected to change under Sub-alternative C2."
BOEM-2024-0001-0371-0028	Section 3.6.1 Commercial and Recreational Fisheries Section: 3.6.1 PDF Page: Global Comment: Please insert a reference to and a discussion of fisheries for highly migratory species (tunas sharks swordfish etc.) which are managed by NMFS's Highly Migratory Species Division. These fisheries are affected by this action but are not referenced in the baseline description other than in Table 3.6.1-1. Section: 3.6.1 PDF Page: Global Comment: Throughout the document particularly under cable emplacement and/or presence of structures please include a discussion of cable preparation activities and cable armoring including UXO detection and removal and boulder	The Atlantic Highly Migratory Species (HMS) Fishery Management Plan (FMP) includes Atlantic billfish, Atlantic tunas, swordfish, and sharks (NMFS 2006, 2017). HMS species are referenced in Section 3.6.1.1.4. as well as Table 3.6.1-1. General text about seabed preparation activities and cable protection were included under the cable emplacement and maintenance IPF in Sections 3.6.1.3.2 and 3.6.1.4.1. Details about the specific activities will be addressed during the project-specific, COP-level NEPA analysis.

Comment No.	Comment	Response
	relocation activities. Such activities are additional impacts that should be identified and considered in this document.	
BOEM-2024-0001-0371-0029	Section: 3.6.1.1.1 PDF Page: 479 Comment: (Table 3.6.1-1) Please ensure that this table includes all species affected by this action and managed by the management bodies listed. Many of the species managed by the ASMFC are not listed in this table (e.g. Atlantic menhaden striped bass Jonah crab etc.). Section: 3.6.1.1.3 PDF Page: 485 Comment: Please ensure that all commercial fisheries affected by this action are adequately described in this section including associated tables such as Table 3.6.1-6. Similar to previous project-specific EISs this section relies exclusively on data from vessels issued permits issued by the NMFS Greater Atlantic Regional Fisheries Office (GARFO). Operations in fisheries such as Atlantic menhaden and other ASMFC-managed fisheries HMS species and species managed by the South Atlantic Fishery Management Council are not well represented in the GARFO data presented in this section. As a result baseline evaluations of fishery operations throughout the six lease areas are underestimated in this DEIS. Further in several tables "all others" data are included in lease-specific reports available on our website but are not included in either the landings or revenue tables. Integration of data for these other fisheries into the FEIS would increase the likelihood that the programmatic EIS can meet BOEM's objectives. Section: 3.6.1.1.4 PDF Page: 514 Comment: (Figure 3.6.1-22) Please ensure that the "Prime Fishing Areas" identified by the New Jersey Department of Environmental Protection are included in this or a similar figure and discussed in the relevant text of this section. These areas include important fishing locations associated with bottom features that would be affected by this action. Evaluation of impacts to these areas including AMMMS to avoid such impacts should be included in the FEIS.	Species such as Atlantic menhaden, striped bass, and Jonah crab managed by the Atlantic States Marine Fisheries Commission (ASMFC) have been added to Table 3.6.1-1. Figure 3.6.1-22 has been updated to include the requested Prime Fishing Grounds data identified by the New Jersey Department of Environmental Protection (NJDEP).
BOEM-2024-0001-0371-0030	Section: 3.6.1.3.1 PDF Page: 516 Comment: Please describe current regional trends in stock biomass and fishery landings/revenues. Section 3.6.1.1 merely presents data without discussing trends in biomass or fishery operations. For example stock assessments could	While one NY Bight project is not anticipated to require port upgrades, some ports have planned improvements to accommodate offshore wind activities across the region, which are described in Appendix D. The impact determination is consistent

Comment No.	Comment	Response
	be referenced to describe biomass trends for important fishery species and patterns of landings/revenues could be described for the top fisheries. If this section concludes that such trends would continue it should summarize what those trends are. Section: 3.6.1.3.1 PDF Page: 518 Comment: Under anchoring please reflect the use of various anchoring techniques such as spud barges and jack-up vessels similar to the text in section 3.6.1.4.1 on page 3.6.1-47. Spud cans have been shown to result in long-term alteration of the bottom which could present operational impacts to mobile gear fishing unless filled in appropriately. Section: 3.6.1.3.1 PDF Page: 519 Comment: Under noise please include a discussion of vibrations transmitted through the foundation and into the seabed. Similar to noise sediment vibration has been shown to result in negative impacts to sessile species particularly shellfish which could have indirect impacts on associated fisheries. We have provided references to relevant scientific research in previous comments on project-specific EISs (OW1 Atl Shores South). Section: 3.6.1.3.2 PDF Page: 520 Comment: Under port utilization please revise impacts from “minor” to “moderate” to be consistent with impact level definitions in Table 3.6.1-17. Consistent with that table port utilization would disrupt fishery operations in affected ports and vessels would have to adjust somewhat for such disruptions over the long term and throughout the operational life of the project depending on the port. Thus port utilization would disrupt normal and routine functions of various fisheries operating out of affected ports and such impacts would be moderate. Section: 3.6.1.3.2 PDF Page: 520 Comment: Under presence of structures please summarize potential impacts to fishery landings and revenues impacted by ongoing projects to accurately characterize baseline impacts using the ongoing and planned projects listed in Table 3.6.1-19. This is similar to the approach for summarizing the landings/revenue exposed of the six leases affected by this action and can facilitate tiering by providing a more accurate baseline for the evaluation of the no action alternative and cumulative impacts. Such data are readily available in the NMFS reports referenced in this section.	with other EISs. More details and analyses will be included at the project-specific, COP-level NEPA analysis. Information about jack-up and spud barge effects has been included in the discussion of anchoring impacts in Section 3.6.1.3. Text has been added to address noise vibration to the seafloor and its potential effects, including recent studies on shellfish (scallop).

Comment No.	Comment	Response
BOEM-2024-0001-0371-0031	Section: 3.6.1.4 PDF Page: 522 Comment: Under anchoring please note that spud barges and jack-up vessels could leave long-term changes to the sea floor that could result in effects to fishing operations unless mitigated through the use of scour or fill. Section: 3.6.1.4 PDF Page: 523 Comment: Under cable emplacement please revise the impact conclusion to moderate instead of minor to be consistent with Table 3.6.1-17. If there are permanent impacts as noted remedial mitigation is needed to eliminate measurable effects. Thus impacts are more appropriately characterized as moderate per Table 3.6.1-17. Section: 3.6.1.4.2 PDF Page: 526 Comment: Under presence of structures please quantify the revenue exposure of fisheries that would be affected by development of wind projects in the six lease areas or reference the tables summarizing revenue exposure in previous sections. A quantitative evaluation of economic impacts for each lease area and the collective areas as a whole is possible along with the qualitative discussion provided herin. The data are available on our website (https://www.fisheries.noaa.gov/resource/data/socioeconomic-impacts-atlantic- offshore-wind-development?utm_medium=email&utm_source=govdelivery) and should be incorporated into this DEIS. In a worst case scenario where all previous fishing activities would be displaced from the proposed lease areas historic revenue exposure could be used to assess potential impacts to commercial fishing operations under Alternative B absent any AMMMs. This would be consistent with an upper bound estimate of impacts found in conventional programmatic EISs and would facilitate tiering for future project-specific impact evaluations. Because the only data presented in this DEIS is from GARFO-permitted vessels such impacts would not be fully reflective of potential impacts to all affected fisheries and should be supplemented with additional sources for other affected fisheries. Also research by Changsheng Chen (https://tethys.pnnl.gov/publications/assessing-potential-impacts-offshore-wind-facilities-regional-sea-scallop-laval-early and https://s3.us-east-1.amazonaws.com/nefmc.org/Doc.14.a-UMASSD_WHOI_short_report_05_6_12_2021_revison.pdf) notes	BOEM has reviewed the impact determinations and found them to be consistent with other EISs. Further details will be provided during the project-specific, COP-level NEPA analysis. Revenue exposure cannot be quantified at the programmatic level, but will be addressed during the project-specific COP-level NEPA analysis. Chen 2021 has been cited in discussion about potential changes in larval distribution from the presence of structures.

Comment No.	Comment	Response
	that it is possible to estimate and evaluate oceanographic impacts on larval distribution. The results of that work and other similar research should be included in this section (or the no action alternative) as an example of the potential consequences to fishery resources and associated fisheries.[Embedded Hyperlink: https://s3.us-east-1.amazonaws.com/nefmc.org/Doc.14.a-UMASSD_WHOI_short_report_05_6_12_2021_revison.pdf)] Section: 3.6.1.4.3 PDF Page: 526 Comment: Please provide data such as cumulative fisheries revenue exposure tables and justification to support the conclusion that the six NY Bight projects when combined with other reasonable foreseeable actions would not "alter the overall state of commercial fisheries and for-hire recreational fishing." This section only includes qualitative general descriptions of potential impacts and does not attempt to quantify the cumulative impacts similar to how cumulative fishery impacts are assessed in project-specific EISs through cumulative revenue exposure tables. Such data are readily available to be integrated into the FEIS. To support the conclusions noted on this page and facilitate tiering of project-specific analysis additional information is needed even if such impacts would not change the overall qualitative impact ratings.	
BOEM-2024-0001-0371-0032	Section: 3.6.1.5 PDF Page: 528 Comment: Please include more detail describing how individual AMMMMs would avoid minimize mitigate or monitor impacts to commercial and for-hire fisheries or move this table below the supporting text that follows. Many of the proposed AMMMMs are not described in a manner that would identify how they relate to fishery operations and how they would avoid minimize mitigate or monitor fishery impacts. For example MUL-24 proposes an undefined adaptive management plan for NMFS trust resources to address as yet unknown issues or information rendering this AMMMM of minimal utility. Similarly MUL-5 proposes to use undefined equipment technology and best practices to reduce noise while MUL-26 proposes a generic environmental monitoring plan that could define mitigation and monitoring measures for all impacts to all resources affected by these leases. MUL-23 proposes adjustments to project design to minimize undefined impacts on environmental resources. However such adjustments are undefined and it is not	AMMM measures included in Alternative C in the Draft PEIS have been subcategorized into previously applied and not previously applied. In addition, some AMMM measures in the Draft PEIS are now recommended RPs for the Final PEIS; these RPs are not part of the Proposed Action. MUL-24 was removed from the Final PEIS based on comments received on the Draft PEIS. MUL-5, MUL-23, MUL-25, and MUL-26 are now recommended RPs for lessees to consider in their projects and can be found in Section 3.6.1.7. The table referred to in the comment is meant to be a summary of the AMMM measures for commercial fisheries and for-hire recreational fishing, and the full text of each AMMM measure is included in Appendix G.

Comment No.	Comment	Response
	likely that they could be made in a timely manner to avoid or minimize impacts to fishery operations given that many lessees have already proposed design parameters making project revisions later in the process (after final AMMMMs are defined through this action) costly and increasing the possibility for project delays. MUL-25 proposes consistent turbine grid layouts and at least one line of orientation spaced at least 1 nm apart. However individual lessees have already proposed different layouts and spacing even for adjacent leases while several do not include at least one line of orientation with turbines 1 nm apart which contradicts the purpose utility and efficacy of this AMMMM. The description of COMFIS-2 provides some detail that enables the reader to better understand how this measure would reduce impacts to fisheries. Additional detail of this nature or text similar to the descriptions of AMMMMs in Appendix G would help the reader understand how the AMMMMs could minimize impacts to fishery operations.	
BOEM-2024-0001-0371-0032-a	Section: 3.6.1.5 PDF Page: 528 Comment: (Table 3.6.1-20) Under COMFIS-1 please reference gear loss and damage compensation plans implemented in previous projects to maximize consistency and effectiveness of this AMMM. Absent further details it is possible that a lessee would implement a gear loss and damage compensation plan that would differ from previous measures implemented for approved projects which could cause confusion and increase burden on affected entities.	Thank you for your comment. COMFIS-1 is now an RP that recommends that lessees implement a gear loss and damage compensatory program and consult BOEM's draft guidance (https://www.boem.gov/sites/default/files/documents/renewable-energy/DRAFT%20Fisheries%20Mitigation%20Guidance%2006232022_0.pdf).
BOEM-2024-0001-0371-0032-b	Section: 3.6.1.5 PDF Page: 528 Comment: (Table 3.6.1-20) Under COMFIS-3 please provide additional detail about how such a monitoring plan would avoid or reduce impacts to scallop populations. We also recommend that a similar AMMMM be listed for other fishery populations that are affected by the lease areas particularly Atlantic surf clam and ocean quahog populations. Additional detail about the objectives of the monitoring plan and how/when it would be implemented is needed to evaluate its effectiveness. A monitoring plan would take time to develop execute and consider the results which would delay the implementation of any efforts to avoid or reduce impacts to scallop populations and	Based on comments received on the Draft PEIS, COMFIS-3 has been broadened to include the development and implementation of a Fisheries and Benthic Monitoring Plan.

Comment No.	Comment	Response
	targeted commercial fisheries. Given that many of the six NY Bight lessees have already proposed turbine layouts and spacing this AMMMM is unlikely to be effective at avoiding or reducing impacts because the resulting data may not be available in time to modify project proposals before the project is approved and construction would begin.	
BOEM-2024-0001-0371-0032-c	Section: 3.6.1.5 PDF Page: 528 Comment: (Table 3.6.1-20) Please include an AMMMM for fisheries operational monitoring program. COMFIS-5 proposes that lessees follow the Fisheries Survey Guidelines for monitoring. This guidance covers biological monitoring it does not cover fisheries operation monitoring. This would ensure impact evaluations are not exceeding what is anticipated and improve compensation mitigation by ensuring accurate predictions. NMFS staff may be able to provide technical assistance with the development of any fisheries operational monitoring program AMMMM	The suggested AMMM measure is beyond the scope of this PEIS and beyond BOEM's jurisdictional authority.
BOEM-2024-0001-0371-0032-d	Section: 3.6.1.5.1 PDF Page: 529 Comment: Please provide sufficient information to support and justify conclusions in this and subsequent sections (e.g. Section 3.6.1.5.4) that the proposed AMMMMs would reduce impacts on fisheries operations from all IPFs analyzed in Alternative B. While the additional discussion of how such AMMMMs relate to fishery operations and IPFs is helpful it is still unclear how such AMMMMs would eliminate the possibility of measurable effects and warrant changing impact conclusions from major to moderate. Even if measurable effects would be eliminated by the implementation of these AMMMMs this document does not guarantee that BOEM will require individual AMMMMs or all of these AMMMMs. Further the text in this section indicates that many would not affect impacts to fishery operations. As we have seen in previous projects the details of the compensation plans are needed to determine their effectiveness at mitigating income losses including whether all fishery operations are included in the compensation plan and eligibility requirements or limitations. Without additional detail including what actions each AMMMM may entail and when such actions would be taken (see comments above on specific AMMMMs)	Alternative C has been divided into two sub-alternatives: Sub-alternative C1 and Sub-alternative C2. Sub-alternative C1 analyzes the AMMM measures that BOEM has required as conditions of approval for previous activities proposed by lessees in COPs submitted for the Atlantic OCS or through related consultations. Sub-alternative C2 analyzes the AMMM measures under Sub-alternative C1 plus the AMMM measures that have not previously been applied. These AMMM measures that have not been previously applied may be less familiar to the offshore wind industry but could further avoid and minimize impacts on resources if applied. In addition, BOEM has reviewed all AMMM measures in Appendix G and identified measures that are RPs for the offshore wind industry. Any previously identified AMMM measure that is an RP has been removed from Alternative C. BOEM encourages lessees to analyze and consider implementing these RPs as they may further avoid and minimize impacts on resources. AMMM measures from Sub-alternative C1 or C2, or a combination of both, may be required as conditions of approval for activities proposed by lessees in project-specific COPs

Comment No.	Comment	Response
	it is difficult to evaluate the effectiveness of most of the proposed AMMMMs. Text in Section 3.6.1.5.4 concludes that the cumulative impacts of Alternative C would continue to be major because some operations would experience substantial disruptions indefinitely even with AMMMMs. For consistency this section should differentiate how this action for the six lease areas based on the proposed AMMMMs would not result in a similar outcome.	submitted for the six NY Bight lease areas. BOEM may also require additional or different measures based on future, site-specific NEPA analysis of project-specific COPs. The overall impact rating conclusions (as shown in PEIS Table 2-4 and Executive Summary Table ES-2) may not always be different under Alternative C when compared to Alternative B, while impacts for specific individual IPFs may be different. Depending on the specific IPF and the resource analyzed, there can be notable differences that change the impact determination for a specific IPF under Alternative C. However, the overall impact rating conclusions for the resource encompasses all IPF impact conclusions. The details of the analysis for each IPF and the justification for the overall impact conclusion for a resource are found in the Chapter 3 resource sections.
BOEM-2024-0001-0371-0033	Section: App G PDF Page: 215 Comment: (Table G-1) Please consider addressing the Environmental Justice Issue described in Table 3.6.4-3 "Potential job and income losses due to disruption of ocean and coastal areas (e.g. commercial fisheries for-hire recreational fishing recreational fishing/tourism) or cultural disruption (subsistence fishing and tribal fishing)" as an AMMM explicitly. The language under EJ compensation (AMMM EJ-4) reads as if commercial and for-hire fisheries do not need to be considered/qualify under this measure with this description of this compensation program: "to address disproportionate and adverse impacts on EJ populations directly tied to OCS offshore wind activities as related to the impact analysis discussed in the COP-specific NEPA review [Bold Italics: that has not been addressed through another mitigation measure.]" The language for COM-FIS 6 AMMM addresses only lost revenue from fishing not loss of jobs cultural disruption or other social factors. Therefore there is a gap in mitigation measures to address this impact. Please clarify that the scope of this compensation plan would cover these social factors. If not please consider a measure that would address this through fair mitigation/compensation.	Refer to response to comment BOEM-2024-0001-0319-0004.

Comment No.	Comment	Response
BOEM-2024-0001-0371-0034	Section 3.6.7 Other Uses Section: 3.6.7.1.6 PDF Page: 678 Comment: If this is including surveys in the entire GAA as stated the Seal Abundance and Turtle Ecology Surveys should be included.	Text has been added to Section 3.6.7.1.6 accordingly.
BOEM-2024-0001-0371-0035	Section: 3.6.7.3.1 PDF Page: 682 Comment: Please provide detail to support the claim that impacts of the No Action Alternative would be of lower intensity than those described for the cumulative impacts. Section: 3.6.7.3.2 PDF Page: 686 Comment: Please add "in survey strata" after sampling. (...by precluding NOAA survey vessels and aircraft from sampling [Bold: in survey strata];) Section: 3.6.7.3.2 PDF Page: 687 Comment: Please add that this implementation strategy also defines stakeholders partners and other ocean users that will be engaged throughout the process and identifies potential resources for successful implementation through the duration of wind energy development in the Northeast U.S. region.	Text has been revised in Section 3.6.7.3.1 in the Final PEIS to remove reference to the No Action Alternative being of lower intensity. The suggested changes to Section 3.6.7.3.2 have been made.
BOEM-2024-0001-0371-0036	Section: 3.6.7.4.1 PDF Page: 691 Comment: Please change "could" to "would" as there is no uncertainty. (One NY Bight project [Crossout: could] [Bold: would] affect survey operations by excluding certain portions of the lease area...) Section: 3.6.7.4.3 PDF Page: 692 Comment: Consider structuring this section in the same format as section 3.6.7.4.1. The labeling of each section is beneficial. Section: 3.6.7.4.4 PDF Page: 694 Comment: Please add " as well as on the commercial fisheries community" after research. (...on fisheries and protected-species research [Bold: as well as on the commercial fisheries community].)	The suggested changes to Sections 2.6.7.4.1, 3.6.7.4.3, and 3.6.7.4.4 have been made.
BOEM-2024-0001-0371-0037	Section: 3.6.7.5 PDF Page: 695 Comment: (Table 3.6.7-6) Please add "to mitigate impacts at the project and regional level." This information is included in the full description of the measure in Appendix G but is omitted here in the summary. It would be beneficial to include in this section as well. Section: 3.6.7.5.2 PDF Page: 697 Comment: Mention of the impact of OU-7 for six projects is omitted from this section please add.	The suggested change to Table 3.6.7-6 has been made. Discussion of OU-7 has been removed from Section 3.6.7.5.2.
BOEM-2024-0001-0371-0038	Section: 3.6.7.1.5 PDF Page: 667 Comment: Comment from NOAA/NOS/IOOS: Please replace the 3 instances of the word	The suggested change has been made.

Comment No.	Comment	Response
	"SeaSonde" on this page with the word "oceanographic". SeaSonde is the product name of just one kind of oceanographic HF-radar manufactured by CODAR Ocean Sensors Ltd. There are other types of oceanographic HF-radars produced by other manufacturers within the New York Bight geographic analysis area too so an inclusive term should be used instead of calling out one specific radar make/model.	
BOEM-2024-0001-0371-0043-b	Section: 3.6.7.5 PDF Page: 695 Comment: Comment from NOAA/NOS/IOOS: In Table 3.6.7-6 the Measure ID #OU-1 and OU-5 should be combined into a single Measure OU-1 in accordance with the COP Terms & Conditions of other OSW projects that have only required a single measure to mitigate interference to oceanographic high-frequency radars (HFRs) in the NOAA IOOS HFR National Network. The updated language to use for that unified Measure Summary which reflects the language used for other OSW geographic analysis area is as follows:[Italic: "This measure proposes establishing a mitigation agreement with the NOAA IOOS Office to reduce interference of project activities with oceanographic high-frequency radar systems. Options to mitigate these effects include sharing near real-time telemetry of ocean surface current and wave data into the public domain via NOAA IOOS and sharing information about the operational state of each WTG."] Section: 3.6.7.5.1 PDF Page: 695-696 Comment: Comment from NOAA/NOS/IOOS: (1) In accordance with the prior comment about combining AMMM measures #OU-1 and OU-5 into a single measure please delete all references to OU-5.(2) In the paragraph on "Presence of structures" replace the following sentences on AMMM measure OU-1:"AMMM measure OU-1 could result in the reduction of impacts for SeaSonde radar systems as data sharing (i.e. turbine orientation and rate nacelle bearing angles and other information about the operational state of each turbine) between turbine and radar operators would allow for the turbine information to be included in the radar signal processing system leading to more accurate radar readings. Modifying existing SeaSonde radars systems with signal processing enhancements and antennae modifications would increase the accuracy of radar readings for ocean current data gathering (Colburn et al. 2020). Wind farm curtailment agreements	See response to comment BOEM-2024-0001-0371-0052.

Comment No.	Comment	Response
	identified under AMMM measure OU-1 require wind farms to cease operations during emergency circumstances which would further reduce radar interference. "with the following text which reflects just a single measure to mitigate interference to oceanographic high-frequency radars (HFRs) in the NOAA IOOS HFR National Network in accordance with the COP Terms & Conditions of other OSW projects:[Italics: "AMMM measure OU-1 would require an oceanographic high-frequency (HF) radar data interference mitigation agreement between the NY Bight lessee and the Surface Currents Program of NOAA's IOOS Office. The lessee in consultation with the NOAA IOOS Office would be responsible for determining if a project would cause HF-radar interference to a degree to which HF-radar performance is no longer within the specific radar systems' operational parameters or fails to meet NOAA IOOS's objectives. The mitigation agreement would provide surface current and wave measurements and only if necessary further information about the operational state of the WTGs to NOAA IOOS to ensure that any impacts on HF-radar systems are adequately mitigated thereby reducing impacts on these radar systems."](3) In accordance with the prior comments on combining AMMM measures #OU-1 and OU-5 into a single measure please delete the (now redundant) paragraph relating to AMMM measure OU-5 that reads as follows: "AMMM measure OU-5 would require a high-frequency data interference mitigation agreement between the NY Bight lessee and the Surface Currents Program of NOAA's IOOS Office. The lessee would be responsible for determining if a project would cause radar interference to a degree to which radar performance is no longer within the specific radar systems' operational parameters or fails to meet NOAA IOOS's objectives. The mitigation agreement would allow for NOAA IOOS to ensure that any impacts on NOAA IOOS's radar systems are adequately mitigated thereby reducing impacts on these radar systems."	
BOEM-2024-0001-0371-0044	Appendix A Section: A.2 and A.3 PDF Page: 3 – 10 Comment: Comment from NOAA ONMS: Appendix A Consultations and Coordination. The areas currently under consideration for the proposed designation of the Hudson Canyon National Marine	Thank you for your comment. Once the COP is submitted for OCS-0537, BOEM will coordinate with U.S. Department of Commerce National Oceanic and Atmospheric Administration (NOAA) ONMS

Comment No.	Comment	Response
	Sanctuary will be directly adjacent to parts of the proposed lease areas. There are potential impacts to sanctuary resources during construction and installation for the project location OCS-0537. As such the NOAA Office of National Marine Sanctuaries (ONMS) should be a consulting agency.	related to the proposed designation of the Hudson Canyon National Marine Sanctuary as part of the COP NEPA EIS analysis.
BOEM-2024-0001-0371-0045	Appendix C Section: Appendix C: Tiering Guidance PDF Page: Global Comment: (Table C-1) It would be helpful for readers and provide greater guidance to the COP-specific NEPA analysis if BOEM included in this section a list of all anticipated COP-specific activities. Each "Impact Analysis" section in Table C-1 asserts that COP-specific NEPA analysis will include quantitative impact analysis based on the relevant IPFs associated with disturbance from each "offshore activity." Specific reference to all the anticipated offshore activities will provide greater guidance for what should be expected in the COP-specific NEPA analysis which will reference this programmatic.	Appendix C is intended to provide high-level information regarding the type of information BOEM anticipates could be incorporated by reference and the additional analysis that is expected at the COP-level NEPA. However, each COP will need to be evaluated to determine what type of activities are proposed and to what extent the PEIS can be incorporated by reference. BOEM is required to analyze each COP as proposed by the developer and does not make decisions on specific offshore activities unless the activities are included in the COP. Examples of COP-specific NEPA analysis can be found in the Final EISs for Empire Wind (https://www.boem.gov/renewable-energy/state-activities/empire-wind), Ocean Wind 1 (https://www.boem.gov/renewable-energy/state-activities/ocean-wind-1), Vineyard Wind 1 (https://www.boem.gov/renewable-energy/state-activities/vineyard-wind-1), Sunrise Wind (https://www.boem.gov/renewable-energy/state-activities/sunrise-wind), and Revolution Wind (https://www.boem.gov/renewable-energy/state-activities/revolution-wind).
BOEM-2024-0001-0371-0046-a	Section: PDF Page: General Comment: Please include an AMMMM that requires the lessee to monitor changes to fishery operations within the lease area as a result of project-specific operations and the effectiveness of any fishery mitigation/compensation plans.	The suggested AMMM measure is beyond the scope of this PEIS and beyond BOEM's jurisdictional authority.
BOEM-2024-0001-0371-0046-b	Section: PDF Page: General Comment: Please include an AMMMM that requires the lessee to mitigate the social and cultural impacts to fishing communities associated with changes to fishing operations as a result of project-specific operations. This could include community development funds or other measures that could be combined with an AMMMM associated with fishery mitigation/compensation.	The proposed AMMM measure goes beyond BOEM's jurisdictional authority with regard to community development funds. Specific fisheries compensatory mitigation would occur at the project-specific COP NEPA review and consultations stage. Environmental Justice populations who fish are covered by other AMMM measures and RPs (see specifically EJ-1a and EJ-3).

Comment No.	Comment	Response
BOEM-2024-0001-0371-0046-c	Appendix G Section: PDF Page: General Comment: A "plan" is a detailed proposal for conducting actions or activities including how what where and when certain actions are being proposed how these actions were developed and decisions related to the actions were made. A plan or plans should be submitted during the regulatory/consultation processes for interagency review. "Reports" are accounts of actions that have been undertaken or observed; a report occurs after an action has taken place (or is underway). At present it is unclear how BOEM can evaluate the effectiveness of a plan at avoiding/minimizing impacts versus requiring substantive avoidance/minimizing of impacts via an AMMMM. Section: PDF Page: General Comment: Noting that a separate effort is underway to evaluate the AMMMs in the context of the planned framework programmatic ESA consultation and that we will be continuing to work with BOEM on the ones relevant to protected species and habitats in that context. Section: PDF Page: General Comment: A number of AMMMs appear to be "voluntary" or require the "consideration" (but not implementation) of planning that could avoid/minimize impacts. We recommend that these AMMMMs be modified to be required so that the effectiveness of these measures at avoiding/minimizing impacts can be analyzed. If they remain voluntary then the effects analysis must clearly indicate that the voluntary measure will have no effect on mitigating adverse effects. We recommend all AMMMMs be considered mandatory and as the introduction to this section states exceptions can be described and explained if "During NEPA review of individual COPs BOEM may identify AMMM measures that do not apply to a specific COP if it can be demonstrated that implementation is not warranted or effective." (p G-1) Section: PDF Page: General Comment: Please include an AMMMM that requires the lessee to monitor changes to fishery operations within the lease area as a result of project-specific operations and the effectiveness of any fishery mitigation/compensation plans. Section: PDF Page: General Comment: Please include an AMMMM that requires the lessee to mitigate the social and cultural impacts to fishing communities associated with changes to fishing operations as a result of project-	Based on comments received on the Draft PEIS, BOEM has reviewed all draft measures and categorized them as 1) AMMM measures previously applied as Terms and Conditions (T&Cs) or through other mechanisms such as a Biological Opinion or Memorandum of Agreement, 2) AMMM measures not previously applied as T&Cs, and 3) RPs. BOEM encourages lessees to analyze and consider implementing these RPs as they may further avoid and minimize impacts. Furthermore, these RPs are also not part of the Proposed Action, Alternative C, which analyzes only AMMM measures previously applied as T&Cs, and AMMM measures not previously applied as T&Cs. Regarding specific recommendations for new mitigation measures, monitoring changes to fishery operations is beyond the scope of this PEIS; mitigation of social and cultural impacts from project-specific operations occurs through fisheries compensatory mitigation (COMFIS-6), and there is one RP to encourage supporting compensatory funding (COMFIS-7). Note that COMFIS-1 (Compensation for gear loss and damage) was combined into COMFIS-6. BOEM continues to do research and understand potential socio-economic impacts of these projects. Avoidance of sensitive habitats, estuarine environments, and embayments during project activities such as plowing, trenching, and dredge material disposal will be determined at the project-specific stage in EFH consultations.

Comment No.	Comment	Response
	specific operations. This could include community development funds or other measures that could be combined with an AMMMM associated with fishery mitigation/compensation. Section: PDF Page: General Comment: Please include an AMMMM that requires construction activities such as plowing trenching and dredging avoid known sensitive habitats and features such as SAV shellfish NJDEP-designed prime fishing grounds etc. Section: PDF Page: General Comment: Please include an AMMMM that requires dredge material disposal activities avoid known sensitive habitats and features such as SAV shellfish NJDEP-designed prime fishing grounds wetlands etc. Section: PDF Page: General Comment: Please include an AMMMM that requires avoiding development/construction in estuarine environments and embayments.	
BOEM-2024-0001-0371-0046-d	Section: PDF Page: General Comment: Please include an AMMMM that requires construction activities such as plowing trenching and dredging avoid known sensitive habitats and features such as SAV shellfish NJDEP-designed prime fishing grounds etc.	Thank you for your comment. Avoidance of specific sensitive habitats will occur at the project-specific level consultations.
BOEM-2024-0001-0371-0046-e	Section: PDF Page: General Comment: Please include an AMMMM that requires dredge material disposal activities avoid known sensitive habitats and features such as SAV shellfish NJDEP-designed prime fishing grounds wetlands etc.	Thank you for your comment. Avoidance of specific sensitive habitats will occur at the project-specific level consultations.
BOEM-2024-0001-0371-0046-f	Section: PDF Page: General Comment: Please include an AMMMM that requires avoiding development/construction in estuarine environments and embayments.	Thank you for your comment. Avoidance of specific sensitive habitats will occur at the project-specific level consultations.
BOEM-2024-0001-0371-0047	Section: PDF Page: 210 Comment: BEN 1: Relocated boulders represent a permanent change to benthic habitat. Please include the effect of boulder relocation in the benthic habitat monitoring plan. Section: PDF Page: 210 Comment: BEN-1: NMFS recommends modifying this AMMM. In order to minimize impacts of boulder relocation on EFH boulders should be relocated to the periphery of the nearest delineated habitat of similar complexity and boulder density. It is unclear why minimization of relocation distance outside of the required relocation zone would equate to a minimized impact to EFH. Section: PDF Page: 210 Comment: BEN-1: Since lessees are	Thank you for your comment. Please refer to the response to comment BOEM-2024-0001-0439-0037. Minor edits have been made to BEN-1. A more detailed measure could be developed in the future as a result of project-specific information and consultations.

Comment No.	Comment	Response
	being instructed to avoid boulders please include in this AMMM measure that if avoidance is not possible the lessee must provide rationale why avoidance was not possible.	
BOEM-2024-0001-0371-0048-a	Section: PDF Page: 211 Comment: Under COMFIS-1 please consider referencing any boulders relocated as a result of project operations (e.g. cable emplacement and wind turbine installation preparation). Marked or unmarked bounders relocated as a result of the project construction activities can lead to gear loss and damage and associated reduction in fishery revenue. This impact should also be considered as part of this AMMM measure and not just be limited to manmade infrastructure components (e.g. mattresses cables turbines) owned by the lessee. We suggest editing the last sentence in the AMMM to read as follows: "For example the Lessee should consider compensation for damaged gear resulting from interactions between the fishing industry and non-marked/non-charted or marked/charted property (e.g. concrete mattresses) of the Lessee as well as gear damaged by charted and non-charted boulders that are relocated as result of project activities."	COMFIS-1 has been combined into COMFIS-6, Fisheries compensatory mitigation. AMMM measures BEN-1 and MUL-40 (previously NAV-1) also contain requirements for boulder avoidance, identification, relocation, and reporting. Nautical maps will be updated with the concrete mattress location. Cable, scour protections, and offshore wind infrastructure in general will all be charted.
BOEM-2024-0001-0371-0048-b	Section: PDF Page: 211 Comment: Please consider modifying COMFIS-3 or creating a new AMMM measure to include a monitoring program for other important fishery resources besides scallops located within the lease areas particularly Atlantic surf clam and ocean quahog resources. COMFIS-3 should also reference and be consistent with BOEM fisheries survey guidelines to the extent that they do not conflict with the intent and purpose of the AMMMM itself. Finally this should reflect and/or reference other similar AMMMMs such as COMFIS-5 and MUL-26.	Thank you for your comment. Based on comments received on the Draft PEIS, COMFIS-3 has been broadened to include a Fisheries and Benthic Monitoring Plan, which includes Atlantic sur clam and ocean quahog. This plan includes fisheries and benthic resources generally. See response to comment BOEM-2024-0001-0371-0048-a for more information on the distinction between COMFIS-3, COMFIS-5, and MUL-26.
BOEM-2024-0001-0371-0048-c	Section: PDF Page: 211 Comment: COM-FIS-4 Fisheries Mitigation states that there is no anticipated enforcing agency because it is "voluntary". However this mitigation measure is critical as it effects the health safety and economic viability of individual operators who have historically used this area. This is an important AMMMM and should be enforced; it should not be a voluntary measure. Coexistence with existing uses including fisheries is a goal of both of	Thank you for your comment. Based on comments received on the Draft PEIS, BOEM has reviewed all draft measures and categorized them as 1) AMMM measures previously applied as T&Cs or through other mechanisms such as a Biological Opinion or Memorandum of Agreement, 2) AMMM measures not previously applied as T&Cs, and 3) RPs. BOEM encourages lessees to analyze and consider implementing these RPs as they may further avoid and minimize impacts. Furthermore, these RPs are also not part of

Comment No.	Comment	Response
	our agencies with respect to offshore wind development but it would be increasingly limited without this AMMMM being enforceable.	the Proposed Action, Alternative C, which analyzes only AMMM measures previously applied as T&Cs and AMMM measures not previously applied as T&Cs. COMFIS-4 has been classified as an RP. Project-specific mitigation measures to reduce impacts will be considered at the project stage.
BOEM-2024-0001-0371-0048-d	Section: PDF Page: 211-212 Comment: COMFIS-4: Several of the static cable design elements and project design elements outlined in this AMMMM are crucial for reducing impacts and improving safety at sea. These planning elements should not be considered "voluntary"; NMFS recommends requiring lessees to provide explanations of their efforts to incorporate project and cable design elements; any instances where the Lessee believes there is technical (and/or economic) infeasibility should be supported by a technical feasibility analysis as appropriate for review by BOEM. In addition NMFS recommends emphasizing the value of shared cable corridors where technically and economically feasible to minimize the total area disturbed. This will have benefits to commercial fisheries Essential Fish Habitat and other resources.	Thank you for your comment. MUL-18 (Shared transmission corridor) is an RP encouraging lessees to coordinate transmission infrastructure among projects.
BOEM-2024-0001-0371-0048-e	Section: PDF Page: 212 Comment: Under COMFIS-5 please clarify the relationship of this AMMM measure with other related AMMMMs such as COMFIS-3 and MUL-26. Language listed in MUL-26 should be incorporated into other similar AMMMMs such as this one when possible. It is important to note that unlike COMFIS-3 and MUL-26 compliance with this AMMMM and BOEM's survey guidance is voluntary. We recommend that all surveys conducted to support individual projects should be consistent with BOEM's guidance and the ROSA fisheries survey framework guidelines.	Based on comments received on the Draft PEIS, BOEM has reviewed all draft measures and categorized them as 1) AMMM measures previously applied as T&Cs or through other mechanisms such as a Biological Opinion or Memorandum of Agreement, 2) AMMM measures not previously applied as T&Cs, and 3) RPs. BOEM encourages lessees to analyze and consider implementing these RPs as they may further avoid and minimize impacts. Furthermore, these RPs are also not part of the Proposed Action, Alternative C, which analyzes only AMMM measures previously applied as T&Cs and AMMM measures not previously applied as T&Cs. COMFIS-3 is an AMMM measure requiring lessees to develop and implement a Fisheries and Benthic Monitoring Plan. COMFIS-5 (Fisheries Survey Guidelines) and BEN-3 (Benthic Survey Guidelines) are RPs that encourage the lessee to follow BOEM's existing guidelines when developing the monitoring plan. MUL-26 has been revised in response to comments received on

Comment No.	Comment	Response
		the Draft PEIS. MUL-26 (Coordination for regional monitoring and surveys) is an RP that is not meant to be a duplicate requirement. This RP now encourages coordination for regional monitoring and surveys.
BOEM-2024-0001-0371-0048-f	Section: PDF Page: 212 Comment: COMFIS - 5. NMFS continues to be concerned about the potential for some survey methods/gear types to result in interactions with protected species including the potential for lethal entanglement. We encourage BOEM to develop mandatory AMMMs that would ensure that fisheries surveys are undertaken in a way that minimizes such risk (e.g. avoiding gill nets utilizing ropeless/on-demand technology for trap/pot surveys) and ensures that necessary ESA and/or MMPA consultations/authorizations are in place prior to any such surveys that may affect protected species.	The Fishery Survey Guidelines (https://www.boem.gov/sites/default/files/documents/about-boem/Fishery-Survey-Guidelines.pdf) already account for use of ropeless technology, especially in proximity to protected species. In reviews for COP surveys with lessees and contractors, BOEM no longer supports the use of gillnets.
BOEM-2024-0001-0371-0048-g	Section: PDF Page: 212 Comment: COMFIS-6: The AMMM states "For losses to commercial and for-hire recreational fishermen the Fund must be based on the revenue exposure for fisheries." Exposure analysis does not cover all potential losses to fishing industry. Developers should be directed to analyze losses beyond historic fishing revenue within the lease areas ("revenue exposure") and work with fishing industry on potential monetary impacts beyond lost revenue - for example transit impacts and additional costs.	Thank you for your comment. Transit impacts and additional costs would come out through the claims process, not through the PEIS. Project details, such as design, will be analyzed during the COP NEPA stage. To the best of BOEM's abilities, development of corridors and transit access in lease and between leases to maintain fishing operations and vessel transit will be completed. BOEM is working with navigation subject matter experts and USCG to develop the corridors and transit access.
BOEM-2024-0001-0371-0049-a	Section: PDF Page: 216 Comment: MM-2 & MM-3: We recommend requiring real-time and long-term PAM monitoring plans that are submitted to BOEM BSEE and NMFS prior to implementation. The plan or plans could incorporate best practices as outlined by the RWSC. Also please consider requiring the use of passive acoustic receivers for acoustic telemetry as instruments to be included in the PAM monitoring plans (like STF-1 but required).	Based on comments received on the Draft PEIS, BOEM has reviewed all draft measures and categorized them as 1) AMMM measures previously applied as T&Cs or through other mechanisms such as a Biological Opinion or Memorandum of Agreement, 2) AMMM measures not previously applied as T&Cs, and 3) RPs. BOEM encourages lessees to analyze and consider implementing these RPs as they may further avoid and minimize impacts. Furthermore, these RPs are also not part of the Proposed Action, Alternative C, which analyzes only AMMM measures previously applied as T&Cs and AMMM measures not previously applied as T&Cs. BOEM's review and revision of AMMM measures has resulted in MM-2 becoming an RP. MM-3 has been revised with additional details about long-term passive acoustic monitoring (PAM).

Comment No.	Comment	Response
BOEM-2024-0001-0371-0049-b	Section: PDF Page: 216 Comment: MM-5: We recommend adding NMFS as a federal agency to review and provide comments on a lessee's NARW Strike Management Plan (only BOEM and BSEE are listed in the Description).	Thank you for your comment. BOEM will continue discussions with NMFS. Further communication and coordination will occur at the project-specific stage.
BOEM-2024-0001-0371-0049-c	Section: PDF Page: 216-217 Comment: MMST-1: Please be consistent when naming the federal agencies that can review and provide comments on a submitted Alternative Monitoring Plan. Sometimes NMFS BOEM and BSEE are listed (in the Description) and other times only BOEM and BSEE are listed. In any location the agencies are named please consistently list NMFS BOEM and BSEE as the federal agencies that can review and comment on a submitted Alternative Monitoring Plan.	Thank you for your comment. BOEM will continue discussions with NMFS. Further coordination and communication will occur at the project-specific stage.
BOEM-2024-0001-0371-0049-d	Section: PDF Page: 220-221 Comment: MMST-12: We recommend requiring something similar to an Alternative Monitoring Plan for geophysical surveys similar to MMST-1 when surveys are conducted in poor sighting conditions or at night.	Thank you for your comment. MMST-12 has been updated to include information about an Alternative Monitoring Plan for geophysical surveys.
BOEM-2024-0001-0371-0049-e	Section: PDF Page: 221-222 Comment: MMST-14: We recommend requiring something similar to an Alternative Monitoring Plan for vessel strike mitigation similar to MMST-1 when vessels are transiting in poor sighting conditions or at night.	Thank you for your comment. MMST-14 was updated to include any construction, operations, or decommissioning vessel transits associated with the project. Please see revised AMMM measure in the Final PEIS for additional detail.
BOEM-2024-0001-0371-0050-a	Section: PDF Page: 226 Comment: MUL-19: Please indicate the duration of the cable monitoring. Recommend monitoring for the lifetime of the project.	MUL-19 has been revised to clarify that monitoring would occur every 3 years until projects are decommissioned.
BOEM-2024-0001-0371-0050-b	Section: PDF Page: 225 Comment: MUL-12: If ecological design elements are incorporated please include the design specifications as part of the benthic and fisheries monitoring plans.	Thank you for your comment. Details regarding ecological design elements are project-specific and will be analyzed at the subsequent COP NEPA stage if proposed as part of the COP.
BOEM-2024-0001-0371-0050-c	Section: PDF Page: 225 Comment: MUL-15: We have several recommendations for marine debris monitoring: Please include the development of a marine debris mitigation plan and note the duration for the marine debris monitoring; we recommend monitoring for the lifetime of the wind project. In addition to annually monitoring at least 10 of the WTGs located closest to shore we recommend that each WTG should be inspected by ROV divers or	MUL-15 has been deleted and incorporated into MUL-1 and now clarifies that surveying and reporting must occur for the first 3 years following COP approval and every 5 years thereafter. MUL-1 also clarifies that lessees may conduct surveys by remotely operated vehicles, divers, or other means, but any images or videos taken during the survey must be submitted with the annual

Comment No.	Comment	Response
	other means at minimum once every 3 years. The WTG marine debris monitoring plan should clearly explain how each WTG will be routinely inspected and results of these inspections can be presented in annual monitoring reports. Please include any gear markings in the monitoring reports which will be important for determining their provenance.	report. BOEM does not plan to require monitoring for 10 WTGs closest to shore at this programmatic stage.
BOEM-2024-0001-0371-0050-d	Section: PDF Page: 225 Comment: MUL-18: As noted in out comment on COMFIS-4 NMFS recommends emphasizing the value of shared cable corridors where technically and economically feasible to minimize the total area disturbed. This will have benefits to commercial fisheries as well as to minimizing impacts to benthic habitat and Essential Fish Habitat. Effort to incorporate these planning elements should not be considered "voluntary"; NMFS recommends requiring lessees to provide explanation of their efforts to incorporate project and cable design elements; any instances where the Lessee believes there is technical (and/or economic) infeasibility should be supported by a technical feasibility analysis as appropriate for review by BOEM.	Based on comments on the Draft PEIS, BOEM has reviewed all AMMM measures, which resulted in many revisions that included separating AMMM measures that have and have not been previously applied; BOEM believes these are all feasible. In addition, several AMMM measures were reclassified as RPs in the Final PEIS. BOEM encourages lessees to analyze and consider implementing these RPs as they may further avoid and minimize impacts. These RPs are also not part of the Proposed Action. MUL-18 is an RP. Additionally, Chapter 2 of the PEIS provides a discussion of transmission configuration options, and notes that transmission infrastructure may be developed, owned, and operated by either a transmission developer or a lessee. In the future, new projects may wish to coordinate with an existing project for purposes of running in parallel to existing infrastructure. BOEM regulations (30 CFR 585.200(b)) state, "A lease issued under this part confers on the lessee the rights to one or more project easements without further competition for the purpose of installing gathering, transmission, and distribution cables; pipelines; and appurtenances on the OCS as necessary for the full enjoyment of the lease." Although BOEM cannot limit a lessee's right to a project easement for submarine cables; BOEM can analyze in the project-specific COP NEPA documents the use of less impactful and/or shared cable corridors, where technically and economically feasible, to minimize resource impacts. Therefore, BOEM may condition COP approval of a project on the easement to an existing offshore transmission point of interconnection (POI).

Comment No.	Comment	Response
BOEM-2024-0001-0371-0050-e	Section: PDF Page: 223 Comment: MUL-2: Habitat data collected from the project should be used to develop all plans including the anchoring plan referenced in this AMMMM; these plans should be submitted as part of the regulatory/consultation processes. The developer should collected habitat data and assess how they will avoid/minimize benthic impacts from anchoring. As written this is a post-ROD measure and the effectiveness of this measure cannot be analyzed.	Thank you for your comment. Fisheries and Benthic Monitoring Plan details can be found in COMFIS-3.
BOEM-2024-0001-0371-0051-a	Section: PDF Page: 234-235 Comment: MUL-38: We recommend adding NMFS as a federal agency that can review and provide feedback on a lessee's noise mitigation plan.	Thank you for your comment. After additional consideration, BOEM has removed MUL-38. Should BOEM consider this at a later date, it will consider adding NMFS as a federal agency that can review and provide feedback on a lessee's noise mitigation plan.
BOEM-2024-0001-0371-0051-b	MUL-12: Where applicable ASGA supports the use of nature-inclusive design elements to possibly provide benefits to marine habitats over traditional materials.	Thank you for your comment.
BOEM-2024-0001-0371-0051-c	Section: PDF Page: 227 Comment: MUL-23: As described above this appears to be a voluntary AMMMM or requires "consideration" but not implementation. This AMMMM should be changed to require the avoidance of known sensitive habitats or features including SAV the Mid-Shelf Scarp NJDEP-designated prime fishing areas hard bottom etc. Additionally this AMMMM should include language regarding reducing a project's footprint within a lease area in order to avoid landscape-scale/large sensitive habitats or features.	Thank you for your comment. MUL-23 has been classified as an RP in the Final PEIS. BOEM encourages lessees to analyze and consider implementing these RPs as they may further avoid and minimize impacts. These RPs are not part of the Proposed Action.
BOEM-2024-0001-0371-0051-d	Section: PDF Page: 227 Comment: Please consider revising MUL-24 to include TOYRs for non-protected species including important commercial and recreational species. TOYRs are useful at minimizing impacts to sensitive life stages of all NOAA trust resources especially larvae juveniles and spawning adults. Minimizing impacts to marine resources will also reduce indirect impacts to commercial and for-hire recreational fisheries and private recreational anglers.	Thank you for your comment. After further consideration, MUL-24 has been deleted because it is covered in other AMMM measures and through consultations.

Comment No.	Comment	Response
BOEM-2024-0001-0371-0051-e	Section: PDF Page: 227 Comment: MUL-24: It is unclear how this adaptive management plan will align with NMFS consultations. Please clarify how this intersects with the consultations and how NMFS would be consulted on this plan.	Thank you for your comment. After further consideration, MUL-24 has been removed.
BOEM-2024-0001-0371-0051-f	Section: PDF Page: 227-228 Comment: MUL-26: Please include in the monitoring plans efforts to evaluate the: effects of benthic habitat modification; effects of boulder relocations; effects of altered hydrodynamics; effects of ecological design elements if used; effects of impingement/entrainment at cooling water intake systems; thermal effects of water discharge at cooling water intake systems	MUL-26 has been revised in response to comments to encourage lessees to coordinate monitoring and survey efforts, meet regional data requirements and standards proposed by the Responsible Offshore Science Alliance (ROSA) and Regional Wildlife Science Collaborative (RWSC), and make results from monitoring publicly available. Additionally, MUL-23 has been classified as an RP in the Final PEIS. BOEM encourages lessees to analyze and consider implementing these RPs as they may further avoid and minimize impact. These RPs are not part of the Proposed Action.
BOEM-2024-0001-0371-0051-g	Section: PDF Page: 227-228 Comment: MUL-26: Please specify what the "other resource-specific monitoring plans" are in order to aid review of environmental monitoring plans. Baseline data collection should also be required as part of a monitoring plan.	MUL-26 has been revised in response to comments to encourage lessees to coordinate monitoring and survey efforts, meet regional data requirements and standards proposed by ROSA and RWSC, and make results from monitoring publicly available. Additionally, MUL-23 has been classified as an RP in the Final PEIS. BOEM encourages lessees to analyze and consider implementing these RPs as they may further avoid and minimize impact. These RPs are not part of the Proposed Action.
BOEM-2024-0001-0371-0051-h	Section: PDF Page: 229 Comment: MUL-30: If this AMMMM is meant to apply to both sea turtles and marine mammals please add marine mammals in to the description here; currently specifications only refer to protections for sea turtles. Or clarify that strike avoidance and shutdown zones during geophysical surveys to avoid impacts to marine mammals are covered in a different AMMMM.	MUL-30 was removed from the Final PEIS because it overlaps with MMST-12.
BOEM-2024-0001-0371-0051-i	Please include an AMMM related to avoiding construction activities during sensitive times of year for various species (time-of-year restrictions) such as migratory fishes (inshore/estuarine) longfin squid spawning (offshore/nearshore) winter flounder spawning/egg/larvae (estuarine) etc.	Time of year restrictions are determined at the project-specific stage through EFH consultation.
BOEM-2024-0001-0371-0052	Section: PDF Page: 235 Comment: In accordance with the prior comment on Section 3.6.7 about combining measures #OU-1 and OU-	The suggested revisions to the AMMM measure are too strict at this programmatic level review. This AMMM measure only

Comment No.	Comment	Response
	5 into a single measure replace the entry in the "Description" cell associated with Measure ID OU-1 with the following unified language (that has been previously applied as a COP Term & Condition) that was developed by the IOOS Surface Currents Program in consultation with NOAA's Office of General Counsel and provided to BOEM's Andrew McGuffin and team: [Italics: The Lessee will enter into a mitigation agreement with NOAA to mitigate operational impacts on oceanographic high-frequency (HF) radars including the following measures:1 HF-radar Interference Analysis and Mitigation. The Lessee's Project has the potential to interfere with oceanographic high-frequency (HF) radar systems in the U.S. Integrated Ocean Observing System (IOOS) which is managed by the IOOS Office within the National Oceanic and Atmospheric Administration (NOAA) pursuant to the Integrated Coastal and Ocean Observation System Act of 2009 (Pub. L. No. 111-11) as amended by the Coordinated Ocean Observation and Research Act of 2020 (Pub. L. No. 116-271 Title I) codified at 33 U.S.C. 36013610 (referred to herein as "IOOS HF-radar"). IOOS HF-radar measures the sea state including ocean surface current velocity and waves in near real time. These data have many vital uses ("mission objectives") including tracking and predicting the movement of spills of hazardous materials or other pollutants monitoring water quality and predicting sea state for safe marine navigation. The U.S. Coast Guard also integrates IOOS HF-radar data into its Search and Rescue systems. The Lessee's Project is within the measurement range of IOOS HF-radar systems. 1.1 Mitigation Requirement Due to the potential interference with IOOS HF-radar and the risk to public health safety and the environment the Lessee must mitigate unacceptable interference with IOOS HF-radar from the Lessee's Project. Interference must be mitigated before commissioning the first WTG or blades start spinning whichever is earlier and interference mitigation must continue throughout operations and decommissioning until the point of decommissioning where all rotor blades are removed. Interference is considered unacceptable if as determined by BOEM in consultation with NOAA's IOOS Office IOOS HF-radar performance falls or may fall	requires lessees to coordinate with radar operators for impact assessment. Analysis of project-specific design during subsequent COP NEPA analysis would be required to determine whether mitigation is required. BOEM has merged OU-1 and OU-5 with some minor revisions.

Comment No.	Comment	Response
	outside any of the specific radar systems' operational parameters or fails or may fail to meet IOOS's mission objectives. 1.2 Mitigation Review. The Lessee must submit to BOEM documentation demonstrating how it will mitigate unacceptable interference with IOOS HF-radar systems in accordance with the Mitigation Requirement. The Lessee must submit this documentation to BOEM (renewable_reporting@boem.gov) at least 120 days prior to commissioning the first WTG or blades start spinning whichever is earlier. If after consultation with the NOAA IOOS Office BOEM deems the mitigation acceptable the Lessee must conduct activities in accordance with the proposed mitigations. If after consultation with NOAA IOOS Office BOEM deems the mitigation unacceptable the Lessee must resolve all comments on the documentation to BOEM's satisfaction. 1.3 Mitigation Agreement. The Lessee is encouraged to enter into an agreement with the NOAA IOOS Office to implement mitigation measures and any such Mitigation Agreement may satisfy the requirement to mitigate unacceptable interference with IOOS HF-radar. The point of contact for the development of a Mitigation Agreement with the NOAA IOOS Office is the Surface Currents Program Manager whose contact information is available at https://ioos.noaa.gov/about/meet-the-ioos-program-office/ and upon request from BOEM. If the parties reach a mitigation agreement the Lessee must submit it to BOEM at renewable_reporting@boem.gov. The Lessee may satisfy its obligations under Section 1.2 by providing BOEM with an executed Mitigation Agreement between the Lessee and NOAA IOOS. If there is any discrepancy between Section 1.2 and the terms of a Mitigation Agreement the terms of the Mitigation Agreement will prevail. 1.4 Mitigation Data Requirements Mitigation required under Section 1.2 must address the following: • 1.4.1 Before commissioning the first WTG or blades start spinning whichever is earlier and continuing throughout the life of the Lessee's Project until the point of decommissioning when all rotor blades are removed the Lessee must make publicly available via NOAA IOOS near real-time accurate numerical telemetry of	

Comment No.	Comment	Response
	surface current velocity wave height wave period wave direction and other oceanographic data measured at the Lessee's Project locations selected by the Lessee in coordination with the NOAA IOOS Office.1.4.2 • 1.4.2 If requested by the NOAA IOOS Office the Lessee must share with IOOS accurate numerical time-series data of blade rotation rates nacelle bearing angles and other information about the operational state of each WTG in the Lessee's Project to aid interference mitigation. 1.5 Additional Notification and Mitigation • 1.5.1 If at any time the NOAA IOOS Office or an HF-radar operator informs the Lessee that the Lessee's Project will cause unacceptable interference to an HF-radar system the Lessee must notify BOEM of the determination and propose new or modified mitigation pursuant to Section 1.5.2 as soon as possible and no later than 30 days from the date on which the determination was communicated. • 1.5.2 If a mitigation measure other than that identified in Section 1.2 is proposed then the Lessee must submit information on the proposed mitigation measure to BOEM for its review and concurrence. If after consultation with the NOAA IOOS Office BOEM deems the mitigation acceptable the Lessee must conduct activities in accordance with the proposed mitigations. The Lessee must resolve all comments on the documentation to BOEM's satisfaction in consultation with the NOAA IOOS Office prior to implementation of the mitigation.] Section: PDF Page: 235Comment: Add a check to the cell [Italics: "Previously Applied as a COP Term and Condition" associated with Measure ID OU-1. This is in accordance with the prior comment about replacing the entry in this Measure's "Description" cell with language from previous COPs that unifies measures OU-1 and OU-5.] Section: PDF Page: 236Comment: [Italics: Delete the row of the table associated with Measure ID OU-5 once you have updated the entry for OU-1 according to comment immediately above. Comment No.	Comment	Response
	done for other OSW geographic analysis areas so OU-5 may now be deleted]	
BOEM-2024-0001-0371-0053	Section: PDF Page: 237 Comment: Please include AMMM measures that address private angler recreational fishing effects. For example private angler fishing seasons especially in NY and NJ go beyond the Rec-1 AMMM seasonality of Memorial Day to labor day. Key recreational species such as striped bass are important to private anglers fishing offshore and marinas and bait and tackle shops and the season extends through the fall into November. Please see the following resources from Hurricane Sandy in NY/NJ for economic impact of disruptions to bass species' prime fishing seasons. https://www.st.nmfs.noaa.gov/Assets/economics/documents/sandy/social-econ-hurricane-sandy.pdf[Embedded Hyperlink: https://www.st.nmfs.noaa.gov/Assets/economics/documents/sandy/social-econ-hurricane-sandy.pdf] Section: PDF Page: 237Comment: Please include AMMM measure that addresses avoiding and mitigating impacts to public fishing access sites that may overlap with onshore offshore wind infrastructure. These sites are not only important for recreation and tourism but minority populations and/or subsistence fishing. Public fishing site register can be found here: https://www.fisheries.noaa.gov/recreational-fishing-data/public-fishing-access-site-register. Some states also have databases on public fishing sites/locations [Embedded Hyperlink: https://www.fisheries.noaa.gov/recreational-fishing-data/public-fishing-access-site-register]	Thank you for your comment. COMFIS-6 requires that lessees establish a compensation/mitigation fund that includes for-hire recreational fishermen. Further discussions about fisheries compensatory mitigation will happen at project-level COP stage and consultation. Project-specific information such as onshore infrastructure that supports offshore wind and its proximity to public fishing access sites can be analyzed in the COP NEPA analysis.
BOEM-2024-0001-0371-0054	Section: PDF Page: 237 Comment: ST-2: Please note that the website https://seaturtlesightings.org/ is only for sea turtles in the New England region. This can be monitored for situational awareness particularly when vessels are traveling to and from New England. Section: PDF Page: 237Comment: STF-1: We recommend making this a requirement as opposed to voluntary. Understanding movement / mixing rates for fish stocks will become important for fisheries stock assessments with development of offshore wind farms. Also consider incorporating this into monitoring plans where sampling designs can be developed to ensure adequate and consistent sampling coverage.	Thank you for your comment. BOEM has reviewed STF-1 and determined it will remain as an RP. ST-2 has been incorporated into MMST-14 and removed from the Final PEIS.

Comment No.	Comment	Response
	For example broader tagging studies should be part of monitoring plans to assess changes in species assemblages.	
BOEM-2024-0001-0371-0055	Additional Comments Section: PDF Page: Global Comment: Climate change is discussed throughout the document but not in the context of being an IPF which is not consistent with other EISs. Further climate change is identified as an IPF in BOEM's "National Environmental Policy Act Documentation for Impact-Producing Factors in the Offshore Wind Cumulative Impacts Scenario on the North Atlantic Outer Continental Shelf" and other EISs. Please either incorporate it as an IPF throughout the document or provide additional explanation for why climate change is not considered an IPF for this PEIS.	Thank you for your comment. In the NY Bight Final PEIS, BOEM analyzed potential climate change impacts on each resource as a part of the ongoing and future conditions under the No Action Alternative. The IPFs identified and analyzed in the NY Bight Final PEIS are directly associated with potential development in the NY Bight lease areas.
BOEM-2024-0001-0371-0056	Section: PDF Page: Global Comment: Comment from NOAA ONMS: The areas currently under consideration for the proposed Hudson Canyon National Marine Sanctuary are directly adjacent to parts of the proposed lease areas. There are potential impacts to sanctuary resources during construction and installation for the project location OCS-0537: high frequency noise and short term impacts from drilling and pile driving turbine construction; after construction there could be low frequency impact over the long term use of turbines in proximity to the sanctuary. Section: PDF Page: Global Comment: NOAA ONMS: Due to the proximity of the lease areas to the areas currently under consideration for the proposed Hudson Canyon National Marine Sanctuary it would be of benefit to require as a condition of any COP Approval notification to the NOAA ONMS and the Hudson Canyon Sanctuary Superintendent should there be any accidents and/or releases into the environment that could have the potential to impact Sanctuary resources.	BOEM will coordinate with NOAA on the status of the marine sanctuary and consider such measures at the COP-specific NEPA stage.
BOEM-2024-0001-0371-0057	Section: PDF Page: Global Comment: Marine mammal impact determinations are inconsistent throughout the document (ES Chapter 2 Chapter 3) and we request BOEM do a QC for consistency. Section: PDF Page: Global Comment: NMFS requests that everywhere impact statements currently read "non-NARW species" it specifies if the impact statement is specific to non-NARW mysticetes or to all marine mammal species.	This section, the Executive Summary, and Chapter 2 have been reviewed to ensure consistency in the impact determinations for marine mammals.

P.4.2 Cooperating State Agencies

P.4.2.1 New Jersey Department of Environmental Protection

Table P.4-7. Responses to Comments from the New Jersey Department of Environmental Protection (BOEM-2024-0001-0448)

Comment No.	Comment	Response
BOEM-2024-0001-0448-0001	Marine Resources Administration Although New Jersey's Marine Resources Administration (MRA) supports the Proposed Action (Alternative C), *The adoption of programmatic avoidance minimization mitigation and monitoring (AMMM) measures that the Bureau of Ocean Energy Management (BOEM) may require as conditions of approval for activities proposed by lessees in Construction and Operations Plans (COPs) submitted for the six NY Bight lease areas*, BOEM should consider the feasibility and effectiveness of each measure being recommended. MRA understands and supports that if the COP-specific National Environmental Policy Act (NEPA) analysis shows that implementation of such measures is not warranted or effective that BOEM may require additional or different measures based on the subsequent site-specific NEPA analysis. The purpose of the Proposed Action is to identify issues, analyze the degree of potential impacts and adopt, as appropriate, AMMM measures. Two goals of the PEIS are analyzing potential impacts if development is authorized in the six NY Bight lease areas and analyzing programmatic AMMM measures for the six NY Bight lease areas. The MRA agrees that the BOEM-selected AMMM measures would be applicable to more than one NY Bight lease area are reasonable and enforceable and allow for flexibility where appropriate. Adoption of programmatic AMMM measures in the first-tier analysis while allowing for additions removals and revisions of these measures as appropriate in the individual second tier Environmental Reviews will help to spread out the effort for stakeholders who review these long and complex documents. This approach should also allow for incorporation of novel mitigation measures as they are developed that respond to the site-specific needs of the unique projects and locations. This tiered approach will facilitate consistency in reviews across projects provide some	BOEM acknowledges New Jersey's Marine Resources Administration's support of Alternative C. BOEM has considered all comments received on AMMM measures and made adjustments to the AMMM measures based on comments as presented in Final PEIS Appendix G. In the selection and analysis of AMMM measures, BOEM considered the feasibility and effectiveness of each measure.

Comment No.	Comment	Response
	predictability reduce impacts to coastal resources and facilitate cooperation between projects.	
BOEM-2024-0001-0448-0002	As stated in Appendix G of the Draft Programmatic Environmental Impact Statement (PEIS) monitoring is critical to evaluating resources impacts and the effectiveness of AMMM measures. The introduction to Appendix G identifies how results may be used specifically "to (1) alter how an AMMM measure identified in the ROD is being implemented (2) revise or develop new mitigation or monitoring measures for which compliance would be required under the COPs for the six NY Bight lease areas (3) develop measures for future projects or (4) contribute to regional efforts for better understanding of the impacts and benefits resulting from offshore wind energy projects in the Atlantic (e.g. potential cumulative impact assessment tool)." This list highlights the importance of adaptive mitigation and is helpful in understanding why monitoring coordination of monitoring and accessibility of results is so important. Monitoring can only be used in these applications if monitoring is designed to answer scientific questions and results are made available and accessible as soon as possible. There should also be a mechanism identified for reviewing monitoring results in the context of each of these uses. The document might benefit from clarification of the overall goal for mitigation and how individual AMMMs are assessed. One might assume that a goal is to reduce impacts to the level of the no action alternative but that is not practical for marine fisheries since the no action alternative for fisheries has a major impact. It's also difficult to understand the value of individual mitigation measures on the affected environment. It seems reasonable to employ any practicable mitigation measure that reduces impacts without affecting the viability of the project not just those that alter the assessment of the impact for the resource with the very broad scale that is used.	Thank you for your comment. Based on comments on the Draft PEIS, BOEM has reviewed all AMMM measures, which resulted in many revisions that included separating AMMMs that have and have not been previously applied; BOEM believes these are all feasible. In addition, several AMMM measures were reclassified as RPs in the Final PEIS. BOEM encourages lessees to analyze and consider implementing these RPs, as they may further avoid and minimize impacts. These RPs are also not part of the Proposed Action. Overall, BOEM strives to take an adaptive approach to assessing impacts when the Project Design Envelope (PDE) is known and requiring mitigation measures.
BOEM-2024-0001-0448-0003	Mitigation regarding collection of information needed for understanding fishery impacts is described in COMFIS-5 Fishery Survey Guidelines. MRA recommends that this AMMM measure is broadened to include (1) a recommendation to participate in ongoing efforts to standardize and economize project-specific and regional	Thank you for your comment. MUL-26 has been revised in response to comments to encourage lessees to coordinate monitoring and survey efforts, meet regional data requirements and standards proposed by ROSA and RWSC, and make results from monitoring publicly available.

Comment No.	Comment	Response
	fisheries monitoring and research and (2) a recommendation that all fishery monitoring results are accessible as soon as practicable to stakeholders. Regional entities (e.g. the Responsible Offshore Science Alliance and the Regional Wildlife Science Consortium) have taken on the task of prioritizing standardizing and coordinating monitoring and supporting data governance across projects and this AMMM should also address the need for participation of lessees in these efforts.	
BOEM-2024-0001-0448-0004	Regarding specific resource-monitoring recommendations MRA recommends that Lessees develop an Atlantic surf clam monitoring plan. AMMM COMFIS-3 recommends that Lessees coordinate with NMFS and potentially impacted scallop fishermen to develop a Scallop Monitoring Plan. New Jersey's highly valuable surf clam industry could lose 15% of revenues to offshore wind and the Atlantic City NJ fleet could lose upwards of 25%[Footnote 1: Munroe D.M. Powell E.N. Klinck J.M. Scheld A.M. Borsetti S. Beckensteiner J. and Hofmann E.E. 2022. The Atlantic surf clam fishery and offshore wind energy development: 1. Model development and verification. ICES J. Mar. Sci. 79(6) 1787-1800.] [Footnote 2: Scheld A. M. Beckensteiner J. Munroe D. M. Powell E. N. Borsetti S. Hofmann E. E. and Klinck J. M. 2022a. The Atlantic Surf clam Fishery and Offshore Wind Energy Development: 2. Assessing Economic Impacts. ICES Journal of Marine Science 79 (6): 180114.]. Losses of these magnitudes and localized overfishing could have cascading impacts on secondary industries. Additionally a complicating factor is the shifting of the surf clam population north and east so using only existing data to evaluate the surf clam resources within the lease areas may severely underestimate the value of the stock. Surveys directed towards a broad age class of surf clam and ocean quahog will inform mitigation. The AMMM measures for Commercial Fisheries include other specific recommendations for mitigating impacts including reducing the risk of cable interactions reducing alteration to the seabed avoiding sensitive habitats use of nature-inclusive design charting obstructions AIS marking navigation training and reducing the size of the area of impact. For example AMMM measures COMFIS-2 and AMMM COMFIS-4 recommend scour protection that reduces the risk of creating new hangs to mitigate impacts to the use of mobile bottom	Thank you for your comment. Based on comments received on the Draft PEIS, COMFIS-3 has been broadened to include a Fisheries and Benthic Monitoring Plan, which includes Atlantic surfclam.

Comment No.	Comment	Response
	gear. As new information and technologies become available MRA looks forward to the availability and utility of additional mitigation measures for individual COPs. The recommendation to use shared cable corridors when possible in AMMM COMFIS-4 recognizes the importance of reducing the area of impacts and supports minimizing impacts to the abundant prime fishing areas identified by our state.	
BOEM-2024-0001-0448-0005	AMMM COMFIS-4 sets a minimum cable burial depth of 3 feet. It should be noted that shallower depths would be inconsistent with New Jerseys enforceable policies as the policies are likely to require 6 feet of burial depth in the near future. Projects installing cables within New Jersey state waters will have to comply with burial depths outlined in our rules and regulations at the time of permitting. MRA notes that a burial depth of 2m minimizes the risk of an anchor from a commercial fishing vessel contacting a cable[Footnote 3: Sharples M. 2011. Offshore Electrical Cable Burial for Wind Farms: State of the Art Standards and Guidance & Acceptable Burial Depths Separation Distances and Sand Wave Effect Bureau of Ocean Energy Management Regulation and Enforcement Offshore Electrical Cable Burial for Offshore Wind Farms on the OCS. https://www.bsee.gov/sites/bsee.gov/files/tap-technical-assessment-program//final-report-offshore-electrical- cable-burial-for-wind-farms.pdf] reduces the risk of a hydraulic clam dredge interacting with the cable4 and provides more reduction in EMF between the cable and the seafloor. NJ's Third Offshore Wind Solicitation required HVDC-based cable and converter technology and future solicitations for Projects that will utilize NJ's Prebuild Infrastructure will also require HVDC technology. Deeper burial can reduce the higher risk of EMF effects3 of HVDC compared to HVAC.	Thank you for your comment. Based on comments received on the Draft PEIS, BOEM has reviewed all draft measures and categorized them as 1) AMMM measures previously applied as T&Cs or through other mechanisms such as a Biological Opinion or Memorandum of Agreement, 2) AMMM measures not previously applied as T&Cs, and 3) RPs. BOEM encourages lessees to analyze and consider implementing these RPs, as they may further avoid and minimize impacts. Furthermore, these RPs are also not part of the Proposed Action, Alternative C, which analyzes only AMMM measures previously applied as T&Cs and AMMM measures not previously applied as T&Cs. BOEM has classified COMFIS-4, Fisheries mitigation, as an RP.
BOEM-2024-0001-0448-0006	The MRA supports the measures described in COMFIS-6 regarding fisheries mitigation and the requirement for projects to establish a fund to compensate commercial and for-hire recreational fishermen for loss of income resulting from displacement from fishing grounds due to project construction and operations._It should be a requirement not just a recommendation that the fund is sufficient to allow compensation to shoreside businesses for losses indirectly	Thank you for your comment. COMFIS-6, Fisheries compensatory mitigation fund, should also allow for compensation to shoreside businesses for losses indirectly related to project development. Revenue exposure data compiled by NOAA/NMFS attempts to capture both commercial and party/charter information. In current T&Cs, these data are the minimum basis for Direct Compensation Program funding. BOEM anticipates that shoreside

Comment No.	Comment	Response
	related to project development. Recognizing the importance of sustaining fisheries and the fishing industry eleven east coast states have developed a detailed description of the need design and development of a trusted Regional Fund Administrator (RFA) for managing and distributing fisheries compensatory mitigation funds for offshore wind in a transparent and equitable manner. BOEM should recommend that lessees utilize and contribute to the Regional Compensation Fund once it is established.	service expected exposed revenue be based off a multiplier on the commercial and for-hire recreational fishing revenues to ensure proper funds are available. However, it should be incumbent upon the shoreside business or service to verify its loss. Additionally, a new RP (COMFIS-7) was created in response to comments to encourage lessees to participate in the Fisheries Compensation Fund. BOEM does not preclude the lessees of the NY Bight from using a regional fund administrator, provided the requirements set forth by BOEM are met. BOEM recognizes the advantages of a single fund, yet also recognizes that a lessee may prefer to better set the terms of a fund for its individual project.
BOEM-2024-0001-0448-0007	The MRA recognizes NOAA Fisheries as the lead agency for the protection of marine mammals and turtles and supports any recommendations provided by that agency regarding potential impacts and mitigation measures. MRA appreciates the strides that BOEM and NOAA have made towards coordinating passive acoustic monitoring in the Mid-Atlantic Region and coordination will continue to advance for these and other resources. Additionally the NJ Research and Monitoring Initiative supports these efforts and has plans to fund the deployment of PAM receivers off our coast that complement the work of other agencies and developers. Regional coordination should be expanded to include aerial surveys.	Thank you for your comment. BOEM may consider expanding regional coordination for aerial surveys. MUL-26 was updated to encourage coordination for regional monitoring and surveys.
BOEM-2024-0001-0448-0008	Land Resource Protection The Division of Land Resource Protection commends BOEM for including references to state specific jurisdictions. The NJDEP will continue to review and permit projects that are within the boundaries of New Jersey State waters and lands. The document outlines that WTGs and OSSs would be mounted on one or a combination of the following foundation types: monopile piled jacket suction bucket (could be mono-bucket suction- bucket jacket or tri-suction pile caissons) or gravity-based foundations (Figure 2-3 through Figure 2-6). Monopile and piled jacket are anticipated to be the most likely foundation types to be used for the NY Bight projects. The possible use of "floating foundations" as a mounting method was not discussed and should be further considered by BOEM. This method	The analysis in the PEIS is based on parameters of a representative project—the RPDE as described in Section 2.1.2.1—which includes multiple potential foundation options as identified with input from the six NY Bight lessees, American Clean Power, National Renewable Energy Laboratory, and the States of New York and New Jersey. Floating foundations were not identified during the development of the RPDE as being a potential foundation type considered in the NY Bight area. The NY Bight area has relatively shallow seabed depths and is suitable for fixed foundations. Floating foundations are a newer technology that is being considered in areas with deeper water, including offshore California and in the Gulf of Maine. The PEIS includes AMMM measures (see Appendix G) to minimize seabed disturbance

Comment No.	Comment	Response
	may reduce the impact to many of the biological resources outlined in chapter 3.5.	impacts and other aspects of foundation installation. During project-specific COP NEPA reviews, BOEM will consider project-specific alternatives to avoid and minimize impacts.
BOEM-2024-0001-0448-0009	Endangered Nongame Species Program According to the DPEIS a study indicated that abandoned or lost fishing nests may get tangled in foundations therefore reducing abandoned gear in the OCS environment. The Endangered Nongame Species Program (ENSP) would like to see more data to support this assertion as there is not a valid benefit to birds without further data to indicate this is a regular occurrence. In reference to the Vattenfall 2023 study about bird movements within an offshore wind farm ENSP would be interested to see how nocturnal movements of birds through offshore wind farms could be studied once more wind farms are developed. In addition to the AMMM measures listed in table 3.5-3.6 ENSP would like BOEM to consider motion smear minimization using data from the 2020 study by Nygard - Efficacy of increased wind turbine visibility to reduce avian fatalities as well as the use of video cameras and radar to detect the rate of strikes avoidance behavior and possible attraction within the OSW farms (or best available technologies).	The beneficial effects of fishing nets/gear removal in the offshore environment (in this case with presence of WTGs) is cited in the PEIS (see Regular et al. 2013). While this study did not look at net/gear removal specific to WTG foundations, it did clearly demonstrate a beneficial effect from removal of nets and gear in the offshore environment. Assuming that WTG foundations would be a source of entanglement, it would be expected that birds in the offshore environment would experience some beneficial effect. BOEM would continue to use the most up-to-date and relevant literature on this potential impact as more offshore wind projects are evaluated on at the Atlantic OCS, including those in the NY Bight lease areas. Details on monitoring nocturnal movements of birds would be developed during the project-specific COP NEPA review, as appropriate. For example, if lessees were to implement RP BB-4, monitoring of nocturnal bird movements could be incorporated into the framework. BOEM previously looked into motion smear (for Ocean Wind 1 offshore New Jersey) and reviewed the commenter's cited study (BOEM notes that the study is actually May et al. 2020 and not Nygard, although Nygard is one of the authors). While BOEM acknowledges the May et al. (2020) study indicates a reduction in bird strikes with wind turbines with a black-painted blade, the results are preliminary, and eight turbines (half with black paint) is not a large sample size. In addition, relatively few bird carcasses were found both before and after painting the blades (a total of 42 dead birds at all eight turbines during the study period of 10 years). It is also not clear if the paint achieves the same results across different bird species, and its efficacy may be site specific. In addition, and more of a determining factor in the use of black paint on wind turbine blades in the United States, FAA's 2020 Obstruction Marking and Lighting Circular (70/7460-1M) includes a

Comment No.	Comment	Response
		section (Section 13) on wind turbine paint requirements (for aviation safety) that states the darkest acceptable paint color is light gray, with preference of pure white. Black paint on wind turbines is not allowed under the FAA circular. BOEM would continue to evaluate technologies to reduce collisions if post-construction monitoring indicates action should be taken.
BOEM-2024-0001-0448-0010	Office of Environmental Justice As outlined in Section 3.4.1 Air Quality the document states that most of the emissions would occur during construction. Due to multiple offshore wind projects occurring simultaneously throughout the east coast construction related emissions could cause adverse air quality impacts in the localized areas surrounding the ports and facilities. Many of the ports and supporting facilities associated with offshore wind development are in or adjacent to NJ overburdened communities such as the Paulsboro Marine Terminal the Repauno Port and Rail Terminal and the New Jersey Wind Port. There is no consideration in this section or section 3.6.4 about possible adverse air quality effects in hyperlocal areas during the construction period. OEJ recommends that hyperlocal air quality impacts be investigated. If adverse impacts are found to occur it is recommended to implement air monitoring programs during construction as a strategy to justify mitigation methods in Overburdened Communities (OBCs) from the impacts of increasing commercial vessel traffic air traffic truck and worker vehicle traffic onshore facility operations etc. The need for monitoring is further highlighted by the DPEIS acknowledgement that conditions will vary.	BOEM acknowledges that the PEIS does not include the specificity needed to make location specific determinations (see Section 3.6.4.2 on scope of the environmental justice analysis). The ports identified in the PEIS may support NY Bight offshore wind development but are representative ports, not necessarily planned. BOEM agrees that hyperlocal air quality impacts should be considered by the COP-level NEPA documents to ensure there are not disproportionately adverse impacts on communities with environmental justice concerns. Table G-2 of Appendix G, *Mitigation and Monitoring,* provides a summary of the RP measures that BOEM encourages lessees to analyze and consider implementing to avoid or reduce impacts on air quality. Thank you for your recommendation to implement air monitoring programs as a strategy to justify mitigation measures in overburdened communities.
BOEM-2024-0001-0448-0011	Transmission/NJ Prebuild Infrastructure The NJ Board of Public Utilities is pursuing an approach to coordinate the construction of offshore wind transmission cables by developing common infrastructure that will house these power cables in shared underground transmission corridors consisting of duct banks and cable vaults for four transmission lines called the Prebuild Infrastructure. NJDEP encourages BOEM to incorporate the review of the coordinated transmission solutions into the New York Bight Final PEIS to the extent practicable.	BOEM notes in Section 2.1.2.1.1 of the Final PEIS that in New York and New Jersey, efforts are underway to develop transmission infrastructure that would allow multiple offshore wind projects to interconnect at an offshore (New York City Public Policy Transmission Need [PPTN]) and nearshore (New Jersey Board of Public Utilities [NJBPU] Prebuild Infrastructure [PBI]) POI. Appendix B, *Supplemental Information and Additional Figures and Tables*, provides additional detail regarding the transmission infrastructure development efforts in New York and New Jersey.

Comment No.	Comment	Response
		Appendix D, *Planned Activities Scenario*, has also been updated to describe the States of New Jersey and New York's public policies and offshore wind goals.

P.4.2.2 New Jersey Board of Public Utilities

Table P.4-8. Responses to Comments from the New Jersey Board of Public Utilities (BOEM-2024-0001-0437)

Comment No.	Comment	Response
BOEM-2024-0001-0437-0001	New Jersey is actively pursuing coordinated transmission solutions to efficiently integrate offshore wind power into the PJM system grid. Through the State Agreement Approach (SAA) NJBPU has awarded the Larrabee Tri-Collector Solution (LCS) to establish a new on-shore Point of Interconnection (POI). The LCS will be capable of incorporating at least 3742 MW of offshore wind capacity through up to four transmission lines. The Board is pursuing an approach to coordinate the construction of these lines by developing common infrastructure that will house these power cables in shared underground transmission corridors consisting of duct banks and cable vaults for four transmission lines. The Board is calling this common infrastructure the "Prebuild" or "PBI." Following discussions with stakeholders and technical experts Board Staff finds that employing the SAA in conjunction with this Prebuild work is necessary to maximize the benefits of SAA 1.0 and the LCS. The Board is currently in the process of soliciting PBI bids from transmission developers and will have further clarity on the precise cable routing of the PBI at the conclusion of the solicitation. This coordinated approach to transmission and associated common cable corridors will minimize environmental and community disturbances arising from on-shore transmission development. We encourage BOEM to incorporate the potential environmental benefits of these coordinated transmission solutions into the NY Bight PEIS.	BOEM notes in Section 2.1.2.1.1 of the Final PEIS that in New York and New Jersey, efforts are underway to develop transmission infrastructure that would allow multiple offshore wind projects to interconnect at an offshore (New York City PPTN) and nearshore (NJBPU PBI) POI. Appendix B, *Supplemental Information and Additional Figures and Tables*, provides additional detail regarding the transmission infrastructure development efforts in New York and New Jersey.
BOEM-2024-0001-0437-0002	The NJBPU also suggests that BOEM considers adding an alternative course of action that incorporates exclusively the avoidance minimization mitigation and monitoring (AMMM) measures which	Refer to response to comment BOEM-2024-0001-0371-0004.

Comment No.	Comment	Response
	are already approved and demonstrated to be commercially viable into the PEIS. The existing options including no AMMMs or all AMMMs which encompass untested or uneconomic measures represent only the end member cases; the latter of which may be overly burdensome for developers. Introducing a middle-ground alternative that includes proven commercially viable AMMMs would better align with established regulatory processes.	

P.4.2.3 New York State Department of State/Department of Environmental Conservation

Table P.4-9. Responses to Comments from the New York State Department of State/Department of Environmental Conservation (BOEM-2024-0001-0317)

Comment No.	Comment	Response
BOEM-2024-0001-0317-0001	The Agencies recommend further consideration of the impacts to native hard-bottom habitat from the installation of cables and turbines. Impacts to native hard-bottom habitat are often permanent impacts negatively affecting species that utilize those areas. While scour protection may provide some mitigation for that loss it is not equal to the value of native hard bottom. Cable protection is not a suitable substitute for hard-bottom species to colonize. The impacts from hard bottom loss on a larger scale could be extremely detrimental to local marine species. [Footnote 10: Rochelle D. Seitz Hkan Wennhage Ulf Bergstrm Romuald N. Lipcius Tom Ysebaert Ecological value of coastal habitats for commercially and ecologically important species ICES Journal of Marine Science Volume 71 Issue 3 March/April 2014 Pages 648665 https://doi.org/10.1093/icesjms/fst152] The Agencies are not aware of studies concluding that introduced hard-bottom in the form of cable or scour protection will be able to replicate the biological value of native hard-bottom both in species recolonization and complexity. If there is not adequate detail on the presence of hard bottom habitat at this time then BOEM should undertake a detailed analysis of impacts to hard bottom habitats during the COP-specific review ensure avoidance is prioritized and evaluate the sufficiency of AMMM	As stated, during the project-specific COP-level NEPA analysis, the seafloor substrates will be described in more detail. While the scour protection may not be equal to the value of native hard-bottom habitat, the best available science indicates that species that require hard substrate for settlement are likely to settle on materials used for cable and scour protection. For example, in a newly published study on the settlement success of the European flat oyster, granite was the substrate with the highest settlement preference (ter Hofstede et al. 2024). Granite is often used in scour protection for offshore wind projects.

Comment No.	Comment	Response
	measures to offset these impacts (e.g. MUL-4 MUL-23 COMFIS-2 COMFIS-4).	
BOEM-2024-0001-0317-0002	Finfish Invertebrates and Essential Fish Habitat (Section 3.5.5): The EMF and cable heat analysis should primarily evaluate dipole bundled high voltage direct current (HVDC) export cables since these will be required for most export cables in the NY Bight due to the distance required to reach shore and state policy initiatives (e.g. mesh-ready). The cumulative impacts section should also acknowledge that interaction rates with finfish and benthic invertebrates increase as more cables with higher capacities are installed. In addition the Agencies continue to recommend a minimum target burial depth of 6 feet for all submarine cables where technically feasible. This burial depth is consistent with BOEM's Draft Fisheries Mitigation Guidance and typically provides sufficient protection to both the cable and maritime users in the area. This depth also reduces the risk of fishing gear interactions and mitigates the effects of EMF on sensitive species that inhabit and transit through a project area. The Agencies also recommend maintaining cables in a bundled state or if unbundling is necessary to bury in a single trench to further reduce EMF and habitat impacts. In addition the New York District U.S. Army Corps of Engineers (USACE) also has a guidance value of a minimum of 7 feet burial depth. [Footnote 9: USACE NY District Nationwide Permit 57 - Electric Utility Line and Telecommunications Activities Permit-specific Regional Conditions b(2)(iv) states "[i]n areas outside of Federal project channels fleeting or anchorage areas the top of the utility line shall be located a minimum of 7 feet below the existing bottom in sediment and 2 feet below the existing bottom in compacted rock."] All certificated NYS offshore wind projects have been required to meet a target burial depth of 6 feet in NYS waters as part of the project-specific NYS Public Service Law Article VII Certification Conditions. Reducing habitat impacts is expected to indirectly benefit ocean users like commercial fishermen by minimizing habitat changes and the risk of interactions with fishing gear.	Text regarding EMF and heat has been added to Section 3.5.5 of the Final PEIS regarding cable heat from HVDC cables. Section 2.1.2 provides the RPDE, which states that 3–19.6 feet (0.9–6 meters) is the anticipated potential range of burial depth; 6 feet (1.8 meters) is the typical target burial depth. Depths may vary based on site-specific factors (e.g., soil type, cable/pipeline crossings, crossing of navigation channels or other federal civil work projects, other federal or state requirements). Cable installation will comply with all permit and certification requirements.
BOEM-2024-0001-0317-0003	Marine Mammals (Section 3.5.6): The Agencies recommend considering and expanding the discussion of noise effects on marine	National Research Council 1994 and 2000 were reviewed and added as references in Section 3.5.6.1.3.

Comment No.	Comment	Response
	mammals. Case studies regarding the impact of low frequency sound on cetaceans and the hearing sensitivity of baleen whales have been in existence for many years. Below are example citations that could be referenced: - National Research Council. 1994. Low-Frequency Sound and Marine Mammals: Current Knowledge and Research Needs. Washington DC: The National Academies Press. https://doi.org/10.17226/4557.- National Research Council. 2000. Marine Mammals and Low-Frequency Sound: Progress Since 1994. Washington DC: The National Academies Press. https://doi.org/10.17226/9756.- Jebelli A. Yagoub MCE Dhillon BS and Lotfi N. 2018. Effect of Low-Frequency Noise on Humpback Whale Behaviors. Journal of Oceanography and Marine Research 6: 186.- Croll D. Clark C. Calambokidis J. Ellison W. and Tershy B. February 2001. Effect of anthropogenic low-frequency noise on the foraging ecology of Balaenoptera whales Animal Conservation Volume 4 Issue 1 pp. 13-27. https://doi.org/10.1017/S1367943001001020.- National Research Council. 2003. Ocean Noise and Marine Mammals. Washington DC: The National Academies Press. https://doi.org/10.17226/10564. Underwater noise from impact and vibratory pile driving drilling and increased vessel noise related to offshore wind development would fall into the low-frequency category. Noise from unexploded ordnances (UXO) detonations would also be audible to low-frequency cetaceans. Baleen hearing range as currently understood has minimal overlap with the noise generated by seafloor mapping surveys. Low-frequency cetaceans may be at risk of masking by lower frequency construction-related vessel traffic but vessel traffic is generally not uncommon in the PEIS study area. With respect to pile driving most energy in pile-driving noise is at low frequencies.	National Research Council 2003 is already referenced in Section 3.5.6.1.3 of the PEIS when discussing potential impacts of noise on marine mammals, and was not carried forward into Section 3.5.6.3.3 because the discussion of vessel noise, vibratory piling, and drilling focused on more recent papers for conciseness in the main body of the PEIS. Jebelli et al. (2018) has not been included in the discussion of geophysical equipment noise effects or any other noise effects section because it lacks applicability to the noise sources in question and relies on highly theoretical assumptions for programmed Autonomous Underwater Vehicle "behavior," not animal behavior, that are not relevant to NY Bight or associated impact assessments. Croll et al. (2001), though focused on low-frequency Navy sonar noise, was added to the discussion of vessel noise in Section 3.5.6.3.3 to illustrate how other factors may drive behavioral changes that are unrelated to low-frequency noise exposure. In response to the latter part of the comment, BOEM agrees all these sources contain sound energy in lower frequencies below 1,000 hertz and would therefore fall more within the low-frequency cetacean hearing range, and this was considered in the assessment of effects in this PEIS. However, another important consideration, which is illustrated by the recommended references provided, is the characteristics of the sound source type and available data show that marine mammal responses differ for impulsive vs. non-impulsive noise; intermittent/pulsed vs. continuous noise; and underwater explosions vs. non-explosive sound sources. Therefore, information provided in Sections 3.5.6.3 and 3.5.6.4 discusses research analyzing low-frequency noise sources from sources with similar characteristics to the source being discussed to comprehensively assess the risk of effects on marine mammals in the PEIS.
BOEM-2024-0001-0317-0004	Commercial Fishing (Section 3.6.1): For clarity the impacts to commercial and for-hire recreational fisheries should be stated separately. That is the FEIS should state specifically what the impacts to commercial fisheries would be and what the impacts to	For this programmatic analysis, the impacts range from negligible to major because project-specific details are not yet known and the analysis considers the impact range across all IPFs.

Comment No.	Comment	Response
	recreational for-hire fisheries would be for each of the alternatives. For example the Draft PEIS currently states that "impacts on commercial fisheries and for-hire recreational fishing are expected to range from negligible to major." [Footnote 11: See PEIS pg. 3.6.1-52] As is it is not clear whether the impacts to each of the commercial and for-hire recreational fisheries are expected to be "major" or whether this is an aggregate or overall level of impact. For comparison BOEM has analyzed the potential impacts to these fishing industries separately in project-specific EISs like the Empire Wind EIS. [Footnote 12: See Empire Wind FEIS pg. 3.9-65: "Therefore BOEM expects that the impacts resulting from the Proposed Action would be moderate to major for commercial fisheries and minor to moderate for for-hire recreational fishing depending on the fishery and fishing vessel."]	
BOEM-2024-0001-0317-0005	6. Mitigation and Monitoring (Appendix G): a. Mariner Communication Plan: As recommended in the State's PEIS scoping comments the Agencies continue to recommend developing a Mariner Communication Plan that addresses all phases of development (Surveys Construction Operations Decommissioning). Robust and targeted outreach continues to be needed across the diverse users in the assessment area including commercial vessel operators commercial fishermen for-hire/charter fishermen recreational fishermen recreational boaters divers etc. Wind development occurring outside of the East Coast's busiest port and shipping lanes necessitates careful coordination to protect the safety of all mariners. This plan would supplement the NY Bight lease stipulation to implement Fisheries Communication Plans. b. Fisheries Mitigation (COMFIS-4): The Agencies continue to recommend a minimum target cable burial depth of 6 feet in state and federal waters for all projects where technically feasible as noted in Item 4 (above). c. Commercial Fisheries Mitigation (COMFIS-6): The Agencies recommend that lessees utilize and contribute to the Regional Compensation Fund once it is established through the 11-State effort. The States are working together to advance a shared vision of a consistent regional approach for the Atlantic Coast's commercial and	Thank you for your comment. Existing notice to mariners covers all phases of development. Burial depth for each project will be specifically determined at the project-specific phase. COMFIS-7 (fisheries compensation fund) has been added to encourage lessees to consider contracting with a neutral third party to process claims, manage and disburse funds, and handle appeals.

Comment No.	Comment	Response
	for-hire recreational fishing industries and supporting infrastructure through the conceptual development of a regional compensation fund to be managed by an independent Regional Fund Administrator. The States have reached consensus on the need for an expert independent party to lead the design and development of an effective claims process and governance structure for the Fund that reflects input from all affected sectors especially those most directly affected fishing enterprises and infrastructure support. With start-up funds secured a request for proposals is expected to be released by NYSERDA in early 2024.	
BOEM-2024-0001-0317-0006	On-going Coordination: The Agencies note that notwithstanding BOEM's obligation to analyze environmental impacts for proposed and future projects within the NY Bight including State waters and relevant upland transmission components the State has a parallel process pursuant to Article VII of New York State Public Service Law 120 et. seq. that analyzes the need for and environmental impacts of transmission components within the State's jurisdictional boundary. By participating in BOEM's NEPA review and as parties to relevant Article VII proceedings NYSDOS NYSDEC and NYSDPS are committed to facilitating continued coordination between the State and federal review processes. The Agencies appreciate the opportunity to provide this input and look forward to continued collaboration as BOEM undertakes an important next step in concluding this federal environmental review.	Thank you. Comment noted.
BOEM-2024-0001-0317-0007	b. The Agencies recommend careful review of the impact levels estimated under Alternatives B and C. The Agencies note that between the stated impacts summary (pp. 2-23 to 2-38) and the text there are no differences in stated impacts for many resource areas even though several AMMM measures are identified that could reduce impacts to those resources if adopted now. The Agencies support establishing AMMMs in the PEIS to address anticipated impacts and are available to assist BOEM in clarifying impact levels between alternatives.	BOEM has clarified that Alternative B serves to compare how impacts would change with the AMMM measures identified in Alternative C. Alternative C now distinguishes between AMMM measures that have been previously applied and those that have not been previously applied. RPs are not analyzed within the alternatives analysis. Refer to response to comment BOEM-2024-0001-0371-0004 for additional information The edits to Alternative C were made to help better distinguish the potential benefits of previously applied and not previously applied AMMM measures.

Comment No.	Comment	Response
BOEM-2024-0001-0317-0008	BOEM "anticipates that the cumulative impacts on benthic resources in the geographic analysis area would likely be negligible to major with moderate beneficial impacts. The incremental impacts for six NY Bight projects with AMMM measures incorporated would be reduced at a functional level although impact determinations would not change. In the context of other reasonably foreseeable environmental trends (Appendix D) the incremental impacts contributed by Alternative C to the cumulative impacts on benthic resources would be noticeable." [Footnote 8: See Draft PEIS pg. 3.5.2-38] This does not identify or illustrate these trends nor relay any direct correlation to offshore wind environmental impacts.	Thank you for your comment. For details regarding impacts on benthic resources from offshore wind projects, see PEIS Section 3.5.2.5 to see how the proposed mitigation measures (AMMM measures) would alter the impacts, if implemented.
BOEM-2024-0001-0317-0009	Level of Impacts: a. The Agencies urge BOEM to refine its impact level definitions to more accurately evaluate the Proposed Action and Alternatives. The cumulative impacts are often too broadly identified to provide a clear picture of how a full build-out would affect the resource area. For example: - BOEM anticipates that "the cumulative impacts on coastal habitat and fauna in the geographic analysis area even with application of AMMM measures under Alternative C would likely be negligible to moderate under six NY Bight projects. In context of reasonably foreseeable environmental trends the incremental impacts contributed by six NY Bight projects to the cumulative impacts on coastal habitat and fauna are unlikely to be detectable." [Footnote 5: See Draft PEIS pg. 3.5.4-20] This presents a wide discrepancy in impact declaration and characterization and does not focus enough on the expected impacts of the Alternatives.	The PEIS uses a four-level classification scheme to characterize the potential beneficial and adverse impacts of the Proposed Action and alternatives. Impact levels described in BOEM's *Programmatic Environmental Impact Statement for Alternative Energy Development and Production and Alternate Use of Facilities on the Outer Continental Shelf* (MMS 2007) were used as the initial basis for establishing adverse impacts specific to each resource. These resource-specific adverse impact level definitions were then further refined based on prior NEPA analyses, scientific literature, and best professional judgment. Impact level ranges are broad due to the large RPDE analyzed. During the project-specific, COP-level NEPA analyses, impact level definitions can be refined to address project-specific impacts.
BOEM-2024-0001-0317-0010	The Agencies recommend that BOEM reconsider the impact level determined for Electric and Magnetic Field (EMF) impacts on benthic resources. As recognized in the Draft PEIS there are significant knowledge gaps regarding this topic and the effects of EMF on most invertebrates are understudied. Of the species-specific in- situ studies conducted to date there is evidence that anthropogenic EMFs can result in an "ecologically significant behavioral response" in little skate and American lobster (Hutchinson et al. 2020) [Footnote 6: Hutchison Z.L. Gill A.B. Sigray P. et al. Anthropogenic electromagnetic	The impact determination is consistent with other EISs. More details and analyses will be included in the project-specific COP NEPA documents.

Comment No.	Comment	Response
	fields (EMF) influence the behavior of bottom-dwelling marine species. Sci Rep 10 4219 (2020). https://doi.org/10.1038/s41598-020-60793-x]. Furthermore, the Draft PEIS references Gill and Desender (2020) [Footnote 7: Gill Andrew B. & Desender Marieke. 2020 State of the Science Report Chapter 5: Risk to Animals from Electromagnetic Fields Emitted by Electric Cables and Marine Renewable Energy Devices. United States. https://doi.org/10.2172/1633088] to support the statement that "no differences have been observed between benthic communities in energized cables compared to controls." However, in this same paper Gill and Desender (2020) conclude that "the lack of specific information has led to the general conclusion that EMFs associated with subsea cables are not harmful and do not pose a risk to biota... However, the lack of evidence does not necessarily equate to a lack of impact." Lack of knowledge about EMF impacts does not mean there will be negligible impacts. Therefore, the Agencies recommend a more conservative impact level determination of "minor" at this time for EMF impacts on benthic resources and more in-situ study on this topic to improve clarity.	
BOEM-2024-0001-0317-0011	Transmission review efficiencies: The Agencies encourage BOEM to identify review efficiencies between the NY Bight PEIS and NYC PPTN project and where possible without delaying either take steps necessary to begin analyzing the environmental effects of the NYC PPTN in the PEIS. The PEIS already analyzes prospective transmission infrastructure associated with projects in the NY Bight leases and could also include regional transmission solutions contemplated by neighboring states. Because portions of the NYC PPTN project may occupy federal waters it is expected to have similar effects and a study area that overlaps with that of the PEIS. This could allow early analysis of environmental effects many of which are already described in the PEIS study area off of New York and in NYC waters as well as potential tiering for a future COP or General Activities Plan associated with the NYC PPTN.	BOEM notes in Section 2.1.2.1.1 of the Final PEIS that in New York and New Jersey, efforts are underway to develop transmission infrastructure that would allow multiple offshore wind projects to interconnect at an offshore (New York City PPTN) and nearshore (NJBPU PBI) POI. Appendix B, *Supplemental Information and Additional Figures and Tables*, provides additional detail regarding the transmission infrastructure development efforts in New York and New Jersey.
BOEM-2024-0001-0317-0012	The Agencies offer the following detailed comments on the Draft PEIS and request that BOEM evaluate and address the following: 1. Preferred Alternative: The Agencies generally support adopting	BOEM acknowledges New York State Agencies’ support of Alternative C.

Comment No.	Comment	Response
	AMMM measures (Alternative C) as a preferred alternative in the PEIS vs. deferring their adoption to the project-specific review (Alternative B).	
BOEM-2024-0001-0317-0013	BOEM's No Action (Alternative A) is not an acceptable path forward based on the analysis of impacts in the Draft PEIS.	BOEM acknowledges New York State Agencies' lack of support of Alternative A.
BOEM-2024-0001-0317-0014	Through Alternative C BOEM has crafted a discrete list of technically feasible AMMM measures tailored to the NY Bight region that provide clear expectations for forthcoming project designs. Clearly prioritizing the PEIS AMMM measures through immediate adoption provides predictability helps address disproportionate effects to frontline communities and buttresses Federal and State investments in climate adaptation and coastal resilience strategies. However the Agencies caution that the effectiveness of the measures finally adopted should be well-supported and maximize federal funding opportunities in part because the costs of offshore wind development are largely borne by the State's ratepayers.	BOEM acknowledges New York State Agencies' support of Alternative C. BOEM has considered all comments received on AMMM measures and made adjustments to the AMMM measures based on comments as presented in Final PEIS Appendix G. Refer to response to comment BOEM-2024-0001-0371-0004 for updates to alternatives in the Final PEIS. The Proposed Action for the Final PEIS is the identification of AMMM measures at the programmatic stage that could avoid, minimize, mitigate, and monitor impacts on resources in the six NY Bight lease areas. No measures will be implemented immediately. These measures may be required as conditions of approval for activities proposed by lessees in COPs submitted for the six NY Bight lease areas. BOEM may require additional or different measures based on future, site-specific NEPA analysis or the parameters of specific COPs. BOEM may also modify the measures at the COP-specific NEPA stage to tailor them to the characteristics of the proposed project and the site(s) of proposed activities, and to ensure conformity with project-specific consultations and authorizations.
BOEM-2024-0001-0317-0015	For example the Agencies believe that incorporating the use of shared transmission corridors in the NY Bight whenever such infrastructure is reasonably available to the proposed offshore platform (MUL-18) is justifiable as a cost-effective and protective approach to development. Shared corridors offer benefits in terms of both cost and reduced impacts to coastal resources ocean users harbor operations and host communities. New York has moved forward to develop offshore transmission infrastructure capable of collecting energy generated at multiple offshore platforms and delivering it to onshore interconnection points. The New York State Public Service Commission (the Commission) by Order issued June 22 2023 initiated	BOEM notes in Section 2.1.2.1.1 of the Final PEIS that in New York and New Jersey, efforts are underway to develop transmission infrastructure that would allow multiple offshore wind projects to interconnect at an offshore (New York City PPTN) and nearshore (NJBPU PBI) POI. Appendix B, *Supplemental Information and Additional Figures and Tables*, provides additional detail regarding the transmission infrastructure development efforts in New York and New Jersey.

Comment No.	Comment	Response
	a competitive process for the submission of proposals to build at least 4700 MW and up to 8000 MW of transmission capacity to serve the State's 9000 MW target (New York City Public Policy Transmission Need; PPTN). [Footnote 3: Case 20-E-0197] This action effectively ensures coordinated transmission and generation project development within a single development envelope. The solicitation will result in selection of the most efficient proposal in late 2025. In support of the New York City PPTN NYSERDA included contract terms in the 2022 offshore wind solicitation (ORECRFP22-1) requiring awardees to make commercially reasonable decisions to change their point of interconnection to those developed through the New York City PPTN upon NYSERDA's request. Subsequently NYSERDA built on this requirement in the 2023 solicitation by capping offshore wind solicitation awards to no more than 1400 MW into New York Independent System Operator's Zone J. Further adjustments in the planned 2025 OREC solicitation will require awardees to connect to the coordinated infrastructure developed pursuant to the New York City PPTN process. Thus the State will effectively mandate compliance with the mitigation measure identified in the Draft PEIS as MUL-18. Should New York expand its target for offshore wind beyond 9000 MW the Agencies expect the Commission and NYSERDA to take a similar approach because of its cost efficiencies and lower overall environmental and community impacts. BOEM's recognition in the PEIS of the value of using shared infrastructure in the NY Bight will align State and federal policy into the future. [Footnote 4: The Agencies further suggest that other Northeast States may make similar policy decisions given the advantages of coordinated transmission planning.]	
BOEM-2024-0001-0317-0016	When considering which AMMM measures to adopt as part of the Final PEIS the Agencies urge BOEM to carefully evaluate each measure's feasibility and proven effectiveness. Where AMMM measures do not meet this benchmark BOEM should consider removing them from the Final PEIS and as appropriate revisit them in the project-specific COP review. The AMMM measures should address the range of anticipated environmental impacts and be written in a manner to allow for flexibility over time in consideration	Thank you for your comment. BOEM has updated the alternatives analysis and reviewed all AMMM measures. Not all AMMM measures are being recommended as COP approval T&Cs in the Final PEIS; many are now identified as RPs. Refer to response to comment BOEM-2024-0001-0371-0004 for additional information.

Comment No.	Comment	Response
	of project feasibility (including economic feasibility) and inclusive of a range of approaches based on feasibility and best available science. Offshore wind energy development is a substantial opportunity to reduce greenhouse gas emissions stemming from the combustion of fossil fuels and the environmental degradation caused by climate change.	
BOEM-2024-0001-0317-0017	Finally the Agencies commend BOEM for providing meaningful community engagement and articulating targeted mitigation measures that address impacts to historically marginalized and disadvantaged communities. By establishing the NY/NJ Environmental Justice Forum at the start of the PEIS BOEM has provided nearly two years of shared learning opportunities across governments tribal nations and diverse community-based organizations in the region. This forum is a means to establish ongoing and long-term engagement with Environmental Justice communities and it provides community representatives with an avenue to offer feedback to BOEM as appropriate. These types of collaborations accelerate the Biden administration's Justice40 initiative and compliment State-led efforts like the NYS Climate Act investments in NYS Disadvantaged Communities and the Offshore Wind Environmental Justice Technical Working Group. Additionally the Draft PEIS includes AMMM measures targeting community engagement as well as an Environmental Justice Compensatory Mitigation Fund through which lessees would make financial contributions to offset disproportionate and adverse impacts to environmental justice communities directly tied to offshore wind activities. BOEM's commitment to supplementing its standard outreach to integrate co-design concepts and seeking regional solutions to adverse cumulative impacts in these ways provides a useful template for future offshore wind environmental reviews across the nation.	Thank you for your comment.
BOEM-2024-0001-0317-0018	We commend BOEM's inclusion of a Representative Project Design Envelope that reflects refinements from recent projects (e.g. uniform turbine layout high- voltage direct current transmission typical six-foot cable burial depth). The Draft PEIS also includes forward-looking AMMM measures such as utilizing a shared transmission corridor	Thank you for your comment.

Comment No.	Comment	Response
	among others. [Footnote 2: The multi-resource Shared Transmission Corridor AMMM or "MUL-18" states: "Lessees should coordinate transmission infrastructure among projects. Where practicable transmission infrastructure should use shared intra- and interregional connections have requirements for meshed infrastructure apply parallel routing with existing and proposed linear infrastructure (including export cables and other existing infrastructure such as power and telecommunication cables pipelines) and limit the combined footprint to minimize impacts and maximize potential capacity. Where possible incorporate cable siting principles and routing measures for export cables and associated substations developed from the Atlantic Offshore Wind Transmission Study and the BOEM/DOE transmission planning effort the NYSERDA's Offshore Wind Cable Corridor Constraints Assessment associated NYS Public Service Commission orders and the results of other state and ISO/RTO transmission planning processes to maximize the utility of Points of Interconnection (POIs). Lessees considering landfall in New Jersey should also comply with the results of the state agreement approach (SAA) and any other future procurements resulting from similar initiatives.]	
BOEM-2024-0001-0317-0019	The Agencies generally concur in the appropriateness of the proposed AMMM measures and encourage BOEM to adopt them subject to the considerations discussed below as baseline requirements for offshore wind development in the NY Bight. Taking this step to adopt well-supported AMMM measures will help achieve efficiencies lower costs and streamline aspects of project permitting and the related environmental reviews while protecting sensitive resources and ocean uses vitally important to the Blue Economy.	Thank you for your comment.

P.4.2.4 Massachusetts Office of Coastal Zone Management

Table P.4-10. Responses to Comments from the Massachusetts Office of Coastal Zone Management (BOEM-2024-0001-0319)

Comment No.	Comment	Response
BOEM-2024-0001-0319-0001	Implementation of this PEIS There is increasing recognition that the scale of offshore wind development on the U.S. East Coast necessitates a regional look at cumulative impacts. In light of this we appreciate that BOEM is employing an analysis in this PEIS that facilitates comparison between one and many (6) projects. We encourage BOEM to continue to consider regional and cumulative impacts during subsequent offshore wind development including in the Gulf of Maine. We also encourage BOEM to employ this regional and cumulative view of impacts as early in the siting and leasing process as possible.	The cumulative impact analysis in the PEIS considers reasonably foreseeable planned activities including federal and non-federal activities not yet undertaken, but sufficiently likely to occur, that a responsible official of ordinary prudence would take such activities into account in reaching a decision (43 CFR 46.30). The federal and non-federal activities, including offshore wind activities, that BOEM must take into account in the analysis of cumulative impacts include, but are not limited to, activities for which there are existing decisions, funding, or proposals identified by BOEM. Reasonably foreseeable planned actions do not include those actions that are highly speculative or indefinite. Cumulative impacts in the Gulf of Maine are analyzed for those resources that have geographic analysis areas that include the Gulf of Maine (e.g., birds, finfish, marine mammals, commercial fisheries).
BOEM-2024-0001-0319-0002	The "tiered" use of this PEIS described in the document will hopefully streamline the project-specific environmental reviews that follow this analysis. The overview of the affected environment and resources in the geographical analysis area the qualitative discussion of impact producing factors (IPF)s and the baseline avoidance minimization mitigation and monitoring (AMMM) measures in the PEIS will allow project specific NEPA reviews to focus on IPFs quantitatively and to address any concerns particular to one project. We expect project specific NEPA analyses will present data and include results of sampling and surveys in lease areas for most resources offshore.	BOEM agrees with the comment.
BOEM-2024-0001-0319-0003	The subsequent project specific NEPA reviews for the six New York Bight leases are expected to incorporate the AMMM measures in this PEIS by reference. The draft PEIS states that under certain circumstances BOEM may exclude some of these measures or add ones not mentioned here. For this PEIS to expedite the NEPA process for any individual project steps should be taken in those subsequent NEPA reviews to make clear to reviewing agencies and the public	For each resource area, Appendix C, *Tiering Guidance*, summarizes the affected environment, impact analysis, and AMMM measures discussed in this PEIS and identifies additional analysis that will be included in the COP-specific NEPA analysis for each lease area. Each COP NEPA analysis will consider the best available data and information that reflect the state of the science at the time of publication. Project-specific agency consultation will be conducted

Comment No.	Comment	Response
	which measures are excluded from and which are additional to the baseline set by this PEIS. If it is clear to agencies what the baseline is and what is different from the baseline reviews can be as efficient focused and helpful for BOEM and project proponents as possible.	for each EIS to inform the development of applicable AMMM measures for each lease area. The COP-specific NEPA ROD for each lease area will describe the specific terms and conditions for which compliance is required (40 CFR 1505.3), including any applicable AMMM measures analyzed in the PEIS.
BOEM-2024-0001-0319-0004	Compensatory Mitigation In this PEIS compensatory mitigation plans are described for birds fisheries and Environmental Justice communities. Hopefully these measures can be implemented effectively and their use can be expanded to other marine and coastal resources and uses. Specifically regarding compensatory mitigation for Environmental Justice communities CZM encourages BOEM to consult Massachusetts' Environmental Justice Strategy [Embedded Hyperlink: https://www.mass.gov/doc/february-2024-environmental-justice-strategy-english/download] for additional guidance and resources. We also look forward to seeing the forthcoming guidance from BOEM on compensatory mitigation approaches including third-party managed regional funds. Compensatory mitigation for wildlife and habitat including protected species commercial fisheries and other resources and uses will benefit from a coordinated regional approach.	BOEM appreciates the feedback on the potential compensatory mitigation measure for environmental justice. BOEM has determined that EJ-4 would be infeasible to implement and enforce within the agency's statutory authority as a condition of approval. Therefore, EJ-4 is no longer an AMMM measure being considered in the PEIS.
BOEM-2024-0001-0319-0005	The relocation of boulders on the seafloor and the installation of scour protection cable armoring and other structures on the seafloor can pose hazards for mobile gear fishermen interfere with other marine uses and may alter seafloor habitat. BOEM should establish clear and consistent guidelines for boulder relocation and bottom disturbance best practices based on advice from relevant federal and state agencies. BOEM should also establish protocols and/or guidance for reporting any relocated boulders and disturbed seabed features to marine users including fishermen research entities and others. While some boulder considerations such as appropriate destination locations may be best handled on a project-by-project basis a regional and comprehensive approach that simplifies and standardizes the reporting of moved boulders and other seafloor hazards across projects and developers is needed. BOEM should specify in this PEIS a	Appendix G includes AMMM measures for boulder identification relocation. The data in Tables 3.6.1-2 and 3.6.1-3 have been updated for New Hampshire and Connecticut. Unfortunately, the values from previous years do change over time, so the date of these newly provided values is provided as a footnote to the table.

Comment No.	Comment	Response
	baseline expectation for reporting boulder relocations to mariners for boulders greater than 0.5 m. As noted above CZM has participated as a cooperating agency in the review of a preliminary version of this draft PEIS. We appreciate the correction of the data transposition and citation errors in Tables 2 and 3 of section 3.6.1.1.2 that were identified during that review. However in the revised table Connecticut is reported to have "1569" in revenue in 2021 (presumably a typo) and New Hampshire's 2021 revenue of 486990 (in $1000s) seems unlikely given that years 2012-2022 were less than a tenth of this amount and there was no commensurate jump in landings for that year. We reiterate our concern that these data should be checked carefully given their importance to estimating the impact of wind development and identifying sufficient mitigation measures to the fishing industry. Although citations have been corrected per our prior comment the URLs currently result in a 404 error which makes checking the data entries more difficult.	

P.4.3 Cooperating Local Agencies

P.4.3.1 New Bedford Port Authority

Table P.4-11. Responses to Comments from the New Bedford Port Authority (BOEM-2024-0001-0444)

Comment No.	Comment	Response
BOEM-2024-0001-0444-0001	As a cooperating agency that participated in the review of the New York Bight Preliminary Draft Programmatic Environmental Impact Statement (PEIS) we appreciate the opportunity BOEM afforded us to comment on the preliminary document. We understand that BOEM attempted to address some of our comments in the final draft document but we are concerned that the document remains problematic by not sufficiently addressing the impact of these areas on commercial fishing. Any EIS document must have at its core an understanding that offshore wind development not only negatively affects the scallop resource it also affects the scallop fishing industry activities. As a mobile gear fishery scallop vessels are among the	The impact on the scallop fishery is addressed in the document. Section 3.6.1.3.2 acknowledges that mobile fishing gear could be limited temporarily or permanently within certain locations within the lease area, which could lead to losses in revenue for the scallop industry. COMFIS-3 attempts to mitigate the impacts by increasing data and knowledge about the scallop fishery, which may result in the future development of other mitigation measures that could benefit the scallop fishery or other commercial or for-hire recreational fisheries.

Comment No.	Comment	Response
	largest vessels in the east coast fishing fleet. Individually they have the least opportunity to be able to maneuver and fish within a wind farm. It is concerning that the items in the PEIS regarding fisheries mitigation take a "one size fits all" approach with ingrained assumptions regarding the ability of commercial fishermen to "adapt" and fish within the WEA.	
BOEM-2024-0001-0444-0002	Although we have never advocated for the "No Action" alternative we are troubled that the draft PEIS does not consider a wider range of alternatives to help avoid minimize and mitigate the effects of OSW on our fishing industry and habitat especially relative to the scallop industry.	The purpose of the PEIS is to identify AMMM measures that could avoid, minimize, mitigate, and monitor impacts on resources in the six NY Bight lease areas. At this programmatic stage, BOEM is not considering individual alternatives or AMMM measures that are project specific. Project-specific alternatives will be considered by BOEM and cooperating agencies at the COP-specific NEPA stage.
BOEM-2024-0001-0444-0003	Although many commercial fishermen and fisheries will be affected the scallop industry will be the fishery most adversely affected by wind development in the New York Bight. While we certainly support items in the PEIS such as the development of a scallop monitoring plan [bold and italicized: (COMFIS-3 Scallop Monitoring Plan)] detailed fisheries mitigation [bold and italicized: (COMFIS-4)] and fisheries compensatory mitigation [bold and italicized: (COMFIS-6)] these items together while important maybe too little or too late to protect the industry after the fact. Monitoring may lead to compensation to the scallop fishermen individually but financial compensation is supposed to take place as the last mitigation phase not as a substitute to other mitigation measures. First and foremost fishermen want to continue to be able to fish safely and productively in the New York Bight where the scallop resources are centered. We remain concerned that financial compensation is seen by BOEM as a substitute or reasonable alternative to other mitigation such as avoidance and minimization.	Thank you for your comment. The NY Bight lease areas were designed to avoid certain commercial fishing activities based on stakeholder input and task force meetings held from 2017 to 2021. The Final Lease Sale Decision Memorandum explains that areas were removed from the leases to avoid the mid-shelf scarp (https://www.boem.gov/sites/default/files/documents/renewable-energy/state-activities/ATLW-8-NY-Bight-Final-Lease-Sale-Decision-Memorandum.pdf). Per the memo, "Specifically, in response to the commercial fishing industry BOEM excluded area adjacent to the scallop access area, included a buffer between select leases and removed areas of high value and benthic diversity." Additional information is found in Section 5.1.4.1 of the memo. BOEM agrees that compensatory mitigation is the last step in the mitigation hierarchy. A tenet of EFH is avoidance first. BOEM will evaluate project-specific impacts based on the project-specific COP before issuing a ROD. BOEM provides this guidance to first look at avoidance and minimization. Guidance on the financial compensation can be found here: https://www.boem.gov/sites/default/files/documents/renewable-energy/DRAFT%20Fisheries%20Mitigation%20Guidance%2006232022_0.pdf.

Comment No.	Comment	Response
		Based on comments received on the Draft PEIS, COMFIS-3 has been broadened to include a Fisheries and Benthic Monitoring Plan, which includes scallops. Project-specific details will be addressed during the COP-level NEPA analysis and NMFS consultation for each project.
BOEM-2024-0001-0444-0004	There remains time to reassess the wind energy development in the Bight. BOEM can still shift offshore wind development away from Mid-Atlantic scallop beds in the Bight and develop reasonable alternatives regarding siting turbine layouts cable burial depths and effects on the scallop species in general.	The PEIS does not approve any projects. Each individual COP submitted by a developer to BOEM will be separately analyzed as required under NEPA and will disclose the full impacts of the construction and installation, O&M, and conceptual decommissioning of the project based on the project design for turbine layout and cable routes proposed by the developer. Refer to Section 3.6.1, *Commercial Fisheries and For-Hire Recreational Fishing*, for discussion and analysis of potential impacts on commercial fishing, including scallop beds. Project-specific NEPA analysis of effects on commercial fishing within a specific lease area will be conducted once a COP is submitted for BOEM review.
BOEM-2024-0001-0444-0005	3.6.3-1 Demographics Employment and Economics The geographic analysis area is flawed in that it fails to account for the economic impact of the project on areas where the primary commercial impact of the NY Bight will be felt. Namely the commercial fishing port(s) where the fish caught in the NY Bight are landed. Over 60% of the economic impact felt by fisheries affected by the NY Bight will be felt in ports and communities in Massachusetts particularly the Port of New Bedford.	Thank you for the comment. Commercial fisheries and for-hire fishing industries are evaluated in Section 3.6.1. The impact assessments include fisheries and ports as far north as Maine. COP-specific NEPA analyses will include all affected communities in assessments when project-specific information is available.
BOEM-2024-0001-0444-0006	3.6.7-21 Scientific Research and Surveys Despite this language "Overall ongoing and reasonably foreseeable planned offshore wind energy projects in the geographic analysis area would likely have major effects on NOAA's scientific research and protected species surveys potentially leading to impacts on fishery participants and communities; as well as potential major impacts on monitoring and assessment activities associated with recovery and conservation programs for protected species" there are no AMMM measures that would specifically address the impact to NOAA stock surveys. In fact all that is provided is that "BOEM is committed to working with NOAA	BOEM has committed to working with NOAA to implement the Federal Survey Mitigation Strategy program. The PEIS addresses the adverse impacts of WTG structures on surveys in Section 3.6.7.4.1, *Scientific Research and Surveys*. Please refer to OU-7 in Table 3.6.7-6 for survey mitigation measures.

Comment No.	Comment	Response
	toward a long-term regional solution to account for changes in survey methodologies as a result of offshore wind farms." This begs the question of how a project can be approved when an issue that impacts two major areas of the NEPA review remains in the "looking for a solution" area of mitigation. While it is good that there is an effort to develop new mitigation measures over the life of the project and an effort to assess cumulative impact there are over 30 leases signed and multiple projects underway with an approved EIS and COP. When it comes to the impacts on the ecosystem and commercial fishing absent a cumulative impact assessment very soon any damage done may be irreversible.	
BOEM-2024-0001-0444-0007	Appendix E: Analysis of Incomplete and Unavailable Information Other sections of the document including [bold and italicized: (E.1.7 Essential Fish Habitat)] and [bold and italicized: (E.1.11 Commercial Fisheries and For-Hire Recreational Fishing)] note the uncertain incomplete or unavailable information related to this wind energy area. BOEM NOAA and other federal agencies must take the opportunity now to fully study monitor and analyze current projects that are already erected and delivering power to the grid most notably (Vineyard Wind I and South Fork Wind) in the Massachusetts and Rhode Island WEA to guide the process of the New York Bight moving forward. Furthermore guidance should be consistent across projects all along the East Coast in terms of grid layout mitigation and data collection. In doing so BOEM in conjunction with their federal partners should have a central database and depository for data collection studies and monitoring activities that are planned ongoing or already have been completed.	Thank you for your comment. The creation of a database is not within the scope of this PEIS. However, the Environmental Studies Program Information System Quarterly Reports include summaries of the BOEM environmental studies that are completed each quarter. They can be found here: https://www.boem.gov/environment/environmental-studies/environmental-studies-information. These studies inform BOEM's policy decisions on the development of energy and mineral resources on the OCS. One such study measured EMFs from alternating and direct currents from a subsea cable in Long Island Sound on American eel movements and migrations (Hutchison et al. 2021).
BOEM-2024-0001-0444-0008	Appendix G: Mitigation and Monitoring As the most profitable fishing port in the nation and the hub for countless onshore businesses and families who rely on the industry we believe that it is vital that the actual impact of the development of offshore wind on the economy and people of Massachusetts be established using the best available data methods and information to truly measure the impact of this project on our fishing industry and those that support it. With that said we commend BOEM for laying out broad mitigation monitoring	Thank you for your comment.

Comment No.	Comment	Response
	and compensatory plans for the expected wind energy development in the New York Bight. These plans are more thorough and specific than past Draft Environmental Impact Statements and are a step in the right direction in fully addressing the potential effects on our commercial fishing industry. Yet steps can be taken (see below) to address the concerns we have relative to the scallop fishery and the economic benefits this fishery has on the Port of New Bedford and the region as a whole.	
BOEM-2024-0001-0444-0009	While we realize that specific locations of potential projects are not known currently we support what is laid out in [bold and italicized: MUL-25] Consistent Turbine Layout Markings and Lighting. [Bold and italicized: MUL-25] Consistent Turbine Layout Markings and Lighting "Lessees should employ consistent turbine grid layouts spacing markings and lighting among lease areas to minimize navigational hazards and facilitate other ocean uses such as fishing and recreational activities. Turbines should have one of the two lines of orientation per lease stipulation spaced at least 1 nautical mile (1.9 kilometers) apart to support navigation safety and Search and Rescue (SAR). This recommended spacing is based on the USCG's 2020 Massachusetts and Rhode Island Port Access Route Study). The spacing would also preserve structure-free areas to facilitate seabird passage and fishing operations. Also per lease stipulations adjacent lease areas that do not adopt the same layout must have an additional setback from shared borders. "We continue to stress that all projects must be consistent in as many areas as possible including the important issue of proper spacing.	Please refer to response to comment BOEM-2024-0001-0370-0001. Project-specific layouts will be analyzed during subsequent NEPA analysis based on information provided in the COP.
BOEM-2024-0001-0444-0010	G-37 It is not clear if BOEM is proposing one fund for the NY Bight or multiple funds. We recommend one fund as it makes it simpler and more straightforward for claimants and makes sure that all claims are handled in the same way. Fisheries mitigation funds that were previously set up contain a one-time payment limitation and no payments should a permit transfer. Such limitations ignore the impact on commercial fishing as a whole and limit mitigation to an individual fisherman. As the life of these projects is 25-30 years the need for mitigation clearly extends past the one-time payment. Any financial	While a payment may be a one-time event or multiple payments over a series of years, the BOEM-recommended duration of mitigation includes the construction period, a cascading percentage of revenue exposure funding for the first 5 years in the operational period, and the decommissioning period. Current drafts of T&Cs state that BSEE will evaluate the need for additional compensatory mitigation consistent with the Annual Certification under 30 CFR 285.633(a). BOEM does not anticipate long-term

Comment No.	Comment	Response
	mitigation plan must include a requirement that any funds not paid out directly to fishermen or shoreside services must be utilized for other mitigation opportunities such as seafood marketing research into fisheries methods gear research etc. Without this the compensation plans combined with the loss of the ability to fish in the areas have the effect of reducing the value of a permit and the attractiveness of commercial fishing as an occupation to any new generation of fishermen. Finally any financial mitigation plan must include the ability of BSEE to require additional funds to be deposited should it become apparent that such funds are necessary to mitigate the impact from the areas.	closures in any given lease area aside from those required for safety during active construction or maintenance activities. COMFIS-7, a new RP developed in response to comments received on the Draft PEIS, encourages lessees to consider participating in a Fisheries Compensation Fund. Furthermore, BOEM does not preclude the lessees of the NY Bight from using a regional fund administrator, provided the requirements set forth from BOEM are met. BOEM recognizes the advantages of a single fund, yet also recognizes that a lessee may prefer to better set the terms of a fund for their individual project. BOEM may also modify the measures at the COP-specific NEPA stage to tailor them to the characteristics of the proposed project and the site(s) of proposed activities, and to ensure conformity with project-specific consultations and authorizations.
BOEM-2024-0001-0444-0011	G-42 At the outset of the comments on the potential NY Bight lease areas there were comments regarding transit corridors. Are such corridors still contemplated? COMFIS-3 is commendable but not sufficient to address the potential issues involved. As indicated in the data put forward in the PEIS scallops are by far the most lucrative catch in the area and the catch around the NY Bight represents a significant portion of the scallop fishery as a whole. The PEIS acknowledges that the scour protection will introduce habitat in prime sandy bottom scallop habitat that did not previously exist. It further acknowledges that such rocky habitats could host scallop predators. The problem is that there does not appear to be any plan as to how to respond to issues that may arise as a result of the scallop monitoring. The problems identified by the scallop fishery involve concerns about turbidity scour pads currents OSS cooling recruitment etc. Absent addressing the concerns in the design and construction of the WEA it is difficult to see how BOEM intends to respond to negative impacts on scallop populations that arise in the monitoring plan.	Thank you for your comment. Based on comments received on the Draft PEIS, COMFIS-3 has been broadened to include a Fisheries and Benthic Monitoring Plan, which still includes scallops. Adaptive management as a result of COMFIS-3 monitoring will be considered on a case-by-case basis. As indicated in COMFIS-3, if the monitoring results deviate substantially from the anticipated impacts, the lessee is encouraged to propose new mitigation measures or monitoring methods, or both, to BOEM and BSEE for review and concurrence. BOEM retains the authority to review a COP and require a revision if circumstances change.
BOEM-2024-0001-0444-0012-a	Furthermore we support [bold and italicized: (MUL-26)] and [bold and italicized: (OU-7)] Monitoring Plan and Federal Survey Mitigation Program and urge BOEM to be as thorough and consistent when it	Thank you for your comment. Monitoring plans are developed as a result of project-specific ESA and EFH consultations.

Comment No.	Comment	Response
	comes time for the development of individual project DEIS construction and operations plans. [Bold and italicized: MUL-26] is a great addition to the procedures required under an EIS and COP. The language should include a requirement that Lessees put forward a plan to address any issues in connection with the required monitoring. Although it may be implied there should be a requirement that the results of such monitoring efforts be public and provided to BSEE and a note that BSEE retains the right to amend any COP or EIS requirements in response to the monitoring. We are also encouraged that compensatory mitigation includes compensation to shoreside businesses for losses associated with project development. These compensation and monitoring programs although not specifically noted shall be required for the entire life of the project and have begun to be addressed in recent BOEM's DEIS's.	
BOEM-2024-0001-0444-0012-b	[Bold and italicized: BEN-2] should contain a requirement that to the extent possible scour pads will be removed from habitat that was sandy bottom before the installation of the WEA. The restoration of the seafloor must be to the condition prior to installation or the damage done to the preexisting ecosystem will be permanent. This would apply to COMFIS-2 as well.	BEN-2 has been renamed MUL-41 because it is a technical requirement that does not mitigate impacts on benthic resources. Instead, it is to monitor scour protection for the integrity of the infrastructure. Scour protection typically will not be removed prior to installation of the offshore wind project and scour protection typically will stay in place for the life of the project. Lessees can request that facilities remain in place in the decommissioning application submitted to BSEE (30 CFR 285.900-285.913), but BOEM approves or does not approve the request (30 CFR 585.434).
BOEM-2024-0001-0444-0012-c	[Bold and italicized: COMFIS-4] contains several "recommendations" Is there a reason these measures are not required? A static cable depth of 2 feet in scallop areas is insufficient. From our conversations with scallop fishermen they are unlikely to take their scallop dredge into an area where the cable depth is only 2 feet as they do not feel comfortable with so little separation between their dredge and the cable especially where the seafloor conditions are constantly changing. We have also heard that the insurance companies insuring the vessels are equally unsure of scallop fishing within the WEA. At a minimum BOEM should require that inter-array cabling is laid out to minimize crossings in the line of orientation for the towers. As the	Thank you for your comment. Based on comments received on the Draft PEIS, BOEM has reviewed all draft measures and categorized them as 1) AMMM measures previously applied as T&Cs or through other mechanisms such as a Biological Opinion or Memorandum of Agreement, 2) AMMM measures not previously applied as T&Cs, and 3) RPs. BOEM encourages lessees to analyze and consider implementing these RPs, as they may further avoid and minimize impacts. Furthermore, these RPs are also not part of the Proposed Action, Alternative C, which analyzes only AMMM measures previously applied as T&Cs and AMMM measures not previously applied as T&Cs.

Comment No.	Comment	Response
	WEA is laid out with a predominant trawl direction in mind it only makes sense to require that inter-array cabling minimizes the chances of conflict between a trawl and the cables. There also needs to be a discussion as to the need for either closed-loop OSS cooling or a reduction in the use or volume of cooling water during times identified by NMFS as critical to scallop larval development.	COMFIS-4 is an RP and burial is recommended at 3 feet below stable seabed as the minimum. Actual depths will be determined at the project-specific phase. Export cable burial depth of 3 to 19.6 feet (0.9 to 6 meters) is the anticipated potential range of burial depth; 6 feet (1.8 meters) is typical target burial depth. Depths may vary based on site-specific factors (e.g., soil type, cable/pipeline crossings, crossing of navigation channels or other federal civil work projects, other federal or state requirements). COMFIS-4, Fisheries mitigation, came directly from the draft Guidelines for Mitigating Impacts to Commercial and Recreational Fisheries on the Outer Continental Shelf Pursuant to 30 CFR Part 585 (https://www.boem.gov/sites/default/files/documents/renewable-energy/DRAFT%20Fisheries%20Mitigation%20Guidance%2006232022_0.pdf). BOEM's ultimate recommendations will follow the Final Fisheries Mitigation Guidance once completed. Project-specific details will be analyzed during the COP NEPA stage.
BOEM-2024-0001-0444-0013	We urge BOEM to reassess mitigation measures alternatives avoidance and minimization methods economic and habitat impacts and other environmental and operations concerns especially relative to the valuable scallop fishery and its operations.	Additional avoidance, minimization, and mitigation will be considered and applied during project-specific EFH consultations. Additionally, economic impacts on scallop fisheries can be addressed through compensatory mitigation (COMFIS-6).

P.5 Responses to Other Agency, Stakeholder, and Public Comments on the Draft PEIS

P.5.1 Purpose and Need

Table P.5-1. Responses to Comments on the Purpose and Need

Comment No.	Comment	Response
BOEM-2024-0001-0089-0001	The NY EIS should be discarded as submitted. There are numerous instances where knowledge gaps exist that are dismissed as inconsequential to the project. Examples include gaps in knowledge of EMF emissions impacting benthic layers and the authors suggest that ongoing studies taking place at Block Island Wind Farm which has consistently operated at a fraction of its stated capacity or not at all should suffice as evidence that the project should forge ahead. This is IRRESPONSIBLE!	The EMF and cable heat IPF discussion under Section 3.5.2.3, *Impacts of Alternative A – No Action on Benthic Resources*, does include a discussion of the differences between HVAC and HVDC and the type and intensity of the EMF they produce. Text has been added to this section and Section 3.5.2.5 stating that cable shielding required by BOEM would block electric fields emitted by HVDC and HVAC cables and that a weak induced electric field would be present if HVAC cables are used. Both sections discuss the impacts of any remaining EMF on benthic invertebrates. In addition, refer to response to comment BOEM-2024-0001-0400-0003 regarding data gaps, uncertainties, and incomplete and unavailable information. BOEM addresses this concern for each resource as required under CEQ regulations (40 CFR 1502.21) in PEIS Appendix E: *Analysis of Incomplete and Unavailable Information*. For NEPA purposes, BOEM believes the NEPA regulatory requirements regarding incomplete and unavailable information have been satisfied in the PEIS.
BOEM-2024-0001-0175-0004	[Bold: BPA:] I encourage you to read [Underline: The Toxic Wings - Damage and casualty of wind turbine blades] First English edition (May 2023): Jan Erik Weinbach Asbjrn Solberg og Brd-Einar Rimereit. THE TURBINE GROUP May 2023. The author states: "The entire western world has enumerated and adopted gigantic development targets with this unproven technology and that without having a scientific basis for the overall scope of consequences for HSE (health safety and environment). It is almost unbelievable and we know of no other industry that have been allowed such "Wild West" conditions ever. The closest we come to historical comparisons is to the tobacco industry which for many decades was allowed to advertise that cigarettes were good for life and health even long after it was widely known that cigarettes have a very negative effect	Each lease area will undergo project-specific environmental analyses through the development and submittal of an SAP and a COP. BOEM will conduct project-specific NEPA analysis of the COP for each lease area, which will include detailed evaluation of impacts and will consider the best available data and information that reflect the state of the science at the time of publication. Calculation of rates is outside the scope of the PEIS and is the responsibility of grid operator and state.

Comment No.	Comment	Response
	on life and health. Smoking cigarettes was an individual choice and the damage caused by these was largely self-inflicted. The toxic emissions from wind turbines are imposed on each and every one of us including the voiceless creatures of nature. The responsibility for this must and will be assigned to those who imposed this on us without a scientific basis about the consequences for life and health". There will be too many negative and irreversible impacts for the limited amount of energy we would get from offshore wind. The benefit will never out measure the costs. Lastly I would like to mention that to date the BPU cannot tell the ratepayers what will be our cost for this venture since offshore wind is built on subsidies which I believe is not economically responsible. I truly hope that you don't realize what will be lost until after it is gone.	
BOEM-2024-0001-0310f	A smaller pilot trial project would be more prudent and give all of us a chance to assess its environmental safety and energy generating efficiency.	BOEM considered but dismissed from further consideration an alternative to build a pilot project (PEIS Chapter 2, Table 2-3). Data from sites that are constructed and operating (e.g., Block Island), as well as the pilot project in Virginia, were incorporated into this PEIS and will be incorporated into the development of project-specific COPs and EISs.
BOEM-2024-0001-0310i	But one of the things I think that is not included in a lot of the BOEM documents is the fact that this industry is not going to produce enough energy for the big cities. The wind turbines does not produce enough energy for the MTA in New York City, for the police, for the Homeland Security, for the hospitals. Wind blows 38 percent of the time. What are you supposed to do for the rest of the time? You have 24/7 backup with the industry that they are saying, you know, you know, reducing. They're actually increasing the oil industry and gas, because we need all this backup because this industry cannot do the job.	Thank you for your comment. BOEM expects that offshore wind development in the NY Bight lease areas would lead to reductions in fossil fuel usage in the U.S. However, the wind turbines would not be a sole source of electricity to the electrical grid; other sources of electric generation—including both renewables and fossil fuels—are connected to the electrical grid and would continue to supply electricity in the event that the wind turbines are shut down for any reason.
BOEM-2024-0001-0310l	The problem with offshore windmills is they're expensive. According to the Energy Information Administration, offshore wind is the most expensive energy resource in our repertoire based on the level cost of energy. The 2002 estimate for offshore wind absent of any government subsidies is $136 per megawatt of electricity. How are we the people of New York and New Jersey going to afford our electric bills? Thank you.	Thank you for your comment. The price of the power generated by the projects will be determined by offtake agreements, also known as power purchase agreements, negotiated between the offshore wind companies and electric distribution companies, subject to each state's offshore wind procurement laws and regulations.

Comment No.	Comment	Response
BOEM-2024-0001-0310m	There's one other thing. I actually wanted the audience to know, but I want to BOEM to know too. This isn't your fault. You're given the task of working with the prospect of offshore wind. And so ahead of that somebody decided to do offshore wind, and the cost of the project and its benefits have been shrouded in mystery and the mystery is starting to clear and the curtain is starting to get drawn back and people are starting to understand the cost figures per person, per home. When we're told and you allow a certain wind farm or a set of wind farms to be built, we're told how many homes that would serve with electricity. We're not told what it costs per home to provide that. 'Cause that cost is on our backs. It shows up in our taxes and in our electric rates eventually. We have to pay all that back to the wind builders. We have to give them their profit they're guaranteed. So I will leave it at this. You can talk to me in the back if you're interested, but what it's showing is that it costs so much money per home that this would serve that for a tiny fraction, that's the cost to build, maintain the whole lifespan and if we add to that also the losses that we know that the seashores will come to, which includes the fisheries, it includes property value losses, the loss to the shore businesses. When you add all that up divided by the number of homes that that's supposed to provide electricity for, it's such a huge number that you could easily come up with alternatives.	Thank you for your comment. The price of the power generated by the projects will be determined by offtake agreements, also known as power purchase agreements, negotiated between the offshore wind companies and electric distribution companies, subject to each state's offshore wind procurement laws and regulations.
BOEM-2024-0001-0310p	I have been involved with many of the anti-wind and pro whale groups in the area, I have not found one fact that can support that there's anything good about these offshore wind turbines going in. Not one. If anybody knows of one, please educate me because I have read environmental impact studies and one of the main things that I would like to request from BOEM is to complete your mission statement. Your mission is to environmentally and economically manage our ocean, and by putting in these wind turbines and rushing them through without, you know, without the studies on how it's affecting the marine life and the ocean and the economy, is just irresponsible. You're not meeting your mission statement. So, BOEM, I would like you to meet your mission statement and be	BOEM's Environmental Studies Program develops, funds, and manages rigorous scientific research specifically to establish information needed for assessing and managing environmental impacts of energy and mineral development on the human, marine, and coastal environments. For more information on this program, please visit https://www.boem.gov/environment/how-we-do-research. Further, BOEM's Office of Renewable Energy Programs depends on science to meet its responsibilities under environmental laws, regulations, and standards. As such, BOEM funds and manages scientific research to inform its decision-making processes for

Comment No.	Comment	Response
	environmentally and economically prudent with our ocean. We've only got one. If we ruin it this is going to be the worst environmental disaster in our lifetime, you know, worse than the polar icecaps and the dinosaurs missing and all that stuff. We cannot get clean water back.	renewable energy projects on the OCS. For more information on Office of Renewable Energy Programs, please visit https://www.boem.gov/environment/environmental-studies/renewable-energy-research.
BOEM-2024-0001-0313-0006	1.3 Purpose and Need for the Proposed Action Page 1-5 states that "A broader approach to the NEPA analysis for the minimum of six COPs expected for the NY Bight lease areas is consistent with Executive Order 14008 "Tackling the Climate Crisis at Home and Abroad" issued on January 27 2021. In that order President Biden stated that the policy of his administration is "to organize and deploy the full capacity of its agencies to combat the climate crisis to implement a Government-wide approach that reduces climate pollution in every sector of the economy; increases resilience to the impacts of climate change; protects public health; conserves our lands waters and biodiversity; delivers environmental justice; and spurs well-paying union jobs and economic growth especially through innovation commercialization and deployment of clean energy technologies and infrastructure." To support the goals outlined in Executive Order 14008 the administration has also announced plans to increase renewable energy production with a goal of 30 gigawatts (GW) of offshore wind energy capacity by 2030. Potential development of the leaseholds would assist with meeting several state mandates for renewable energy. New Jersey's goal of 11 GW of offshore wind energy generation by 2040 is outlined in New Jersey Executive Order No. 307 issued on September 21 2022. New York's requirement of 9.0 GW of offshore wind energy generation by 2035 is outlined in the Climate Leadership and Community Protection Act signed into law on July 18 2019. Additionally an estimated 1618 GW of offshore wind energy may be necessary to ensure New York State achieves its Climate Act mandates (New York State Climate Action Council 2022). Based on a conservatively estimated power ratio of 3 megawatts per square kilometer BOEM estimates that full development of leases in this area has the potential to create up to 5.6 to 7 GW of offshore wind energy."	The PEIS only analyzes six lease areas on the Atlantic OCS; other projects not analyzed in the PEIS would contribute to New Jersey and New York state goals. These include Empire Wind, Atlantic Shores North, and Atlantic Shores South. These other projects are analyzed as part of the cumulative effects analysis. The 5–7 GW expected from the six NY Bight lease areas is based on a conservative power ratio of 3 megawatts per square kilometer (MW/km^2). The NY Bight leases each have operations terms of 33 years that commence on the date of COP approval. Lessees may request an extension of their lease in accordance with lease terms and BOEM regulations. Cumulative impacts are addressed in the PEIS for each resource and for each alternative, including the No Action Alternative; the methodology is explained in PEIS Chapter 3, pages 3-1 through 3-3.

Comment No.	Comment	Response
	Comment: It is unclear how dedicating 48800 acres of lease area and the associated structures and disturbance meets the objectives specifically protection of public health; conservation of our lands waters and biodiversity stated above; in fact this project appears to directly contravene those policies. For context the entire Town of Oyster Bay comprises approximately 108 400 acres. The best-case scenario presented in the PEIS at full optimization of the project at 7GW is still less than the overly ambitious state mandate of 9GW of offshore wind energy further the lifespan of a WTG is only approximately 30 years. There is no discussion about the net generation of how these mandates will be achieved and how that figure is calculated into the equation upon expiration of the WTG's useful lifespan not only would it appear that a lease extension would be needed for continuous operation but WTGs would have to be decommissioned and replaced. The larger plans of scale and cumulative impacts must be adequately addressed in the final PEIS. Though the goals for alternative energy requirements are reiterated throughout the documents as a guiding qualifier for expeditiously proceeding with the review of these projects the details are omitted and unavailable thereby making it impossible to meaningfully review and consider the comprehensive cumulative synergistic direct and indirect impacts.	
BOEM-2024-0001-0331-0001	We are not opposed to clean energy in general and seek only that where it is pursued it be done in a reasonable and consistent manner and not leave major collateral damage in its wake. According to the Federal Register BOEM states that the purpose of the Draft PEIS is to analyze the potential impacts of the New York Bight along with identifying possible changes to those impacts that could result from adopting certain avoidance minimization mitigation and monitoring measures (AMMM). After public input BOEM will decide on whether to adopt one or all of the AMMM measures outlined in the DPEIS and make them conditions of approval for activities proposed by the lessees in their construction and operation plans (COPS) or defer the decision to adopt such measures to each project-specific environmental review. According to the diagram about the process the PEIS analyzes the programmatic avoidance minimization mitigation and monitoring measures that could apply to the New	Thank you for your comment. BOEM shares the same goal to ensure projects are developed responsibly. The Final PEIS includes several identified AMMM measures (refer to Appendix G) to avoid, minimize, and mitigate impacts from potential development of the six NY Bight lease areas.

Comment No.	Comment	Response
	York Bight leases and includes a focused regional cumulative analysis.	
BOEM-2024-0001-0331-0030	The BOEM PEIS lacks any discussion concerning intermittent offshore wind's contribution to grid unreliability how this will be mitigated and at what cost. For the first time in August 21 2023 the North American Electric Reliability Corporation (NERC) identified energy policy as a risk priority for grid reliability because the heightened legislative focus and mandates regarding decarbonization decentralization and electrification. The organization holds that the emerging resource mix is more susceptible to long-term widespread and extreme events like sustained loss of wind power. (https://www.nerc.com/news/Pages/Collective- Focus-Imperative-for-Mitigating-Emerging-Risks-to-Grid-Reliability.aspx) If the purpose of the projects is to meet the governor's goal by executive order for the State to sell 100% clean energy by 2035 including 11 GW of offshore wind how do the wind developers and BOEM propose to back up the wind when it is not blowing? What is the cost of this backup? What are the plans and cost of battery backup storage systems? According to Science Daily "energy droughts" in wind and solar can last a week. (DOE/Pacific Northwest National Laboratory December 11 2023) . BOEM and wind developers use a misleading measurement called a capacity factor in their discussions of offshore wind energy output but this number typically 50% - is misleading in that it is an average. This average does not account for the times when generated wind energy exceeds demand and when wind energy is less than demand. For example there could be days when the wind turbines are only producing 20% of their energy capacity but demand requires 80% capacity. There will be other days when wind energy supply will be at 70% of its capacity but demand will only be at 50%. A rigorous multiyear supply/demand accounting would inform us of the balancing costs back-up costs and grid costs related to the true issues of intermittency.	BOEM's responsibility under the Energy Policy Act of 2005 is to issue renewable energy leases, easements, and rights-of-way (ROWs) for activities on the OCS. The purpose of the PEIS is to present a programmatic analysis of the six NY Bight lease areas to characterize the types of impacts that could occur and mitigation measures that could minimize those effects. Grid reliability is outside of BOEM's regulatory authority and the scope of the PEIS. The grid operator is responsible for managing the reliability of the grid. While offshore wind in the NY Bight would provide a new source of energy to the states of New York and New Jersey, other sources of energy would still be generated. BOEM's calculations of capacity are an assessment of total lease capacity and are not used to estimate power operations. Costs for power are considered through state solicitations and are factored into utility rates. To date BOEM has not received COPs proposing battery energy storage systems. Other developers may choose to develop battery systems to capture offshore wind, and those projects would be required to be reviewed and permitted separately, although they would be outside BOEM's jurisdiction. However, the offshore wind projects do not require backup power or battery storage systems, and each project has independent utility.
BOEM-2024-0001-0334-0002	Be advised that the issues below as well as those you will receive from others represent a grave concern regarding BOEM's performance in protecting the interests of the New Jersey public. BOEM appears to ignore most of the significant impacts raised in their own EIS documents as well as the concerns raised by the well-	The PEIS was developed through coordination with federal agencies, Tribal Nations, and state and local partners, and the AMMM measures seek to avoid, minimize, or mitigate potential impacts. Project-specific NEPA analysis will provide additional site-specific data and incorporate advances in technology and

Comment No.	Comment	Response
	researched public. The approvals of the projects to date seem to only ensure that the projects move forward with the appearance of having been fully vetted and the mainstream press bolsters that perception to the public. A critical viewpoint is now widespread and if successful will lead to new and increased pressures to prevent offshore wind projects from proceeding in New Jersey on the East Coast and around the coastal areas of the USA.	understanding of these areas. Additional coordination with regulatory agencies is required as part of the approval of the project-specific approaches.
BOEM-2024-0001-0345-0003	New York City and Long Island are on the front lines of climate change. The NYSERDA white paper on the Climate Leadership and Community Protection Act asserts that one major obstacle the state faces to meet our climate change goals is that there is a "tale of two grids." Upstate uses 88% zero-emission resources but only represents 1/3rd of the energy load while downstate is 2/3rds of the load and 69% fossil fuels. The only way to see a just transition from polluting fossil fuels to renewable energy downstate is by utilizing offshore wind. New York has several offshore wind projects moving through the regulatory process which if approved will power millions of homes with clean renewable energy and bring New York significantly closer to our goal of 9000 MW of offshore wind. These projects are also kickstarting an "offshore wind-ustry" in the state which are already slated to create nearly 7000 jobs in project development manufacturing installation and operations and maintenance while creating over $12 billion in economic benefits to the state. They will also allow the state to close down antiquated polluting fossil fuel fired power plants which will improve air quality in our region and provide $1 billion in health benefits to New Yorkers in vulnerable and frontline communities.	Comment noted.
BOEM-2024-0001-0354-0017	True science involves constantly emerging new evidence and findings along with the ever-changing challenges imposed as to prior conclusions. As such contrary to the. Non-scientific "group think" and massive amounts of money driven public relations press releases behind the current wind turbine projects such sentiment ignores scientific methods of ongoing experimenting at the very least through realistic peer reviewed scientific pilot projects. True science involves constantly emerging new evidence and findings. This process necessarily continually involves the ongoing application of extensive scientific research which is then applied to the previously	This PEIS highlights regional issues; the details in the project-specific COP NEPA documents will provide additional site-specific information and incorporate advances in technology and scientific understanding as the projects advance. In addition, refer to response to comment BOEM-2024-0001-0400-0003 regarding data gaps, uncertainties, and incomplete and unavailable information. BOEM addresses this concern for each resource as required under CEQ regulations (40 CFR 1502.21) in PEIS Appendix E: *Analysis of Incomplete and Unavailable Information*. For NEPA purposes, BOEM believes the

Comment No.	Comment	Response
	accepted theories. Such a true application of peer reviewed science especially applied to growingly_ obsolete wind turbine construction would support the revision if not rejection of prior dogma as to allegedly "settled science". As I have testified previously only from a partially facetious standpoint the rush to judgment approach as to this specific proposal to construct massive windfarms off New Jersey represents non-scientific "group think" with the devastating potential to trample upon scientific inquiry and research. Such immense pressure from those supporting such colossal development of this offshore industrial site off of the precious New Jersey Coast unfortunately has facilitated many knee-jerk feel-good reactions which totally ignore the required economic and scientific vetting process. During a prior era particularly relevant to the coast of New Jersey our town and I were subjected to enormous pressures exerted by those supporting ocean dumping. Generated by a foreign corporation's pipeline off our beautiful and incalculably valuable portion of the New Jersey shore. Similar subconscious and actual influences are once again being exerted in favor of a foreign corporation looking to create another potential ocean dumping site off New Jersey's shoreline. I would truly beseech BOEM officials to rise above the narrow bureaucratic rubber-stamping of the within proposal in favor of the true application of scientific method to the entire cumulative and indirect impacts of the current project as well to windfarms off of New Jersey's Coast in general. Just as one heartfelt objector testified in a virtual hearing as to the threats proposed by foreign corporations to our country's national symbol the bald eagle these threats are very real whether proposed by a non-American entity or a corporation based in our own country.	NEPA regulatory requirements regarding incomplete and unavailable information have been satisfied in the PEIS.
BOEM-2024-0001-0355-0004	Unreliable energy so a back-up energy supply would still be needed.	Comment noted. Grid reliability is the responsibility of the state grid operators. While offshore wind in the NY Bight would provide a new source of energy to the states of New York and New Jersey, other sources of energy would still be generated.
BOEM-2024-0001-0355-0017	In addition it seems BOEM is rushing this process with little or no information. I am opposed to approval of the OSW projects at this time until MORE DATA AND MORE STUDIES are conducted. There are way too many unknowns and "insufficient data" per BOEMs PEIS. From p. 5 of the PEIS they state "The Atlantic OCS is considered by	Refer to response to comment BOEM-2024-0001-0400-0003 regarding data gaps, uncertainties, and incomplete and unavailable information. BOEM addresses this concern for each resource as required under CEQ regulations (40 CFR 1502.21) in PEIS Appendix E, *Analysis of Incomplete and Unavailable*

Comment No.	Comment	Response
	BOEM to be a "Frontier Region" where little information exists about the geologic conditions and how those conditions may impact development of offshore wind farms." On page 12 they state "site investigation and characterization for such projects is generally focused on a limited area." Does this make sense on a barrier island where the water table is high and you can compromise the water resource on one part and not another? How can you approve such a project without knowing so much of the necessary information to make a thoughtful decision that will affect SO MANY humans and marine creatures in multiple negative ways? At the very minimum there should be a pilot study done to collect more information on our specific region before going for this massive disruption to and destruction to marine life human life real estate and tourism.	*Information*. For NEPA purposes, BOEM believes the NEPA regulatory requirements regarding incomplete and unavailable information have been satisfied in the PEIS. In addition, this PEIS will not result in the approval of any activities in the NY Bight lease areas. Each lease holder is required to conduct project-specific environmental analyses, which include development and submittal of a COP as required under 30 CFR 585.628. BOEM will conduct project-specific NEPA analysis of the COP for each lease area that will focus on providing site- and project-specific analyses that were not already addressed by the PEIS. Appendix C, *Tiering Guidance*, summarizes the affected environment, impact analysis, and AMMM measures for each resource area discussed in this PEIS and identifies additional analysis that BOEM anticipates may be included in the COP-specific NEPA analysis for each lease area and cable route as the projects advance. Further, BOEM considered but dismissed from further consideration an alternative to build a pilot project (PEIS Chapter 2, Table 2-3). Data from sites that are constructed and operating (e.g., Block Island), as well as the pilot project in Virginia, were incorporated into this PEIS and will be incorporated into the development of project specific COPs and EISs.
BOEM-2024-0001-0356-0003	The second more recent information that has been acknowledged is inadequate is from the NJBPU published 2/14/24: "Atlantic hurricanes pose a significant potential threat to the State's burgeoning OSW sector. Despite this risk relatively little technical research has been devoted to quantifying and assessing Atlantic hurricane impact upon OSW projects. As a result regulators developers and insurers have limited tools at their disposal to mitigate this risk or ascertain whether the risk warrants design modifications. The prevailing uncertainty surrounding what is widely perceived as a substantial threat to OSW largely without scientific or engineering backing serves as a considerable obstacle to the development of OSW Development of advanced technical research quantifying and assessing hurricane risk is therefore necessary to aid developers regulators and insurers in mitigating hurricane risk and providing improved design standard baselines." These studies	As stated in PEIS Section 2.3, the engineering specifications of the WTGs and their ability to sufficiently withstand weather events, including hurricane-level events, are independently evaluated by a certified verification agent when reviewing the Facility Design Report and Fabrication and Installation Report according to international standards. One of these standards calls for the structure to be able to withstand a 50-year return interval event. An additional standard includes withstanding 3-second gusts of a 500-year return interval event, which would correspond to Category 5 hurricane windspeeds. It is in the best interest of the lessees to construct and operate a viable project and minimize risk as much as possible; they are responsible for ensuring the WTGs are designed and constructed to withstand such events and to ensure the integrity of the structures would not be compromised.

Comment No.	Comment	Response
	should've been performed and the results published long before any of the EIS's for any lease were approved. This is absolutely absurd and are yet more glaring reasons that OSW is being pushed through the regulatory processes prematurely and unchecked.	
BOEM-2024-0001-0357-0002	As requested by the BOEM the bulk of our comments here are on the New York Bight program EIS to make it a more useful document. However it is not the document that is of paramount concern here. Rather it is the BOEM decision making process itself relative to the requirements of the Administrative Procedures Act the Outer continental Shelf Lands Act and the National Environmental Policy Act and the dictates of common sense which we believe is fundamentally unreasonable and flawed in at least two major respects: First, the BOEM does not consider the full, real environmental impact to an area when it approves projects, and Second, it does not engage expert and other public input before it makes the most important decisions, i.e., on wind turbine location, number, megawatt size and gear drive. Both of these defects are discussed below.	The purpose of the PEIS, as described in Chapter 1, *Purpose and Need*, is to analyze the effects from potential development activities in the six NY Bight lease areas and to identify and analyze AMMM measures that could reduce those effects. The PEIS does not approve any projects. Each individual COP submitted by a developer to BOEM will be separately analyzed as required under NEPA and will disclose the full impacts of the construction and installation, O&M, and conceptual decommissioning of the project, including cumulative effects. During the COP-specific NEPA process, BOEM will hold a public comment period at the start of the NEPA process (scoping) and, following that, will release the Draft NEPA document, whereby members of the public and agencies can provide input to help inform the NEPA process, alternatives, and mitigation measures to identify and minimize environmental effects. Additionally, throughout the NEPA process, BOEM will work closely with Cooperating Tribal Governments and federal and state agencies to assist with assessing impacts and identifying mitigation measures. BOEM will analyze each COP as proposed by the developer and does not make decisions on number of turbines, MW size, and gear size that applicants include in the COP. BOEM may analyze different alternatives and mitigations—such as the number of turbines, MW size, and gear size—as part of the NEPA review process, project-specific consultations, and decision process.
BOEM-2024-0001-0362-0027	High-road Equitable Environmentally Responsible Development Outer Continental Shelf Lands Act BGA believes that standards for high-road equitable and environmentally responsible development are consistent with federal statute. In Section 8 of OCSLA Congress declared that it is the authority of the Secretary of the Interior (delegated to BOEM) to "grant a lease easement or right-of-way" for activities that "produce or support production transportation or transmission of energy from sources other than oil and gas" in a	Comment noted. Section 1.4, *Regulatory Overview*, of the Final PEIS describes the regulatory authority for renewable energy leasing on the OCS.

	sharing." [Footnote viii: White House FACT SHEET: Biden Administration Jumpstarts Offshore Wind Energy Projects to Create Jobs March 29 2021. https://www.whitehouse.gov/briefing-room/statements-releases/2021/03/29/fact-sheet-biden-administration-jumpstarts- offshore-wind-energy-projects-to-create-jobs/]	
BOEM-2024-0001-0362-0031	Recent global events have made it abundantly clear that our national security is strongly tied to our energy security to which domestic manufacturing plays a critical role. The U.S. Department of Energy and the North American Electric Reliability Corporation jointly-commissioned a report assessing risks to the U.S. electricity generation and distribution infrastructure. The summary of the report observed that the "bulk power system is dependent on long supply chains often with non-domestic sources and links" and determined that the "increased reliance on foreign manufacturers with critical components and essential spare parts manufactured abroad (e.g. HV transformers)" means the "supply chain itself represents an important potential vulnerability." [Footnote xv: North American Electric Reliability Corporation High-Impact Low-Frequency Event Risk Impact to the North American Bulk Power System at page 30 (June 2010). https://www.energy.gov/ceser/downloads/high-impact-low-frequency-risk-north-american- bulk-power-system-june-2010.] The report recommends that "efforts should be considered to bring more of the supply chain and manufacturing base for these critical assets back to North America." [Footnote xvi: Ibid at 27]	Comment noted.
BOEM-2024-0001-0383-0007	OSCLA: BOEM quotes the Outer Continental Shelf Lands Act regarding the Secretary's legislative requirement to "ensure that any activity under [subsection 8(p)] is carried out in a manner that provides for (A) safety; (B) protection of the environment.. (I) prevention of interference with reasonable uses (as determined by the Secretary) of the exclusive economic zone the high seas and the territorial seas.." etc. [Footnote 21: PEIS at New York Bight Draft Programmatic Environmental Impact Statement Volume 1 Chapters 1-4 (boem.gov) p. 1-6 1-7.] The agency then quotes a 2021 agency memo that states that the law as written in fact does not require the Secretary to ensure achievement of these various "goals" but to balance them.[Footnote 22: Ibid p. 1-7.]We disagree. The term	The Solicitor’s Opinion of December 14, 2020, M-37059, was withdrawn on April 9, 2021, by M-37067 for the reasons explained in the latter opinion. The Solicitor’s M-opinions on matters within the jurisdiction of the Department of the Interior (DOI) are binding on BOEM (see 209 Department Manual 3.2(A)(11)). Therefore, BOEM is bound to follow the interpretation of the OCSLA put forth in M-Opinion 37607.

Comment No.	Comment	Response
	"ensure" means "ensure". It does not mean balance. By not ensuring safety by not ensuring prevention of interference with reasonable uses- such as federally permitted commercial fishing on the OCS- BOEM is in violation of the law. The agency cannot rewrite the meaning of the word "ensure" with an internal agency memo. Furthermore the agency memo written in 2021 directly contradicts a corresponding agency memo written only five months prior in 2020. We have attached that memo along with this comment. The 2021 memo purports to overturn the previous 2020 memo this reinterpretation coinciding with a change in Administration but the law cannot mean two different things. Simply because an Administration changes does not mean that the law changes. Congress changed nothing. The definition of the word "ensure" did not change in the English language between 2020 and 2021.BOEM cannot add words to statute that do not exist in the statute; it must take the legislative language at face value. The PEIS states that the law imposes only a "a general duty" and "does not require the Secretary to ensure that the goals are achieved to a particular degree" but allows the Secretary to "balance" what it refers to as "goals". These listed requirements are not goals; they are legal standards. The law says the Secretary must "ensure" that these legislative standards are met. The word "ensure" defined by Merriam-Webster means "to make sure certain or safe: guarantee." [Footnote 23: See Ensure Definition & Meaning - Merriam-Webster.] The Secretary must guarantee these standards. It is clear from the discussion on navigational impacts in the AMMM section below the commercial fishing impacts contained in our attached USCG comments as well as the lack of regulatory benchmarks regarding high resolution geophysical surveys discussed below- which requires stronger regulatory protections by both BOEM and NOAA when being conducted in the Gulf of Mexico by other offshore energy industries than in the Atlantic by offshore wind developers- that BOEM is not guaranteeing that these OSCLA standards are met.	
BOEM-2024-0001-0403-0002	The content of the PEIS is also grossly insufficient to account for the various impacts on nearly half a million acres of ocean land leased throughout the six lease areas: Bluepoint Wind Attentive Energy Community Offshore Wind Atlantic Shores Offshore Wind Bight	For each resource area, Appendix C, *Tiering Guidance*, summarizes the affected environment, impact analysis, and AMMM measures discussed in this PEIS and identifies additional

Comment No.	Comment	Response
	Invenergy Wind Offshore and Vineyard Mid-Atlantic. Tellingly the record $4.3 billion secured through these leases indicates that the profitability of these leases far outweighs any real assessment of the impacts and consequences of industrializing one of our last untapped and pristine natural resources. The PEIS by BOEM's own estimation anticipates 1103 wind turbines 22 offshore substations 44 offshore export cables of 1772 miles in length and 1583 miles of inter array cables between the six projects throughout the Bight. The document sites estimated impacts from negligible to major in a variety of areas but without citing sufficient baseline data due to the absence of such data. To issue a PEIS on the six lease areas without the existence of baseline data and "because the size and design of the NY Bight wind farms are unknown at this stage" is shortsighted grossly inappropriate and negligent. Unfortunately, further issuance of project-specific Environmental Impact Statements have been hamstrung by the federal 2020 NEPA rule change which will limit future EISs to 150 to 300 pages for "proposals of unusual scope or complexity". This means that we will never fully understand the impacts and will be to borrow a term from NMFS "building the ship while sailing it."	analysis that will be included in the COP-specific NEPA analysis for each lease area. Each lease area will undergo project-specific environmental analyses through the development and submittal of a COP. BOEM will conduct project-specific NEPA analysis of the COP for each lease area, which will include detailed evaluation of impacts and will consider the best available data and information that reflect the state of the science at the time of publication. BOEM has prepared several EISs for offshore wind projects within the required page limits and has not found that the page limits prevent a thorough analysis.
BOEM-2024-0001-0406-0008	BOEM's Proposed Action Violates NEPA and the APA BOEM's proposed action "the adoption of AMMM measures such that the potential impacts described in Alternative B may be avoided reduced or mitigated" Draft PEIS 2.1.3 (p. 2-16) would run afoul of both NEPA and the Administrative Procedures Act (APA) creating considerable legal risk for BOEM and jeopardizing the utility of its programmatic NEPA analysis if BOEM does not amend the proposed action in its Final PEIS. As BOEM describes it in the Draft PEIS the proposed action calls for "adopting programmatic AMMM measures that BOEM would require as conditions of approval for activities proposed by lessees in COPs submitted for the NY Bight lease areas unless future COP-specific NEPA analysis shows that implementation of such measures is not warranted or effective." Draft PEIS 1.3 (p.1-4) (emphasis added). BOEM then states that "[t]he Record of Decision (ROD) for the PEIS will state which of the AMMM measures analyzed in the PEIS BOEM has committed to adopting and if not why they were not adopted." Id. This proposed action would establish for	The Proposed Action for the Final PEIS includes the identification of AMMM measures at the programmatic stage that could avoid, minimize, mitigate, and monitor impacts on resources in the six NY Bight lease areas. These measures may be required as conditions of approval for activities proposed by lessees in the COPs submitted for the six NY Bight lease areas. BOEM may require additional or different measures based on future, site-specific NEPA analysis or the parameters of specific COPs. BOEM may also modify the measures at the COP-specific NEPA stage to tailor them to the characteristics of the proposed project and the site(s) of proposed activities, and to ensure conformity with project-specific consultations and authorizations. BOEM has modified the PEIS language describing the Proposed Action and refined the language throughout the PEIS to make clear that this PEIS is *not imposing* any AMMM measures—and therefore is not establishing a presumption at COP review that a lessee would need to rebut—but is identifying those AMMM

Comment No.	Comment	Response
	the six NYB lessees a presumption at COP review that BOEM will impose the full suite of AMMM measures from the Final PEIS on their projects unless the lessees can make a specific showing in their COPs that specific measures are not "warranted or effective." This approach unlawfully shifts the burden from BOEM to the lessee an approach which is legally problematic in at least two key respects.	measures that BOEM may impose at the COP-specific NEPA stage. Because those AMMM measures are identified and analyzed now, the expectation is that the analysis at the COP-specific NEPA stage can be more streamlined and efficient.
BOEM-2024-0001-0406-0009	BOEM's Proposed Action Inappropriately Imposes Substantive Obligations Through a Procedural Statute NEPA is a procedural statute requiring an agency to analyze the environmental impacts of a proposed federal action. 42 U.S.C. 4331. While the NEPA regulations obligate an agency to provide a "detailed discussion of possible mitigation measures" when preparing an EIS it does not impose "a substantive requirement that a complete mitigation plan be actually formulated and adopted." Robertson v. Methow Valley Citizens Council 490 U.S. 332 35152 (1989). Thus while BOEM has appropriately discussed in detail the AMMM measures that could be applied during COP-specific NEPA analysis any adoption of those measures must be done through substantive statutes that grant BOEM and other permitting agencies the authority to require such measures. In this case BOEM's substantive authority to impose mitigation measures derives from the Outer Continental Shelf Lands Act (OCSLA) and its implementing regulations. In particular 30 CFR 585.620-628 establishes the COP review process and states that BOEM "will prepare an appropriate NEPA analysis" id. At 628(b) and then "upon completion of technical and environmental reviews will specify terms and conditions to be incorporated into the COP." Id. At 628(f)(1). Because BOEM's authority to impose mitigation measures is explicitly contingent on its review of a submitted COP it would be premature to invoke that authority in a PEIS. Moreover as noted above many of the proposed AMMM measures lie outside of BOEM's statutory and regulatory authority and would need to be "adopted" by other federal state and/or local agencies (if indeed they could be required or enforced at all). By proposing to "adopt" AMMM measures in a programmatic NEPA document divorced from an OCSLA decision point BOEM effectively and illegally converts NEPA to a substantive statute.[Footnote 1: It is no defense that BOEM would retain the discretion to not impose particular AMMM measures if	The Proposed Action for the Final PEIS includes the identification of AMMM measures at the programmatic stage that could avoid, minimize, mitigate, and monitor impacts on resources in the six NY Bight lease areas. These measures may be required as conditions of approval for activities proposed by lessees in the COPs submitted for the six NY Bight lease areas. BOEM may require additional or different measures based on future, site-specific NEPA analysis or the parameters of specific COPs. BOEM may also modify the measures at the COP-specific NEPA stage to tailor them to the characteristics of the proposed project and the site(s) of proposed activities, and to ensure conformity with project-specific consultations and authorizations. BOEM has modified the PEIS language describing the Proposed Action and refined the language throughout the PEIS to make clear that this PEIS is *not imposing* any AMMM measures—and therefore is not establishing any substantive obligations at this programmatic stage—but is identifying those AMMM measures that BOEM may impose at the COP-specific NEPA stage. Because those AMMM measures are identified and analyzed now, the expectation is that the analysis at the COP-specific NEPA stage can be more streamlined and efficient.

Comment No.	Comment	Response
	lessees can demonstrate in their COPs that an "adopted" measure is not "warranted or effective." The proposed action still would constitute a substantive imposition of AMMM measures before COP submittal with the burden now shifted to lessees to prove in their COPs that such measures should not be required.]	
BOEM-2024-0001-0406-0010	BOEM's Proposed Action Appears to Constitute a De Facto Rulemaking in Violation of the APA By imposing a new standard of review on all projects within the NY Bight BOEM has also effectively engaged in de facto rulemaking in violation of the APA. Subject to very limited exceptions the APA requires that any adoption of or amendment to a federal regulation go through the notice and comment rulemaking process. 5 U.S.C. 553. Substantive agency rules which change or impose rights and obligations of regulated parties may not be imposed through informal pronouncements; to do so represents a violation of the APA's rulemaking procedure. See e.g. Cmty. Nutrition Inst. V. Young 818 F.2d 943 946-47 (D.C. Cir. 1987); see also Phillips Petroleum Co. v. Johnson 22 F.3d 616 621 (5th Cir. 1994) ("A party may not be adversely affected by a [substantive] rule in violation of [APA notice and comment] requirements."). BOEM's proposed action while not styled as an amendment to its regulations imposes a new standard that upends the COP review process established in BOEM's existing regulations and seeks to apply a new set of requirements (i.e. the full suite of AMMM measures) to all offshore wind projects in the NY Bight. As noted in the section above BOEM's regulations require that it "specify terms and conditions" of COP approval "upon completion of technical and environmental reviews" of a submitted COP. 30 CFR 585.628(f)(1). If the ROD is issued as BOEM proposes all six NYB lessees would face a presumptive array of requirements prior to submitting a COP and prior to BOEM conducting any of its environmental or technical reviews of those COPs. The lessees would then be required to demonstrate in their COPs that individual measures are not "warranted or effective" a standard found nowhere in OCSLA or BOEM's regulations. This would create a new standard of review that effectively shifts BOEM's burden to demonstrate that specific AMMM measures are needed based on its review of the project to the lessees. That is exactly the type of	The Proposed Action for the Final PEIS includes the identification of AMMM measures at the programmatic stage that could avoid, minimize, mitigate, and monitor impacts on resources in the six NY Bight lease areas. These measures may be required as conditions of approval for activities proposed by lessees in the COPs submitted for the six NY Bight lease areas. BOEM may require additional or different measures based on future, site-specific NEPA analysis or the parameters of specific COPs. BOEM may also modify the measures at the COP-specific NEPA stage to tailor them to the characteristics of the proposed project and the site(s) of proposed activities, and to ensure conformity with project-specific consultations and authorizations. BOEM has modified the PEIS language describing the Proposed Action and refined the language throughout the PEIS to make clear that this PEIS is *not imposing* any AMMM measures. It is not establishing or imposing any substantive obligations at this programmatic stage. Nor does the proposed action purport to change the standard in BOEM's regulations governing review of COPs. For those reasons, the proposed action is not a de facto rulemaking. Instead, it is identifying those AMMM measures that BOEM may impose at the COP-specific NEPA stage. Because those AMMM measures are identified and analyzed now, the expectation is that the analysis at the COP-specific NEPA stage can be more streamlined and efficient.

Comment No.	Comment	Response
	change in the rights and obligations of regulated parties that can only be done through notice and comment rulemaking.[Footnote 2: The fact that this particular Draft PEIS "only" applies to six lessees is of little consequence. BOEM is in the process of conducting a similar programmatic review for its five California leases see https://www.boem.gov/renewable-energy/state-activities/california-offshore-wind-programmatic-environmental-impact and has given every indication that it will continue to use the PEIS mechanism to create efficiencies in its future COP reviews. It is reasonable to expect that the choices BOEM makes in this PEIS process will inform subsequent programmatic reviews in other wind energy areas.	
BOEM-2024-0001-0406-0029	Finally BOEM should also consider declining to issue a ROD with the Final PEIS. Even in its draft form the PEIS does not make any "decisions" that trigger environmental effects and that remains the case if revised as suggested herein. No decision of that sort is made until BOEM makes a decision on an individual COP that has been the subject of a full-blown EIS. Any decision flowing from this PEIS is therefore premature. Moreover there is no formal requirement in NEPA the CEQ regulations or Department of the Interior (DOI) regulations that a programmatic NEPA analysis must include a ROD if no decision is being made. Eliminating the ROD would make clear to the public that this PEIS is primarily intended to facilitate early identification and analysis of important issues and impacts common to all NYB leases and not to narrow BOEM's or lessees' options at the COP stage or impose substantive requirements as with the presumptive application of the full suite of AMMM measures analyzed in the Draft PEIS.	Comment noted. A ROD could identify those AMMM measures BOEM may apply as conditions of approval for the COPs submitted for the NY Bight leases. This documentation does not constitute final agency action but may be integrated into the ROD for each individual project. Identification of the measures BOEM may apply does not narrow options at the COP stage because BOEM may require additional or different measures based on future, site-specific NEPA analysis or the parameters of specific COPs. BOEM may also modify the measures at the COP-specific NEPA stage to tailor them to the characteristics of the proposed project and the site(s) of proposed activities, and to ensure conformity with project-specific consultations and authorizations.
BOEM-2024-0001-0423-0001	A rational and timely permitting process is vital to meeting the goals of Executive Order 14008 ("Tackling the Climate Crisis at Home and Abroad" issued on January 27 2021) New Jersey's goal of 11 GW of offshore wind energy generation by 2040 (as outlined in New Jersey Executive Order No. 307 issued on September 21 2022) and New York's requirement of 9.0 GW of offshore wind energy generation by 2035 (as outlined in the Climate Leadership and Community Protection Act signed into law on July 18 2019).	Comment noted.

Comment No.	Comment	Response
	The permitting process for offshore wind is already extremely robust and Ocean Winds had expressed concern when the New York Bight PEIS process was announced as we feared that the PEIS had the potential to complicate and delay an already challenging process. Setting aside those concerns our Bluepoint Wind team has been working cooperatively with BOEM since it published its Notice of Intention (NOI) to prepare a PEIS on July 15 2022. The eighteen months between NOI and Draft PEIS is concerning and is impacting development of Construction and Operation Plans (COPs) for NY Bight lessees. It is disappointing that initial promises from BOEM that this PEIS will speed and not hinder project permitting and development do not seem to be materializing. That said Ocean Winds hopes that the Final PEIS will be issued on schedule and future PEIS efforts will proceed in a more expeditious manner. Further we note that this PEIS will set a precedent for the PEIS process in California and beyond. As such we urge BOEM to be thoughtful in its approach so that its actions in this process do not hinder development of an industry already facing a series of challenges on both coasts.	
BOEM-2024-0001-0423-0030	Purpose and Need for the Proposed Action Ocean Winds supports the [bold and italicized: intent] of the PEIS namely to reduce redundancies across COP-specific NEPA analyses and help BOEM make timely decisions on COPs for the six lease areas covered by the Draft PEIS. Rather than leading to a more efficient process for individual COP approvals the scale and scope of the proposed AMMMs represent a significant expansion beyond past precedent and ensures a longer process for reviewing individual COPs when developers inevitably consider alternatives to the AMMMs in their individual COP submittals. This in turn will lengthen and complicate what is already a challenging federal permitting process. The Draft PEIS continues a troubling trend of the federal government continuing to raise the bar for offshore wind when compared to other maritime industries many of which are known to cause meaningful negative impact to the sensitive resources that the AMMMs proposed in the Draft PEIS are intended to protect. Ocean Winds also notes that the six months-long delay in the release of the Draft PEIS has negatively impacted project timelines which hinder	The AMMM measures considered in the PEIS include measures that have been included in previous COP approvals, as well as those proposed through the scoping process. In response to numerous comments on the Draft PEIS AMMM measures, BOEM has reviewed all AMMM measures and has made several changes to the measures as presented in Final PEIS Appendix G. In summary, BOEM has split the AMMM measures into AMMM measures that BOEM has required as conditions of approval from previous activities proposed by lessees in COPs submitted and AMMM measures that have not been applied as terms and conditions of approval for previous activities proposed by lessees in COPs. In addition, BOEM has identified RPs that could be considered at the project-specific COP NEPA review. Refer to response to comment BOEM-2024-0001-0371-0004 regarding revisions to Alternative C. Further, this PEIS is *not imposing* any AMMM measures; it is identifying those AMMM measures that BOEM may impose at the COP-specific NEPA stage. Because those AMMM measures

Comment No.	Comment	Response
	the purpose and need of BOEM making timely decisions on COPs for the NY Bight leases and we urge BOEM not to allow further delays to the Final PEIS. As discussed above the delay associated with this PEIS along with the overreach in the substance of the document sets a concerning precedent for future PEIS processes.	are identified and analyzed now, the expectation is that the analysis at the COP-specific NEPA stage can be more streamlined and efficient. Regarding PEIS timelines and delays, BOEM is working as efficiently as possible to ensure an adequate NEPA document is developed that meets all the statutory and regulatory requirements.
BOEM-2024-0001-0426-0002	History is full of bad government decisions that seemed like a good idea at the time. Take the Homestead Act for example where settlers were given free acreage in Kansas Oklahoma East Texas and elsewhere to farm. The governments' objectives were economic development continuation of a young country's "Manifest Destiny" westward and an increase in agricultural production. Most settlers farmed land or grazed cattle but soon unanticipated consequences began to appear. Farmers plowed over prairie grasses and planted dryland wheat. As the demand for wheat grew cattle grazing decreased and more acres were plowed and planted. When the world market for wheat became oversupplied prices dropped and farmers reacted to their loss of revenue by planting more wheat to make up on volume what they were losing on price. This dry land farming led to the systematic destruction of prairie grass. With the land gradually being stripped bare environmental damage began to occur. Finally with the drought of 1930 over farmed land blew away. The heartland of the U.S. became a vast dust bowl. An article by Jonathan Coppess from the University of Illinois Urbana-Champaign on the Dust Bowl offers haunting parallels for New Jersey clean energy policy:'' As one of the worst environmental disasters in our history the Dust Bowl was a confluence of policy human activities climatic shifts and the outer bounds of nature's tolerance. It should counsel humility about the ability of humans to perpetually push natural resources for their benefit The dust bowl was triggered by an extreme drought -part of a natural cycle over which we had little knowledge and Jess control - but it had been built by policies and misguided actions in an unfamiliar environment" Into the Unknown An often-quoted remark from Donald Rumsfeld former Secretary of Defense during a discussion linking Iraq with weapons of mass destruction states:" Reports that say that something hasn't	BOEM analyzes offshore wind projects using the best available science and information and seeks input from the public, agencies, and Tribal Nations to inform its decisions. For the PEIS, BOEM has identified information that was incomplete or unavailable for the evaluation of reasonably foreseeable impacts in Appendix E, *Analysis of Incomplete and Unavailable Information*.

Comment No.	Comment	Response
	happened are always interesting to me because as we know there are known knowns; there are things we know we know. We also know there are known unknowns; that is to say we know there are some things we do not know. But there are also unknown unknowns- the ones we don't know we don't know. And if one looks throughout the history of our country and other free countries it is the latter category that tends to be the difficult one." Known Unknows and Unknown. Unknows So are there any "known unknowns" and more troubling "unknown unknowns" lurking beneath the surface of efforts to accelerate offshore wind development?	
BOEM-2024-0001-0426-0008	Here at home PSE&G and Eversource have backed off from prior investment commitments to offshore wind. Do we understand why? There are other questions as well that have barely been explored at least publicly. Regarding national security an open field of hundreds of turbines in the middle of the Atlantic is an inviting soft target for terrorists or adversarial nations. How will we defend these resources?	The purpose of the PEIS, as described in Chapter 1, *Purpose and Need*, is to analyze the effects from potential development activities in the six NY Bight lease areas and to identify and analyze AMMM measures that could reduce those effects. Questions related to financial investments and national security are outside the scope of the PEIS. As stated in PEIS Section 2.3, non-routine activities and events, such as a terrorist attacks, are impossible to predict with certainty and are not analyzed in detail. In addition, PEIS Appendix E, *Analysis of Incomplete and Unavailable Information*, Section E.1.17, states that there is uncertainty regarding national security, but that the information that is available is appropriate for this programmatic level of analysis. Subsequent project-specific environmental analysis will be required for each individual COP.
BOEM-2024-0001-0439-0003	To address these concerns, the OSW industry urges BOEM to ensure that the final PEIS does not impose new analytical burdens or substantive requirements on lessees but instead serves as an analytical tool that improves the efficiency of the environmental review of COP-specific proposals within the NY Bight through tiering. To ensure this outcome: The Purpose and Need of the Proposed Action should be an analysis of AMMMs that BOEM *may* consider as conditions of approval.	BOEM has modified the PEIS language describing the Proposed Action and refined the language throughout the PEIS to make clear that this PEIS is *not imposing* any AMMM measures—and therefore is not establishing any substantive obligations at this programmatic stage—but is identifying those AMMM measures that BOEM may impose at the COP-specific NEPA stage. Because those AMMM measures are identified and analyzed now, the expectation is that the analysis at the COP-specific NEPA stage can be more streamlined and efficient.

Comment No.	Comment	Response
BOEM-2024-0001-0439-0007	BOEM should not adopt AMMMs through NEPA. NEPA requires federal agencies to assess the environmental effects of their proposed actions prior to making decisions.[Footnote 5: 42 U.S.C. 4331.] Importantly NEPA is merely a procedural statute- it authorizes the use of substantive authorities for improved environmental outcomes but imposes no substantive requirements.[Footnote 6: NEPA only requires a "reasonably complete discussion of possible mitigation measures" to allow for a fair evaluation of avoidable and unavoidable environmental consequences.[Footnote 7: See id. At 352.] The Supreme Court has warned that there is no requirement under NEPA "that a complete mitigation plan be actually formulated and adopted."[Footnote 8: Id.] Indeed the Court has held that it would be "inconsistent" with NEPA's procedural focus "to demand the presence of a fully developed plan that will mitigate environmental harm."[Footnote 9: Id. At 353; see also Citizens Against Burlington Inc. v. Busey 938 F.2d 190 205-06 (D.C. Cir.) (agency not required to finish mitigation studies or execute mitigation plans before project begins) cert. denied 502 U.S. 994 (1991); Communities Inc. v. Busey 956 F.2d 619 625-26 (6th Cir.) (EIS lacking complete remediation plan adequate where sufficient investigation was conducted to identify mitigation alternatives and make reasonable estimate of cost) cert. denied 506 U.S. 953 (1992).] In short NEPA requires agencies to take a "hard look" at the environmental impacts of actions being proposed under substantive statutes over which they have authority such as OCSLA. NEPA itself does not provide authority to impose requirements or limit actions.[Footnote 10: Ibid. at 351.("other statutes may impose substantive environmental obligations on federal agencies but NEPA merely prohibits uninformed rather than unwise agency action.")]	BOEM has modified the PEIS language describing the Proposed Action and refined the language throughout the PEIS to make clear that this PEIS is *not imposing* any AMMM measures. It is not establishing or imposing any substantive obligations at this programmatic stage. Instead, it is identifying those AMMM measures that BOEM may impose at the COP-specific NEPA stage. Because those AMMM measures are identified and analyzed now, the expectation is that the analysis at the COP-specific NEPA stage can be more streamlined and efficient.
BOEM-2024-0001-0439-0009	The Purpose and Need of the Proposed Action inappropriately shifts burden to developers. The Proposed Action proposes to "[adopt] measures *unless* future COP-specific NEPA analysis shows that implementation of measures is not warranted or effective"[Footnote 12: Draft PEIS ES-3.] Separate from the issue of adopting substantive measures discussed above the proposal to wait for site specific analysis to show that a measure is not warranted inappropriately shifts the burden to developers to prove that specific AMMMs	In an effort to create a more efficient process, the PEIS analyzes AMMM measures that have been applied previously through the COP-specific NEPA process. BOEM has modified the PEIS language describing the Proposed Action and refined the language throughout the PEIS to make clear that this PEIS is *not imposing* any AMMM measures—and therefore is not shifting the burden to developers—but is identifying those AMMM measures that BOEM may impose at

Comment No.	Comment	Response
	should not be imposed at the COP approval stage. This will significantly increase the costs to developers to study analyze and disprove the appropriateness of certain measures. This is a burden found in neither NEPA nor BOEM regulations nor other reviewing statutes. The final PEIS should not require site-specific analysis to disprove the need for prematurely adopted AMMMs. Rather the PEIS should help inform the site-specific NEPA review but ultimately the analysis in the site-specific NEPA document should determine which AMMMs are reasonable and necessary for the project under review.	the COP-specific NEPA stage. Because those AMMM measures are identified and analyzed now, the expectation is that the analysis at the COP-specific NEPA stage can be more streamlined and efficient. In addition, see response to comment BOEM-2024-0001-0423-0030 regarding BOEM's review and revisions of AMMM measures in the PEIS and identification of RPs.
BOEM-2024-0001-0439-0010	The Purpose and Need of the Proposed Action The Adoption of AMMMs is contrary to BOEM's authority under OCSLA and NEPA. BOEM states that the Proposed Action for the Draft PEIS is "the adoption of programmatic AMMM measures that BOEM would require as conditions of approval for activities proposed by lessees in COPs submitted for the NY Bight lease areas unless future COP-specific NEPA analysis shows that implementation of measures is not warranted or effective."[Footnote 13: Draft PEIS ES-3.] Stating that BOEM "would require" the AMMMs as conditions of approval is contrary to BOEM's authority under OCSLA's implementing regulations. First under BOEM's implementing regulations the agency cannot use a PEIS to "pre-approve" COP terms and conditions. Doing so prematurely imposes a substantive burden on lessees and inappropriately preempts the COP approval process. BOEM regulations outlining the COP approval process state that BOEM conducts an environmental review once the lessee has submitted a COP and that "upon completion of our technical and environmental reviews and other reviews required by Federal Law BOEM may approve disapprove or approve with modifications your COP. If we approve your COP we will specify terms and conditions to be incorporated into your COP."[Footnote 14: 30 C.F.R. 585.628(f).] Importantly BOEM approves a COP including mitigation measures upon completion of the environmental review. In short as required by regulation a lessee submits a COP which includes proposed measures to reduce impacts from the proposed activities within the COP to BOEM. BOEM subsequently reviews the COP for completeness and sufficiency and conducts an environmental review on the COP. It is at this stage that BOEM determines which AMMMs	The Proposed Action for the Final PEIS includes the identification of AMMM measures at the programmatic stage that could avoid, minimize, mitigate, and monitor impacts on resources in the six NY Bight lease areas. These measures may be required as conditions of approval for activities proposed by lessees in the COPs submitted for the six NY Bight lease areas. BOEM may require additional or different measures based on future, site-specific NEPA analysis or the parameters of specific COPs. BOEM may also modify the measures at the COP-specific NEPA stage to tailor them to the characteristics of the proposed project and the site(s) of proposed activities, and to ensure conformity with project-specific consultations and authorizations. BOEM has modified the PEIS language describing the Proposed Action and refined the language throughout the PEIS to make clear that this PEIS is *not imposing* any AMMM measures—and therefore is not prematurely adopting AMMM measures through the PEIS—but is identifying those AMMM measures that BOEM may impose at the COP-specific NEPA stage. Because those AMMM measures are identified and analyzed now, the expectation is that the analysis at the COP-specific NEPA stage can be more streamlined and efficient.

Comment No.	Comment	Response
	should be included in the environmental review for analysis and which AMMMs should be selected for adoption as terms and conditions of plan approval. In contradiction to these regulations BOEM is proposing to rely on this PEIS to prematurely adopt AMMMs prior to COP review and approval. While BOEM can certainly rely on a PEIS to analyze the impacts of appropriate AMMMs (as discussed in more detail below) it should not use the PEIS as authority to impose a substantive burden on a lessee prior to the COP review and approval.[Footnote 15: As noted in the section below it is no defense that a lessee may theoretically rebut the adoption of an AMMM at the COP stage by demonstrating that it is not "warranted or effective." This new burden is not found in BOEM's regulations.]	
BOEM-2024-0001-0439-0011	Premature adoption of AMMMs may also inadvertently overlook consultation processes such as under the Endangered Species Act (ESA) which begins with review of a fully developed site- specific action in sufficient detail to assess the effects of the action on listed species and critical habitat.[Footnote 16: 50 C.F.R. 402.14(c)(1)(i) (requiring detailed description of proposed action to initiate ESA consultation).] If the activity is allowed by an incidental take statement any reasonable and prudent measures imposed as a result of the ESA process "cannot alter the basic design location scope duration or timing of the action and may involve only minor changes."[Footnote 17: Id. 402.14(i)(2).] Similarly the Marine Mammal Protection Act ("MMPA") authorization process begins with a developer's application to conduct site-specific activities and any conditions imposed must be "practicable" and may not unduly interfere with the activity's implementation.[Footnote 18: 16 U.S.C. 1371(a)(5)(A)(i)(II)(aa) ("practicable" requirement for conditions in incidental take regulations provision); id. 1371(a)(5)(D)(ii)(I) ("practicable" requirement for conditions in incidental harassment authorizations); see Nat. Res. Def. Council Inc. v. Pritzker 828 F.3d 1125 1134-35 (9th Cir. 2016) (interpreting "least practicable adverse impact" requirement under 16 U.S.C. 1371(a)(5)(A)(i)(II)(aa)); id. At 1135 n.9. (eliminating 99% of oceans from sonar activity would be more protective of marine mammals "[b]ut it would not be practicable because it would so restrict military options for readiness	BOEM has modified the PEIS language describing the Proposed Action and refined the language throughout the PEIS to make clear that this PEIS is *not imposing* any AMMM measures—and therefore is not prematurely adopting AMMM measures through the PEIS—but is identifying those AMMM measures that BOEM may impose at the COP-specific NEPA stage. Because those AMMM measures are identified and analyzed now, the expectation is that the analysis at the COP-specific NEPA stage can be more streamlined and efficient. Identification of AMMM measures through the PEIS process would supplement and inform but not supplant the identification of measures at the project-level ESA consultation. Based on comments provided on the Draft PEIS, BOEM revised AMMM measures as presented in Appendix G. Some of these measures would mitigate impacts on ESA-listed species. During project-level ESA consultation, agencies may identify additional measures to minimize effects on federally listed species.

Comment No.	Comment	Response
	training that it would render such training ineffective").] Other environmental review statutes including the Clean Air Act and the Clean Water Act contain similar requirements to review site- specific plans and limit agencies' conditioning authority over proposed activities.[Footnote 19: 40 C.F.R. 1502.24 (To the fullest extent possible agencies shall prepare draft environmental impact statements concurrent and integrated with environmental impact analyses and related surveys and studies required by all other Federal environmental review laws and Executive orders applicable to the proposed action including the Fish and Wildlife Coordination Act (16 U.S.C. 661 et seq.) the National Historic Preservation Act of 1966 (54 U.S.C. 300101 et seq.) and the Endangered Species Act of 1973 (16 U.S.C. 1531 et seq.).] As such any AMMMs that would potentially be required under the ESA MMPA or other environmental statutes should not be adopted prior to the completion of the consultation process. In the final PEIS, BOEM should clarify that the Proposed Action is an analysis of AMMMs that BOEM may consider as conditions of approval. As such future site-specific analysis would determine whether an AMMM considered in the draft PEIS is warranted rather than determining whether such measure is [italicized: not warranted.] Under this scenario BOEM would still rely on the PEIS to provide an environmental analysis of impacts and to tier site-specific reviews but it would not prematurely require the adoption of specific AMMMs. The final PEIS would include an analysis of all reasonable AMMMs that BOEM may require as terms and conditions of COP approval. BOEM would not be required to re-analyze each AMMM included in the final PEIS when reviewing and approving a COP. As such the final PEIS would allow for consistency standardization and a more efficient environmental review process at the site-specific level.	
BOEM-2024-0001-0452-0001	Purpose of a PEIS We applaud BOEM for initiating this Programmatic Environmental Impact Statement (PEIS) specific to mitigation measures for regional OSW projects. This action appears partially responsive to longstanding fishing industry requests to better assess the cumulative impacts of the numerous OSW projects in the permitting pipeline and to conduct dedicated analyses regarding fisheries-	Section 1.2, Table 1-1, *History of BOEM planning and leasing activities in the NY Bight*, summarizes the history of BOEM's planning process and lease sale for the NY Bight, including the 2018 Call for Information and Nominations, the 2021 identification of the WEAs, and the Draft and Final Environmental Assessment (EA) for commercial and research leases. The table also summarizes the public notification and public comment

Comment No.	Comment	Response
	specific mitigation measures that should be included as Terms and Conditions of any OSW project approval. [Footnote 10: As described in later sections of these comments a PEIS can only meet BOEM's obligations to avoid minimize and mitigate impacts to the environment if conducted in advance of lease issuance and if it includes all activities related to the proposed action in this case the multiple phases of OSW development. Instead the timing of this PEIS after leases have been issued results in the most meaningful opportunities to avoid impacts identified through environmental review to have already been lost.] The federal OSW leasing program needs substantially more attention devoted toward developing and incorporating fisheries and ecosystem data not less and this PEIS should not result in reduced scrutiny in the downstream approval of any OSW project. Rather we reiterate previous well known requests to BOEM to develop measurable criteria for excluding areas from development when risks to the physical and human environment exceed acceptable thresholds and apply those on regional and project-specific bases in all regions. Disappointingly the draft PEIS only evaluates the six OSW leases in the NY Bight excluding the existing leases on the east coast and anticipated addition of Central Atlantic WEAs all which contribute to cumulative effects to many of the same species oceanographic systems and fisheries. The draft PEIS also does not explain how BOEM's ongoing development of fisheries mitigation guidelines will interface with the findings of the final PEIS.	periods that were conducted as part of the process. The analysis and development of the WEA in the NY Bight are summarized in the *New York Bight Area Identification Memorandum Pursuant to 30 CFR 585.211(b),* which is found on BOEM's website: https://www.boem.gov/sites/default/files/documents/renewable-energy/Memorandum%20for%20Area%20ID%20in%20the%20NY%20Bight.pdf. Each individual COP submitted by a developer to BOEM will be separately analyzed as required under BOEM's regulations, and that analysis will disclose the full impacts of the construction and installation, O&M, and conceptual decommissioning of the project. For each resource area, Appendix C, *Tiering Guidance*, summarizes the affected environment, impact analysis, and AMMM measures discussed in this PEIS and identifies additional analysis that BOEM anticipates may be included in the COP-specific NEPA analysis for each lease area. BOEM assesses the cumulative effects of the NY Bight projects in combination with ongoing and planned reasonably foreseeable activities, which are defined in Section 3.3.1. In addition, BOEM would have the opportunity to consider new information in each individual COP-specific NEPA document about what other activities are reasonably foreseeable at the time. Table 3.6.1-21 provides an RP, COMFIS-5, which recommends that lessees follow the Fisheries Survey Guidelines issued by BOEM with regards to pre-, during- and post-construction fisheries monitoring survey plan design.
BOEM-2024-0001-0469-0002	Purpose of and Need for the Proposed Action The Draft PEIS states that the purpose of the proposed action is to: "identify issues analyze degree of potential impacts and adopt as appropriate AMMM measures This PEIS will reduce redundancies across COP-specific NEPA analyses including very similar affected environments impacts and mitigation measures and will allow for future project-specific NEPA documents to be focused on the project-specific impacts not considered in the PEIS or those impacts that warrant further consideration. The Proposed Action is needed to help BOEM make timely decisions on COPs submitted for the six	The purpose of the PEIS, as described in Chapter 1, *Purpose and Need*, is to analyze the effects from potential development activities in the six NY Bight lease areas and to identify and analyze AMMM measures that could reduce those effects. The PEIS does not approve any projects. Each individual COP submitted by a developer to BOEM will be separately analyzed as required under NEPA and will disclose the full impacts of the construction and installation, O&M, and conceptual decommissioning of the project. For each resource area, Appendix C, *Tiering Guidance*, summarizes the affected

Comment No.	Comment	Response
	NY Bight lease areas." [Footnote 5: BUREAU OF OCEAN ENERGY MGMT. NEW YORK BIGHT DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT at 1-4 1-5 (Jan. 2024).] The agency's main goal in taking this approach clearly appears to be expediting review and approvals of future OSW projects. This is concerning as there are many knowledge gaps regarding the marine life in this region and the potential effect of creating a vast array of OSW installations. [Footnote 6: E.g. BUREAU OF OCEAN ENERGY MGMT. NEW YORK BIGHT DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT appx. E (Jan. 2024); BUREAU OCEAN ENERGY MGMT. & NAT'L OCEANIC & ATMOSPHERIC ADMIN. BOEM & NOAA FISHERIES NORTH ATLANTIC RIGHT WHALE AND OFFSHORE WIND STRATEGY at 9 (Jan. 2024) (citing Dorrell RM Lloyd CJ Lincoln BJ Rippeth TP Taylor JR Caulfield CP Sharples J Polton JA Scannell BD Greaves DM et al. 2022. Projected cross-shore changes in upwelling induced by offshore wind farm development along the California coast. Communications Earth & Environment. 4(4):116. Doi:10.1038/s43247-023-00780-y).]Sound science takes time; as does planning to determine and assess the impacts and take actions to avoid minimize and/or mitigate accordingly. Doing less puts marine life at grave risk.	environment, impact analysis, and AMMM measures discussed in this PEIS and identifies additional analysis that BOEM anticipates may be included in the COP-specific NEPA analysis for each lease area. During the COP-specific NEPA process, BOEM will hold a public comment period at the start of the NEPA process (scoping) and following the release of the Draft NEPA document, whereby members of the public and agencies can provide input to help inform the NEPA process, alternatives, and mitigation measures to identify and minimize environmental effects. Additionally, throughout the NEPA process BOEM works closely with Cooperating Tribal Governments and federal and state agencies to assist with assessing impacts and identifying mitigation measures.
BOEM-2024-0001-0469-0003	The Draft PEIS assumes the maximum use scenario that projects will use the most impactful range of the project design envelope. However for some factors BOEM predicts that impacts will be "negligible to major "the entire possible range of impacts because the actual impacts will depend on the individual parameters of the project. [Footnote 7: NEW YORK BIGHT DRAFT ENVIRONMENTAL IMPACT STATEMENT supra note 5 at ES-10-13] In addition the Tiering Guidance appendix states that the impact analysis in the PEIS for categories such as marine mammals cannot be used for individual Construction and Operations Plan ("COP") environmental reviews under the National Environmental Policy Act ("NEPA"). [Footnote 8: Id. At appx. C.] Taken together this all calls into question the utility of	The PEIS does not approve any projects. Each individual COP submitted by a developer to BOEM will be separately analyzed as required under NEPA and will disclose the full impacts of the construction and installation, O&M, and conceptual decommissioning of the project. Project-specific analyses that tier from or incorporate by reference this PEIS will evaluate whether a project would have greater, equal, fewer, or different impacts than those that were analyzed in the PEIS by considering the level of action analyzed and the particularities of the site. Refer to Appendix C, *Tiering Guidance*, for specific recommendations by resource topic regarding how the PEIS may be incorporated by reference in the future COP-specific NEPA

Comment No.	Comment	Response
	attempting to analyze such project-dependent impacts on a programmatic scale.	documents; this appendix also identifies additional analysis that would likely be required as part of the COP-specific NEPA analysis once detailed and site-specific project information is available.
BOEM-2024-0001-0469-0004	In absence of a PEIS avoidance minimization and mitigation ("AMMM") measures would be analyzed in the NEPA reviews of individual projects on a case-by-case basis. BOEM proposes choosing Alternative C adopting mitigation measures on a programmatic level i.e. for all six projects. [Footnote 9: Id. At ES-3]. According to BOEM representatives this would allow the agency to simply "check a box" applying the mitigation measure once they determined the measure applied to the individual project instead of performing an individual analysis on the mitigation measure. However for many affected resources the projected impacts remain constant between Alternative B (deferring adoption of mitigation measures until the individual NEPA review) and Alternative C especially for cumulative impacts. BOEM representatives stated that they would refine the mitigation measures as OSW develops and expressed that they were especially interested in comments on the mitigation measures themselves which COA provides later in Section VI. While COA does not wish to discourage the development and adaptation of AMMM measures it is unacceptable that currently available AMMM measures do not appear to be effective based on these projections.	Each individual COP submitted by a developer to BOEM will be separately analyzed as required under NEPA and will disclose the full impacts of the construction and installation, O&M, and conceptual decommissioning of the project. Project-specific analyses that tier from or incorporate by reference this PEIS will evaluate whether a project would have greater, equal, fewer, or different impacts than those that were analyzed in the PEIS by considering the level of action analyzed and the particularities of the site. Based on public and agency comments on the Draft PEIS, BOEM has revised several AMMM measures, which are described in Appendix G, *Mitigation and Monitoring*.
BOEM-2024-0001-0469-0005	Additionally the Draft PEIS references New York and New Jersey's statutory mandate and executive orders (respectively) requiring a certain amount of wind energy generation by a target year as well as the federal government's Executive Order 14008 and the associated goal to generate thirty (30) gigawatts of OSW capacity by 2030. The federal goal was developed by the Departments of Interior, Energy, Commerce, and Transportation but there is no detailed documentation or analysis on how these goals were developed and what environmental technological or economic standards they meet nor any public transparency or review. All these goals are intended to boost renewable energy development but the goals do not go through the same environmental review processes as the individual projects created to meet them.	Section 1.3, *Purpose of and Need for the Proposed Action*, describes the purpose of the Proposed Action, which supports Executive Order 14008 “Tackling the Climate Crisis at Home and Abroad” and President Biden administration’s goal of 30 GW of offshore wind capacity by 2030. Goals set by the federal government or the states are not federal actions that require NEPA review.

Comment No.	Comment	Response
BOEM-2024-0001-0469-0006	In summary the purpose and need statement prioritizes speed over due process and filling scientific knowledge gaps. The programmatic approach is of limited help when so many impacts must be considered at the individual COP review stage and the AMMM measures do not appear to change the overall environmental impacts in many cases. Further the push for OSW development is based on aspirational goals.	Project-specific analyses that tier from or incorporate by reference this PEIS will evaluate whether a project would have greater, equal, fewer, or different impacts than those that were analyzed in the PEIS by considering the level of action analyzed and the particularities of the site. Refer to Appendix C, *Tiering Guidance*, for specific recommendations by resource topic regarding how the PEIS may be incorporated by reference in the future COP-specific NEPA documents; this appendix also identifies additional analysis that would likely be required as part of the COP-specific NEPA analysis once detailed and site-specific project information is available.
BOEM-2024-0001-0470-0004	The amounts of installed capacity and number of Wind Turbine Generators (WTGs) in the planned projects as described in the PEIS are inconsistent and seriously misleading:--On page ES-4 the PEIS states “Based on a conservatively estimated power ratio of 3 megawatts per square kilometer BOEM estimates that full development of leases in this area has the potential to create up to 5.6 to 7 GW of offshore wind energy."--On the same page the PEIS states an estimated 16-18 GW of offshore wind energy may be necessary to ensure New York State achieves its Climate Act mandates (New York State Climate Action Council 2022).--On page ES-7 of the PEIS BOEM states that "For the analysis of six NY Bight projects BOEM anticipates development of 1103 WTGs 22 offshore substations (OSSs) 44 offshore export cables totaling 1772 miles (2852 kilometers) and 1582 miles (2546 kilometers) of inter-array cables across the six NY Bight lease areas."---This assertion that the six NY Bight projects would build "up to 1103 WTGS" is repeated on PEIS page 2-16.--On page 3.4.1-8 the PEIS says the NY Bight Projects evaluated in the PEIS would construct an estimated 9922 MW of renewable power from the installation of 713 WTGs citing Table D2-1 in Appendix D.---Table D2-1 indicates only 8822 MW will be installed by the current projects and require 615 WTGs---Table D2-1 further indicates that a further 1103 WTGs are planned but fails to disclose the resulting installed MWs. (Using a ratio analysis of the data provided in Table D2-1 if 615 WTGs will produce 8822 MW of installed capacity then 1103 WTGs would constitute another 15822 MW installed).--The Table in Appendix D appears to conflict with text	The estimated power ratio of 3 MW per square kilometer and an estimate of 5.6 to 7 GW for total generating capacity of the NY Bight leases presented in Section 1.3 of the PEIS are derived from the BOEM December 2021 Final Sale Notice for the NY Bight leases. BOEM has added a footnote to this statement in Section 1.3 clarifying the source of this information. The power-generating capacity from the Final Sale Notice is provided for informational purposes and is not used in the analysis of the alternatives. The analysis of the alternatives is based on the parameters of the RPDE described in Section 2.1.2 of Chapter 2. BOEM recognizes that as technology advances and as projects are designed to maximize power output, the actual generation capacity of the NY Bight lease areas could be greater. Refined estimates of the anticipated generation capacity of each project proposed in the NY Bight lease areas will be described in each COP and project-level NEPA analysis. The purpose and need states the PEIS supports state climate goals, but it is not intended to meet state obligations. BOEM’s leasing process for offshore wind is independent of state goals and solicitations. BOEM is required to assess COPs as submitted by developers; its role is not to design projects to meet state goals. The estimate of 9,922 MW of renewable power in Section 3.4.1.1 (now 9,561 MW due to updates to ongoing and planned offshore wind projects in PEIS Appendix D) is describing ongoing and planned offshore wind in the geographic analysis area for air

Comment No.	Comment	Response
	elsewhere in the PEIS and indicates the total planned buildout of OSW in the NY Bight leases is 26644 MW.	quality, excluding the NY Bight project. In Table D2-1, the combined number of turbines for all six NY Bight projects (1,103 WTGs) is presented, consistent with the estimates presented in the six-project RPDE in Chapter 2. To avoid speculation, the total generating capacity of the NY Bight leases is not described. The generating capacity of a turbine or a project does not directly relate to impacts; it is rather the physical dimensions of the WTGs and other parameters that relate to environmental impacts.
BOEM-2024-0001-0470-0005	[Bold: II. COMMENTS][Underline: 1. Segmentation:] [Bold: The PEIS violates 38 CFR Section 200.4 by improperly segmenting the Proposed Action from the full complement of OSW projects and installed Wind Turbine Generators (WTGs) needed to meet the dual legal requirements of service load obligations and applicable state mandates for renewable energy.] The purpose of the Proposed Actions is to build and operate OSW facilities that produce "renewable" electricity from sources approved under NY law and NJ Executive Order to meet what is now and re- mains in the future a long-established "service obligation" [Footnote 1: Federal law defines the "service obligation" as a requirement applicable to or the exercise of authority granted to an electric utility under Federal State or local law or under long-term contracts to provide electric service to end-users or to a distribution utility (16 USC Section 824q).] to provide electricity to end-use consumers. Switching the existing generation from fossil fuels and nuclear power to renewables such as offshore wind requires full assessment of the impacts of building out the full complement of OSW facilities that will be needed so a) the public is fully informed of the magnitude of the federal action and b) complete and cumulative impacts can be assessed. This "segmenting" of OSW projects is a blatant violation of NEPA and its regulations given the stated purpose of the PEIS is to assess the "potential biological socioeconomic physical and cultural impacts that could result from development activities for six commercial wind energy leases in an area offshore New Jersey and New York known as the New York Bight (NY Bight)" (PEIS page ES-3).	The regulations identified in the comment (38 CFR 200.4) do not apply to BOEM or the DOI. The purpose of the PEIS, as described in Chapter 1, *Purpose and Need*, is to analyze the effects from potential development activities in the six NY Bight lease areas and to identify and analyze AMMM measures that could reduce those effects. The PEIS does not approve any projects. Each individual COP submitted by a developer to BOEM will be separately analyzed as required under NEPA and will disclose the full impacts of the construction and installation, O&M, and conceptual decommissioning of the project. For each resource area, Appendix C, *Tiering Guidance*, summarizes the affected environment, impact analysis, and AMMM measures discussed in this PEIS and identifies additional analysis that BOEM anticipates may be included in the COP-specific NEPA analysis for each lease area. BOEM assesses the cumulative effects of each project in combination with ongoing and planned reasonably foreseeable activities, which are defined in Section 3.3.1. The cumulative effects analysis in the PEIS considers ongoing and planned offshore wind activities. This analysis will be reviewed and augmented at the COP specific stage to ensure that each project is considered in the context of reasonably foreseeable activities. In the PEIS, BOEM considers the effects of the addition of the six NY Bight projects to other ongoing and planned projects in accordance with NEPA.
BOEM-2024-0001-0470-0010	[Italics: c) The forecast growth in electricity demand by industry regulators cannot be met by the segmented OSW Projects described in the PEIS]The planned 8822/9922 MW construction under the	The purpose of the PEIS, as described in Chapter 1, *Purpose and Need*, is to analyze the effects from potential development activities in the six NY Bight lease areas and to identify and

Comment No.	Comment	Response
	Proposed Action is well below the 20 MW total needed for the initial compliance with NYS CLCPA and the NJ EO and woefully below what NYISO growth forecasts indicate will be needed for full NYS compliance alone. The PEIS borders on fraudulent in its failure to fully disclose and assess the full effects of building out and operating the total number of WTGs needed to "meet" renewable goals and mandates given the realities of demand growth and service obligation; the full buildout will generate compounding and cumulative damage to irreplaceable maritime assets from construction and operation of both WTGs and attendant transmission facilities that are effectively ignored. Nor does the PEIS disclose and analyze the amount of non-intermittent electric generation (nuclear hydro fossil etc) along with storage/battery facilities that will be needed to ensure reliable electric supplies during the 60% downtime experienced by OSW generation or storage facilities.	analyze AMMM measures that could reduce those effects. The PEIS does not approve any projects. The purpose and need further states that the PEIS supports federal goals of 30 GW and state goals, but it is not intended to meet state obligations. BOEM's leasing process for offshore wind is entirely independent of state goals and solicitations. BOEM is required to assess COPs as submitted by developers; its role is not to design projects to meet state goals. The PEIS does disclose the cumulative effects of buildout of other ongoing and planned offshore wind projects on the OCS within the geographic area of analysis for each resource. Regarding other sources of energy, the PEIS is analyzing wind development in six offshore wind lease areas, and the analysis of other sources of energy or battery storage is outside the scope of this PEIS.
BOEM-2024-0001-0470-0011	-[Italics: New York]Page 3.4.1-6 of the PEIS notes that the New York State Energy Research and Development Agency (NY- SERDA) led the development of the New York State Offshore Wind Master Plan is leading the coordination of offshore wind opportunities in New York State and is supporting the development of 9000 MW of offshore wind energy by 2035.[Table 4: NYSERDA Projected Generation and Fuel Type]NYSERDA Generation Model: Upstate 2030; Demand Load (Gigawatt Hours/ GWh): 51223; Percentage Renewable: 70%; Percentage Offshore Wind: 0%NYSERDA Generation Model: Downstate 2030; Demand Load (Gigawatt Hours/ GWh): 100455; Percentage Renewable: 70%; Percentage Offshore Wind: 24%NYSERDA Generation Model: Upstate 2040; Demand Load (Gigawatt Hours/ GWh): 74905; Percentage Renewable: 75%; Percentage Offshore Wind: 0%NYSERDA Generation Model: Downstate 2040; Demand Load (Gigawatt Hours/ GWh): 132601; Percentage Renewable: 90%; Percentage Offshore Wind: 33%[Table End][Bold: Source: NYSERDA.NY.Gov]On its [Underline: "Story of Our Grid"] page NYSERDA divides the NYCA into Up- and Downstate regions to illustrate how various fuel types will be used to deliver the NYISO-measured load demand. NYSERDA calculations of future demand levels (using numbers similar but not equal to those of the	The purpose of the PEIS, as described in Chapter 1, *Purpose and Need*, is to analyze the effects from potential development activities in the six NY Bight lease areas and to identify and analyze AMMM measures that could reduce those effects. The PEIS does not approve any projects. The purpose and need further states that the PEIS supports federal goals of 30 GW and state goals, but it is not intended to meet state obligations. BOEM's leasing process for offshore wind is entirely independent of state goals and solicitations. BOEM is required to assess COPs as submitted by developers; its role is not to design projects to meet state goals. Additionally, BOEM can only act as authorized under OCSLA, and it has no control over how much energy/electricity is needed or what other types of energy sources are used. Each individual COP submitted by a developer to BOEM will be analyzed separately as required under NEPA and will disclose the full impacts of the construction and installation, O&M, and conceptual decommissioning of the project. For each resource area, Appendix C, *Tiering Guidance*, summarizes the affected environment, impact analysis, and AMMM measures discussed in this PEIS and identifies additional analysis that BOEM anticipates

Comment No.	Comment	Response
	NYISO) and planned renewable contributions for the NYS Grid are summarized in Table 4. [Footnote 3: The total demand included in the NYSERDA calculations for 2030 are lower and the 2040 estimates are higher than the forecasts in the NYISO Gold Book provided in Table 2. NYSERDA does not provide estimates to 2053] [Footnote 4: New York City demand is currently about 55000 GWh a little over half of the forecast 2030 Downstate demand for ~100000 GWh.] NYSERDA's Upstate/Downstate demand ratios run about one-third/two-thirds of the total load demand in the NYCA. Applying those ratios to the 2053 NYISO forecast downstate demand will approximate 155113 GWh. The "Story of Our Grid" webpage states that "Downstate load is completely met with zero emissions generation in 2040" a claim that is based on 33% of load being met with offshore wind. Applying this 33% requirement to the 2053 demand forecast means that more than [Bold: 50000 GWh] of OSW generation is necessary meet the CPCLA mandates in 2053. [Footnote 5: Calculations of GWh from OSW WTGs herein use a capacity factor of 40% a three-year average of global capacity factors for 2020 to 2022 reported in 2024 by Statista.] Sourcing the 2040 downstate demand with 33% OSW production (as planned by NYSERDA) would require WTG capacity to make [Bold: 43758 GWh.] As noted above were the projects to actually total 9922 MW from 713 WTGs (vice 8822 MW from 613 WTGs) electric generation could approach [Bold: 35000 GWh of electricity.] Assuming NY gets 50% of the output from the set (segment) of projects analyzed in the PEIS [Bold: the 2053 demand shortfall would be more than 30000 GWh.] Looked at another way meeting the 2053 downstate demand of over 155000 GWh with 33% OSW [Bold: (50000 GWh)] requires about [Bold: 15000 MW of installed OSW capacity.] This means NYS alone requires nearly half of all the off-shore wind in the Administration’s Program to actually meet its CPCLA obligations. The PEIS completely fails to disclose the reasonably foreseeable future actions needed to secure the actual MW/WTG buildout needed to produce the 50000 GWh to meet the NYS mandate alone.[Table Start: Eastern Seaboard Homes]Eastern Seaboard States: ME; "HOMES" (in millions): 0.57Eastern Seaboard States: MA; "HOMES" (in millions): 2.71Eastern Seaboard States: RI; "HOMES" (in millions): 0.42Eastern	may be included in the COP-specific NEPA analysis for each lease area. BOEM assesses the cumulative effects of each project in combination with ongoing and planned reasonably foreseeable activities, which are defined in Section 3.3.1. The cumulative effects analysis in the PEIS considers ongoing and planned offshore wind activities. This analysis will be reviewed and augmented at the COP-specific stage to ensure that each project is considered in the context of reasonably foreseeable activities. In the PEIS, BOEM considers the effects of the addition of the six NY Bight projects to other ongoing and planned projects in accordance with NEPA.

Comment No.	Comment	Response
	Seaboard States: CT; "HOMES" (in millions): 1.39Eastern Seaboard States: NY; "HOMES" (in millions): 7.53Eastern Seaboard States: NJ; "HOMES" (in millions): 3.39Eastern Seaboard States: PA; "HOMES" (in millions): 5.14Eastern Seaboard States: DE; "HOMES" (in millions): 0.45Eastern Seaboard States: MD; "HOMES" (in millions): 2.29Eastern Seaboard States: VA; "HOMES" (in millions): 3.24Eastern Seaboard States: NC; "HOMES" (in millions): 4.01Eastern Seaboard States: SC; "HOMES" (in millions): 1.97Eastern Seaboard States: GA; "HOMES" (in millions): 3.88Eastern Seaboard States: FL; "HOMES" (in millions): 8.15Eastern Seaboard States: Total; "HOMES" (in millions): 45.14[Table End][Bold: Source: US Census Bureau] For purposes of grid stability and reliability as well as delivering forecast demand requirements it is important to note that the Downstate/NYC demand for 50000 GWh includes vast municipal enterprise systems such as subways wastewater treatment plants hospitals emergency services (police fire emergency medical) street and traffic lights all requiring 24/7 electricity supply in copious amounts for all residents but especially underserved and environ- mental justice populations. Describing actual turbine electricity production in euphemistic misleading comparisons about powering "X Million Homes" is highly deceptive. As Table 5 shows the Eastern Seaboard has over 45 million "homes." Breaking down the deceptive tagline about the vaunted Atlantic OSW program powering "10 Million Homes" if the planned 30 GW installed can serve 10 million homes 45 million homes will require 135 GW installed. The US Department of Energy typically cites 412 offshore WTGs as the requirement per gigawatt meaning that powering [Bold: all] the East coast homes (and [Bold: just] the homes) with the needed 135 gigawatts of wind at 412 turbines per gigawatt puts over 55000 turbines in the irreplaceable maritime system of the Atlantic a far cry for the 600-700 turbine segment analyzed in the PEIS.	
BOEM-2024-0001-0470-0012	[Italics: New Jersey]Data on load growth in New Jersey is not as clear due to its inclusion in the multi-state Pennsylvania/Jersey/Maryland ISO (PJM). The [Underline: 2024 PJM Load Forecast Report] states that the total annual energy use throughout the PJM footprint is expected to increase nearly 40% by 2039 from the current 813328 to 1021955 GWh. Of that about 30000 GWh of additional demand is	Please see response to comment BOEM-2024-0001-0470-0011.

Comment No.	Comment	Response
	identified as coming from the four NJ utility zones summarized in Table 6. [Footnote 6: The total NJ load growth was calculated by subtracting the 2024 load forecast amount from the 2039 load forecast amount for the four NJ service zones listed in Table E-1 ANNUAL NET ENERGY (GWh) AND GROWTH RATES FOR EACH PJM MID- ATLANTIC ZONE AND GEOGRAPHIC REGION 2024 – 2034 summarized on pages 71-72 of the 2024 PJM Load Forecast Report linked above.][Table 6: NJ Forecast Load Increases]NJ Utility Zone: Atlantic Electric (AE); Load increase 2024-2039 (GWh): 2556NJ Utility Zone: Jersey Central Power & Light (JCPL); Load increase 2024-2039 (GWh): 11380NJ Utility Zone: Public Service Electric & Gas (PS); Load increase 2024-2039 (GWh): 15155NJ Utility Zone: Rockland Electric (East) (RECO); Load increase 2024-2039 (GWh): 341NJ Utility Zone: Total; Load increase 2024-2039 (GWh): 29432[Table End][Source: 2024 PJM Load Forecast Report]According to the [underline: U.S. Department of Energy's Energy Information Agency (EIA)] New Jersey plants of all types produced 65061 GWh of electricity in 2022 of which 33394 GWh came from natural gas production. [Footnote 7: US EIA New Jersey Electricity Profile 2022. New Jersey currently has 26 natural gas-fired power plants.] The entire mandated 11000 MW of OSW installed capacity (only a fraction of which will come from the Proposed Action being evaluated) could only produce about 39000 GWh. This means that full buildout of the NJ EO goal (one-third of the total Atlantic OSW planned by the Biden Administration) might produce enough electricity to replace natural gas plants or increase production to meet load growth from data centers and electric vehicles [Bold: but not both.] It is hard to conceive how the purpose of the action to make the New Jersey grid emission-free is satisfied if only the disclosed segment of OSW wind construction is used. These arithmetic impossibilities become even more glaring and problematic when considering the 2023 acceleration of clean energy goals in [Underline: NJ Executive Order 315]. Previously the 2019 EMP required 100 percent clean energy by 2050; the new EO 315 deadline is 2035. Notably the NJ State Senate recently woke suddenly from a green-dream when a bill authorizing a public referendum on amending the state’s Constitution to ban construction of new power plants that burn natural gas or other	

Comment No.	Comment	Response
	fossil fuels was amended to allow the construction of such plants if they are to be primarily used as emergency backup power sources. The carve-out manages the damaging grid reliability risks exposed when Superstorm Sandy knocked out power in 2012 causing nearly a billion gallons of untreated sewage to flow into area waterways because sewage plants lacked accessible backup generation. The New Jersey arithmetic again demonstrates that the realities of the service obligation and actual OSW electricity production confirm these projects are but a fractional segmented portion of the actions needed to meet the overall energy production goals not just renewable standards.	
BOEM-2024-0001-0470-0013	[Italics: c) The final EIS analysis must analyze the fully aggregated (not segmented) complement of operational generation assets and storage capacity needed to reliably satisfy the identified electricity demand (including growth) while combatting the climate crisis through deployment of clean energy technologies and infrastructure.]The PEIS must redefine the Proposed Action as including construction and operation of the full complement of WTGs and storage facilities needed to meet both the known load requirements and renewable portfolio standards simultaneously. Without properly defined and unsegmented actions any evaluation or adoption of so-called programmatic avoidance minimization mitigation and monitoring (AMMM) measures remains inaccurate insufficient misleading and violative of the spirit and letter of the National Environmental Policy Act and its attendant regulations.	Please see response to comment BOEM-2024-0001-0470-0011.
BOEM-2024-0001-0470-0020 and BOEM-2024-0001-0470-0021	[Bold: III. SUMMARY]-In spite of high populations and significant population density East Coast states almost universally achieve the lowest per capita carbon emissions in the country based on their historic underwriting of clean energy and transport systems. --Inland states with whom eastern states are competing for new manufacturing facilities and other economic development opportunities still make significant portions of their electricity from coal and natural gas. This keeps electricity prices low and attracts businesses that use electricity as operational fuel at the same time greenhouse gas emission levels remain high. --Forcing eastern states to shut down clean capacity and/or prematurely retire non-coal electricity production facilities in favor	Please see response to comment BOEM-2024-0001-0470-0011. BOEM has authority under OCSLA to authorize renewable energy activities on the OCS and evaluates projects as proposed by developers under its regulations. Electricity rates are not within the scope of the PEIS and are part of agreements with the state and developer.

Comment No.	Comment	Response
	of massive expenditures for OSW facilities that are merely presumed to be “environmentally preferable” (all evidence to the contrary) further increases already high east coast electricity prices and exacerbates [Underline: competitive advantage already accruing to fossil-electric generating states.]	
BOEM-2024-0001-0470-0022 and BOEM-2024-0001-0470-0023	For an industry as damaging dangerous and risky as OSW whether by design or function BOEM's system of programmatic EISs coupled with tiered analysis for subsequent issuance of various construction permits and approvals woefully fails to meet the most basic principles and requirements of the National Environmental Policy Act and this PEIS is no different. --Analyses separated into geographically disperse lease-areas inevitably suffer from improper segmentation fail to assess cumulative impacts and ignore the macro-socioeconomic impacts that will affect businesses and populations across large areas because these projects involve electricity as fundamental to survival in today’s times as air and water.	Please see response to comment BOEM-2024-0001-0470-0011. The PEIS is a regional analysis and not an analysis on specific individual lease areas.
BOEM-2024-0001-0470-0024	BOEM cannot willfully ignore the realities and plain arithmetic of electricity demand growth when assessing the viability and effects of eliminating electric generation plants that can meet critical survival needs sanitation transportation communication safety education food security inter alia in favor of expensive unreliable and damaging WTGs that cannot do the job without multiple layers of storage backup along with additive transmission facilities. These sine qua non co-components bring compounding as well as cumulative negative effects to the areas where they must be built and operated. --By 2053 downstate New York electricity demand growth is forecast to be over 155000 GWh (two-thirds of 253020 GWh); producing 33% of that load with OSW (50000 GWh) requires the output of about 15000 MW of installed OSW capacity far more than the current acknowledged projects could deliver to the NY Grid. --By 2039 New Jersey is forecast to add 29432 GWh to its demand load and also plans to replace 33394 GWh of current electricity produced by natural gas plants both with OSW. Satisfying this actual requirement for 62826 GWh of clean/renewable electricity for NJ’s portion of the PJM grid with OSW would necessitate more than the planned 11 GW installed capacity.	Please see response to comment BOEM-2024-0001-0470-0011. Offshore wind would likely be in addition to other energy sources. Wind energy would displace fossil fuel energy to the extent that it is offered to the grid at a lower price than the bids from fossil-fueled energy sources.

Comment No.	Comment	Response
	--Electricity demand in these two states alone have an estimated requirement for about 26 GW of installed OSW to meet service obligations almost 87% of the entire 30 GW Atlantic Offshore Wind Program planned by the Biden Administration. --To the extent the current Proposed Actions build less than 26000 GW installed OSW capacity in the NY Bight to meet concurrent demand growth and portfolio standards additional undisclosed energy storage facilities will also be required to reliably assure service obligation generation levels. The size location and full suite of impacts from the construction and operation of such storage facilities along with all necessary transmission and distribution infrastructure must be included in any and all environmental impact analysis to prevent improper segmentation and assure full cumulative impact analysis.	
BOEM-2024-0001-0470-0025	No amount of mitigation can be accurately assessed or planned in the absence of accurate and fully disclosed impacts and effects from building and operating the full complement of OSW WTGs and attendant storage/transmission facilities needed to meet the knowable and known amounts of electricity required to sustain the populations and assets of the affected states. The environmentally preferable option for greening the nation's electricity portfolio does not involve the green eastern seaboard states. Real decarbonization will come from discontinuing the 675000 GWh of electricity still produced with coal plants in the US few if any of which are in Atlantic Seaboard states. --No agency of federal state or local government should use public funds to subsidize or under- write premature retirement and/or displacement of existing non-coal electricity production assets until existing coal plants are first replaced by the ratepayers who benefit from them (especially those in states with the highest GHG outputs per capita).	Please see response to comment BOEM-2024-0001-0470-0011.
BOEM-2024-0001-0474-0004	Among other reasons the action is Arbitrary because the BOEM administrative process favors the private interests of offshore wind developers to the detriment of the citizen stakeholders and the general public. Among other reasons the action is Arbitrary because the energy goals established in Executive Orders and Presidential Proclamations are not within the authority of the Executive Branch	Please see response to comment BOEM-2024-0001-0470-0011. BOEM's responsibility under the Energy Policy Act of 2005 is to issue renewable energy leases, easements, and ROWs for activities on the OCS (see PEIS Section 1.4, *Regulatory Overview*).

Comment No.	Comment	Response
	and do not have the force of law as the authority belongs in the legislative branch of government. Among other reasons the action is Arbitrary because the energy goals established by Executive Orders and presidential proclamations usurp personal freedoms. Among other reasons the action is Arbitrary because fees paid by the leaseholders and other funds collected from leaseholders and offshore wind developers are illegally and improperly deposited to the United States Treasury without dedication to the specific purpose and recognition of the cost of harm and remediation to the ocean. Among other reasons the action is Arbitrary because the leasehold interests restrict and interfere with the right to travel of all citizens and all members of the public.	
BOEM-2024-0001-0528c	Beginning with offshore wind, transforming the ocean into a giant power plant. This despite the fact that the industry is in economic and technological turmoil, as evidenced by the abandonment of many projects by Ørsted and others, as well as technological challenges and failures, such as the inadequate grid to even accept the energy generated.	BOEM's responsibility under the Energy Policy Act of 2005 is to issue renewable energy leases, easements, and ROWs for activities on the OCS. The purpose of the PEIS is to identify issues and analyze potential impacts for the six NY Bight lease areas. Grid reliability is outside of BOEM's regulatory authority and the scope of the PEIS. The grid operator is responsible for managing the reliability of the grid. While offshore wind in the NY Bight would provide a new source of energy to the states of New York and New Jersey, other sources of energy would still be generated.
BOEM-2024-0001-0528c	And yet this PEIS seeks to streamline and expedite the issuance of these industrial scale offshore wind projects on these 6 lease areas which impact over nearly a half 1 million acres. To be clear, Clean Ocean action is not opposed to the idea of offshore wind, Clean Ocean Action opposes this reckless scope, scale and speed currently underway due to its lack of robust, independent science, transparency, good governance, and due diligence. Our ocean deserves better. A fair pilot project and independent cost benefit analysis, and also public transparency.	Thank you for your comment. The purpose of the Proposed Action is to describe issues, analyze degree of potential impacts, and identify, as appropriate, AMMM measures. BOEM is preparing this Final PEIS because of the close proximity of the six NY Bight lease area, their similar level of development due to the leases being awarded from the same auction, the close timing of the anticipated COP submissions, and the high, near-term demand from the states of New York and New Jersey for electricity generated by offshore wind. This PEIS will reduce redundancies across COP-specific NEPA analyses, including very similar affected environments, impacts, and mitigation measures, and it will allow for future project-specific NEPA documents to be focused on the project-specific impacts not considered in the PEIS or those impacts that warrant further consideration.

Comment No.	Comment	Response
		BOEM will still conduct project-specific NEPA analysis of the COP for each lease area, and it will focus on providing site- and project-specific analyses that were not already addressed by the PEIS. Project-specific alternatives will be considered by BOEM and cooperating agencies at the COP NEPA stage. Further, BOEM considered but dismissed from further consideration an alternative to build a pilot project (PEIS Chapter 2, Table 2-3). Data from sites that are constructed and operating (e.g., Block Island), as well as the pilot project in Virginia, were incorporated into this PEIS and will be incorporated into the development of project-specific COPs and EISs.
BOEM-2024-0001-0528f	Despite a growing demand for energy, the scale, scope, and speed of these offshore wind projects has continued to be a concern, but with this PES, it seems, the intent is to move even faster.	Thank you for your comment. The purpose of the Proposed Action is to describe issues, analyze degree of potential impacts, and identify, as appropriate, AMMM measures. BOEM is preparing this Final PEIS because of the close proximity of the six NY Bight lease areas, their similar level of development due to the leases being awarded from the same auction, the close timing of the anticipated COP submissions, and the high, near-term demand from the states of New York and New Jersey for electricity generated by offshore wind. This PEIS will reduce redundancies across COP-specific NEPA analyses, including very similar affected environments, impacts, and mitigation measures, and it will allow for future project-specific NEPA documents to be focused on the project-specific impacts not considered in the PEIS or those impacts that warrant further consideration. The expectation is that the analysis at the COP NEPA stage can be more streamlined and efficient. BOEM will still conduct project-specific NEPA analysis of the COP for each lease area, and it will focus on providing site- and project-specific analyses that were not already addressed by the PEIS. Project-specific alternatives will be considered by BOEM and cooperating agencies at the COP NEPA stage.
BOEM-2024-0001-0528w	The environmental impacts of the individual projects will vary greatly, depending on which design elements they choose. Yet the PEIS would allow them to use, depending on the resource, the same characterization of the affected environment and or qualitative impacts estimated in the PEIS for the environmental reviews of the	Please see response to comment BOEM-2024-0001-0528f for information on the purpose of this PEIS and subsequent COP NEPA reviews.

Comment No.	Comment	Response
	individual projects. This will expedite the environmental review process and threaten the quality of the analysis.	
BOEM-2024-0001-0529k	Instead, the government has set its sights primarily on fast tracking, massive ocean industrialization, transforming the ocean into a giant offshore power plant. Despite the fact that the industry is in economic and technological turmoil.	Please see response to comment BOEM-2024-0001-0528f for information on the purpose of this PEIS and subsequent COP NEPA reviews.
BOEM-2024-0001-0529o	The scale, scope and speed of these offshore wind projects has always been a concern, but with this PEIS it seems the intent is to move even faster.	Please see response to comment BOEM-2024-0001-0528f for information on the purpose of this PEIS and subsequent COP NEPA reviews.
BOEM-2024-0001-0529t	The stated purpose and need for this PEIS is to consider the combined impacts of these projects in order to streamline offshore wind development in response to President Biden's executive order calling for a certain amount of offshore wind energy to be to be developed by 2040, it's 11 gigawatts. This presupposes that offshore wind projects must be developed in this area which runs counter to the purpose of the National Environmental, Environmental Policy Act, which is to analyze the effects of projects before deciding to build them. The purpose in this section also incorrectly claims that BOEM can predict the environmental impacts of projects with wide ranges of design elements in a helpful way. Because choosing different foundations, different numbers of turbines or different types of substations, just to name a few examples, will have very different environmental impacts depending on which part of the range a developer chooses. That is likely why the range of impacts for the different factors can be as high as negligible to major. Yet the PEIS would allow BOEM to use, depending on the factor, the same characterization of the affected environment and the same qualitative impacts estimated in the PEIS and the environmental reviews of the individual projects. This is what we mean when we say that speeding up the environmental review process comes at the expense of the quality of the analysis.	Please see response to comment BOEM-2024-0001-0528f for information on the purpose of this PEIS and subsequent COP NEPA reviews.
nguBOEM-2024-0001-0439-0008	In the introduction BOEM states that it is developing this Draft PEIS "to (1) identify analyze and [italicized: adopt] programmatic AMMM measures that could be applied to the six NY Bight lease areas."[Footnote 11: Draft PEIS at ES-1.] It appears that BOEM is proposing to use NEPA to impose substantive requirements on	BOEM has modified the PEIS language describing the Proposed Action and refined the language throughout the PEIS to make clear that this PEIS is *not imposing* any AMMM measures. It is not establishing or imposing any substantive obligations at this programmatic stage. Instead, it is identifying those AMMM

Comment No.	Comment	Response
	lessees without identifying the authority for each of the AMMMs. As stated BOEM cannot use NEPA as the statutory mechanism to adopt these AMMM measures it can only rely on NEPA to analyze the impacts of adopting or not adopting said measures under other statutes. As discussed in detail below adopting AMMMs at the PEIS stage prior to COP review is contrary to BOEM's implementing regulations under OCSLA. The final PEIS and Record of Decision (ROD) should clarify that BOEM is [italicized: considering] rather than [italicized: adopting] the proposed AMMMs. In this way the PEIS does not inappropriately impose substantive requirements on projects but instead provides an analysis of these AMMMs which can help inform and provide a more efficient path to project specific environmental reviews and approval. As discussed below however this efficiency is only possible if the preferred alternative selected in the ROD considers only those AMMMs that are reasonable and economically and technically feasible.	measures that BOEM may impose at the COP-specific NEPA stage. Because those AMMM measures are identified and analyzed now, the expectation is that the analysis at the COP-specific NEPA stage can be more streamlined and efficient.

P.5.2 Proposed Action and Alternatives

Table P.5-2. Responses to Comments on the Proposed Action and Alternatives

Comment No.	Comment	Response
BOEM-2024-0001-0403-0002	The content of the PEIS is also grossly insufficient to account for the various impacts on nearly half a million acres of ocean land leased throughout the six lease areas: Bluepoint Wind Attentive Energy Community Offshore Wind Atlantic Shores Offshore Wind Bight Invenergy Wind Offshore and Vineyard Mid-Atlantic. Tellingly the record $4.3 billion secured through these leases indicates that the profitability of these leases far outweighs any real assessment of the impacts and consequences of industrializing one of our last untapped and pristine natural resources. The PEIS by BOEM's own estimation anticipates 1103 wind turbines 22 offshore substations 44 offshore export cables of 1772 miles in length and 1583 miles of inter array cables between the six projects throughout the Bight. The document sites estimated impacts from negligible to major in a variety of areas but without citing sufficient baseline data due to the absence of such	For each resource area, Appendix C, *Tiering Guidance*, summarizes the affected environment, impact analysis, and AMMM measures discussed in this PEIS and identifies additional analysis that will be included in the COP-specific NEPA analysis for each lease area. Each lease area will undergo project-specific environmental analyses through the development and submittal of a COP. BOEM will conduct project-specific NEPA analysis of the COP for each lease area, which will include detailed evaluation of impacts and will consider the best available data and information that reflect the state of the science at the time of publication. BOEM has prepared several EISs for offshore wind projects within the required page limits and has not found that the page limits prevent a thorough analysis.

Comment No.	Comment	Response
	data. To issue a PEIS on the six lease areas without the existence of baseline data and "because the size and design of the NY Bight wind farms are unknown at this stage" is shortsighted grossly inappropriate and negligent. Unfortunately, further issuance of project-specific Environmental Impact Statements have been hamstrung by the federal 2020 NEPA rule change which will limit future EISs to 150 to 300 pages for "proposals of unusual scope or complexity". This means that we will never fully understand the impacts and will be to borrow a term from NMFS "building the ship while sailing it."	
BOEM-2024-0001-0089-0001	The NY EIS should be discarded as submitted. There are numerous instances where knowledge gaps exist that are dismissed as inconsequential to the project. Examples include gaps in knowledge of EMF emissions impacting benthic layers and the authors suggest that ongoing studies taking place at Block Island Wind Farm which has consistently operated at a fraction of its stated capacity or not at all should suffice as evidence that the project should forge ahead. This is IRRESPONSIBLE!	The EMF and cable heat IPF discussion under Section 3.5.2.3, *Impacts of Alternative A – No Action on Benthic Resources*, does include a discussion of the differences between HVAC and HVDC and the type and intensity of the EMF they produce. Text has been added to this section and Section 3.5.2.5 stating that cable shielding required by BOEM would block electric fields emitted by HVDC and HVAC cables and that a weak induced electric field would be present if HVAC cables are used. Both sections discuss the impacts of any remaining EMF on benthic invertebrates. In addition, refer to response to comment BOEM-2024-0001-0400-0003 regarding data gaps, uncertainties, and incomplete and unavailable information. BOEM addresses this concern for each resource as required under CEQ regulations (40 CFR 1502.21) in PEIS Appendix E: *Analysis of Incomplete and Unavailable Information*. For NEPA purposes, BOEM believes the NEPA regulatory requirements regarding incomplete and unavailable information have been satisfied in the PEIS.
BOEM-2024-0001-0175-0004	[Bold: BPA:] I encourage you to read [Underline: The Toxic Wings - Damage and casualty of wind turbine blades] First English edition (May 2023): Jan Erik Weinbach Asbjrn Solberg og Brd-Einar Rimereit. THE TURBINE GROUP May 2023. The author states: "The entire western world has enumerated and adopted gigantic development targets with this unproven technology and that without having a scientific basis for the overall scope of consequences for HSE (health safety and environment). It is almost unbelievable and we know of no other industry that have been allowed such "Wild West" conditions ever. The closest we come to historical comparisons is to	Each lease area will undergo project-specific environmental analyses through the development and submittal of an SAP and a COP. BOEM will conduct project-specific NEPA analysis of the COP for each lease area, which will include detailed evaluation of impacts and will consider the best available data and information that reflect the state of the science at the time of publication. Calculation of rates is outside the scope of the PEIS and is the responsibility of grid operator and state.

Comment No.	Comment	Response
	the tobacco industry which for many decades was allowed to advertise that cigarettes were good for life and health even long after it was widely known that cigarettes have a very negative effect on life and health. Smoking cigarettes was an individual choice and the damage caused by these was largely self-inflicted. The toxic emissions from wind turbines are imposed on each and every one of us including the voiceless creatures of nature. The responsibility for this must and will be assigned to those who imposed this on us without a scientific basis about the consequences for life and health". There will be too many negative and irreversible impacts for the limited amount of energy we would get from offshore wind. The benefit will never out measure the costs. Lastly I would like to mention that to date the BPU cannot tell the ratepayers what will be our cost for this venture since offshore wind is built on subsidies which I believe is not economically responsible. I truly hope that you don't realize what will be lost until after it is gone.	
BOEM-2024-0001-0313-0006	1.3 Purpose and Need for the Proposed Action Page 1-5 states that "A broader approach to the NEPA analysis for the minimum of six COPs expected for the NY Bight lease areas is consistent with Executive Order 14008 "Tackling the Climate Crisis at Home and Abroad" issued on January 27 2021. In that order President Biden stated that the policy of his administration is "to organize and deploy the full capacity of its agencies to combat the climate crisis to implement a Government-wide approach that reduces climate pollution in every sector of the economy; increases resilience to the impacts of climate change; protects public health; conserves our lands waters and biodiversity; delivers environmental justice; and spurs well-paying union jobs and economic growth especially through innovation commercialization and deployment of clean energy technologies and infrastructure." To support the goals outlined in Executive Order 14008 the administration has also announced plans to increase renewable energy production with a goal of 30 gigawatts (GW) of offshore wind energy capacity by 2030. Potential development of the leaseholds would assist with meeting several state mandates for renewable energy. New Jersey's goal of 11 GW of offshore wind energy generation by 2040 is outlined in	The PEIS only analyzes six lease areas on the Atlantic OCS; other projects not analyzed in the PEIS would contribute to New Jersey and New York state goals. These include Empire Wind, Atlantic Shores North, and Atlantic Shores South. These other projects are analyzed as part of the cumulative effects analysis. The 5–7 GW expected from the six NY Bight lease areas is based on a conservative power ratio of 3 megawatts per square kilometer (MW/km^2). The NY Bight leases each have operations terms of 33 years that commence on the date of COP approval. Lessees may request an extension of their lease in accordance with lease terms and BOEM regulations. Cumulative impacts are addressed in the PEIS for each resource and for each alternative, including the No Action Alternative; the methodology is explained in PEIS Chapter 3, pages 3-1 through 3-3.

Comment No.	Comment	Response
	New Jersey Executive Order No. 307 issued on September 21 2022. New York's requirement of 9.0 GW of offshore wind energy generation by 2035 is outlined in the Climate Leadership and Community Protection Act signed into law on July 18 2019. Additionally an estimated 1618 GW of offshore wind energy may be necessary to ensure New York State achieves its Climate Act mandates (New York State Climate Action Council 2022). Based on a conservatively estimated power ratio of 3 megawatts per square kilometer BOEM estimates that full development of leases in this area has the potential to create up to 5.6 to 7 GW of offshore wind energy." Comment: It is unclear how dedicating 48800 acres of lease area and the associated structures and disturbance meets the objectives specifically protection of public health; conservation of our lands waters and biodiversity stated above; in fact this project appears to directly contravene those policies. For context the entire Town of Oyster Bay comprises approximately 108 400 acres. The best-case scenario presented in the PEIS at full optimization of the project at 7GW is still less than the overly ambitious state mandate of 9GW of offshore wind energy further the lifespan of a WTG is only approximately 30 years. There is no discussion about the net generation of how these mandates will be achieved and how that figure is calculated into the equation upon expiration of the WTG's useful lifespan not only would it appear that a lease extension would be needed for continuous operation but WTGs would have to be decommissioned and replaced. The larger plans of scale and cumulative impacts must be adequately addressed in the final PEIS. Though the goals for alternative energy requirements are reiterated throughout the documents as a guiding qualifier for expeditiously proceeding with the review of these projects the details are omitted and unavailable thereby making it impossible to meaningfully review and consider the comprehensive cumulative synergistic direct and indirect impacts.	
BOEM-2024-0001-0331-0001	We are not opposed to clean energy in general and seek only that where it is pursued it be done in a reasonable and consistent manner and not leave major collateral damage in its wake. According to the Federal Register BOEM states that the purpose of the Draft PEIS is to	Thank you for your comment. BOEM shares the same goal to ensure projects are developed responsibly. The Final PEIS includes several identified AMMM measures (refer to Appendix

Comment No.	Comment	Response
	analyze the potential impacts of the New York Bight along with identifying possible changes to those impacts that could result from adopting certain avoidance minimization mitigation and monitoring measures (AMMM). After public input BOEM will decide on whether to adopt one or all of the AMMM measures outlined in the DPEIS and make them conditions of approval for activities proposed by the lessees in their construction and operation plans (COPS) or defer the decision to adopt such measures to each project-specific environmental review. According to the diagram about the process the PEIS analyzes the programmatic avoidance minimization mitigation and monitoring measures that could apply to the New York Bight leases and includes a focused regional cumulative analysis.	G) to avoid, minimize, and mitigate impacts from potential development of the six NY Bight lease areas.
BOEM-2024-0001-0331-0030	The BOEM PEIS lacks any discussion concerning intermittent offshore wind's contribution to grid unreliability how this will be mitigated and at what cost. For the first time in August 21 2023 the North American Electric Reliability Corporation (NERC) identified energy policy as a risk priority for grid reliability because the heightened legislative focus and mandates regarding decarbonization decentralization and electrification. The organization holds that the emerging resource mix is more susceptible to long-term widespread and extreme events like sustained loss of wind power. (https://www.nerc.com/news/Pages/Collective- Focus-Imperative-for-Mitigating-Emerging-Risks-to-Grid-Reliability.aspx) If the purpose of the projects is to meet the governor's goal by executive order for the State to sell 100% clean energy by 2035 including 11 GW of offshore wind how do the wind developers and BOEM propose to back up the wind when it is not blowing? What is the cost of this backup? What are the plans and cost of battery backup storage systems? According to Science Daily "energy droughts" in wind and solar can last a week. (DOE/Pacific Northwest National Laboratory December 11 2023) . BOEM and wind developers use a misleading measurement called a capacity factor in their discussions of offshore wind energy output but this number typically 50% - is misleading in that it is an average. This average does not account for the times when generated wind energy exceeds demand and when wind energy is less than demand. For example there could be days when	BOEM's responsibility under the Energy Policy Act of 2005 is to issue renewable energy leases, easements, and rights-of-way (ROWs) for activities on the OCS. The purpose of the PEIS is to present a programmatic analysis of the six NY Bight lease areas to characterize the types of impacts that could occur and mitigation measures that could minimize those effects. Grid reliability is outside of BOEM's regulatory authority and the scope of the PEIS. The grid operator is responsible for managing the reliability of the grid. While offshore wind in the NY Bight would provide a new source of energy to the states of New York and New Jersey, other sources of energy would still be generated. BOEM's calculations of capacity are an assessment of total lease capacity and are not used to estimate power operations. Costs for power are considered through state solicitations and are factored into utility rates. To date BOEM has not received COPs proposing battery energy storage systems. Other developers may choose to develop battery systems to capture offshore wind, and those projects would be required to be reviewed and permitted separately, although they would be outside BOEM's jurisdiction. However, the offshore wind projects do not require backup power or battery storage systems, and each project has independent utility.

Comment No.	Comment	Response
	the wind turbines are only producing 20% of their energy capacity but demand requires 80% capacity. There will be other days when wind energy supply will be at 70% of its capacity but demand will only be at 50%. A rigorous multiyear supply/demand accounting would inform us of the balancing costs back-up costs and grid costs related to the true issues of intermittency.	
BOEM-2024-0001-0334-0002	Be advised that the issues below as well as those you will receive from others represent a grave concern regarding BOEM's performance in protecting the interests of the New Jersey public. BOEM appears to ignore most of the significant impacts raised in their own EIS documents as well as the concerns raised by the well-researched public. The approvals of the projects to date seem to only ensure that the projects move forward with the appearance of having been fully vetted and the mainstream press bolsters that perception to the public. A critical viewpoint is now widespread and if successful will lead to new and increased pressures to prevent offshore wind projects from proceeding in New Jersey on the East Coast and around the coastal areas of the USA.	The PEIS was developed through coordination with federal agencies, Tribal Nations, and state and local partners, and the AMMM measures seek to avoid, minimize, or mitigate potential impacts. Project-specific NEPA analysis will provide additional site-specific data and incorporate advances in technology and understanding of these areas. Additional coordination with regulatory agencies is required as part of the approval of the project-specific approaches.
BOEM-2024-0001-0345-0003	New York City and Long Island are on the front lines of climate change. The NYSERDA white paper on the Climate Leadership and Community Protection Act asserts that one major obstacle the state faces to meet our climate change goals is that there is a "tale of two grids." Upstate uses 88% zero-emission resources but only represents 1/3rd of the energy load while downstate is 2/3rds of the load and 69% fossil fuels. The only way to see a just transition from polluting fossil fuels to renewable energy downstate is by utilizing offshore wind. New York has several offshore wind projects moving through the regulatory process which if approved will power millions of homes with clean renewable energy and bring New York significantly closer to our goal of 9000 MW of offshore wind. These projects are also kickstarting an "offshore wind-ustry" in the state which are already slated to create nearly 7000 jobs in project development manufacturing installation and operations and maintenance while creating over $12 billion in economic benefits to the state. They will also allow the state to close down antiquated polluting fossil fuel fired power plants which will improve air quality	Comment noted.

Comment No.	Comment	Response
	in our region and provide $1 billion in health benefits to New Yorkers in vulnerable and frontline communities.	
BOEM-2024-0001-0354-0017	True science involves constantly emerging new evidence and findings along with the ever-changing challenges imposed as to prior conclusions. As such contrary to the. Non-scientific "group think" and massive amounts of money driven public relations press releases behind the current wind turbine projects such sentiment ignores scientific methods of ongoing experimenting at the very least through realistic peer reviewed scientific pilot projects. True science involves constantly emerging new evidence and findings. This process necessarily continually involves the ongoing application of extensive scientific research which is then applied to the previously accepted theories. Such a true application of peer reviewed science especially applied to growingly_ obsolete wind turbine construction would support the revision if not rejection of prior dogma as to allegedly "settled science". As I have testified previously only from a partially facetious standpoint the rush to judgment approach as to this specific proposal to construct massive windfarms off New Jersey represents non-scientific "group think" with the devastating potential to trample upon scientific inquiry and research. Such immense pressure from those supporting such colossal development of this offshore industrial site off of the precious New Jersey Coast unfortunately has facilitated many knee-jerk feel-good reactions which totally ignore the required economic and scientific vetting process. During a prior era particularly relevant to the coast of New Jersey our town and I were subjected to enormous pressures exerted by those supporting ocean dumping. Generated by a foreign corporation's pipeline off our beautiful and incalculably valuable portion of the New Jersey shore. Similar subconscious and actual influences are once again being exerted in favor of a foreign corporation looking to create another potential ocean dumping site off New Jersey's shoreline. I would truly beseech BOEM officials to rise above the narrow bureaucratic rubber-stamping of the within proposal in favor of the true application of scientific method to the entire cumulative and indirect impacts of the current project as well to windfarms off of New Jersey's Coast in general. Just as one heartfelt objector testified in a virtual hearing as to the threats	This PEIS highlights regional issues; the details in the project-specific COP NEPA documents will provide additional site-specific information and incorporate advances in technology and scientific understanding as the projects advance. In addition, refer to response to comment BOEM-2024-0001-0400-0003 regarding data gaps, uncertainties, and incomplete and unavailable information. BOEM addresses this concern for each resource as required under CEQ regulations (40 CFR 1502.21) in PEIS Appendix E: *Analysis of Incomplete and Unavailable Information*. For NEPA purposes, BOEM believes the NEPA regulatory requirements regarding incomplete and unavailable information have been satisfied in the PEIS.

Comment No.	Comment	Response
	proposed by foreign corporations to our country's national symbol the bald eagle these threats are very real whether proposed by a non-American entity or a corporation based in our own country.	
BOEM-2024-0001-0355-0004	Unreliable energy so a back-up energy supply would still be needed.	Comment noted. Grid reliability is the responsibility of the state grid operators. While offshore wind in the NY Bight would provide a new source of energy to the states of New York and New Jersey, other sources of energy would still be generated.
BOEM-2024-0001-0355-0017	In addition it seems BOEM is rushing this process with little or no information. I am opposed to approval of the OSW projects at this time until MORE DATA AND MORE STUDIES are conducted. There are way too many unknowns and "insufficient data" per BOEMs PEIS. From p. 5 of the PEIS they state "The Atlantic OCS is considered by BOEM to be a "Frontier Region" where little information exists about the geologic conditions and how those conditions may impact development of offshore wind farms." On page 12 they state "site investigation and characterization for such projects is generally focused on a limited area." Does this make sense on a barrier island where the water table is high and you can compromise the water resource on one part and not another? How can you approve such a project without knowing so much of the necessary information to make a thoughtful decision that will affect SO MANY humans and marine creatures in multiple negative ways? At the very minimum there should be a pilot study done to collect more information on our specific region before going for this massive disruption to and destruction to marine life human life real estate and tourism.	Refer to response to comment BOEM-2024-0001-0400-0003 regarding data gaps, uncertainties, and incomplete and unavailable information. BOEM addresses this concern for each resource as required under CEQ regulations (40 CFR 1502.21) in PEIS Appendix E, *Analysis of Incomplete and Unavailable Information*. For NEPA purposes, BOEM believes the NEPA regulatory requirements regarding incomplete and unavailable information have been satisfied in the PEIS. In addition, this PEIS will not result in the approval of any activities in the NY Bight lease areas. Each lease holder is required to conduct project-specific environmental analyses, which include development and submittal of a COP as required under 30 CFR 585.628. BOEM will conduct project-specific NEPA analysis of the COP for each lease area that will focus on providing site- and project-specific analyses that were not already addressed by the PEIS. Appendix C, *Tiering Guidance*, summarizes the affected environment, impact analysis, and AMMM measures for each resource area discussed in this PEIS and identifies additional analysis that BOEM anticipates may be included in the COP-specific NEPA analysis for each lease area and cable route as the projects advance. Further, BOEM considered but dismissed from further consideration an alternative to build a pilot project (PEIS Chapter 2, Table 2-3). Data from sites that are constructed and operating (e.g., Block Island), as well as the pilot project in Virginia, were incorporated into this PEIS and will be incorporated into the development of project specific COPs and EISs.

Comment No.	Comment	Response
BOEM-2024-0001-0356-0003	The second more recent information that has been acknowledged is inadequate is from the NJBPU published 2/14/24: "Atlantic hurricanes pose a significant potential threat to the State's burgeoning OSW sector. Despite this risk relatively little technical research has been devoted to quantifying and assessing Atlantic hurricane impact upon OSW projects. As a result regulators developers and insurers have limited tools at their disposal to mitigate this risk or ascertain whether the risk warrants design modifications. The prevailing uncertainty surrounding what is widely perceived as a substantial threat to OSW largely without scientific or engineering backing serves as a considerable obstacle to the development of OSW Development of advanced technical research quantifying and assessing hurricane risk is therefore necessary to aid developers regulators and insurers in mitigating hurricane risk and providing improved design standard baselines." These studies should've been performed and the results published long before any of the EIS's for any lease were approved. This is absolutely absurd and are yet more glaring reasons that OSW is being pushed through the regulatory processes prematurely and unchecked.	As stated in PEIS Section 2.3, the engineering specifications of the WTGs and their ability to sufficiently withstand weather events, including hurricane-level events, are independently evaluated by a certified verification agent when reviewing the Facility Design Report and Fabrication and Installation Report according to international standards. One of these standards calls for the structure to be able to withstand a 50-year return interval event. An additional standard includes withstanding 3-second gusts of a 500-year return interval event, which would correspond to Category 5 hurricane windspeeds. It is in the best interest of the lessees to construct and operate a viable project and minimize risk as much as possible; they are responsible for ensuring the WTGs are designed and constructed to withstand such events and to ensure the integrity of the structures would not be compromised.
BOEM-2024-0001-0357-0002	As requested by the BOEM the bulk of our comments here are on the New York Bight program EIS to make it a more useful document. However it is not the document that is of paramount concern here. Rather it is the BOEM decision making process itself relative to the requirements of the Administrative Procedures Act the Outer continental Shelf Lands Act and the National Environmental Policy Act and the dictates of common sense which we believe is fundamentally unreasonable and flawed in at least two major respects: First, the BOEM does not consider the full, real environmental impact to an area when it approves projects, and Second, it does not engage expert and other public input before it makes the most important decisions, i.e., on wind turbine location, number, megawatt size and gear drive. Both of these defects are discussed below.	The purpose of the PEIS, as described in Chapter 1, *Purpose and Need*, is to analyze the effects from potential development activities in the six NY Bight lease areas and to identify and analyze AMMM measures that could reduce those effects. The PEIS does not approve any projects. Each individual COP submitted by a developer to BOEM will be separately analyzed as required under NEPA and will disclose the full impacts of the construction and installation, O&M, and conceptual decommissioning of the project, including cumulative effects. During the COP-specific NEPA process, BOEM will hold a public comment period at the start of the NEPA process (scoping) and, following that, will release the Draft NEPA document, whereby members of the public and agencies can provide input to help inform the NEPA process, alternatives, and mitigation measures to identify and minimize environmental effects. Additionally, throughout the NEPA process, BOEM will work closely with Cooperating Tribal Governments and federal and state agencies to assist with assessing impacts and identifying mitigation

Comment No.	Comment	Response
		measures. BOEM will analyze each COP as proposed by the developer and does not make decisions on number of turbines, MW size, and gear size that applicants include in the COP. BOEM may analyze different alternatives and mitigations—such as the number of turbines, MW size, and gear size—as part of the NEPA review process, project-specific consultations, and decision process.
BOEM-2024-0001-0362-0027	High-road Equitable Environmentally Responsible Development Outer Continental Shelf Lands Act BGA believes that standards for high-road equitable and environmentally responsible development are consistent with federal statute. In Section 8 of OCSLA Congress declared that it is the authority of the Secretary of the Interior (delegated to BOEM) to "grant a lease easement or right-of-way" for activities that "produce or support production transportation or transmission of energy from sources other than oil and gas" in a manner that provides for:"(A) Safety;(B) Protection of the environment;(C) Prevention of waste;(D) Conservation of the natural resources of the Outer Continental Shelf;(E) Coordination with relevant Federal agencies;(F) Protection of national security interests of the United States;(G) Protection of correlative rights in the Outer Continental Shelf;(H) A fair return to the United States;(I) Prevention of interferences with reasonable uses of the exclusive economic zone the high seas and the territorial seas;(J) Consideration of a. The location of and any schedule relating to a lease easement or right-of- way for an area of the Outer Continental Shelf; and b. Any other use of the sea or seabed including use for a fishery a sea lane a potential site of a deep-water port or navigation;(K) Public notice and comment on any proposal submitted for a lease easement or right-of-way under this subsection; and(L) Oversight inspection research monitoring and enforcement related to a lease easement or right-of-way under this subsection." [Footnote v: U.S. Code 1337 - Leases easements and rights-of-way on the outer Continental Shelf. https://www.law.cornell.edu/uscode/text/43/1337] High road standards touch on many of these imperatives including safety; protection of the environment; conservation of natural resources; protection of national security; fair return to the United States;	Comment noted. Section 1.4, *Regulatory Overview*, of the Final PEIS describes the regulatory authority for renewable energy leasing on the OCS.

Comment No.	Comment	Response
	consideration of other uses; and oversight inspection and resource monitoring. Environmentally responsible development robust stakeholder engagement equitable distribution of benefits and attention to quality job creation domestically are all foundational to OCSLA requirements. In addition to the authority granted to BOEM to facilitate energy development on the Outer Continental Shelf (OCS) the president has authority to direct requirements on leases of the OCS and precedent exists for the president to do so. Current BOEM leases include terms mandated by presidential Executive Order 11246 which prohibits employment discrimination and establishes affirmative action requirements for nonexempt federal contractors and subcontractors. [Footnote vi: DOL Executive Order 11246 Equal Employment Opportunity Sept. 24 1965. https://www.dol.gov/agencies/ofccp/executive-order-11246/as-amended] Article II 1 of the U.S. Constitution provides that "executive power shall be vested in" the president. Such power gives the president the right in the absence of an express congressional declaration to the contrary to control the terms upon which public lands or property may be sold leased or used by private individuals or entities. [Footnote vii: Case text United States v. Midwest Oil Co. Feb. 23 1915. Available online: https://casetext.com/case/united-states-v-midwest- oil-co]	
BOEM-2024-0001-0362-0028	In Executive Order 14008 Tackling the Climate Crisis at Home and Abroad issued January 27 2021 President Biden stated that it is the policy of the United States: "to organize and deploy the full capacity of its agencies to combat the climate crisis to implement a Government-wide approach that reduces climate pollution in every sector of the economy; increases resilience to the impacts of climate change; protects public health; conserves our lands waters and biodiversity; delivers environmental justice; and spurs well-paying union jobs and economic growth especially through innovation commercialization and deployment of clean energy technologies and infrastructure." This executive order further emphasizes that "[t]his Nation needs millions of construction manufacturing engineering and skilled-trades workers to build a new American infrastructure and clean energy economy." [Footnote ix: White House Executive Order on Tackling the Climate Crisis at Home and Abroad Jan. 27	Comment noted. Section 1.3, *Purpose of and Need for the Proposed Action*, describes the purpose of the Proposed Action, which supports Executive Order 14008 “Tackling the Climate Crisis at Home and Abroad.”

	2021. https://www.whitehouse.gov/briefing-room/presidential-actions/2021/01/27/executive-order-on-tackling-the-climate-crisis-at- home-and-abroad/] President Biden further states "Agencies shall seek to increase the Federal Government's resilience against supply chain disruptions. Such disruptions put the Nation's manufacturing sector at risk as well as consumer access to critical goods and services." Additionally President Biden directed all agencies to "adhere to the requirements of the Made in America Laws in making clean energy energy efficiency and clean energy procurement decisions" consistent with Executive Order 14005 Ensuring the Future Is Made in All of America by All of America's Workers. [Footnote x: White House Executive Order on Ensuring the Future Is Made in All of America by All of America's Workers Jan. 25 2021. https://www.whitehouse.gov/briefing-room/presidential-actions/2021/01/25/executive-order-on-ensuring-the-future-is-made-in- all-of-america-by-all-of-americas-workers/] President Biden has also emphasized the need to maximize utilization of domestic content as we advance climate and clean energy solutions in order to strengthen U.S. manufacturing. President Biden's executive order on America's supply chains issued February 24 2021 states "[t]he United States needs resilient diverse and secure supply chains to ensure our economic prosperity and national security." It continues to say "resilient American supply chains will revitalize and rebuild domestic manufacturing capacity maintain America's competitive edge in research and development and create well-paying jobs. They will also support small businesses promote prosperity advance the fight against climate change and encourage economic growth in communities of color and economically distressed areas."	
BOEM-2024-0001-0362-0029	Executive Orders on Domestic Manufacturing Environmental Justice and Union Labor President Biden has reinforced in various executive orders that it is the policy of the federal government to pursue solutions to the climate crisis with attention to union labor domestic manufacturing environmental justice and protection of natural resources. The announcement of the national offshore wind target to deploy 30 gigawatts (GW) of offshore wind by 2030 further underscored this approach. The White House fact sheet containing that announcement declared: "The President recognizes that a	Comment noted. Section 1.3, *Purpose of and Need for the Proposed Action*, describes the purpose of the Proposed Action, which supports President Biden administration's goal of 30 GW of offshore wind capacity by 2030.

Comment No.	Comment	Response
	thriving offshore wind industry will drive new jobs and economic opportunity up and down the Atlantic Coast in the Gulf of Mexico and in Pacific waters. The industry will also spawn new supply chains that stretch into America's heartland as illustrated by the 10000 tons of domestic steel that workers in Alabama and West Virginia are supplying to a Texas shipyard where Dominion Energy is building the Nation's first Jones Act compliant turbine installation vessel. "Federal leadership in close coordination with states and in partnership with the private sector unions and other key stakeholders is needed to catalyze the deployment of offshore wind at scale. "the Administration is taking coordinated steps to support rapid offshore wind deployment and job creation:1. Advance ambitious wind energy projects to create good-paying union jobs2. Investing in American infrastructure to strengthen the domestic supply chain and deploy offshore wind energy3. Supporting critical research and data-sharing." [Footnote viii: White House FACT SHEET: Biden Administration Jumpstarts Offshore Wind Energy Projects to Create Jobs March 29 2021. https://www.whitehouse.gov/briefing-room/statements-releases/2021/03/29/fact-sheet-biden-administration-jumpstarts- offshore-wind-energy-projects-to-create-jobs/]	
BOEM-2024-0001-0362-0031	Recent global events have made it abundantly clear that our national security is strongly tied to our energy security to which domestic manufacturing plays a critical role. The U.S. Department of Energy and the North American Electric Reliability Corporation jointly-commissioned a report assessing risks to the U.S. electricity generation and distribution infrastructure. The summary of the report observed that the "bulk power system is dependent on long supply chains often with non-domestic sources and links" and determined that the "increased reliance on foreign manufacturers with critical components and essential spare parts manufactured abroad (e.g. HV transformers)" means the "supply chain itself represents an important potential vulnerability." [Footnote xv: North American Electric Reliability Corporation High-Impact Low-Frequency Event Risk Impact to the North American Bulk Power System at page 30 (June 2010). https://www.energy.gov/ceser/downloads/high-impact-low-frequency-risk-north-american- bulk-power-system-june-	Comment noted.

Comment No.	Comment	Response
	2010.] The report recommends that "efforts should be considered to bring more of the supply chain and manufacturing base for these critical assets back to North America." [Footnote xvi: Ibid at 27]	
BOEM-2024-0001-0383-0007	OSCLA: BOEM quotes the Outer Continental Shelf Lands Act regarding the Secretary's legislative requirement to "ensure that any activity under [subsection 8(p)] is carried out in a manner that provides for (A) safety; (B) protection of the environment.. (I) prevention of interference with reasonable uses (as determined by the Secretary) of the exclusive economic zone the high seas and the territorial seas.." etc. [Footnote 21: PEIS at New York Bight Draft Programmatic Environmental Impact Statement Volume 1 Chapters 1-4 (boem.gov) p. 1-6 1-7.] The agency then quotes a 2021 agency memo that states that the law as written in fact does not require the Secretary to ensure achievement of these various "goals" but to balance them.[Footnote 22: Ibid p. 1-7.]We disagree. The term "ensure" means "ensure". It does not mean balance. By not ensuring safety by not ensuring prevention of interference with reasonable uses- such as federally permitted commercial fishing on the OCS-BOEM is in violation of the law. The agency cannot rewrite the meaning of the word "ensure" with an internal agency memo. Furthermore the agency memo written in 2021 directly contradicts a corresponding agency memo written only five months prior in 2020. We have attached that memo along with this comment. The 2021 memo purports to overturn the previous 2020 memo this reinterpretation coinciding with a change in Administration but the law cannot mean two different things. Simply because an Administration changes does not mean that the law changes. Congress changed nothing. The definition of the word "ensure" did not change in the English language between 2020 and 2021.BOEM cannot add words to statute that do not exist in the statute; it must take the legislative language at face value. The PEIS states that the law imposes only a "a general duty" and "does not require the Secretary to ensure that the goals are achieved to a particular degree" but allows the Secretary to "balance" what it refers to as "goals". These listed requirements are not goals; they are legal standards. The law says the Secretary must "ensure" that these legislative standards are met. The word "ensure" defined by	The Solicitor’s Opinion of December 14, 2020, M-37059, was withdrawn on April 9, 2021, by M-37067 for the reasons explained in the latter opinion. The Solicitor’s M-opinions on matters within the jurisdiction of the Department of the Interior (DOI) are binding on BOEM (see 209 Department Manual 3.2(A)(11)). Therefore, BOEM is bound to follow the interpretation of the OCSLA put forth in M-Opinion 37607.

Comment No.	Comment	Response
	Merriam-Webster means "to make sure certain or safe: guarantee." [Footnote 23: See Ensure Definition & Meaning - Merriam-Webster.] The Secretary must guarantee these standards. It is clear from the discussion on navigational impacts in the AMMM section below the commercial fishing impacts contained in our attached USCG comments as well as the lack of regulatory benchmarks regarding high resolution geophysical surveys discussed below- which requires stronger regulatory protections by both BOEM and NOAA when being conducted in the Gulf of Mexico by other offshore energy industries than in the Atlantic by offshore wind developers- that BOEM is not guaranteeing that these OSCLA standards are met.	
BOEM-2024-0001-0406-0008	BOEM's Proposed Action Violates NEPA and the APA BOEM's proposed action "the adoption of AMMM measures such that the potential impacts described in Alternative B may be avoided reduced or mitigated" Draft PEIS 2.1.3 (p. 2-16) would run afoul of both NEPA and the Administrative Procedures Act (APA) creating considerable legal risk for BOEM and jeopardizing the utility of its programmatic NEPA analysis if BOEM does not amend the proposed action in its Final PEIS. As BOEM describes it in the Draft PEIS the proposed action calls for "adopting programmatic AMMM measures that BOEM would require as conditions of approval for activities proposed by lessees in COPs submitted for the NY Bight lease areas unless future COP-specific NEPA analysis shows that implementation of such measures is not warranted or effective." Draft PEIS 1.3 (p.1-4) (emphasis added). BOEM then states that "[t]he Record of Decision (ROD) for the PEIS will state which of the AMMM measures analyzed in the PEIS BOEM has committed to adopting and if not why they were not adopted." Id. This proposed action would establish for the six NYB lessees a presumption at COP review that BOEM will impose the full suite of AMMM measures from the Final PEIS on their projects unless the lessees can make a specific showing in their COPs that specific measures are not "warranted or effective." This approach unlawfully shifts the burden from BOEM to the lessee an approach which is legally problematic in at least two key respects.	The Proposed Action for the Final PEIS includes the identification of AMMM measures at the programmatic stage that could avoid, minimize, mitigate, and monitor impacts on resources in the six NY Bight lease areas. These measures may be required as conditions of approval for activities proposed by lessees in the COPs submitted for the six NY Bight lease areas. BOEM may require additional or different measures based on future, site-specific NEPA analysis or the parameters of specific COPs. BOEM may also modify the measures at the COP-specific NEPA stage to tailor them to the characteristics of the proposed project and the site(s) of proposed activities, and to ensure conformity with project-specific consultations and authorizations. BOEM has modified the PEIS language describing the Proposed Action and refined the language throughout the PEIS to make clear that this PEIS is *not imposing* any AMMM measures—and therefore is not establishing a presumption at COP review that a lessee would need to rebut—but is identifying those AMMM measures that BOEM may impose at the COP-specific NEPA stage. Because those AMMM measures are identified and analyzed now, the expectation is that the analysis at the COP-specific NEPA stage can be more streamlined and efficient.
BOEM-2024-0001-0406-0009	BOEM's Proposed Action Inappropriately Imposes Substantive Obligations Through a Procedural Statute NEPA is a procedural statute requiring an agency to analyze the environmental impacts of	The Proposed Action for the Final PEIS includes the identification of AMMM measures at the programmatic stage that could avoid, minimize, mitigate, and monitor impacts on resources in the six

Comment No.	Comment	Response
	a proposed federal action. 42 U.S.C. 4331. While the NEPA regulations obligate an agency to provide a "detailed discussion of possible mitigation measures" when preparing an EIS it does not impose "a substantive requirement that a complete mitigation plan be actually formulated and adopted." Robertson v. Methow Valley Citizens Council 490 U.S. 332 35152 (1989). Thus while BOEM has appropriately discussed in detail the AMMM measures that could be applied during COP-specific NEPA analysis any adoption of those measures must be done through substantive statutes that grant BOEM and other permitting agencies the authority to require such measures. In this case BOEM's substantive authority to impose mitigation measures derives from the Outer Continental Shelf Lands Act (OCSLA) and its implementing regulations. In particular 30 CFR 585.620-628 establishes the COP review process and states that BOEM "will prepare an appropriate NEPA analysis" id. At 628(b) and then "upon completion of technical and environmental reviews will specify terms and conditions to be incorporated into the COP." Id. At 628(f)(1). Because BOEM's authority to impose mitigation measures is explicitly contingent on its review of a submitted COP it would be premature to invoke that authority in a PEIS. Moreover as noted above many of the proposed AMMM measures lie outside of BOEM's statutory and regulatory authority and would need to be "adopted" by other federal state and/or local agencies (if indeed they could be required or enforced at all). By proposing to "adopt" AMMM measures in a programmatic NEPA document divorced from an OCSLA decision point BOEM effectively and illegally converts NEPA to a substantive statute.[Footnote 1: It is no defense that BOEM would retain the discretion to not impose particular AMMM measures if lessees can demonstrate in their COPs that an "adopted" measure is not "warranted or effective." The proposed action still would constitute a substantive imposition of AMMM measures before COP submittal with the burden now shifted to lessees to prove in their COPs that such measures should not be required.]	NY Bight lease areas. These measures may be required as conditions of approval for activities proposed by lessees in the COPs submitted for the six NY Bight lease areas. BOEM may require additional or different measures based on future, site-specific NEPA analysis or the parameters of specific COPs. BOEM may also modify the measures at the COP-specific NEPA stage to tailor them to the characteristics of the proposed project and the site(s) of proposed activities, and to ensure conformity with project-specific consultations and authorizations. BOEM has modified the PEIS language describing the Proposed Action and refined the language throughout the PEIS to make clear that this PEIS is *not imposing* any AMMM measures—and therefore is not establishing any substantive obligations at this programmatic stage—but is identifying those AMMM measures that BOEM may impose at the COP-specific NEPA stage. Because those AMMM measures are identified and analyzed now, the expectation is that the analysis at the COP-specific NEPA stage can be more streamlined and efficient.
BOEM-2024-0001-0406-0010	BOEM's Proposed Action Appears to Constitute a De Facto Rulemaking in Violation of the APA By imposing a new standard of review on all projects within the NY Bight BOEM has also effectively engaged in de facto rulemaking in	The Proposed Action for the Final PEIS includes the identification of AMMM measures at the programmatic stage that could avoid, minimize, mitigate, and monitor impacts on resources in the six NY Bight lease areas. These measures may be required as

Comment No.	Comment	Response
	violation of the APA. Subject to very limited exceptions the APA requires that any adoption of or amendment to a federal regulation go through the notice and comment rulemaking process. 5 U.S.C. 553. Substantive agency rules which change or impose rights and obligations of regulated parties may not be imposed through informal pronouncements; to do so represents a violation of the APA's rulemaking procedure. See e.g. Cmty. Nutrition Inst. V. Young 818 F.2d 943 946-47 (D.C. Cir. 1987); see also Phillips Petroleum Co. v. Johnson 22 F.3d 616 621 (5th Cir. 1994) ("A party may not be adversely affected by a [substantive] rule in violation of [APA notice and comment] requirements."). BOEM's proposed action while not styled as an amendment to its regulations imposes a new standard that upends the COP review process established in BOEM's existing regulations and seeks to apply a new set of requirements (i.e. the full suite of AMMM measures) to all offshore wind projects in the NY Bight. As noted in the section above BOEM's regulations require that it "specify terms and conditions" of COP approval "upon completion of technical and environmental reviews" of a submitted COP. 30 CFR 585.628(f)(1). If the ROD is issued as BOEM proposes all six NYB lessees would face a presumptive array of requirements prior to submitting a COP and prior to BOEM conducting any of its environmental or technical reviews of those COPs. The lessees would then be required to demonstrate in their COPs that individual measures are not "warranted or effective" a standard found nowhere in OCSLA or BOEM's regulations. This would create a new standard of review that effectively shifts BOEM's burden to demonstrate that specific AMMM measures are needed based on its review of the project to the lessees. That is exactly the type of change in the rights and obligations of regulated parties that can only be done through notice and comment rulemaking.[Footnote 2: The fact that this particular Draft PEIS "only" applies to six lessees is of little consequence. BOEM is in the process of conducting a similar programmatic review for its five California leases see https://www.boem.gov/renewable-energy/state-activities/california-offshore-wind-programmatic-environmental-impact and has given every indication that it will continue to use the PEIS mechanism to create efficiencies in its future COP reviews. It is	conditions of approval for activities proposed by lessees in the COPs submitted for the six NY Bight lease areas.. BOEM may require additional or different measures based on future, site-specific NEPA analysis or the parameters of specific COPs. BOEM may also modify the measures at the COP-specific NEPA stage to tailor them to the characteristics of the proposed project and the site(s) of proposed activities, and to ensure conformity with project-specific consultations and authorizations. BOEM has modified the PEIS language describing the Proposed Action and refined the language throughout the PEIS to make clear that this PEIS is *not imposing* any AMMM measures. It is not establishing or imposing any substantive obligations at this programmatic stage. Nor does the proposed action purport to change the standard in BOEM's regulations governing review of COPs. For those reasons, the proposed action is not a de facto rulemaking. Instead, it is identifying those AMMM measures that BOEM may impose at the COP-specific NEPA stage. Because those AMMM measures are identified and analyzed now, the expectation is that the analysis at the COP-specific NEPA stage can be more streamlined and efficient.

Comment No.	Comment	Response
	reasonable to expect that the choices BOEM makes in this PEIS process will inform subsequent programmatic reviews in other wind energy areas.	
BOEM-2024-0001-0406-0029	Finally BOEM should also consider declining to issue a ROD with the Final PEIS. Even in its draft form the PEIS does not make any "decisions" that trigger environmental effects and that remains the case if revised as suggested herein. No decision of that sort is made until BOEM makes a decision on an individual COP that has been the subject of a full-blown EIS. Any decision flowing from this PEIS is therefore premature. Moreover there is no formal requirement in NEPA the CEQ regulations or Department of the Interior (DOI) regulations that a programmatic NEPA analysis must include a ROD if no decision is being made. Eliminating the ROD would make clear to the public that this PEIS is primarily intended to facilitate early identification and analysis of important issues and impacts common to all NYB leases and not to narrow BOEM's or lessees' options at the COP stage or impose substantive requirements as with the presumptive application of the full suite of AMMM measures analyzed in the Draft PEIS.	Comment noted. A ROD could identify those AMMM measures BOEM may apply as conditions of approval for the COPs submitted for the NY Bight leases. This documentation does not constitute final agency action but may be integrated into the ROD for each individual project. Identification of the measures BOEM may apply does not narrow options at the COP stage because BOEM may require additional or different measures based on future, site-specific NEPA analysis or the parameters of specific COPs. BOEM may also modify the measures at the COP-specific NEPA stage to tailor them to the characteristics of the proposed project and the site(s) of proposed activities, and to ensure conformity with project-specific consultations and authorizations.
BOEM-2024-0001-0423-0001	A rational and timely permitting process is vital to meeting the goals of Executive Order 14008 ("Tackling the Climate Crisis at Home and Abroad" issued on January 27 2021) New Jersey's goal of 11 GW of offshore wind energy generation by 2040 (as outlined in New Jersey Executive Order No. 307 issued on September 21 2022) and New York's requirement of 9.0 GW of offshore wind energy generation by 2035 (as outlined in the Climate Leadership and Community Protection Act signed into law on July 18 2019). The permitting process for offshore wind is already extremely robust and Ocean Winds had expressed concern when the New York Bight PEIS process was announced as we feared that the PEIS had the potential to complicate and delay an already challenging process. Setting aside those concerns our Bluepoint Wind team has been working cooperatively with BOEM since it published its Notice of Intention (NOI) to prepare a PEIS on July 15 2022. The eighteen months between NOI and Draft PEIS is concerning and is impacting development of Construction and Operation Plans (COPs) for NY Bight lessees. It is disappointing that initial promises from BOEM that	Comment noted.

Comment No.	Comment	Response
	this PEIS will speed and not hinder project permitting and development do not seem to be materializing. That said Ocean Winds hopes that the Final PEIS will be issued on schedule and future PEIS efforts will proceed in a more expeditious manner. Further we note that this PEIS will set a precedent for the PEIS process in California and beyond. As such we urge BOEM to be thoughtful in its approach so that its actions in this process do not hinder development of an industry already facing a series of challenges on both coasts.	
BOEM-2024-0001-0423-0030	Purpose and Need for the Proposed Action Ocean Winds supports the [bold and italicized: intent] of the PEIS namely to reduce redundancies across COP-specific NEPA analyses and help BOEM make timely decisions on COPs for the six lease areas covered by the Draft PEIS. Rather than leading to a more efficient process for individual COP approvals the scale and scope of the proposed AMMMs represent a significant expansion beyond past precedent and ensures a longer process for reviewing individual COPs when developers inevitably consider alternatives to the AMMMs in their individual COP submittals. This in turn will lengthen and complicate what is already a challenging federal permitting process. The Draft PEIS continues a troubling trend of the federal government continuing to raise the bar for offshore wind when compared to other maritime industries many of which are known to cause meaningful negative impact to the sensitive resources that the AMMMs proposed in the Draft PEIS are intended to protect. Ocean Winds also notes that the six months-long delay in the release of the Draft PEIS has negatively impacted project timelines which hinder the purpose and need of BOEM making timely decisions on COPs for the NY Bight leases and we urge BOEM not to allow further delays to the Final PEIS. As discussed above the delay associated with this PEIS along with the overreach in the substance of the document sets a concerning precedent for future PEIS processes.	The AMMM measures considered in the PEIS include measures that have been included in previous COP approvals, as well as those proposed through the scoping process. In response to numerous comments on the Draft PEIS AMMM measures, BOEM has reviewed all AMMM measures and has made several changes to the measures as presented in Final PEIS Appendix G. In summary, BOEM has split the AMMM measures into AMMM measures that BOEM has required as conditions of approval from previous activities proposed by lessees in COPs submitted and AMMM measures that have not been applied as terms and conditions of approval for previous activities proposed by lessees in COPs. In addition, BOEM has identified RPs that could be considered at the project-specific COP NEPA review. Refer to response to comment BOEM-2024-0001-0371-0004 regarding revisions to Alternative C. Further, this PEIS is *not imposing* any AMMM measures; it is identifying those AMMM measures that BOEM may impose at the COP-specific NEPA stage. Because those AMMM measures are identified and analyzed now, the expectation is that the analysis at the COP-specific NEPA stage can be more streamlined and efficient. Regarding PEIS timelines and delays, BOEM is working as efficiently as possible to ensure an adequate NEPA document is developed that meets all the statutory and regulatory requirements.
BOEM-2024-0001-0426-0002	History is full of bad government decisions that seemed like a good idea at the time. Take the Homestead Act for example where settlers were given free acreage in Kansas Oklahoma East Texas and	BOEM analyzes offshore wind projects using the best available science and information and seeks input from the public, agencies, and Tribal Nations to inform its decisions. For the PEIS,

Comment No.	Comment	Response
	elsewhere to farm. The governments' objectives were economic development continuation of a young country's "Manifest Destiny" westward and an increase in agricultural production. Most settlers farmed land or grazed cattle but soon unanticipated consequences began to appear. Farmers plowed over prairie grasses and planted dryland wheat. As the demand for wheat grew cattle grazing decreased and more acres were plowed and planted. When the world market for wheat became oversupplied prices dropped and farmers reacted to their loss of revenue by planting more wheat to make up on volume what they were losing on price. This dry land farming led to the systematic destruction of prairie grass. With the land gradually being stripped bare environmental damage began to occur. Finally with the drought of 1930 over farmed land blew away. The heartland of the U.S. became a vast dust bowl. An article by Jonathan Coppess from the University of Illinois Urbana-Champaign on the Dust Bowl offers haunting parallels for New Jersey clean energy policy:’’ As one of the worst environmental disasters in our history the Dust Bowl was a confluence of policy human activities climatic shifts and the outer bounds of nature’s tolerance. It should counsel humility about the ability of humans to perpetually push natural resources for their benefit The dust bowl was triggered by an extreme drought -part of a natural cycle over which we had little knowledge and Jess control - but it had been built by policies and misguided actions in an unfamiliar environment" Into the Unknown An often-quoted remark from Donald Rumsfeld former Secretary of Defense during a discussion linking Iraq with weapons of mass destruction states:" Reports that say that something hasn't happened are always interesting to me because as we know there are known knowns; there are things we know we know. We also know there are known unknowns; that is to say we know there are some things we do not know. But there are also unknown unknowns-the ones we don't know we don't know. And if one looks throughout the history of our country and other free countries it is the latter category that tends to be the difficult one." Known Unknows and Unknown. Unknows	BOEM has identified information that was incomplete or unavailable for the evaluation of reasonably foreseeable impacts in Appendix E, *Analysis of Incomplete and Unavailable Information*.

Comment No.	Comment	Response
	So are there any "known unknowns" and more troubling "unknown unknowns" lurking beneath the surface of efforts to accelerate offshore wind development?	
BOEM-2024-0001-0426-0008	Here at home PSE&G and Eversource have backed off from prior investment commitments to offshore wind. Do we understand why? There are other questions as well that have barely been explored at least publicly. Regarding national security an open field of hundreds of turbines in the middle of the Atlantic is an inviting soft target for terrorists or adversarial nations. How will we defend these resources?	The purpose of the PEIS, as described in Chapter 1, *Purpose and Need*, is to analyze the effects from potential development activities in the six NY Bight lease areas and to identify and analyze AMMM measures that could reduce those effects. Questions related to financial investments and national security are outside the scope of the PEIS. As stated in PEIS Section 2.3, non-routine activities and events, such as a terrorist attacks, are impossible to predict with certainty and are not analyzed in detail. In addition, PEIS Appendix E, *Analysis of Incomplete and Unavailable Information*, Section E.1.17, states that there is uncertainty regarding national security, but that the information that is available is appropriate for this programmatic level of analysis. Subsequent project-specific environmental analysis will be required for each individual COP.
BOEM-2024-0001-0439-0003	To address these concerns, the OSW industry urges BOEM to ensure that the final PEIS does not impose new analytical burdens or substantive requirements on lessees but instead serves as an analytical tool that improves the efficiency of the environmental review of COP-specific proposals within the NY Bight through tiering. To ensure this outcome: The Purpose and Need of the Proposed Action should be an analysis of AMMMs that BOEM *may* consider as conditions of approval.	BOEM has modified the PEIS language describing the Proposed Action and refined the language throughout the PEIS to make clear that this PEIS is *not imposing* any AMMM measures—and therefore is not establishing any substantive obligations at this programmatic stage—but is identifying those AMMM measures that BOEM may impose at the COP-specific NEPA stage. Because those AMMM measures are identified and analyzed now, the expectation is that the analysis at the COP-specific NEPA stage can be more streamlined and efficient.
BOEM-2024-0001-0439-0007	BOEM should not adopt AMMMs through NEPA. NEPA requires federal agencies to assess the environmental effects of their proposed actions prior to making decisions.[Footnote 5: 42 U.S.C. 4331.] Importantly NEPA is merely a procedural statute- it authorizes the use of substantive authorities for improved environmental outcomes but imposes no substantive requirements.[Footnote 6: NEPA only requires a "reasonably complete discussion of possible mitigation measures" to allow for a fair evaluation of avoidable and unavoidable environmental consequences.[Footnote 7: See id. At 352.] The Supreme Court has	BOEM has modified the PEIS language describing the Proposed Action and refined the language throughout the PEIS to make clear that this PEIS is *not imposing* any AMMM measures. It is not establishing or imposing any substantive obligations at this programmatic stage. Instead, it is identifying those AMMM measures that BOEM may impose at the COP-specific NEPA stage. Because those AMMM measures are identified and analyzed now, the expectation is that the analysis at the COP-specific NEPA stage can be more streamlined and efficient.

Comment No.	Comment	Response
	warned that there is no requirement under NEPA "that a complete mitigation plan be actually formulated and adopted."[Footnote 8: Id.] Indeed the Court has held that it would be "inconsistent" with NEPA's procedural focus "to demand the presence of a fully developed plan that will mitigate environmental harm."[Footnote 9: Id. At 353; see also Citizens Against Burlington Inc. v. Busey 938 F.2d 190 205-06 (D.C. Cir.) (agency not required to finish mitigation studies or execute mitigation plans before project begins) cert. denied 502 U.S. 994 (1991); Communities Inc. v. Busey 956 F.2d 619 625-26 (6th Cir.) (EIS lacking complete remediation plan adequate where sufficient investigation was conducted to identify mitigation alternatives and make reasonable estimate of cost) cert. denied 506 U.S. 953 (1992).] In short NEPA requires agencies to take a "hard look" at the environmental impacts of actions being proposed under substantive statutes over which they have authority such as OCSLA. NEPA itself does not provide authority to impose requirements or limit actions.[Footnote 10: Ibid. at 351.("other statutes may impose substantive environmental obligations on federal agencies but NEPA merely prohibits uninformed rather than unwise agency action.")]	
nguBOEM-2024-0001-0439-0008	In the introduction BOEM states that it is developing this Draft PEIS "to (1) identify analyze and [italicized: adopt] programmatic AMMM measures that could be applied to the six NY Bight lease areas."[Footnote 11: Draft PEIS at ES-1.] It appears that BOEM is proposing to use NEPA to impose substantive requirements on lessees without identifying the authority for each of the AMMMs. As stated BOEM cannot use NEPA as the statutory mechanism to adopt these AMMM measures it can only rely on NEPA to analyze the impacts of adopting or not adopting said measures under other statutes. As discussed in detail below adopting AMMMs at the PEIS stage prior to COP review is contrary to BOEM’s implementing regulations under OCSLA. The final PEIS and Record of Decision (ROD) should clarify that BOEM is [italicized: considering] rather than [italicized: adopting] the proposed AMMMs. In this way the PEIS does not inappropriately impose substantive requirements on projects but instead provides an analysis of these AMMMs which can help inform and provide a more efficient path to project specific environmental reviews and approval. As discussed below however	BOEM has modified the PEIS language describing the Proposed Action and refined the language throughout the PEIS to make clear that this PEIS is *not imposing* any AMMM measures. It is not establishing or imposing any substantive obligations at this programmatic stage. Instead, it is identifying those AMMM measures that BOEM may impose at the COP-specific NEPA stage. Because those AMMM measures are identified and analyzed now, the expectation is that the analysis at the COP-specific NEPA stage can be more streamlined and efficient.

Comment No.	Comment	Response
	this efficiency is only possible if the preferred alternative selected in the ROD considers only those AMMMs that are reasonable and economically and technically feasible.	
BOEM-2024-0001-0439-0009	The Purpose and Need of the Proposed Action inappropriately shifts burden to developers. The Proposed Action proposes to "[adopt] measures *unless* future COP-specific NEPA analysis shows that implementation of measures is not warranted or effective"[Footnote 12: Draft PEIS ES-3.] Separate from the issue of adopting substantive measures discussed above the proposal to wait for site specific analysis to show that a measure is not warranted inappropriately shifts the burden to developers to prove that specific AMMMs should not be imposed at the COP approval stage. This will significantly increase the costs to developers to study analyze and disprove the appropriateness of certain measures. This is a burden found in neither NEPA nor BOEM regulations nor other reviewing statutes. The final PEIS should not require site-specific analysis to disprove the need for prematurely adopted AMMMs. Rather the PEIS should help inform the site-specific NEPA review but ultimately the analysis in the site-specific NEPA document should determine which AMMMs are reasonable and necessary for the project under review.	In an effort to create a more efficient process, the PEIS analyzes AMMM measures that have been applied previously through the COP-specific NEPA process. BOEM has modified the PEIS language describing the Proposed Action and refined the language throughout the PEIS to make clear that this PEIS is *not imposing* any AMMM measures—and therefore is not shifting the burden to developers—but is identifying those AMMM measures that BOEM may impose at the COP-specific NEPA stage. Because those AMMM measures are identified and analyzed now, the expectation is that the analysis at the COP-specific NEPA stage can be more streamlined and efficient. In addition, see response to comment BOEM-2024-0001-0423-0030 regarding BOEM's review and revisions of AMMM measures in the PEIS and identification of RPs.
BOEM-2024-0001-0439-0010	The Purpose and Need of the Proposed Action The Adoption of AMMMs is contrary to BOEM's authority under OCSLA and NEPA. BOEM states that the Proposed Action for the Draft PEIS is "the adoption of programmatic AMMM measures that BOEM would require as conditions of approval for activities proposed by lessees in COPs submitted for the NY Bight lease areas unless future COP-specific NEPA analysis shows that implementation of measures is not warranted or effective."[Footnote 13: Draft PEIS ES-3.] Stating that BOEM "would require" the AMMMs as conditions of approval is contrary to BOEM's authority under OCSLA's implementing regulations. First under BOEM's implementing regulations the agency cannot use a PEIS to "pre-approve" COP terms and conditions. Doing so prematurely imposes a substantive burden on lessees and inappropriately preempts the COP approval process. BOEM regulations outlining the COP approval process state that BOEM conducts an environmental review once the lessee has submitted a COP and that "upon completion of our technical and	The Proposed Action for the Final PEIS includes the identification of AMMM measures at the programmatic stage that could avoid, minimize, mitigate, and monitor impacts on resources in the six NY Bight lease areas. These measures may be required as conditions of approval for activities proposed by lessees in the COPs submitted for the six NY Bight lease areas. BOEM may require additional or different measures based on future, site-specific NEPA analysis or the parameters of specific COPs. BOEM may also modify the measures at the COP-specific NEPA stage to tailor them to the characteristics of the proposed project and the site(s) of proposed activities, and to ensure conformity with project-specific consultations and authorizations. BOEM has modified the PEIS language describing the Proposed Action and refined the language throughout the PEIS to make clear that this PEIS is *not imposing* any AMMM measures—and therefore is not prematurely adopting AMMM measures through the PEIS—but is identifying those AMMM measures that BOEM

Comment No.	Comment	Response
	environmental reviews and other reviews required by Federal Law BOEM may approve disapprove or approve with modifications your COP. If we approve your COP we will specify terms and conditions to be incorporated into your COP."[Footnote 14: 30 C.F.R. 585.628(f).] Importantly BOEM approves a COP including mitigation measures upon completion of the environmental review. In short as required by regulation a lessee submits a COP which includes proposed measures to reduce impacts from the proposed activities within the COP to BOEM. BOEM subsequently reviews the COP for completeness and sufficiency and conducts an environmental review on the COP. It is at this stage that BOEM determines which AMMMs should be included in the environmental review for analysis and which AMMMs should be selected for adoption as terms and conditions of plan approval. In contradiction to these regulations BOEM is proposing to rely on this PEIS to prematurely adopt AMMMs prior to COP review and approval. While BOEM can certainly rely on a PEIS to analyze the impacts of appropriate AMMMs (as discussed in more detail below) it should not use the PEIS as authority to impose a substantive burden on a lessee prior to the COP review and approval.[Footnote 15: As noted in the section below it is no defense that a lessee may theoretically rebut the adoption of an AMMM at the COP stage by demonstrating that it is not "warranted or effective." This new burden is not found in BOEM's regulations.]	may impose at the COP-specific NEPA stage. Because those AMMM measures are identified and analyzed now, the expectation is that the analysis at the COP-specific NEPA stage can be more streamlined and efficient.
BOEM-2024-0001-0439-0011	Premature adoption of AMMMs may also inadvertently overlook consultation processes such as under the Endangered Species Act (ESA) which begins with review of a fully developed site- specific action in sufficient detail to assess the effects of the action on listed species and critical habitat.[Footnote 16: 50 C.F.R. 402.14(c)(1)(i) (requiring detailed description of proposed action to initiate ESA consultation).] If the activity is allowed by an incidental take statement any reasonable and prudent measures imposed as a result of the ESA process "cannot alter the basic design location scope duration or timing of the action and may involve only minor changes."[Footnote 17: Id. 402.14(i)(2).] Similarly the Marine Mammal Protection Act ("MMPA") authorization process begins with a developer's application to conduct site-specific activities and any	BOEM has modified the PEIS language describing the Proposed Action and refined the language throughout the PEIS to make clear that this PEIS is *not imposing* any AMMM measures—and therefore is not prematurely adopting AMMM measures through the PEIS—but is identifying those AMMM measures that BOEM may impose at the COP-specific NEPA stage. Because those AMMM measures are identified and analyzed now, the expectation is that the analysis at the COP-specific NEPA stage can be more streamlined and efficient. Identification of AMMM measures through the PEIS process would supplement and inform but not supplant the identification of measures at the project-level ESA consultation. Based on comments provided on the Draft PEIS, BOEM revised AMMM measures as presented in

Comment No.	Comment	Response
	conditions imposed must be "practicable" and may not unduly interfere with the activity's implementation.[Footnote 18: 16 U.S.C. 1371(a)(5)(A)(i)(II)(aa) ("practicable" requirement for conditions in incidental take regulations provision); id. 1371(a)(5)(D)(ii)(I) ("practicable" requirement for conditions in incidental harassment authorizations); see Nat. Res. Def. Council Inc. v. Pritzker 828 F.3d 1125 1134-35 (9th Cir. 2016) (interpreting "least practicable adverse impact" requirement under 16 U.S.C. 1371(a)(5)(A)(i)(II)(aa)); id. At 1135 n.9. (eliminating 99% of oceans from sonar activity would be more protective of marine mammals "[b]ut it would not be practicable because it would so restrict military options for readiness training that it would render such training ineffective").] Other environmental review statutes including the Clean Air Act and the Clean Water Act contain similar requirements to review site- specific plans and limit agencies' conditioning authority over proposed activities.[Footnote 19: 40 C.F.R. 1502.24 (To the fullest extent possible agencies shall prepare draft environmental impact statements concurrent and integrated with environmental impact analyses and related surveys and studies required by all other Federal environmental review laws and Executive orders applicable to the proposed action including the Fish and Wildlife Coordination Act (16 U.S.C. 661 et seq.) the National Historic Preservation Act of 1966 (54 U.S.C. 300101 et seq.) and the Endangered Species Act of 1973 (16 U.S.C. 1531 et seq.).] As such any AMMMs that would potentially be required under the ESA MMPA or other environmental statutes should not be adopted prior to the completion of the consultation process. In the final PEIS, BOEM should clarify that the Proposed Action is an analysis of AMMMs that BOEM may consider as conditions of approval. As such future site-specific analysis would determine whether an AMMM considered in the draft PEIS is warranted rather than determining whether such measure is [italicized: not warranted.] Under this scenario BOEM would still rely on the PEIS to provide an environmental analysis of impacts and to tier site-specific reviews but it would not prematurely require the adoption of specific AMMMs. The final PEIS would include an analysis of all reasonable AMMMs that BOEM may require as terms and conditions of COP approval. BOEM would not be required to re-	Appendix G. Some of these measures would mitigate impacts on ESA-listed species. During project-level ESA consultation, agencies may identify additional measures to minimize effects on federally listed species.

Comment No.	Comment	Response
	analyze each AMMM included in the final PEIS when reviewing and approving a COP. As such the final PEIS would allow for consistency standardization and a more efficient environmental review process at the site-specific level.	
BOEM-2024-0001-0452-0001	Purpose of a PEIS We applaud BOEM for initiating this Programmatic Environmental Impact Statement (PEIS) specific to mitigation measures for regional OSW projects. This action appears partially responsive to longstanding fishing industry requests to better assess the cumulative impacts of the numerous OSW projects in the permitting pipeline and to conduct dedicated analyses regarding fisheries-specific mitigation measures that should be included as Terms and Conditions of any OSW project approval. [Footnote 10: As described in later sections of these comments a PEIS can only meet BOEM's obligations to avoid minimize and mitigate impacts to the environment if conducted in advance of lease issuance and if it includes all activities related to the proposed action in this case the multiple phases of OSW development. Instead the timing of this PEIS after leases have been issued results in the most meaningful opportunities to avoid impacts identified through environmental review to have already been lost.] The federal OSW leasing program needs substantially more attention devoted toward developing and incorporating fisheries and ecosystem data not less and this PEIS should not result in reduced scrutiny in the downstream approval of any OSW project. Rather we reiterate previous well known requests to BOEM to develop measurable criteria for excluding areas from development when risks to the physical and human environment exceed acceptable thresholds and apply those on regional and project-specific bases in all regions. Disappointingly the draft PEIS only evaluates the six OSW leases in the NY Bight excluding the existing leases on the east coast and anticipated addition of Central Atlantic WEAs all which contribute to cumulative effects to many of the same species oceanographic systems and fisheries. The draft PEIS also does not explain how BOEM's ongoing development of fisheries mitigation guidelines will interface with the findings of the final PEIS.	Section 1.2, Table 1-1, *History of BOEM planning and leasing activities in the NY Bight*, summarizes the history of BOEM's planning process and lease sale for the NY Bight, including the 2018 Call for Information and Nominations, the 2021 identification of the WEAs, and the Draft and Final Environmental Assessment (EA) for commercial and research leases. The table also summarizes the public notification and public comment periods that were conducted as part of the process. The analysis and development of the WEA in the NY Bight are summarized in the *New York Bight Area Identification Memorandum Pursuant to 30 CFR 585.211(b),* which is found on BOEM's website: https://www.boem.gov/sites/default/files/documents/renewable-energy/Memorandum%20for%20Area%20ID%20in%20the%20NY%20Bight.pdf. Each individual COP submitted by a developer to BOEM will be separately analyzed as required under BOEM's regulations, and that analysis will disclose the full impacts of the construction and installation, O&M, and conceptual decommissioning of the project. For each resource area, Appendix C, *Tiering Guidance*, summarizes the affected environment, impact analysis, and AMMM measures discussed in this PEIS and identifies additional analysis that BOEM anticipates may be included in the COP-specific NEPA analysis for each lease area. BOEM assesses the cumulative effects of the NY Bight projects in combination with ongoing and planned reasonably foreseeable activities, which are defined in Section 3.3.1. In addition, BOEM would have the opportunity to consider new information in each individual COP-specific NEPA document about what other activities are reasonably foreseeable at the time. Table 3.6.1-21 provides an RP, COMFIS-5, which recommends that lessees follow the Fisheries Survey Guidelines issued by BOEM with regards to

Comment No.	Comment	Response
		pre-, during- and post-construction fisheries monitoring survey plan design.
BOEM-2024-0001-0469-0002	Purpose of and Need for the Proposed Action The Draft PEIS states that the purpose of the proposed action is to: "identify issues analyze degree of potential impacts and adopt as appropriate AMMM measures This PEIS will reduce redundancies across COP-specific NEPA analyses including very similar affected environments impacts and mitigation measures and will allow for future project-specific NEPA documents to be focused on the project-specific impacts not considered in the PEIS or those impacts that warrant further consideration. The Proposed Action is needed to help BOEM make timely decisions on COPs submitted for the six NY Bight lease areas." [Footnote 5: BUREAU OF OCEAN ENERGY MGMT. NEW YORK BIGHT DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT at 1-4 1-5 (Jan. 2024).] The agency's main goal in taking this approach clearly appears to be expediting review and approvals of future OSW projects. This is concerning as there are many knowledge gaps regarding the marine life in this region and the potential effect of creating a vast array of OSW installations. [Footnote 6: E.g. BUREAU OF OCEAN ENERGY MGMT. NEW YORK BIGHT DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT appx. E (Jan. 2024); BUREAU OCEAN ENERGY MGMT. & NAT'L OCEANIC & ATMOSPHERIC ADMIN. BOEM & NOAA FISHERIES NORTH ATLANTIC RIGHT WHALE AND OFFSHORE WIND STRATEGY at 9 (Jan. 2024) (citing Dorrell RM Lloyd CJ Lincoln BJ Rippeth TP Taylor JR Caulfield CP Sharples J Polton JA Scannell BD Greaves DM et al. 2022. Anthropogenic mixing in seasonally stratified shelf seas by offshore wind farm infrastructure. Frontiers in Marine Science. 9:830927. Doi:10.3389/fmars.2022.830927 and Raghukumar K Nelson T Jacox M Chartrand C Fiechter J Chang G Cheung L Roberts J. 2023. Projected cross-shore changes in upwelling induced by offshore wind farm development along the California coast. Communications Earth & Environment. 4(4):116. Doi:10.1038/s43247-023-00780-y).]Sound science takes time; as does planning to determine and assess the impacts and take actions to avoid minimize and/or mitigate accordingly. Doing less puts marine life at grave risk.	The purpose of the PEIS, as described in Chapter 1, *Purpose and Need*, is to analyze the effects from potential development activities in the six NY Bight lease areas and to identify and analyze AMMM measures that could reduce those effects. The PEIS does not approve any projects. Each individual COP submitted by a developer to BOEM will be separately analyzed as required under NEPA and will disclose the full impacts of the construction and installation, O&M, and conceptual decommissioning of the project. For each resource area, Appendix C, *Tiering Guidance*, summarizes the affected environment, impact analysis, and AMMM measures discussed in this PEIS and identifies additional analysis that BOEM anticipates may be included in the COP-specific NEPA analysis for each lease area. During the COP-specific NEPA process, BOEM will hold a public comment period at the start of the NEPA process (scoping) and following the release of the Draft NEPA document, whereby members of the public and agencies can provide input to help inform the NEPA process, alternatives, and mitigation measures to identify and minimize environmental effects. Additionally, throughout the NEPA process BOEM works closely with Cooperating Tribal Governments and federal and state agencies to assist with assessing impacts and identifying mitigation measures.

Comment No.	Comment	Response
BOEM-2024-0001-0469-0003	The Draft PEIS assumes the maximum use scenario that projects will use the most impactful range of the project design envelope. However for some factors BOEM predicts that impacts will be "negligible to major "the entire possible range of impacts because the actual impacts will depend on the individual parameters of the project. [Footnote 7: NEW YORK BIGHT DRAFT ENVIRONMENTAL IMPACT STATEMENT supra note 5 at ES-10-13] In addition the Tiering Guidance appendix states that the impact analysis in the PEIS for categories such as marine mammals cannot be used for individual Construction and Operations Plan ("COP") environmental reviews under the National Environmental Policy Act ("NEPA"). [Footnote 8: Id. At appx. C.] Taken together this all calls into question the utility of attempting to analyze such project-dependent impacts on a programmatic scale.	The PEIS does not approve any projects. Each individual COP submitted by a developer to BOEM will be separately analyzed as required under NEPA and will disclose the full impacts of the construction and installation, O&M, and conceptual decommissioning of the project. Project-specific analyses that tier from or incorporate by reference this PEIS will evaluate whether a project would have greater, equal, fewer, or different impacts than those that were analyzed in the PEIS by considering the level of action analyzed and the particularities of the site. Refer to Appendix C, *Tiering Guidance*, for specific recommendations by resource topic regarding how the PEIS may be incorporated by reference in the future COP-specific NEPA documents; this appendix also identifies additional analysis that would likely be required as part of the COP-specific NEPA analysis once detailed and site-specific project information is available.
BOEM-2024-0001-0469-0004	In absence of a PEIS avoidance minimization and mitigation ("AMMM") measures would be analyzed in the NEPA reviews of individual projects on a case-by-case basis. BOEM proposes choosing Alternative C adopting mitigation measures on a programmatic level i.e. for all six projects. [Footnote 9: Id. At ES-3]. According to BOEM representatives this would allow the agency to simply "check a box" applying the mitigation measure once they determined the measure applied to the individual project instead of performing an individual analysis on the mitigation measure. However for many affected resources the projected impacts remain constant between Alternative B (deferring adoption of mitigation measures until the individual NEPA review) and Alternative C especially for cumulative impacts. BOEM representatives stated that they would refine the mitigation measures as OSW develops and expressed that they were especially interested in comments on the mitigation measures themselves which COA provides later in Section VI. While COA does not wish to discourage the development and adaptation of AMMM measures it is unacceptable that currently available AMMM measures do not appear to be effective based on these projections.	Each individual COP submitted by a developer to BOEM will be separately analyzed as required under NEPA and will disclose the full impacts of the construction and installation, O&M, and conceptual decommissioning of the project. Project-specific analyses that tier from or incorporate by reference this PEIS will evaluate whether a project would have greater, equal, fewer, or different impacts than those that were analyzed in the PEIS by considering the level of action analyzed and the particularities of the site. Based on public and agency comments on the Draft PEIS, BOEM has revised several AMMM measures, which are described in Appendix G, *Mitigation and Monitoring*.
BOEM-2024-0001-0469-0005	Additionally the Draft PEIS references New York and New Jersey's statutory mandate and executive orders (respectively) requiring a certain amount of wind energy generation by a target year as well as	Section 1.3, *Purpose of and Need for the Proposed Action*, describes the purpose of the Proposed Action, which supports Executive Order 14008 “Tackling the Climate Crisis at Home and

Comment No.	Comment	Response
	the federal government's Executive Order 14008 and the associated goal to generate thirty (30) gigawatts of OSW capacity by 2030. The federal goal was developed by the Departments of Interior, Energy, Commerce, and Transportation but there is no detailed documentation or analysis on how these goals were developed and what environmental technological or economic standards they meet nor any public transparency or review. All these goals are intended to boost renewable energy development but the goals do not go through the same environmental review processes as the individual projects created to meet them.	Abroad" and President Biden administration's goal of 30 GW of offshore wind capacity by 2030. Goals set by the federal government or the states are not federal actions that require NEPA review.
BOEM-2024-0001-0469-0006	In summary the purpose and need statement prioritizes speed over due process and filling scientific knowledge gaps. The programmatic approach is of limited help when so many impacts must be considered at the individual COP review stage and the AMMM measures do not appear to change the overall environmental impacts in many cases. Further the push for OSW development is based on aspirational goals.	Project-specific analyses that tier from or incorporate by reference this PEIS will evaluate whether a project would have greater, equal, fewer, or different impacts than those that were analyzed in the PEIS by considering the level of action analyzed and the particularities of the site. Refer to Appendix C, *Tiering Guidance*, for specific recommendations by resource topic regarding how the PEIS may be incorporated by reference in the future COP-specific NEPA documents; this appendix also identifies additional analysis that would likely be required as part of the COP-specific NEPA analysis once detailed and site-specific project information is available.
BOEM-2024-0001-0470-0004	The amounts of installed capacity and number of Wind Turbine Generators (WTGs) in the planned projects as described in the PEIS are inconsistent and seriously misleading:--On page ES-4 the PEIS states "Based on a conservatively estimated power ratio of 3 megawatts per square kilometer BOEM estimates that full development of leases in this area has the potential to create up to 5.6 to 7 GW of offshore wind energy."--On the same page the PEIS states an estimated 16-18 GW of offshore wind energy may be necessary to ensure New York State achieves its Climate Act mandates (New York State Climate Action Council 2022).--On page ES-7 of the PEIS BOEM states that "For the analysis of six NY Bight projects BOEM anticipates development of 1103 WTGs 22 offshore substations (OSSs) 44 offshore export cables totaling 1772 miles (2852 kilometers) and 1582 miles (2546 kilometers) of inter-array cables across the six NY Bight lease areas."---This assertion that the six NY Bight projects would build "up to 1103 WTGS" is repeated on	The estimated power ratio of 3 MW per square kilometer and an estimate of 5.6 to 7 GW for total generating capacity of the NY Bight leases presented in Section 1.3 of the PEIS are derived from the BOEM December 2021 Final Sale Notice for the NY Bight leases. BOEM has added a footnote to this statement in Section 1.3 clarifying the source of this information. The power-generating capacity from the Final Sale Notice is provided for informational purposes and is not used in the analysis of the alternatives. The analysis of the alternatives is based on the parameters of the RPDE described in Section 2.1.2 of Chapter 2. BOEM recognizes that as technology advances and as projects are designed to maximize power output, the actual generation capacity of the NY Bight lease areas could be greater. Refined estimates of the anticipated generation capacity of each project proposed in the NY Bight lease areas will be described in each COP and project-level NEPA analysis.

Comment No.	Comment	Response
	PEIS page 2-16.--On page 3.4.1-8 the PEIS says the NY Bight Projects evaluated in the PEIS would construct an estimated 9922 MW of renewable power from the installation of 713 WTGs citing Table D2-1 in Appendix D.---Table D2-1 indicates only 8822 MW will be installed by the current projects and require 615 WTGs---Table D2-1 further indicates that a further 1103 WTGs are planned but fails to disclose the resulting installed MWs. (Using a ratio analysis of the data provided in Table D2-1 if 615 WTGs will produce 8822 MW of installed capacity then 1103 WTGs would constitute another 15822 MW installed).--The Table in Appendix D appears to conflict with text elsewhere in the PEIS and indicates the total planned buildout of OSW in the NY Bight leases is 26644 MW.	The purpose and need states the PEIS supports state climate goals, but it is not intended to meet state obligations. BOEM's leasing process for offshore wind is independent of state goals and solicitations. BOEM is required to assess COPs as submitted by developers; its role is not to design projects to meet state goals. The estimate of 9,922 MW of renewable power in Section 3.4.1.1 (now 9,561 MW due to updates to ongoing and planned offshore wind projects in PEIS Appendix D) is describing ongoing and planned offshore wind in the geographic analysis area for air quality, excluding the NY Bight project. In Table D2-1, the combined number of turbines for all six NY Bight projects (1,103 WTGs) is presented, consistent with the estimates presented in the six-project RPDE in Chapter 2. To avoid speculation, the total generating capacity of the NY Bight leases is not described. The generating capacity of a turbine or a project does not directly relate to impacts; it is rather the physical dimensions of the WTGs and other parameters that relate to environmental impacts.
BOEM-2024-0001-0470-0005	[Bold: II. COMMENTS][Underline: 1. Segmentation:] [Bold: The PEIS violates 38 CFR Section 200.4 by improperly segmenting the Proposed Action from the full complement of OSW projects and installed Wind Turbine Generators (WTGs) needed to meet the dual legal requirements of service load obligations and applicable state mandates for renewable energy.] The purpose of the Proposed Actions is to build and operate OSW facilities that produce "renewable" electricity from sources approved under NY law and NJ Executive Order to meet what is now and re- mains in the future a long-established "service obligation" [Footnote 1: Federal law defines the "service obligation" as a requirement applicable to or the exercise of authority granted to an electric utility under Federal State or local law or under long-term contracts to provide electric service to end-users or to a distribution utility (16 USC Section 824q).] to provide electricity to end-use consumers. Switching the existing generation from fossil fuels and nuclear power to renewables such as offshore wind requires full assessment of the impacts of building out the full complement of OSW facilities that will be needed so a) the public is fully informed of the magnitude of the federal action	The regulations identified in the comment (38 CFR 200.4) do not apply to BOEM or the DOI. The purpose of the PEIS, as described in Chapter 1, *Purpose and Need*, is to analyze the effects from potential development activities in the six NY Bight lease areas and to identify and analyze AMMM measures that could reduce those effects. The PEIS does not approve any projects. Each individual COP submitted by a developer to BOEM will be separately analyzed as required under NEPA and will disclose the full impacts of the construction and installation, O&M, and conceptual decommissioning of the project. For each resource area, Appendix C, *Tiering Guidance*, summarizes the affected environment, impact analysis, and AMMM measures discussed in this PEIS and identifies additional analysis that BOEM anticipates may be included in the COP-specific NEPA analysis for each lease area. BOEM assesses the cumulative effects of each project in combination with ongoing and planned reasonably foreseeable activities, which are defined in Section 3.3.1. The cumulative effects analysis in the PEIS considers ongoing and planned

Comment No.	Comment	Response
	and b) complete and cumulative impacts can be assessed. This "segmenting" of OSW projects is a blatant violation of NEPA and its regulations given the stated purpose of the PEIS is to assess the "potential biological socioeconomic physical and cultural impacts that could result from development activities for six commercial wind energy leases in an area offshore New Jersey and New York known as the New York Bight (NY Bight)" (PEIS page ES-3).	offshore wind activities. This analysis will be reviewed and augmented at the COP specific stage to ensure that each project is considered in the context of reasonably foreseeable activities. In the PEIS, BOEM considers the effects of the addition of the six NY Bight projects to other ongoing and planned projects in accordance with NEPA.
BOEM-2024-0001-0470-0010	[Italics: c) The forecast growth in electricity demand by industry regulators cannot be met by the segmented OSW Projects described in the PEIS]The planned 8822/9922 MW construction under the Proposed Action is well below the 20 MW total needed for the initial compliance with NYS CLCPA and the NJ EO and woefully below what NYISO growth forecasts indicate will be needed for full NYS compliance alone. The PEIS borders on fraudulent in its failure to fully disclose and assess the full effects of building out and operating the total number of WTGs needed to "meet" renewable goals and mandates given the realities of demand growth and service obligation; the full buildout will generate compounding and cumulative damage to irreplaceable maritime assets from construction and operation of both WTGs and attendant transmission facilities that are effectively ignored. Nor does the PEIS disclose and analyze the amount of non-intermittent electric generation (nuclear hydro fossil etc) along with storage/battery facilities that will be needed to ensure reliable electric supplies during the 60% downtime experienced by OSW generation or storage facilities.	The purpose of the PEIS, as described in Chapter 1, *Purpose and Need*, is to analyze the effects from potential development activities in the six NY Bight lease areas and to identify and analyze AMMM measures that could reduce those effects. The PEIS does not approve any projects. The purpose and need further states that the PEIS supports federal goals of 30 GW and state goals, but it is not intended to meet state obligations. BOEM's leasing process for offshore wind is entirely independent of state goals and solicitations. BOEM is required to assess COPs as submitted by developers; its role is not to design projects to meet state goals. The PEIS does disclose the cumulative effects of buildout of other ongoing and planned offshore wind projects on the OCS within the geographic area of analysis for each resource. Regarding other sources of energy, the PEIS is analyzing wind development in six offshore wind lease areas, and the analysis of other sources of energy or battery storage is outside the scope of this PEIS.
BOEM-2024-0001-0470-0011	-[Italics: New York]Page 3.4.1-6 of the PEIS notes that the New York State Energy Research and Development Agency (NY- SERDA) led the development of the New York State Offshore Wind Master Plan is leading the coordination of offshore wind opportunities in New York State and is supporting the development of 9000 MW of offshore wind energy by 2035.[Table 4: NYSERDA Projected Generation and Fuel Type]NYSERDA Generation Model: Upstate 2030; Demand Load (Gigawatt Hours/ GWh): 51223; Percentage Renewable: 70%; Percentage Offshore Wind: 0%NYSERDA Generation Model: Downstate 2030; Demand Load (Gigawatt Hours/ GWh): 100455; Percentage Renewable: 70%; Percentage Offshore Wind:	The purpose of the PEIS, as described in Chapter 1, *Purpose and Need*, is to analyze the effects from potential development activities in the six NY Bight lease areas and to identify and analyze AMMM measures that could reduce those effects. The PEIS does not approve any projects. The purpose and need further states that the PEIS supports federal goals of 30 GW and state goals, but it is not intended to meet state obligations. BOEM's leasing process for offshore wind is entirely independent of state goals and solicitations. BOEM is required to assess COPs as submitted by developers; its role is not to design projects to meet state goals. Additionally, BOEM

	24%NYSERDA Generation Model: Upstate 2040; Demand Load (Gigawatt Hours/ GWh): 74905; Percentage Renewable: 75%; Percentage Offshore Wind: 0%NYSERDA Generation Model: Downstate 2040; Demand Load (Gigawatt Hours/ GWh): 132601; Percentage Renewable: 90%; Percentage Offshore Wind: 33%[Table End][Bold: Source: NYSERDA.NY.Gov]On its [Underline: "Story of Our Grid"] page NYSERDA divides the NYCA into Up- and Downstate regions to illustrate how various fuel types will be used to deliver the NYISO-measured load demand. NYSERDA calculations of future demand levels (using numbers similar but not equal to those of the NYISO) and planned renewable contributions for the NYS Grid are summarized in Table 4. [Footnote 3: The total demand included in the NYSERDA calculations for 2030 are lower and the 2040 estimates are higher than the forecasts in the NYISO Gold Book provided in Table 2. NYSERDA does not provide estimates to 2053] [Footnote 4: New York City demand is currently about 55000 GWh a little over half of the forecast 2030 Downstate demand for ~100000 GWh.] NYSERDA's Upstate/Downstate demand ratios run about one-third/two-thirds of the total load demand in the NYCA. Applying those ratios to the 2053 NYISO forecast downstate demand will approximate 155113 GWh. The "Story of Our Grid" webpage states that "Downstate load is completely met with zero emissions generation in 2040" a claim that is based on 33% of load being met with offshore wind. Applying this 33% requirement to the 2053 demand forecast means that more than [Bold: 50000 GWh] of OSW generation is necessary meet the CPCLA mandates in 2053. [Footnote 5: Calculations of GWh from OSW WTGs herein use a capacity factor of 40% a three-year average of global capacity factors for 2020 to 2022 reported in 2024 by Statista.] Sourcing the 2040 downstate demand with 33% OSW production (as planned by NYSERDA) would require WTG capacity to make [Bold: 43758 GWh.] As noted above were the projects to actually total 9922 MW from 713 WTGs (vice 8822 MW from 613 WTGs) electric generation could approach [Bold: 35000 GWh of electricity.] Assuming NY gets 50% of the output from the set (segment) of projects analyzed in the PEIS [Bold: the 2053 demand shortfall would be more than 30000 GWh.] Looked at another way meeting the 2053 downstate demand of over	can only act as authorized under OCSLA, and it has no control over how much energy/electricity is needed or what other types of energy sources are used. Each individual COP submitted by a developer to BOEM will be analyzed separately as required under NEPA and will disclose the full impacts of the construction and installation, O&M, and conceptual decommissioning of the project. For each resource area, Appendix C, *Tiering Guidance*, summarizes the affected environment, impact analysis, and AMMM measures discussed in this PEIS and identifies additional analysis that BOEM anticipates may be included in the COP-specific NEPA analysis for each lease area. BOEM assesses the cumulative effects of each project in combination with ongoing and planned reasonably foreseeable activities, which are defined in Section 3.3.1. The cumulative effects analysis in the PEIS considers ongoing and planned offshore wind activities. This analysis will be reviewed and augmented at the COP-specific stage to ensure that each project is considered in the context of reasonably foreseeable activities. In the PEIS, BOEM considers the effects of the addition of the six NY Bight projects to other ongoing and planned projects in accordance with NEPA.

Comment No.	Comment	Response
	155000 GWh with 33% OSW [Bold: (50000 GWh)] requires about [Bold: 15000 MW of installed OSW capacity.] This means NYS alone requires nearly half of all the off-shore wind in the Administration's Program to actually meet its CPCLA obligations. The PEIS completely fails to disclose the reasonably foreseeable future actions needed to secure the actual MW/WTG buildout needed to produce the 50000 GWh to meet the NYS mandate alone.[Table Start: Eastern Seaboard Homes]Eastern Seaboard States: ME; "HOMES" (in millions): 0.57Eastern Seaboard States: MA; "HOMES" (in millions): 2.71Eastern Seaboard States: RI; "HOMES" (in millions): 0.42Eastern Seaboard States: CT; "HOMES" (in millions): 1.39Eastern Seaboard States: NY; "HOMES" (in millions): 7.53Eastern Seaboard States: NJ; "HOMES" (in millions): 3.39Eastern Seaboard States: PA; "HOMES" (in millions): 5.14Eastern Seaboard States: DE; "HOMES" (in millions): 0.45Eastern Seaboard States: MD; "HOMES" (in millions): 2.29Eastern Seaboard States: VA; "HOMES" (in millions): 3.24Eastern Seaboard States: NC; "HOMES" (in millions): 4.01Eastern Seaboard States: SC; "HOMES" (in millions): 1.97Eastern Seaboard States: GA; "HOMES" (in millions): 3.88Eastern Seaboard States: FL; "HOMES" (in millions): 8.15Eastern Seaboard States: Total; "HOMES" (in millions): 45.14[Table End][Bold: Source: US Census Bureau] For purposes of grid stability and reliability as well as delivering forecast demand requirements it is important to note that the Downstate/NYC demand for 50000 GWh includes vast municipal enterprise systems such as subways wastewater treatment plants hospitals emergency services (police fire emergency medical) street and traffic lights all requiring 24/7 electricity supply in copious amounts for all residents but especially underserved and environ- mental justice populations. Describing actual turbine electricity production in euphemistic misleading comparisons about powering "X Million Homes" is highly deceptive. As Table 5 shows the Eastern Seaboard has over 45 million "homes." Breaking down the deceptive tagline about the vaunted Atlantic OSW program powering "10 Million Homes" if the planned 30 GW installed can serve 10 million homes 45 million homes will require 135 GW installed. The US Department of Energy typically cites 412 offshore WTGs as the requirement per gigawatt meaning that powering [Bold: all] the East coast homes (and [Bold:	

Comment No.	Comment	Response
	just] the homes) with the needed 135 gigawatts of wind at 412 turbines per gigawatt puts over 55000 turbines in the irreplaceable maritime system of the Atlantic a far cry for the 600-700 turbine segment analyzed in the PEIS.	
BOEM-2024-0001-0470-0012	[Italics: New Jersey]Data on load growth in New Jersey is not as clear due to its inclusion in the multi-state Pennsylvania/Jersey/Maryland ISO (PJM). The [Underline: 2024 PJM Load Forecast Report] states that the total annual energy use throughout the PJM footprint is expected to increase nearly 40% by 2039 from the current 813328 to 1021955 GWh. Of that about 30000 GWh of additional demand is identified as coming from the four NJ utility zones summarized in Table 6. [Footnote 6: The total NJ load growth was calculated by subtracting the 2024 load forecast amount from the 2039 load forecast amount for the four NJ service zones listed in Table E-1 ANNUAL NET ENERGY (GWh) AND GROWTH RATES FOR EACH PJM MID- ATLANTIC ZONE AND GEOGRAPHIC REGION 2024 – 2034 summarized on pages 71-72 of the 2024 PJM Load Forecast Report linked above.][Table 6: NJ Forecast Load Increases]NJ Utility Zone: Atlantic Electric (AE); Load increase 2024-2039 (GWh): 2556NJ Utility Zone: Jersey Central Power & Light (JCPL); Load increase 2024-2039 (GWh): 11380NJ Utility Zone: Public Service Electric & Gas (PS); Load increase 2024-2039 (GWh): 15155NJ Utility Zone: Rockland Electric (East) (RECO); Load increase 2024-2039 (GWh): 341NJ Utility Zone: Total; Load increase 2024-2039 (GWh): 29432[Table End][Source: 2024 PJM Load Forecast Report]According to the [underline: U.S. Department of Energy's Energy Information Agency (EIA)] New Jersey plants of all types produced 65061 GWh of electricity in 2022 of which 33394 GWh came from natural gas production. [Footnote 7: US EIA New Jersey Electricity Profile 2022. New Jersey currently has 26 natural gas-fired power plants.] The entire mandated 11000 MW of OSW installed capacity (only a fraction of which will come from the Proposed Action being evaluated) could only produce about 39000 GWh. This means that full buildout of the NJ EO goal (one-third of the total Atlantic OSW planned by the Biden Administration) might produce enough electricity to replace natural gas plants or increase production to meet load growth from data centers and electric vehicles [Bold: but not both.] It is hard to conceive how the	Please see response to comment BOEM-2024-0001-0470-0011.

Comment No.	Comment	Response
	purpose of the action to make the New Jersey grid emission-free is satisfied if only the disclosed segment of OSW wind construction is used. These arithmetic impossibilities become even more glaring and problematic when considering the 2023 acceleration of clean energy goals in [Underline: NJ Executive Order 315]. Previously the 2019 EMP required 100 percent clean energy by 2050; the new EO 315 deadline is 2035. Notably the NJ State Senate recently woke suddenly from a green-dream when a bill authorizing a public referendum on amending the state's Constitution to ban construction of new power plants that burn natural gas or other fossil fuels was amended to allow the construction of such plants if they are to be primarily used as emergency backup power sources. The carve-out manages the damaging grid reliability risks exposed when Superstorm Sandy knocked out power in 2012 causing nearly a billion gallons of untreated sewage to flow into area waterways because sewage plants lacked accessible backup generation. The New Jersey arithmetic again demonstrates that the realities of the service obligation and actual OSW electricity production confirm these projects are but a fractional segmented portion of the actions needed to meet the overall energy production goals not just renewable standards.	
BOEM-2024-0001-0470-0013	[Italics: c) The final EIS analysis must analyze the fully aggregated (not segmented) complement of operational generation assets and storage capacity needed to reliably satisfy the identified electricity demand (including growth) while combatting the climate crisis through deployment of clean energy technologies and infrastructure.]The PEIS must redefine the Proposed Action as including construction and operation of the full complement of WTGs and storage facilities needed to meet both the known load requirements and renewable portfolio standards simultaneously. Without properly defined and unsegmented actions any evaluation or adoption of so-called programmatic avoidance minimization mitigation and monitoring (AMMM) measures remains inaccurate insufficient misleading and violative of the spirit and letter of the National Environmental Policy Act and its attendant regulations.	Please see response to comment BOEM-2024-0001-0470-0011.
BOEM-2024-0001-0470-	[Bold: III. SUMMARY]-In spite of high populations and significant population density East Coast states almost universally achieve the	Please see response to comment BOEM-2024-0001-0470-0011.

Comment No.	Comment	Response
0020 and BOEM-2024-0001-0470-0021	lowest per capita carbon emissions in the country based on their historic underwriting of clean energy and transport systems. --Inland states with whom eastern states are competing for new manufacturing facilities and other economic development opportunities still make significant portions of their electricity from coal and natural gas. This keeps electricity prices low and attracts businesses that use electricity as operational fuel at the same time greenhouse gas emission levels remain high. --Forcing eastern states to shut down clean capacity and/or prematurely retire non-coal electricity production facilities in favor of massive expenditures for OSW facilities that are merely presumed to be "environmentally preferable" (all evidence to the contrary) further increases already high east coast electricity prices and exacerbates [Underline: competitive advantage already accruing to fossil-electric generating states.]	BOEM has authority under OCSLA to authorize renewable energy activities on the OCS and evaluates projects as proposed by developers under its regulations. Electricity rates are not within the scope of the PEIS and are part of agreements with the state and developer.
BOEM-2024-0001-0470-0022 and BOEM-2024-0001-0470-0023	For an industry as damaging dangerous and risky as OSW whether by design or function BOEM's system of programmatic EISs coupled with tiered analysis for subsequent issuance of various construction permits and approvals woefully fails to meet the most basic principles and requirements of the National Environmental Policy Act and this PEIS is no different. --Analyses separated into geographically disperse lease-areas inevitably suffer from improper segmentation fail to assess cumulative impacts and ignore the macro-socioeconomic impacts that will affect businesses and populations across large areas because these projects involve electricity as fundamental to survival in today's times as air and water.	Please see response to comment BOEM-2024-0001-0470-0011. The PEIS is a regional analysis and not an analysis on specific individual lease areas.
BOEM-2024-0001-0470-0024	BOEM cannot willfully ignore the realities and plain arithmetic of electricity demand growth when assessing the viability and effects of eliminating electric generation plants that can meet critical survival needs sanitation transportation communication safety education food security inter alia in favor of expensive unreliable and damaging WTGs that cannot do the job without multiple layers of storage backup along with additive transmission facilities. These sine qua non co-components bring compounding as well as cumulative negative effects to the areas where they must be built and operated.	Please see response to comment BOEM-2024-0001-0470-0011. Offshore wind would likely be in addition to other energy sources. Wind energy would displace fossil fuel energy to the extent that it is offered to the grid at a lower price than the bids from fossil-fueled energy sources.

Comment No.	Comment	Response
	--By 2053 downstate New York electricity demand growth is forecast to be over 155000 GWh (two-thirds of 253020 GWh); producing 33% of that load with OSW (50000 GWh) requires the output of about 15000 MW of installed OSW capacity far more than the current acknowledged projects could deliver to the NY Grid. --By 2039 New Jersey is forecast to add 29432 GWh to its demand load and also plans to replace 33394 GWh of current electricity produced by natural gas plants both with OSW. Satisfying this actual requirement for 62826 GWh of clean/renewable electricity for NJ's portion of the PJM grid with OSW would necessitate more than the planned 11 GW installed capacity. --Electricity demand in these two states alone have an estimated requirement for about 26 GW of installed OSW to meet service obligations almost 87% of the entire 30 GW Atlantic Offshore Wind Program planned by the Biden Administration. --To the extent the current Proposed Actions build less than 26000 GW installed OSW capacity in the NY Bight to meet concurrent demand growth and portfolio standards additional undisclosed energy storage facilities will also be required to reliably assure service obligation generation levels. The size location and full suite of impacts from the construction and operation of such storage facilities along with all necessary transmission and distribution infrastructure must be included in any and all environmental impact analysis to prevent improper segmentation and assure full cumulative impact analysis.	
BOEM-2024-0001-0470-0025	No amount of mitigation can be accurately assessed or planned in the absence of accurate and fully disclosed impacts and effects from building and operating the full complement of OSW WTGs and attendant storage/transmission facilities needed to meet the knowable and known amounts of electricity required to sustain the populations and assets of the affected states. The environmentally preferable option for greening the nation's electricity portfolio does not involve the green eastern seaboard states. Real decarbonization will come from discontinuing the 675000 GWh of electricity still produced with coal plants in the US few if any of which are in Atlantic Seaboard states.	Please see response to comment BOEM-2024-0001-0470-0011.

Comment No.	Comment	Response
	--No agency of federal state or local government should use public funds to subsidize or under- write premature retirement and/or displacement of existing non-coal electricity production assets until existing coal plants are first replaced by the ratepayers who benefit from them (especially those in states with the highest GHG outputs per capita).	
BOEM-2024-0001-0474-0004	Among other reasons the action is Arbitrary because the BOEM administrative process favors the private interests of offshore wind developers to the detriment of the citizen stakeholders and the general public. Among other reasons the action is Arbitrary because the energy goals established in Executive Orders and Presidential Proclamations are not within the authority of the Executive Branch and do not have the force of law as the authority belongs in the legislative branch of government. Among other reasons the action is Arbitrary because the energy goals established by Executive Orders and presidential proclamations usurp personal freedoms. Among other reasons the action is Arbitrary because fees paid by the leaseholders and other funds collected from leaseholders and offshore wind developers are illegally and improperly deposited to the United States Treasury without dedication to the specific purpose and recognition of the cost of harm and remediation to the ocean. Among other reasons the action is Arbitrary because the leasehold interests restrict and interfere with the right to travel of all citizens and all members of the public.	Please see response to comment BOEM-2024-0001-0470-0011. BOEM's responsibility under the Energy Policy Act of 2005 is to issue renewable energy leases, easements, and ROWs for activities on the OCS (see PEIS Section 1.4, *Regulatory Overview*).
BOEM-2024-0001-0528c	Beginning with offshore wind, transforming the ocean into a giant power plant. This despite the fact that the industry is in economic and technological turmoil, as evidenced by the abandonment of many projects by Ørsted and others, as well as technological challenges and failures, such as the inadequate grid to even accept the energy generated.	BOEM's responsibility under the Energy Policy Act of 2005 is to issue renewable energy leases, easements, and ROWs for activities on the OCS. The purpose of the PEIS is to identify issues and analyze potential impacts for the six NY Bight lease areas. Grid reliability is outside of BOEM's regulatory authority and the scope of the PEIS. The grid operator is responsible for managing the reliability of the grid. While offshore wind in the NY Bight would provide a new source of energy to the states of New York and New Jersey, other sources of energy would still be generated.
BOEM-2024-0001-0528c	And yet this PEIS seeks to streamline and expedite the issuance of these industrial scale offshore wind projects on these 6 lease areas which impact over nearly a half 1 million acres. To be clear, Clean Ocean action is not opposed to the idea of offshore wind, Clean	Thank you for your comment. The purpose of the Proposed Action is to describe issues, analyze degree of potential impacts, and identify, as appropriate, AMMM measures. BOEM is preparing this Final PEIS because of the close

Comment No.	Comment	Response
	Ocean Action opposes this reckless scope, scale and speed currently underway due to its lack of robust, independent science, transparency, good governance, and due diligence. Our ocean deserves better. A fair pilot project and independent cost benefit analysis, and also public transparency.	proximity of the six NY Bight lease area, their similar level of development due to the leases being awarded from the same auction, the close timing of the anticipated COP submissions, and the high, near-term demand from the states of New York and New Jersey for electricity generated by offshore wind. This PEIS will reduce redundancies across COP-specific NEPA analyses, including very similar affected environments, impacts, and mitigation measures, and it will allow for future project-specific NEPA documents to be focused on the project-specific impacts not considered in the PEIS or those impacts that warrant further consideration. BOEM will still conduct project-specific NEPA analysis of the COP for each lease area, and it will focus on providing site- and project-specific analyses that were not already addressed by the PEIS. Project-specific alternatives will be considered by BOEM and cooperating agencies at the COP NEPA stage. Further, BOEM considered but dismissed from further consideration an alternative to build a pilot project (PEIS Chapter 2, Table 2-3). Data from sites that are constructed and operating (e.g., Block Island), as well as the pilot project in Virginia, were incorporated into this PEIS and will be incorporated into the development of project-specific COPs and EISs.
BOEM-2024-0001-0528f	Despite a growing demand for energy, the scale, scope, and speed of these offshore wind projects has continued to be a concern, but with this PES, it seems, the intent is to move even faster.	Thank you for your comment. The purpose of the Proposed Action is to describe issues, analyze degree of potential impacts, and identify, as appropriate, AMMM measures. BOEM is preparing this Final PEIS because of the close proximity of the six NY Bight lease areas, their similar level of development due to the leases being awarded from the same auction, the close timing of the anticipated COP submissions, and the high, near-term demand from the states of New York and New Jersey for electricity generated by offshore wind. This PEIS will reduce redundancies across COP-specific NEPA analyses, including very similar affected environments, impacts, and mitigation measures, and it will allow for future project-specific NEPA documents to be focused on the project-specific impacts not considered in the PEIS or those impacts that warrant further

Comment No.	Comment	Response
		consideration. The expectation is that the analysis at the COP NEPA stage can be more streamlined and efficient. BOEM will still conduct project-specific NEPA analysis of the COP for each lease area, and it will focus on providing site- and project-specific analyses that were not already addressed by the PEIS. Project-specific alternatives will be considered by BOEM and cooperating agencies at the COP NEPA stage.
BOEM-2024-0001-0528w	The environmental impacts of the individual projects will vary greatly, depending on which design elements they choose. Yet the PEIS would allow them to use, depending on the resource, the same characterization of the affected environment and or qualitative impacts estimated in the PEIS for the environmental reviews of the individual projects. This will expedite the environmental review process and threaten the quality of the analysis.	Please see response to comment BOEM-2024-0001-0528f for information on the purpose of this PEIS and subsequent COP NEPA reviews.
BOEM-2024-0001-0529k	Instead, the government has set its sights primarily on fast tracking, massive ocean industrialization, transforming the ocean into a giant offshore power plant. Despite the fact that the industry is in economic and technological turmoil.	Please see response to comment BOEM-2024-0001-0528f for information on the purpose of this PEIS and subsequent COP NEPA reviews.
BOEM-2024-0001-0529o	The scale, scope and speed of these offshore wind projects has always been a concern, but with this PEIS it seems the intent is to move even faster.	Please see response to comment BOEM-2024-0001-0528f for information on the purpose of this PEIS and subsequent COP NEPA reviews.
BOEM-2024-0001-0529t	The stated purpose and need for this PEIS is to consider the combined impacts of these projects in order to streamline offshore wind development in response to President Biden's executive order calling for a certain amount of offshore wind energy to be to be developed by 2040, it's 11 gigawatts. This presupposes that offshore wind projects must be developed in this area which runs counter to the purpose of the National Environmental, Environmental Policy Act, which is to analyze the effects of projects before deciding to build them. The purpose in this section also incorrectly claims that BOEM can predict the environmental impacts of projects with wide ranges of design elements in a helpful way. Because choosing different foundations, different numbers of turbines or different types of substations, just to name a few examples, will have very different environmental impacts depending on which part of the	Please see response to comment BOEM-2024-0001-0528f for information on the purpose of this PEIS and subsequent COP NEPA reviews.

Comment No.	Comment	Response
	range a developer chooses. That is likely why the range of impacts for the different factors can be as high as negligible to major. Yet the PEIS would allow BOEM to use, depending on the factor, the same characterization of the affected environment and the same qualitative impacts estimated in the PEIS and the environmental reviews of the individual projects. This is what we mean when we say that speeding up the environmental review process comes at the expense of the quality of the analysis.	
BOEM-2024-0001-0310f	A smaller pilot trial project would be more prudent and give all of us a chance to assess its environmental safety and energy generating efficiency.	BOEM considered but dismissed from further consideration an alternative to build a pilot project (PEIS Chapter 2, Table 2-3). Data from sites that are constructed and operating (e.g., Block Island), as well as the pilot project in Virginia, were incorporated into this PEIS and will be incorporated into the development of project-specific COPs and EISs.
BOEM-2024-0001-0310i	But one of the things I think that is not included in a lot of the BOEM documents is the fact that this industry is not going to produce enough energy for the big cities. The wind turbines does not produce enough energy for the MTA in New York City, for the police, for the Homeland Security, for the hospitals. Wind blows 38 percent of the time. What are you supposed to do for the rest of the time? You have 24/7 backup with the industry that they are saying, you know, you know, reducing. They're actually increasing the oil industry and gas, because we need all this backup because this industry cannot do the job.	Thank you for your comment. BOEM expects that offshore wind development in the NY Bight lease areas would lead to reductions in fossil fuel usage in the U.S. However, the wind turbines would not be a sole source of electricity to the electrical grid; other sources of electric generation—including both renewables and fossil fuels—are connected to the electrical grid and would continue to supply electricity in the event that the wind turbines are shut down for any reason.
BOEM-2024-0001-0310l	The problem with offshore windmills is they're expensive. According to the Energy Information Administration, offshore wind is the most expensive energy resource in our repertoire based on the level cost of energy. The 2002 estimate for offshore wind absent of any government subsidies is $136 per megawatt of electricity. How are we the people of New York and New Jersey going to afford our electric bills? Thank you.	Thank you for your comment. The price of the power generated by the projects will be determined by offtake agreements, also known as power purchase agreements, negotiated between the offshore wind companies and electric distribution companies, subject to each state's offshore wind procurement laws and regulations.
BOEM-2024-0001-0310m	There's one other thing. I actually wanted the audience to know, but I want to BOEM to know too. This isn't your fault. You're given the task of working with the prospect of offshore wind. And so ahead of	Thank you for your comment. The price of the power generated by the projects will be determined by offtake agreements, also known as power purchase agreements, negotiated between the offshore wind companies and electric distribution companies,

Comment No.	Comment	Response
	that somebody decided to do offshore wind, and the cost of the project and its benefits have been shrouded in mystery and the mystery is starting to clear and the curtain is starting to get drawn back and people are starting to understand the cost figures per person, per home. When we're told and you allow a certain wind farm or a set of wind farms to be built, we're told how many homes that would serve with electricity. We're not told what it costs per home to provide that. 'Cause that cost is on our backs. It shows up in our taxes and in our electric rates eventually. We have to pay all that back to the wind builders. We have to give them their profit they're guaranteed. So I will leave it at this. You can talk to me in the back if you're interested, but what it's showing is that it costs so much money per home that this would serve that for a tiny fraction, that's the cost to build, maintain the whole lifespan and if we add to that also the losses that we know that the seashores will come to, which includes the fisheries, it includes property value losses, the loss to the shore businesses. When you add all that up divided by the number of homes that that's supposed to provide electricity for, it's such a huge number that you could easily come up with alternatives.	subject to each state's offshore wind procurement laws and regulations.
BOEM-2024-0001-0310p	I have been involved with many of the anti-wind and pro whale groups in the area, I have not found one fact that can support that there's anything good about these offshore wind turbines going in. Not one. If anybody knows of one, please educate me because I have read environmental impact studies and one of the main things that I would like to request from BOEM is to complete your mission statement. Your mission is to environmentally and economically manage our ocean, and by putting in these wind turbines and rushing them through without, you know, without the studies on how it's affecting the marine life and the ocean and the economy, is just irresponsible. You're not meeting your mission statement. So, BOEM, I would like you to meet your mission statement and be environmentally and economically prudent with our ocean. We've only got one. If we ruin it this is going to be the worst environmental	BOEM's Environmental Studies Program develops, funds, and manages rigorous scientific research specifically to establish information needed for assessing and managing environmental impacts of energy and mineral development on the human, marine, and coastal environments. For more information on this program, please visit https://www.boem.gov/environment/how-we-do-research. Further, BOEM's Office of Renewable Energy Programs depends on science to meet its responsibilities under environmental laws, regulations, and standards. As such, BOEM funds and manages scientific research to inform its decision-making processes for renewable energy projects on the OCS. For more information on Office of Renewable Energy Programs, please visit

Comment No.	Comment	Response
	disaster in our lifetime, you know, worse than the polar icecaps and the dinosaurs missing and all that stuff. We cannot get clean water back.	https://www.boem.gov/environment/environmental-studies/renewable-energy-research.

P.5.3 Air Quality and Greenhouse Gases

Table P.5-3. Responses to Comments on Air Quality and Greenhouse Gases

Comment No.	Comment	Response
BOEM-2024-0001-0436-0004	Also potential development of the leaseholds would assist with meeting several state mandates for renewable energy. New Jersey's goal of 11 GW of offshore wind energy generation by 2040 is outlined in New Jersey Executive Order No. 307 issued on September 21 2022. New York's requirement of 9.0 GW of offshore wind energy generation by 2035 is outlined in the Climate Leadership and Community Protection Act signed into law on July 18 2019. Additionally an estimated 1618 GW of offshore wind energy may be necessary to ensure New York State achieves its Climate Act mandates (New York State Climate Action Council 2022). Based on a conservatively estimated power ratio of 3 megawatts per square kilometer BOEM estimates that full development of leases in this area has the potential to create up to 5.6 to 7 GW of offshore wind energy.	BOEM agrees that development of offshore wind energy projects would help meet state mandates for renewable energy.
BOEM-2024-0001-0093-0001	I would like to be on record as in favor of the Offshore wind projects in the New York bight. As Chair of the Franklin Township Environmental Commission we are working too minimize fossil fuel use. I believe that Off Shore wind will help in fight against Global warming.	BOEM agrees that development of offshore wind energy projects (to the extent they displace fossil fuels) would help reduce GHG emissions that contribute to climate change.
BOEM-2024-0001-0171-0001	[Underline: Climate & Environment]-As we know all too well the climate crisis poses an imminent threat to coastal communities and states across the entire Northeast. We've continued to experience inland flooding sea level rise severe rain historic snowfalls devastating hurricanes and other extreme weather events and as the climate crisis worsens so will the weather.-To achieve the necessary carbon emission reductions to protect our communities from the	BOEM agrees that development of offshore wind energy projects (to the extent they displace fossil fuels) would help reduce GHG emissions that contribute to climate change.

Comment No.	Comment	Response
	climate crisis we need a major transition in our energy sector now. The only way to protect and sustain our communities and our environment is the safe and responsible transition to 100 percent clean energy and the development of clean energy sources like offshore wind.-Wind energy is clean energy. Unlike energy from sources like coal or methane gas wind energy does not require burning fossil fuels and does not release harmful climate-destabilizing pollution.-By cutting our fossil fuel reliance offshore wind will help alleviate the impacts of climate change statewide. Our communities have already faced the impacts of inland flooding severe rain and weather events. This can go on no more.	
BOEM-2024-0001-0273-0001	Off-shore wind energy is a vital source for low emission energy and the health of our planet. Please make haste to build healthy off-shore wind turbines now.	BOEM agrees that development of offshore wind energy projects (to the extent they displace fossil fuels) would help reduce air pollutant emissions and reduce GHG emissions that contribute to climate change.
IsBOEM-2024-0001-0284-0001	Offshore wind is advertised as "green" or "clean" energy. In my opinion OSW provides no positive impact on the environment and is neither green or clean. According to Boem "Overall it is anticipated that there would be no collective impact on global warming as a result of OSW projects including the Proposed Action alone....". It is my understanding that OSW turbines may actually increase ocean temperatures. I have seen photos of wind turbines with oil lubricant and Sulfur Hexafluoride (SF6) oozing out of them. This leakage can potentially pollute our oceans.	Final PEIS Section 3.4.1.4 discusses the potential impact of the project alternatives on GHG emissions that contribute to climate change. Final PEIS Section 3.4.1.4.3 and Appendix B Section B.1.4 discuss potential impacts of WTGs on ocean temperatures. Final PEIS Sections 3.4.1.3.2 and 3.4.1.4.1 discuss the potential for chemical spills. SF_6 is a colorless gas. A leak of SF_6 would be addressed by repair of the associated switchgear. Applicants would be required, through its OCS air permit, to have leak detection and repair procedures in place prior to operation of WTGs.
BOEM-2024-0001-0284-0003	Offshore wind turbines are more susceptible to extreme weather. Do we know what impact a Category 3 or 4 or a northeaster will have on the stability of these wind turbines? Perhaps that should be studied before committing to hundreds of wind turbines off our shores. I am asking for more research to be done before committing our coastal communities to this inefficient unclean and environmentally unfriendly energy option.	Final PEIS Section 2.3 discusses design features of WTGs to accommodate extreme weather including hurricanes.
BOEM-2024-0001-0313-0028	3.4.1-10 Affected Environment and Environmental Consequences. Offshore wind energy development could help reduce emissions from onshore energy sources potentially improving regional air	The assumptions and calculations underlying the projections commented on are provided in the studies referenced by the commenter.

Comment No.	Comment	Response
	quality and reducing GHGs. Millstein et al. (2018) estimated that between 2007 and 2015 wind power in the US avoided as much as 127698000 metric tons (MT) of CO2 per year 147000 MT of SO2 per year 93000 MT of NOX per year and 9000 MT of PM2.5 per year. A study by the U.S. Department of Energy (USDOE) estimated emissions for a future scenario with wind energy supplying 10 percent of total U.S. electricity demand by 2020 20 percent by 2030 and 35 percent by 2050. The study estimated cumulative emissions reductions from 2013 to 2050 of 2.6 million MT of SO2 4.7 million MT of NOX and 0.5 million MT of PM2.5 (USDOE 2015). Similarly the study scenario was estimated to reduce GHG emissions in the electric sector by 130 million MT of CO2 equivalent (CO2e) in 2020 380 million MT CO2e in 2030 and 510 million MT CO2e in 2050 (USDOE 2015). An analysis by Barthelmie and Pryor (2021) calculated that depending on global trends in GHG emissions and the amount of wind energy expansion development of wind energy could reduce predicted increases in global surface temperature by 0.51.4 degrees Fahrenheit (F) (0.30.8 degrees Celsius [C]) by 2100." Comment Projections to arrive at these statistics and the assumptions and calculations should be substantiated as it is unclear whether factors including construction emissions GHGs associated with manufacturing of the WTGs and all structures is included the emissions from decommissioning and disposal nor does it include the fact that the lifespan of these turbines is approximately 30 years; by 2050 wind turbines in place and presumably used in these calculations will have to be retired so the net impacts may be misleading. It is also a common concern how local impacts and benefits will be felt by the residents these regional and global trends should be contextualized for this project. Is there any impact to ozone which is a concern on long island in the summer months? These projections also appear to have a set of assumptions and offsets for displacing the use of fossil fuels not the net increase assuming these alternative energy methods are an additional energy source and not a substitute. 3.4.1-10 Affected Environment and Environmental Consequences. The section on accidental releases states "Ongoing and planned	Estimates of construction emissions are presented in Final PEIS Section 3.4.1.4.1. Decommissioning emissions were not quantified. As stated in Final PEIS Section 3.4.1.4.1, emissions from manufacturing are not included in the analysis. However, life cycle considerations are discussed in Section 3.4.1.4.1. As indicated in Section 3.4.1.4.1, although wind energy has higher upstream emissions than many other generation methods, its life-cycle GHG emissions are orders of magnitude lower than from other generation methods. Wind energy development (to the extent that it displaces fossil fuel energy) is expected to reduce emissions of NOx and VOC from power plants, which could lead to reduced formation of ozone (O_3) that could affect Long Island. Wind energy would displace fossil fuel energy to the extent that it is offered to the grid at a lower price than the bids from fossil-fueled energy sources. BOEM expects that wind energy would be substituted for and not add to energy from fossil-fueled energy sources. Final PEIS Sections 3.4.1.3.2 and 3.4.1.4.1 discuss the potential for air quality impacts from accidental chemical spills.

Comment No.	Comment	Response
	offshore wind activities could release air toxics or HAPs because of accidental chemical spills within the air quality geographic analysis area.	
BOEM-2024-0001-0313-0031	Section 3.4.1.5.4 Conclusions" Impacts of Alternative C. As with Alternative B development of the NY Bight projects with application of AMMM measures under Alternative C would result in a net decrease in overall emissions over the region compared to the emissions from traditional fossil-fuel power plants. Impact ratings under Alternative C are the same as expected with Alternative B; however the amount of emissions could be less with Alternative C because of the emission reductions achieved by implementation of AMMM measures."	As discussed in Section 3.4.1.5.4, impacts under Alternative C are expected to be less than under Alternative B.
BOEM-2024-0001-0313-0032	General Comments about the section on Air Quality There are concerns regarding the utilization of sulfur hexafluoride as it appears that the technology is either not available and there is no mandate that alternatives be utilized. All mitigation measures identified above are presented with the qualifier "if/as feasible" with no discussion about how this would be implemented. There should be additional discussion regarding compliance and consistency with NYSDEC documents recently released " As part of DEC's ongoing implementation of the Climate Leadership and Community Protection Act (Climate Act) on Dec. 28 2023 DEC filed draft regulations to reduce emissions of two potent greenhouse gases hydrofluorocarbons (HFCs) and sulfur hexafluoride (SF6). HFCs are extremely potent greenhouse gases (GHGs) often used in refrigeration and cooling that have hundreds to thousands of times higher global warming potential than natural refrigerants. As recommended by the Climate Action Council in the Scoping Plan DEC filed proposed amendments to 6 NYCRR Part 494 to further reduce greenhouse gas emissions from refrigerants foams and aerosol propellants. SF6 is the most potent greenhouse gas and in New York State is used in electric power transmission and distribution equipment. As also recommended by the Scoping Plan DEC also filed a new draft regulation 6 NYCRR Part 495 which includes among other requirements a program to phase down the use of SF6 in gas-insulated equipment (GIE) used by the electricity sector." (source: NYSDEC Climate Action Highlights February 2024)	The proposed regulation 6 New York Codes, Rules and Regulations (NYCRR) Part 495, Sulfur Hexafluoride Standards and Reporting, would phase out the use of SF_6 in gas-insulated equipment beginning in 2026. BOEM is recommending RP AQ-1, which would encourage lessees to use a substitute insulator gas rather than SF_6 in the switchgear and transmission systems, if feasible. Final PEIS Section 3.4.1.5.1 discusses mitigation measures. The Final PEIS does not quantify emissions from construction vehicle traffic. However, vehicle traffic would contribute only a small proportion of total project emissions. As stated in Final PEIS Section 3.4.1.4.1, emissions from manufacturing are not included in the analysis. However, lifecycle considerations are discussed in Section 3.4.1.4.1. As indicated in Section 3.4.1.4.1, although wind energy has higher upstream emissions than many other generation methods, its lifecycle GHG emissions are orders of magnitude lower than from other generation methods. The Final PEIS does not quantify emissions from stationary sources, vehicles, production of energy used on the project site or by vehicles, and waste disposal. However, these sources are expected to contribute only a small proportion of total project emissions.

Comment No.	Comment	Response
	It does not appear that the cumulative air quality impacts from construction vehicle traffic of personnel to job sites is included in the impact analysis nor is the air quality impacts of manufacturing and mining of raw materials to produce the wind turbines the associated infrastructure and other materials integral to the proposed action. It stands to reason that this is part of the overall emissions calculation that would not be emitted if not for the creation of this proposed action and as such should be part of the calculation and net impact analysis. It should be noted even the NYSDEC Policy document recommends analysis of direct and indirect emissions when evaluating the impacts of greenhouses gasses "When GHG emissions are considered in an EIS total annual emissions should be presented as short tons of carbon dioxide or for other types of GHGs as both short tons and as equivalent to short tons of CO2 using the most up-to-date global warming potential factors as determined by the Intergovernmental Panel on Climate Change (IPCC) and published in the most recent Assessment Report on Climate Change. In cases when GHGs are analyzed in an EIS both direct and indirect GHG emissions should be assessed. Each of these categories includes both stationary and mobile sources. Direct GHG emissions will include both stack and fugitive emissions from combustion processes or industrial processes conducted on-site and from fleet vehicles owned (or leased) and operated by the project proponent and associated with the project. Indirect GHG emissions will include emissions generated by energy plants (off-site) supplying energy used on the site of the proposed project during its operation and from vehicle trips to or from the project site during its operation where vehicles are not owned or operated by the project proponent (i.e. freight deliveries employee commuting customer visits). Another source of indirect emissions is the generation transportation treatment and disposal of wastes generated at the site. Waste generation is typically reported in an EIS and should also be evaluated for its contributions to GHG emissions and included in the quantification of total annual emissions." (source: NYSDEC Policy "Assessing Energy Use and Greenhouse Gas Emissions in	

Comment No.	Comment	Response
	Environmental Impact Statements" Issuing Authority Office of Air Energy and Climate)	
BOEM-2024-0001-0313-0033	Affected Environment and Environmental Consequences 3.4.1-4 The PEIS states "The CAA prohibits federal agencies from approving any activity that does not conform to a State Implementation Plan. This prohibition applies only with respect to nonattainment or maintenance areas. Conformity to a State Implementation Plan means conformity to a State Implementation Plan's purpose of reducing the severity and number of violations of the NAAQS to achieve attainment of such standards. The activities for which BOEM has authority are outside of any nonattainment or maintenance area and therefore not subject to the requirement to show conformity. However agencies issuing future approvals related to offshore wind projects in the NY Bight are responsible for evaluating the applicability of the CAA General Conformity requirements to their actions." Comment - There is also a concern with the way the impact analysis is compartmentalized for one representative NY Bight Project in terms of air quality the impacts to air quality could be concentrated based on the timing of certain construction activities and could have a synergistic adverse impact to considerations like ozone formation for which there are significant considerations. This also does not account nor analysis for the cumulative impacts of the surrounding planned projects which in terms of air quality could certainly have a localized impact especially during construction and decommissioning of the various projects. It is also concerning that the above paragraph appears to obviate responsibility for air quality concerns based on distance to the shoreline despite the project components and connections that are connected to this larger plan of scale and potentially shared infrastructure with surrounding projects.	Final PEIS Sections 3.4.1.4.3 and 3.4.1.5.3 discuss cumulative impacts. In the absence of COP-specific project proposals, available data are insufficient to determine specific locations of cumulative impacts. BOEM's determination that its actions are not subject to the requirement to show conformity is not related to distance from shore but follows from the language of the General Conformity Rule.
BOEM-2024-0001-0331-0017	BOEM excluded the amount of fossil fuels and chemicals that will be used by the New York Bight projects but we assume based on the number of turbines it will be 55% more than the following numbers for the other NY/NJ projects: coolants 2 million gallons; oils 4 million gallons; diesel fuel 1 million gallons. Including all NY/NJ projects there will be 36000 acres of seabed disturbance for export cables	Final PEIS Section 3.4.1.3.2 discusses potential quantities of fuels and chemicals. In the absence of COP-specific project proposals, any quantitative estimates for fuels, chemicals, and other project characteristics are uncertain.

Comment No.	Comment	Response
	and 33000 acres of disturbance for interarray cables. There will be 827 acres of scour protection and 737 acres of cable hard protection excluding NY Bight since no numbers are provided but we assume the Bight will add 2424 more acres of scour and hard protection in the ocean. There will be over 11 tons of carbon dioxide added to the NJ/NY atmosphere during the construction of the projects.	
BOEM-2024-0001-0331-0036	The PEIS Fails to Address GHG Emissions and SF6 and Mitigation is Inconsistent with the Project's Goals The section AQ Table G-1 of mitigation measures for reducing GHG is nothing more than window dressing. The mitigation measure AQ-1 acknowledges that the offshore wind developers will continue to use SF6 and must evaluate the "feasibility of using non SF6". Lessees are "encouraged" to replace diesel fuel with alternatives and "encouraged" to replace combustion engines with zero -emissions technologies. These mitigation measures have no teeth in actually requiring developers to take any real measures to reduce their carbon footprint. According to the EPA SF6 is the most potent greenhouse gas known to date. It has an atmospheric lifetime of 3200 years and a "relatively small amount of SF6 can have a significant impact on global climate change." Previous EIS documents have significantly minimized the amount of SF6 that will be used in the offshore wind projects. In previous documents BOEM recognizes SF6 as "the most potent greenhouse gas known." Offshore wind developers and BOEM have incomplete of not only the number of offshore substations (OSS) but it has failed to mention the use of SF6 in each of the turbines. The PEIS does not disclose the potential full amount of SF6 that may be used in the projects. The PEIS fails to mention the use of SF6 in each wind turbine generator. Considering that BOEM has admitted in previous EIS documents that there is a yearly loss of SF6 from switchgear disclosing the full amounts that may be used in these projects is crucial. The PEIS does not disclose expected leakage of SF6 in its table listing project emissions. There is no mention of a potential accidental release of SF6 such as happened at the Seagreen offshore wind area in the North Sea in June of 2022 forcing the crew to evacuate their rig. The EPA states that leaks of SF6 can occur during "installation maintenance and servicing and decommissioning" of equipment that contains the gas. The PEIS does	Final PEIS Section 3.4.1.4.1 discusses SF_6 and provides the estimated quantity of SF_6 for one representative project. BOEM encourages lessees to analyze and consider implementing AQ-1 as a RP, as outlined in Table G-2. Measure AQ-1 addresses SF_6 management. Compliance efforts will also be addressed through the USEPA's OCS air permitting process. The lessee will be required to follow all applicable federal, state, and local laws regarding the use and management of SF_6. The environmental decision document for each COP-specific NEPA review will describe the specific terms and conditions of the AMMM measures for which compliance is required.

Comment No.	Comment	Response
	not fulfill its purpose outlining the environmental impact concerning SF6 use since that does not begin and end with the Atlantic Shores projects. As BOEM has previously stated (1) "the impact of GHG emissions does not depend upon the source location." Since numerous wind energy projects in the NJ/NY area will be using SF6 in OSSs and wind turbines the singular approach in evaluating the environmental impact of just NY Bight makes the PEIS flawed and too limited to fulfill its purpose.	
BOEM-2024-0001-0334-0013	Is climate change really happening for the reasons we think? If not need to rush into offshore wind Is moot. Are CO2 reductions by the US meaningful against grosser CO2 emissions elsewhere? Is offshore wind even effective in a green sense?- If green/renewable energy has merit and we want it Is offshore wind even the best choice?	Issues around selection of offshore wind energy for development are public policy questions that are beyond the scope of an EIS and outside of BOEM's authority; therefore, they should be addressed at the federal and state level.
BOEM-2024-0001-0334-0015	Great questions. To the last question I submit it is NOT the best "renewable" choice. It is now becoming clear that the investment required to serve a given number of homes with offshore wind is tremendously overpriced. It can be demonstrated that for small fraction of the offshore wind investment those homes would be better served by their own solar energy system panels and a storage battery. Easily 1/3 the cost or less. These would be supplied by a program to install them by a fully funded state program. If the public comes to understand this they will reject having offshore wind put on their backs and will insist that NJ comes up with a plan that puts the same investment into installing a solar system on every suitable home instead. Period. Case closed. BOEM will be out of the wind business. And maybe out of the ocean leasing business too. Representatives Jeff Van Drew and Chris Smith have been apprised of this. SEE ORIGINAL COMMENT FOR IMAGE: If a Far More Cost Effective Alternative to Off-Shore Wind (OSW) exists NOW that;	Issues around selection of offshore wind energy for development, and its costs, are public policy questions that are beyond the scope of an EIS and outside of BOEM's authority; therefore, they should be addressed at the federal and state level.
BOEM-2024-0001-0345-0001	CCE strongly supports advancing well-sited environmentally responsible renewable energy projects and phasing out the use of antiquated fossil fuels on Long Island and throughout New York State. Thank you for the opportunity to comment on this important renewable energy guidance document. CCE is supportive of this process to streamline the permitting for the six NY Bight projects to ensure that they move forward in both an environmentally responsible and timely manner.	BOEM agrees that development of offshore wind energy projects (to the extent they displace fossil fuels) would bring about climate and environmental benefits.

Comment No.	Comment	Response
BOEM-2024-0001-0345-0002	New York State is a leader in the fight against climate change and a national champion for offshore wind having passed the strongest climate change law in the nation in 2019. The state is working towards achieving mandates of 70% renewable energy by 2030 carbon free electricity by 2040 and a net zero carbon economy by 2050. We cannot achieve these goals particularly in downstate New York without also achieving or exceeding our target of 9000 MW of offshore wind. The Biden administration has announced plans to tackle climate change and put forth a goal of reaching a net-zero carbon economy by 2050. We must work aggressively to support responsibly-sited renewable energy projects like Excelsior Wind Attentive Energy and Community Offshore Wind to meet these critical state and federal goals.	BOEM agrees that development of offshore wind energy projects would help meet state mandates for renewable energy.
BOEM-2024-0001-0345-0004	Climate Change and Wildlife CCE thanks BOEM for its thorough assessment of impacts to fish birds and marine species which should be mitigated to the greatest extent possible. As we know the most immediate impact to these species is climate change. The real danger facing our beaches fisheries and coastal communities is not a wind farm it is rising sea levels ocean acidification warming waters and extreme weather events. These events continue to be a significant threat to downstate New York and to adversely impact our estuaries and our coastal communities. The environmental benefits of advancing offshore wind farms to reduce climate impacts needs to be weighed against any potential impacts associated with construction of offshore wind farms. [Bold Italics: CCE believes that offshore wind is one significant part of the antidote in fighting climate change.] Long Island and New York City are already experiencing negative ecological and economic impacts of climate change. We need to be at the forefront of the transition to renewable energy and offshore wind development in the US.	BOEM agrees that development of offshore wind energy projects would (to the extent they displace fossil fuels) help reduce GHG emissions that contribute to climate change. Potential impacts of construction activities on each resource area are discussed in the respective sections of the Final PEIS.
BOEM-2024-0001-0345-0005	The National Ocean and Atmospheric Administration (NOAA) predicts under a worst- case scenario a 6 ft sea level rise will cause most of the barrier islands and Long Island homes south of Merrick Road (route 27A) to be flooded or under water with more than 150 municipalities impacted. Homes and infrastructure are already being raised including roads in Freeport Lindenhurst Smithtown and Southampton as well as the Shelter Island ferry while residents in the	As discussed in the Final PEIS, development of offshore wind energy projects (to the extent they displace fossil fuels) would help reduce GHG emissions that contribute to climate change including the impacts noted by the commenter.

Comment No.	Comment	Response
	most vulnerable communities are facing managed retreat and home buyouts. These communities are in an exceptionally vulnerable position to extreme weather events. Superstorm Sandy destroyed or damaged 95000 buildings on Long Island and caused $19 billion in damages to New York City. We are experiencing the increasing occurrence of "hundred-year storms" and increased precipitation during rain and snow events and the problem will only get worse. NOAA predicts that in a worst-case sea level rise scenario the average high tide in NYC will be 2 feet higher than the storm surge during Superstorm Sandy. High costs of repairing damage from extreme weather events like Superstorm Sandy and Hurricane Irene coupled with the need to raise homes and pay increased flood insurance premiums are impacting struggling homeowners in coastal communities. In addition to major storms south shore communities are already experiencing "sunny day flooding" due to higher tides. This means on sunny day there is still street flooding and property damage. Extreme weather events are not our only challenge. Warmer winters coupled with longer hotter summers are creating more hospitable conditions for invasive species deer ticks and mosquitos that carry diseases and reduced agricultural yields. Increased summer temperatures and more severe heat waves also degrade air quality increase health care costs and put lives at risk. In the U.S. air pollution from burning fossil fuels leads to annual losses of $600 billion and the loss of 230000 lives. In NYC approximately 130 residents die each year just from heat waves with the number expected to rise over the coming century. Both Suffolk County and NYC regularly receive an "F" for air quality by the American Lung Association and experience disproportionately high rates of asthma heart disease and other chronic health issues in disadvantaged communities. Transitioning to offshore wind will significantly curb air pollution and provide quantifiable health benefits for New Yorkers. Air pollution reductions from the first 2400 MW of offshore wind in New York would be valued at roughly $1 billion and would avoid an estimated 100 premature deaths each year.	

Comment No.	Comment	Response
	Ocean acidity has increased 30% since the industrial revolution and there are documented negative impacts to sea scallops squid clams oysters and other species in the northeast. The catastrophic lobster die-off in the Long Island Sound is mainly attributed to warmer waters. The native lobster species and its historic maritime industry declined 90%. The industry used to account for tens of millions of dollars annually. The loss of this fishery is not only an economic loss but also means this historic maritime culture is slipping away.	
BOEM-2024-0001-0345-0006	It is critical that BOEM measure all potential impacts of offshore wind projects in comparison to the adverse impacts of fossil fuels and include climate change impacts that would result from a "No Action" alternative.[Bold Underline: The choice is not between wind and nothing; it is between wind and fossil fuels.] For instance if we generate 3000 MW of power with offshore wind BOEM needs to compare any environmental impacts associated with this generation of power to environmental impacts of 3000 MW generated by fossil fuels. What are the emissions associated with each over the expected life of the wind farm? Findings under the "No Action" alternative are substantial and serve to illustrate that while all energy projects have some negative impacts the impacts of doing nothing and continuing our reliance on fossil fuels are significant and unacceptable. Potential adverse impacts under the "No Action" alternative for several categories including the fishing industry finfish invertebrates and essential fish habitat marine mammals and sea turtles coastal habitats and wetlands due to climate change. Including but limited to the impacts of warming ocean waters shifts in food sources impacts associated with increased acidification in both ocean waters and estuarine systems. As well as the continued impacts of oil and gas leaks and spills into the marine environment when conducting fossil fuel exploration activities and general operation of extraction of fossil fuels. Potential adverse impacts on air quality due to increased greenhouse gas emissions and air pollutants on water quality and on environmental justice communities.	Final PEIS Section 3.4.1.4 presents estimated emissions from NY Bight wind projects and the emissions from fossil-fuel power generation that would be avoided (to the extent that the wind projects displace fossil fuels). For each resource area, the respective sections of the Final PEIS analyze the potential adverse impacts with the No Action Alternative.

Comment No.	Comment	Response
BOEM-2024-0001-0345-0007	Ultimately the offshore wind cooling systems would cause substantially less impact than the "No Action" alternative and would also offset the fossil fuel pollution entering our communities and local waterways leading to improved water quality and air quality in local Long Island communities. [Bold Italics: CCE asks that BOEM include an analysis of the benefits of decreased fossil fuel pollution as offshore wind allows us to retire these plants.]	Final PEIS Section 3.4.1.4 discusses the emissions from fossil-fuel power generation that would be avoided (to the extent that wind projects displace fossil fuels) with NY Bight offshore wind development.
BOEM-2024-0001-0345-0008	CCE also thanks BOEM for evaluating not only the potential adverse environmental impacts but also the potential benefits including air quality improvements in disadvantaged communities due to decreased fossil fuel pollution	Thank you for your comment.
BOEM-2024-0001-0345-0013	Opponents of offshore wind testified during the virtual public hearings that offshore wind projects will have no overall impact on climate change. Transitioning from old antiquated fossil fuels plant to wind power will absolutely have positive impacts locally. It would be helpful for BOEM to provide specific data comparing the greenhouse gas emissions from local fossil fuel plants on our air and water quality vs the emissions we will see over the lifespan of these offshore wind projects. Offshore wind farms are NOT meant to be additive to the power grid but rather the specific goal is to replace and shutter existing fossil fuel power stations.	Final PEIS Section 3.4.1.4 discusses the emissions with NY Bight offshore wind development as well as the avoided emissions from fossil-fuel power generation (to the extent that wind projects displace fossil fuels).
BOEM-2024-0001-0355-0002	Wind Turbines…Not green. Not the answer to reducing carbon footprint - they actually utilize a lot of fossil fuels and create a lot of greenhouse gases in the manufacturing transportation installation and maintenance.	As stated in Final PEIS Section 3.4.1.4.1, emissions from mining and manufacturing are not included in the analysis. However, lifecycle considerations are discussed in Section 3.4.1.4.1. As indicated in Section 3.4.1.4.1, although wind energy has higher upstream emissions than many other generation methods, its lifecycle GHG emissions are orders of magnitude lower than from other generation methods.
BOEM-2024-0001-0362-0032	Strengthening the nation's supply chains can result in environmental benefits as well. Energy intensive manufacturers in the United States are relatively clean compared to competitors. As one example "[s]teel exporters to the U.S. emit 50-100+% more CO2 emissions per ton than U.S. producers on average." [Footnote xvii: CUR Consulting Leveraging a Carbon Advantage: Impacts of a Border Carbon Adjustment and Carbon Fee on the US Steel Industry 2021. https://clcouncil.org/reports/leveraging-a-carbon-advantage.pdf?v1]	BOEM agrees that strengthening domestic supply chains and increasing domestic content can lead to environmental benefits.

Comment No.	Comment	Response
	Use of domestic content can also reduce shipping distance and thus emissions resulting from long-distance maritime transportation. The International Maritime Organization estimates that maritime shipping generated 1 billion tons of greenhouse gases per year from 2007-2012. Another study estimates that maritime shipping emissions are forecasted to rise between 35% and 210% by 2050. [Footnote xviii: The Journal of Labor and Society Right-to-work Laws and Fatalities in Construction June 2011. https://deepblue.lib.umich.edu/bitstream/handle/2027.42/98283/j.1743-4580.2011.00334.x.pdf?sequence=1]	
BOEM-2024-0001-0383-0022	Wind Wake Effect: BOEM's PEIS section regarding wind wake effect seems to deliberately exclude newer information that demonstrate even New York Bight specific impacts. For example Appendix B of the PEIS briefly discusses "wake effect" and quotes a Christiansen paper from 2005. Yet it does not incorporate a paper from the same author Christiansen from 2022 which discusses wind wake effect in more detail and even concludes that "surface temperature primarily increases in the vicinity of offshore wind farms" due to the wind farm wake effect and that the resulting "large-scale surface heating of up to 0.1 degrees C imitates the effects of climate change." [Footnote 56: See Christiansen et al "Emergence of Large-Scale Hydrodynamic Structures Due to Atmospheric Offshore Wind Farm Wakes" Frontiers in Marine Science 2022 at https://www.frontiersin.org/articles/10.3389/fmars.2022.818501/full p. 12.] It also excludes a 2022 report by ArcVera Renewables entitled "Estimating Long-Range External Wake Losses in Energy Yield and Operational Performance Assessments Using the WRF Wind Farm Parameterization" which specifically analyzed the potential for large project to project wake impacts for the New York Bight lease areas resulting in simulations depicting wind speed deficits of 7% up to 100 km away from the wind facility with a 28.9% loss of wind at the wind farm itself. [Footnote 57: Stoelinga et. al. "Estimating Long-Range External Wake Losses in Energy Yield and Operational Performance Assessments Using the WRF Wind Farm Parameterization" ArcVera Renewables 2022.] We request that these be included.	Discussion of the two references requested by the commenter has been added to Appendix B.

Comment No.	Comment	Response
BOEM-2024-0001-0383-0023	Additionally the newest 2024 study by Pryor and Barthelmie "Power Production Inter- and Intra-Array Wake Losses from the U.S. East Coast Offshore Wind Energy Lease Areas" found the New York Bight leases to be some of the most impacted leases in all US waters by the wind wake effect: "The climatological mean wake loss for NYBIG is 31.0%...The cumulative wake extent increases with the total number of wind turbines installed and this is systematically the highest for the NYBIG layout the 'second generation' lease areas in NYBIG are significantly impacted by their wind farm wakes in multiple flow regimes (Figures 4 and 5). Further for the NYBIG layout when the Fitch WFP is used there is no area south of Long Island that is not covered by the combined shadow of the existing LA." [Footnote 58: Pryor and Barthelmie "Power Production Inter- and Intra-ArrayWake Losses from the U.S. East Coast Offshore Wind Energy Lease Areas" Energies 2024 available at Power Production Inter- and Intra-Array Wake Losses from the U.S. East Coast Offshore Wind Energy Lease Areas (Journal Article) | OSTI.GOV p. 14 16-17.] The study concludes that "The offshore wind energy deployments being developed along the U.S. east coast far exceed those that characterize existing offshore wind deployments and so are expected to experience greater wake losses." [Footnote 59: Ibid p. 25.]This information contains tremendous implications for both environmental impacts and affects to the Mid Atlantic Cold Pool as well as the cost/benefit analysis expected to result from construction of the New York Bight leases. It is clear that the production and the claimed power output will not reach the nameplate capacity of the project and that the purported project "benefits" will be significantly curtailed by wind wake effects for these leases in particular. BOEM should also include in its analysis how the wind wakes from the NY Bight projects will be expected to curtail production of previously approved projects.	Because wind wake effects influence the amount of energy produced by a wind farm, BOEM expects that applicants will take wind wake effects into account in planning wind farm developments. BOEM will consider including changes in energy production due to wind wake effects in future estimates of avoided emissions to the extent data are available.
BOEM-2024-0001-0394-0001	Claimed tonnage of carbon dioxide emissions spared annually is not supported by the disclosures in the DEIS which omits carbon emissions that will necessarily occur as the result of the project resulting from mining and materials production for refined steel and concrete materials. We've calculated for steel production and have yet to calculate for concrete. The infrastructure is massive; It is not	As stated in Final PEIS Section 3.4.1.4.1, emissions from mining and manufacturing are not included in the analysis. However, lifecycle considerations are discussed in Section 3.4.1.4.1. As indicated in Section 3.4.1.4.1, although wind energy has higher upstream emissions than many other generation methods, its

Comment No.	Comment	Response
	appropriate to omit this when calculating emissions as other types of power plants do not require anywhere near the amount of materials to build. The cumulative effect of Mayflower Wind project combined with other wind power plants is an enormous increase the metal and concrete surface area in the marine environment (a.k.a marine industrialization or marine urbanization) is expected to cause a population explosion of sessile (attached) filter-feeding heterotrophs which will reduce autotrophic plankton (photosynthetic plankton) density over the Outer Continental Shelf and via this mechanism its capacity to serve as a carbon buffer (which is important for pulling carbon dioxide out of the atmosphere) may be impaired.	lifecycle GHG emissions are orders of magnitude lower than from other generation methods. As living organisms, phytoplankton themselves respire and therefore produce CO_2. The consumption of phytoplankton by filter-feeding organisms (such as those that may colonize WTG foundations and scour protection) plays an important role in the carbon cycle; the loss of phytoplankton to consumers results in the creation of fecal pellets and pseudofeces that fall to the bottom and can eventually become buried, serving as a major CO_2 sink. BOEM is not aware of any scientific studies documenting a decrease in phytoplankton abundance in the presence of other large offshore structures such as oil and gas rigs in locations such as the Gulf of Mexico, which currently has over 4,000 rigs, nor is BOEM aware of any studies documenting increased CO_2 in the presence of these offshore structures.
BOEM-2024-0001-0421-0001	It is essential that we continue to develop sustainable sources of energy that do not add pollutants to the air we breathe or contribute to global warming. I support the Biden administration's efforts to build offshore wind power by 2030 and urge the Bureau of Ocean Energy Management to conduct a timely and thorough environmental review for the six offshore wind projects proposed for the New York Bight.	BOEM agrees that development of offshore wind energy projects (to the extent that they displace fossil fuels) would bring about climate and environmental benefits. The Final PEIS thoroughly evaluates the potential environmental impacts of six projects to the extent possible at the programmatic level. BOEM expects that further, more specific analysis will be performed as additional information becomes available when applicants file COPs for projects.
BOEM-2024-0001-0423-0011	Other AMMM Measures of Concern Air Quality The air quality AMMMs are disproportionate to BOEM's own impact analysis are an overreach of jurisdiction and are duplicative of EPA air permitting. In its Table 2-4 (summary and comparison of impacts among alternatives) BOEM states that the "no action" alternative "would result in overall moderate impacts" for the cumulative impact scenario. Alternative B would also result in moderate impacts however in Alternative B BOEM notes that:[italicized: "six NY Bight projects and other offshore wind projects would have moderate beneficial impacts on air quality in the region surrounding six NY Bight projects to the extent that energy produced by offshore wind projects would displace energy produced by fossil-fuel power plants."][Footnote 2: Draft PEIS Table 2-4 page 2-24.]	AMMM measures fall within BOEM's authority under 30 CFR 585.102(b) to approve COPs with conditions. AMMM measures address BOEM's concerns, which may not be precisely the same as EPA's, or they may address impacts that are outside of EPA's OCS permitting jurisdiction. Comment on Table 2-4 acknowledged. Regarding Alternative C, the fact that beneficial impacts would occur during O&M does not reduce the need and desirability of reducing impacts during both construction and O&M. AMMM measures fall within BOEM's authority to approve COPs with conditions. AMMM measures address BOEM's concerns, which may not be precisely the same as EPA's, or they may address impacts that are outside of EPA's OCS permitting jurisdiction.

Comment No.	Comment	Response
	Alternative C does not alter the moderate negative impacts that would occur even under no action yet BOEM seemingly ignores the beneficial impacts of offshore wind and would impose specified AMMM Measures that have never been required in other COP approvals.AQ-1 through AQ-5 require the Lessee to evaluate the feasibility of each listed measure and each AMMM concludes with the statement that [italicized: "Any instances where the Lessee believes there is technical (and/or economic) infeasibility must be supported by a technical feasibility analysis as appropriate for review and concurrence by BOEM and BSEE [the Bureau of Safety and Environmental Enforcement]."] The Clean Air Act and not the PEIS is the appropriate mechanism for regulating the emissions associated with the NY Bight projects. These AMMMs duplicate the EPA process and requirements. Moreover as noted in the Draft PEIS these projects will have beneficial impact on air quality. Creating additional regulatory requirements and costs given the existence of EPA process would undermine and slow achievement of that net benefit and create cost that would ultimately flow back to electricity customers.	
BOEM-2024-0001-0423-0019	[bold: AQ-6 and AQ-7] relate to onshore measures that are regulated by the states and local governments (and again are outside of BOEM's jurisdiction) and therefore should not be included in the PEIS. Lastly and as a general matter on air quality Ocean Winds notes that there is already a shortage of Jones Act compliant marine construction and support vessels in the U.S. The offshore wind industry competes with oil and gas developers and other maritime users for this same small fleet of vessels (e.g. platform supply vessels service operations vessels crew transfer vessels offshore tugs barges anchor handling vessels jack-up vessels etc.). As it is in the hands of vessel owners and port operators whether to adopt the proposed measures put forward in the air quality AMMMs they may find it less expensive and more profitable to support work outside the offshore wind industry where these restrictions are not in place. This would further limit the availability of usable vessels and ports to our industry putting further pressure on project viability.	AQ-6 and AQ-7 are included in the Final PEIS as RPs. BOEM encourages the lessees to consider the feasibility of these mitigation measures in their individual projects. AMMM measures fall within BOEM’s authority under 30 CFR 585.102(b) to approve COPs with conditions. A lessee has the option to demonstrate that an AMMM measure is infeasible. BOEM expects that excessive costs and unavailability of vessels could be factors in a demonstration that an AMMM measure is infeasible on a case-by-case basis.

Comment No.	Comment	Response
BOEM-2024-0001-0426-0001	H.L. Mencken once said "there is always an easy solution to every problem - neat plausible and wrong." He could be speaking to New Jersey's current quest to achieve the very worthwhile objective of 100% clean energy by 2035. A major focus in this plan is significant investment and development of an offshore wind industry off the New Jersey coast. Clean energy is certainly something we should strive for but in many ways our current blind crusade devil be damned towards the implementation of offshore wind does present troubling questions which may not have been sufficiently addressed yet.	BOEM agrees that development of offshore wind energy projects would help meet state mandates for renewable energy.
BOEM-2024-0001-0426-0010	From an ecological standpoint too many differing opinions still exist on the effect on birds fish mammals and the overall ocean environment. The effect of hurricanes with high winds and huge waves on thousand-foot structures permanently anchored to the ocean floor present other questions. Offshore Wind Requires a Second Look at True Motives H.L. Mencken also once said: "The urge to save humanity is almost always a false front for the urge to rule." Our clean energy future and our environment are far too important to be driven by special interests naive idealism or for-profit developers. Fred Fastiggi-Principal Shoreline Energy Advisors	Final PEIS Section 2.3 discusses design features of WTGs to accommodate extreme weather, including hurricanes.
BOEM-2024-0001-0433-0001	New Jersey is on the frontlines of the climate crisis with ever increasing sea level rise heavy rain events and both coastal and inland flooding. To achieve the necessary carbon emission reductions to protect our communities from the climate crisis we need a major transition in our energy sector now. Offshore wind is one of our greatest clean energy solutions that will benefit the local economy and communities here in our state without the further burning of fossil fuels.	BOEM agrees that development of offshore wind energy projects (to the extent that they displace fossil fuels) would help reduce GHG emissions that contribute to climate change.
BOEM-2024-0001-0433-0003	Offshore wind will also benefit the overall air quality of our region which suffers greatly from a dense population and overwhelming industry pollution. We need to invest in offshore wind to bring relief to people who suffer from asthma heart disease and other medical conditions. The projects in these lease areas will directly allow our communities in NJ to breathe easier and we urge BOEM to move quickly to protect the health of our future generations.	BOEM agrees that development of offshore wind energy projects (to the extent that they displace fossil fuels) would reduce air pollutant emissions from power plants.

Comment No.	Comment	Response
BOEM-2024-0001-0436-0004	Environmental Benefits of Offshore Wind Development The PEIS should clarify the climate (i.e. greenhouse gas emission reduction) air quality and other environmental benefits of offshore wind development and view alternatives and AMMMs in that context. The PEIS is generally focused on negative environmental impacts without a balanced discussion of how offshore wind development is essential for transitioning our national energy supply and reducing environmental impacts. [Footnote 4: See e.g. Affected Environment and Environmental Consequences 3.4.1-10 ("Increasing energy production from offshore wind projects could reduce regional GHG emissions by displacing energy from fossil fuels. The amount of emissions reduction from displaced generation is uncertain because the future grid mix is not known. This reduction would likely more than offset the relatively small GHG emissions from offshore wind projects. This reduction in regional GHG emissions would be noticeable in the regional context and contribute incrementally to addressing climate change and would represent a moderate beneficial impact in the regional context but a negligible beneficial impact in the global context.").]	Final PEIS Section 3.4.1.4.1 provides estimates of GHG reductions, avoided health effects, and the social cost of GHGs. Issues around reducing the carbon intensity of the national energy supply are public policy questions that are beyond the scope of an EIS and outside of BOEM's authority. These issues should be addressed at the federal and state level.
BOEM-2024-0001-0436-0005	The PEIS vastly underestimates energy production from lease areas and conducted an impact assessment based off only 8.6 GW of reasonably foreseeable wind power on the OCS. Table 3.4.1-4.	Table 3.4.1-4 presents an example scenario, as discussed in Final PEIS Section 3.4.1.3.2, and does not represent the potential generation capacity or avoided health impact of developing all lease areas in the NY Bight. Table 3.4.1-7 provides the estimated avoided health impacts of one representative project comprising 280 WTGs.
BOEM-2024-0001-0436-0006	The environmental benefits from offshore wind therefore have been discounted and negative impacts (e.g. construction air emissions) have been overstated. In the impact assessment the Final PEIS must address the environmental benefits of offshore wind development particularly as context for analysis of Clean Air Act criteria air pollutants and greenhouse gas emissions from construction and operations.	Final PEIS Section 3.4.1.4.1 provides estimates of environmental benefits, including criteria pollutant and GHG emissions reductions, avoided health effects (to the extent that wind projects displace fossil fuels), and the social cost of GHGs.
BOEM-2024-0001-0439-0025	Furthermore climate change benefits need to be further explained throughout the PEIS. For example in the air section the PEIS states that "offshore wind projects" would "represent a moderate beneficial impact in the regional context but a negligible beneficial impact in the global context."[Footnote 50: Draft PEIS at 112790]	A determination of “moderate” or “negligible” is a qualitative evaluation. The “30x30 goals” may refer to the U.S. Department of Energy (DOE) Offshore Wind Energy Strategy, a summary of DOE’s efforts to meet President Biden’s goal to deploy 30 GW of offshore wind energy by 2030 and set the nation on a pathway to

Comment No.	Comment	Response
	These statements can be confusing and misleading as noted by several speakers at the public hearings. Whenever global climate change impact is discussed it should be explained in the context of the outsized contribution offshore wind will have on meeting US 30x30 goals and the importance of US reductions as it is a major producer worldwide of greenhouse gas emissions.	110 GW or more by 2050. Discussion of the DOE strategy has been added to Final PEIS Section 3.4.1.
BOEM-2024-0001-0467-0001	UPROSE and NYC-EJA strongly urge amending and adopting Alternative C (Proposed Action) to account for the cumulative impacts of air pollution. Specifically we urge Alternative C to prioritize the elimination rather than simply the reduction of air pollutants arising from direct and indirect offshore wind activities in the New York Bight. This must be realized in a requirement by BOEM that lessees electrify vehicles and vessels directly involved in offshore wind activities in the New York Bight and prioritize low co-pollutant fuels over traditional marine or fossil fuels where electrification is technically infeasible. BOEM must also require lessees to avoid using "false solutions" like natural gas propane and hydrogen as a facade to address climate and environmental justice impacts. Advocates and researchers recognize these technologies as fuels that 1) continue to emit air pollutants when combusted disproportionately in climate and environmental justice communities in similar or greater amounts as other fossil fuels and 2) do not significantly reduce greenhouse gas emissions <insert source here>.	BOEM's designation of the AQ AMMM measures as RPs encourages lessees to consider practices such as electrification and the use of low-carbon fuels. Lessees are also encouraged to provide justifications if these RPS are determined to be infeasible. Final PEIS Table 3.4.1-10 lists the AMMM measures for air quality/GHGs.
BOEM-2024-0001-0468-0001	Potential development of the lease holdings would assist with meeting several state mandates for renewable energy including New Jersey's goal of 11 GW of offshore wind energy generation by 2040 is outlined in New Jersey Executive Order No. 307 issued on September 21 2022; New York's requirement of 9 GW of offshore wind energy generation by 2035 is outlined in the Climate Leadership and Community Protection Act signed into law on July 18 2019. Additionally an estimated 16-18 GW of offshore wind energy may be necessary to ensure New York State achieves its Climate Act mandates (New York State Climate Action Council 2022). Based on a conservatively estimated power ratio of 3 megawatts per square kilometer BOEM estimates that full development of leases in this area has the potential to create up to 5.6 to 7 GW of offshore wind energy.	BOEM agrees that development of offshore wind energy projects would help meet state mandates for renewable energy.

Comment No.	Comment	Response
BOEM-2024-0001-0506-0001	I support the orderly and equitable development of offshore wind energy capture installations in the New York Bight. They can add significantly to renewable energy capture in this area as vitally needed in order to reduce the use of CO2-producing fossil fuel for electricity generation.	BOEM agrees that development of offshore wind energy projects (to the extent that they displace fossil fuels) would help reduce GHG emissions that contribute to climate change.
BOEM-2024-0001-0522-0003	Health I support offshore wind development because a transition to clean energy won't just fight climate change it will also help improve the air New Jerseyans breathe. While our state's air has improved in recent decades it still ranks among the worst in the nation. We need to invest in offshore wind to bring relief to people who suffer from asthma heart disease and other medical conditions. The transition to cleanly produced offshore wind will bring particular benefits to those most at risk of heart and lung conditions: children and seniors. I'm calling on BOEM to act quickly to secure our clean energy future to protect the health of an entire generation of children. I urge you to proceed with the offshore wind leases in the New York Bight. It is critical to center community engagement and prioritize the advancement of this project that will help reduce pollution mitigate against the worst impacts of climate change and bring family-sustaining jobs to the area.	BOEM agrees that development of offshore wind energy projects (to the extent that they displace fossil fuels) would reduce air pollutant emissions from power plants.
BOEM-2024-0001-0522-0005	Please commit to this project and reject efforts to slow it down or block it so that New Jersey communities and the environment can be protected from harmful pollution and the worst effects of fossil-fuel-driven climate change.	BOEM is committed to facilitating offshore wind energy development in an economically and environmentally responsible way. For any COP-based project, the lessee is responsible for meeting applicable permitting and regulatory requirements.
BOEM-2024-0001-0523-0001	My interest in supporting renewable energy projects generally and the Beacon Wind project in particular is simply because like many parents in my community I worry about the local and global environmental conditions they will inherit. The scientific consensus is absolutely clear that to avert the most devastating impacts of climate change for future generations---for our children and grandchildren---we must act urgently to reduce carbon pollution and supporting renewable energy projects like Beacon Wind is absolutely crucial to that.	This comment refers to Beacon Wind and, as such, is not a comment on the NY Bight Final PEIS. BOEM agrees that development of offshore wind energy projects (to the extent they displace fossil fuels) would help reduce GHG emissions that contribute to climate change.
BOEM-2024-0001-0523-0002	First the Beacon Wind project will provide energy to New York City's power grid and thereby let New York City begin transitioning away from the fracked gas power that New Yorkers are so strongly	This comment refers to Beacon Wind and, as such, is not a comment on the NY Bight PEIS. BOEM agrees that development of offshore wind energy projects (to the extent that they displace

Comment No.	Comment	Response
	opposed to as witnessed by the overwhelming opposition to NRG's proposed Williams pipeline recently. Fracked gas in addition to being a greenhouse gas pollutes our communities' air and contributes to poor health outcomes including asthma which many Brooklyn children disproportionately suffer from. Fracked gas pipelines pollute all the communities they pass through but especially those with vaporizers which is why New Yorkers worked so hard recently to defeat National Grid's plan for new vaporizers in North Brooklyn. Again projects like Beacon will enable us to begin transitioning away from these sources. Second without offshore wind New York will not be able to meet its mandate for clean energy as specified by New York's Climate Leadership and Community Protection Act (CLCPA).	fossil fuels) would support state renewable energy mandates, reduce air pollutant emissions, and reduce GHG emissions that contribute to climate change.
BOEM-2024-0001-0523-0004	I encourage BOEM in writing the draft and final EIS to consider the important environmental risks and damages of NOT taking advantage of this opportunity. In doing so BOEM would miss an important opportunity to help our communities reduce their greenhouse gas emissions improve local air quality and protect biodiversity globally through reducing greenhouse gasses. To summarize for those of us who are parents and want to protect our children's future the only reasonable course of action today is to support efforts to transition to clean energy sources rapidly. The Beacon Wind project is an excellent opportunity to do that and to build cleaner healthier communities here in New York for our children. That's why so many Brooklyn families support this project and I hope BOEM will too.	This comment refers to Beacon Wind and, as such, is not a comment on the NY Bight PEIS. BOEM agrees that development of offshore wind energy projects (to the extent they displace fossil fuels) would reduce air pollutant emissions and reduce GHG emissions that contribute to climate change.
BOEM-2024-0001-0528c	In addition, there's no evidence that this industrialization will stop climate change. In fact, by BOEM's own admission, quote, There will be no collective impact on global warming as a result of offshore wind projects.	No single project can reduce GHG emissions enough to have a measurable impact by itself on climate change. The GHG emission reductions from one NY Bight project would contribute individually, in combination with all other GHG reductions, toward slowing the rate of climate change.
BOEM-2024-0001-0528z	For all those stating that we need to do this, as other commenters mentioned, according to BOEM's Vineyard Wind, FEIS. Page 76, quote overall, it is anticipated that there would be no collective impact on global warming as a result of offshore wind projects end quote. It seems like cumulative sum cumulative impacts, equal cumulative assumptions.	Please refer to response to comment BOEM-2024-0001-0528c for more information on impacts from offshore wind projects on GHG emissions.

Comment No.	Comment	Response
BOEM-2024-0001-0529n	BOEM has already admitted in their documents that these turbines will have no effect on climate change. According to Page 76, BOEM's Vineyard Wind 1 FEIS Volume 2	Please refer to response to comment BOEM-2024-0001-0528c for more information on impacts from offshore wind projects on GHG emissions.
BOEM-2024-0001-0528bb	The South Bronx has remained the poorest urban Congressional district in the U.S. It's also afflicted with some of the worst air pollution rates in the state and country. We experience it by being near the vehicle intensive pollution of the Deegan, the Bruckner, and the Cross Bronx highways, the pollution of industrial and warehouse facilities, and the power, authority, and natural gas plants in Morris, in Port Morris, among others. The Bronx is Community District One, in which I live, has the highest childhood asthma hospitalization rates in the city.	Thank you for your comment. Please see Section 3.4.1.1., *Description of the Affected Environment and Future Baseline Conditions*, for more information on designated nonattainment or maintenance areas for carbon monoxide (CO), particulate matter with diameter of 2.5 microns and smaller ($PM_{2.5}$), or O_3 in the geographic analysis area. BOEM will conduct project-specific NEPA analysis of the COP for each lease area that will focus on providing additional site- and project-specific analyses that were not already addressed by the PEIS.
BOEM-2024-0001-0528gg	We're about to destroy an entire, the entire ecosystem with the mass construction when BOEM's own documents state and I quote overall it is anticipated that there will be no collective impact on global warming as a result of offshore wind projects. Now that is quoted.	Please refer to response to comment BOEM-2024-0001-0528c for more information on impacts from offshore wind projects on GHG emissions.
BOEM-2024-0001-0310g	In the applicant's own admission, offshore wind will have little to no effect on climate change or reducing the carbon footprint.	Please refer to response to comment BOEM-2024-0001-0528c for more information on impacts from offshore wind projects on GHG emissions.
BOEM-2024-0001-0310h	In BOEM's own documents it states, "Overall, it is anticipated that there will be no collective impact on global warming as a result of offshore wind projects."	Please refer to response to comment BOEM-2024-0001-0528c for more information on impacts from offshore wind projects on GHG emissions.
BOEM-2024-0001-0310l	U.S. Government Bureau of Ocean Energy Management, BOEM, admits that U.S. offshore wind projects would by themselves probably have an admitted impact on global emissions and climate change and the benefit would be negligible.	Please refer to response to comment BOEM-2024-0001-0528c for more information on impacts from offshore wind projects on GHG emissions.
BOEM-2024-0001-0310n	BOEM's own documents claim that offshore wind will have little to no effect on global warming and carbon emissions. BOEM also claims that offshore wind will have a dampening effect on the wind, reducing the winds ability to cool sea surface temperatures.	Please refer to response to comment BOEM-2024-0001-0528c for more information on impacts from offshore wind projects on GHG emissions. Please see Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative*, *Presence of Structures*, which discusses hydrodynamics, including atmospheric wakes.

Comment No.	Comment	Response
BOEM-2024-0001-0310o	According to another BOEM document, "Overall, it is anticipated that there would be no collective impact on global warming as a result of offshore wind projects," stated in Vineyard Winds' final Environmental Impact Statement.	Please refer to response to comment BOEM-2024-0001-0528c for more information on impacts from offshore wind projects on GHG emissions.
BOEM-2024-0001-0310q	As far as I know, the greenhouse emissions expended to build and install these turbines is completely left out of the EIS calculation requirements. 2000 ton 6-inch thick steel wall monopoles from Germany and tower assemblies from Spain and lifted and pounded into place by foreign flagged gigantic ships, generator nacelles filled with rare earth components and blade assemblies weighing tens of hundreds of tons more, all the geotechnical surveys and support operations completely left out. I consider that intentional deception. Maybe things aren't as green as they'd like us to believe. All proposed sources of energy should be required to have cradle-to-grave calculations so we can make honest decisions.	Please refer to response to comment BOEM-2024-0001-0528hh for more information on emissions from manufacturing.
BOEM-2024-0001-0529hh	I mean to sum up, BOEM itself states, there will be no collective impact on global warming as a result of offshore wind projects. These projects are not the answer.	Please refer to response to comment BOEM-2024-0001-0528c for more information on impacts from offshore wind projects on GHG emissions.
BOEM-2024-0001-0529hh	And I think you know anybody that picks up the documents and reads and will find right away that fossil fuels are used in all phases of turbine manufacturing, construction, the operation of the wind for our projects, the maintenance, and will be so, well also in the decommissioning, and that's through net increases and carbon emissions from increase shipping, trucking, helicopter traffic, all used to construct and maintain these, not to mention all the steel and other fossil fuels or other products that need, rely on fossil fuels to be constructed, so. The documents also reveal the amounts of, significant amounts of petrochemicals and lubricants necessary for operation of the turbines ongoing, I suggest people look into that.	As stated in Final PEIS Section 3.4.1.4.1, emissions from manufacturing and other "upstream" sources are not included in the analysis. However, life cycle considerations are discussed in Section 3.4.1.4.1. As indicated in Section 3.4.1.4.1, although wind energy has higher upstream emissions than many other generation methods, its lifecycle GHG emissions are orders of magnitude lower than from other generation methods.

P.5.4 Water Quality

Table P.5-4. Responses to Comments on Water Quality

Comment No.	Comment	Response
BOEM-2024-0001-0175-0002	No one has explained in detail a few of my concerns such as:[Bold: Substations“] "An open loop cooling system is used to dissipate heat from the conversion of AC to DC . Cool water is taken in and comes out up to 8100000 per day at 86-90f with chlorine residuals as they use that to keep pipes clear." If you are truly concerned with climate change and warming oceans why would you even consider putting that many millions of gallons of sea water at that temperature which will be chemically treated back into the ocean? How will this not negatively and/or irreversibly impact the ocean and its inhabitants? Multiply that amount of sea water by how many substations will be in place multiplied by 365 days in a year times 25 years. I suggest someone should read [Underline: Marine ecological impact analysis of residual chlorine ...] by S Youping 2023 where he states "The free residual chlorine in seawater is more toxic to aquatic organisms".	Additional analysis has been added to Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative, Discharges/Intakes,* to further describe the minimal impacts of the open loop cooling system.
BOEM-2024-0001-0180-0003	The wind farm development of the New York Bight will cause the certain pollution of our ocean through blade erosion petrochemical leakage and electromagnetic radiation presented by underground cables. Documented neurological problems will occur to the human population living in close proximity. There will be negative effects to our wind currents and deep water currents. I understand your stance of a need to mitigate the effects of climate change but destroying our ocean is not the answer. At least give the public scientists and our elected officials time to properly review this document and related research.	Thank you for your comment. Please see the Presence of Structures IPF and Accidental Releases IPF discussions within Sections 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative*; 3.4.2.4.1, *Impacts of One project;* 3.4.2.4.2, *Impacts of Six Projects*; and 3.4.2.5, *Impacts of Alternative C (Proposed Action) – Identification of AMMM Measures at the Programmatic Stage*.
BOEM-2024-0001-0259-0001	It is imperative that the development of wind energy farms receive adequate research evaluation and modeling of potential inter-annual effects on the local ecosystem from the first development-related activities to post-operations years after installations. As noted in a recent BOEM supported study producing a Consensus Report by National Academies of Sciences Engineering and Medicine in 2023: Potential Hydrodynamic Impacts of Offshore Wind Energy on Nantucket Shoals Regional Ecology: An Evaluation from Wind to Whales. Washington DC: The National Academies Press.	Please see Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative, Presence of structures* for the discussion of hydrodynamic effects.

Comment No.	Comment	Response
	https://doi.org/10.17226/27154 "the impacts on ecosystems from development and operation of offshore wind may be difficult to distinguish from natural and other anthropogenic variability (including climate change)". Further "A single offshore wind turbine can alter local hydrodynamics... arrays of turbines in a wind farm or at multiple adjacent offshore wind farms...become more complex with implications for both local and regional circulation. Understanding these hydrodynamic effects is essential to develop predictions of the potential impacts of wind farms on the region's ecosystem from phytoplankton to marine mammals". (p.2)	
BOEM-2024-0001-0313-0018	Offshore Activities and Facilities Page 2-7 states "One NY Bight project would install between 50 and 280 WTGs within a NY Bight lease area in a grid layout at a minimum spacing of 0.6 by 0.6 nautical mile (1.1 by 1.1 kilometers). The WTGs considered would have a rotor diameter up to 1214 feet (370 meters) and a blade tip height that extends up to 1312 feet (400 meters) above mean sea level (AMSL) (Figure 2-2). A single NY Bight project would install 15 OSSs that would serve as common collection points for power from the WTGs as well as the origin for the offshore export cables that deliver power to shore (Figure 2- 1). NY Bight lessees may use HVAC or HVDC technology to transmit power from the wind farms to shore.2 Different equipment would be required on each OSS depending on whether HVAC or HVDC technology is used. An HVAC system is typically used to transport energy onshore when the wind farm is within about 30 miles (50 kilometers) of the shore (Middleton and Barnhart 2022). Due to the distance of the NY Bight lease areas to shore (which at their closest points are between 22 and 45 miles [35 and 72 kilometers] offshore) if HVAC OSSs are chosen an HVAC booster station or a reactive compensation station may be required along the export cable route to offset against power losses between the offshore wind farm and the grid. HVAC booster stations are generally similar in size and foundation type to an OSS. HVDC systems operate by converting the alternating current (AC) high voltage electricity produced by the WTGs to direct current (DC) for transport to shore and then once onshore convert the electricity back to AC for distribution to the grid. HVDC systems do not experience the same losses in power experienced on AC transmission	Thank you for your comment. CWA Section 316(b) requires NPDES permits to ensure that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available to minimize adverse environmental impacts. This should be included in the project-specific, COP-level NEPA analysis. Please see Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative, Discharges/Intakes,* which discusses the minimal impacts of the open loop cooling system. The project-specific, COP-level NEPA analysis will also provide greater details.

Comment No.	Comment	Response
	lines at long distances and do not require booster stations along the export cable route. Because of the large amount of heat generated during the conversion of AC to DC at the HVDC converter OSS located in the wind farm these systems must be cooled when operating. The most common type of cooling system is an open loop system that intakes cool filtered sea water and discharges warmer water back into the ocean. Chemicals such as bleach (sodium hypochlorite) may be used in order to prevent growth in the system and keep pipes clean (Middleton and Barnhart 2022)." Comment Additional information on the amount of heat transferred into the surrounding waterbody and potential impacts from the "large amount of heat" generated as identified above should be analyzed. Potential impacts of thermal pollution and the direct and indirect impacts to the ecosystem dynamic and sensitive organisms in the pathway of this heat transfer must be evaluated. It is also concerning that there are no quantifiable metrics regarding he cumulative impacts of all offshore substations in the NY Bight Area as well as those planned for Empire Wind (and other planned offshore wind developments) which again are substantially contiguous to OSC-A 0544. There should also be a discussion of the chemicals mentioned above and how that will impact the ecosystem including water quality habitat wildlife etc. which are not sufficiently evaluated in the PEIS.	
BOEM-2024-0001-0313-0021	There is no discussion of the chemical composition of the significant amount of grout that will be used and the impacts to the quality of the water body is leaching and natural degradation occurs. However based on simple publicly available manufacturing specifications from suppliers to other offshore wind turbine grout suppliers it appears that the grout needed would consist of seawater resistant grout material composition and may further include polycarboxylate-based synthetic plasticizers polyglycol-based defoaming agent; calcium sulphur aluminate-based hardener among other chemical additives that may have an impact to benthic organisms and degrade water quality. If any of the byproducts or leached materials could adversely impact the ecosystem dynamic this issue should at least be discussed and/or conditions placed as mitigation measures on the grout utilized. For example in the case of preparing a grout material composition by containing a high strength admixture the following	Potential contaminants other than accidental releases are discussed in Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative*, under the Presence of structures IPF and Discharges/Intakes IPF. However, the project-specific, COP-level NEPA analysis will provide greater detail for each of the NY Bight lease areas.

Comment No.	Comment	Response
	mechanism is typically generated - the high strength admixture reacts with calcium aluminate among components of cement thereby generating ettringite; the ettringite reacts with a calcium hydroxide generated by a hydration reaction between water and cement thereby forming a calcium silicate hydrate. Further scientific studies have indicated that "The results show that chloride ions induced corrosion of steel bars in offshore RC structures is highly influenced by the concentration of sulfate ions. The sulfate ions induced concrete expansion and cracking from ettringite formation could potentially accelerate chloride ions induced corrosion of steel bars in concrete ultimately the premature failure of the offshore RC structures. (source: Degradation of concrete in marine environment under coupled chloride and sulfate attack: A numerical and experimental study December 2022). Page 2-15 goes on to state "Annual maintenance campaigns are expected to be needed for general upkeep (e.g. bolt tensioning crack and coating inspection safety equipment inspection cleaning high-voltage component service and blade inspection) and replacement of consumable components (e.g. lubrication oil changes). BOEM anticipates OSSs would also undergo annual maintenance to both medium-voltage and high voltage systems auxiliary systems and safety systems as well as topside structural inspections. Portions of the topsides may require the reapplication of corrosion-resistant coating. Routine maintenance and refueling would also be performed on generators located on the OSSs." Comment Building on the comments and concerns above regarding water quality impacts there is no discussion in the PEIS regarding mitigation measures specifically pertaining to water quality impacts of the chemicals proposed and peripherally referenced in these sections. Analysis of hazardous material composition and their potential impacts and mitigation measures if needed are not provided and should be an integral component of the FEIS. Are emerging contaminants such as PFAs or 14 -dioxane used in coatings what is the chemical composition of the specialty cleaning products used and will there be measures to protect the waterbody and dependent organisms from the addition of these chemicals? Anti- fouling paint has an environmental legacy of adverse impacts to the marine ecosystem are these corrosion	

Comment No.	Comment	Response
	resistant coatings safe and the scientific studies substantiating same should be provided as appendices in the PEIS and conditions of these leases. There should also be additional discussion of protection measures for the lubricants and oil in terms of water quality and mitigation measures.	
BOEM-2024-0001-0313-0022	Later in the PEIS there is a paragraph on incidental releases and future planning documents that would be prepared but these standard measures and plans should be provided now for review and comment also these should be part of the proactive planning process not a reactionary measure in case of an incidental release. (page 2-22 "Chemical spills or releases: For offshore activities these include inadvertent releases from refueling vessels spills from routine maintenance activities and any more significant spills as a result of a catastrophic event. All vessels would be certified to conform to vessel O&M protocols designed to minimize risk of fuel spills and leaks. Developers would prepare an Oil Spill Response Plan (OSRP) and would be expected to comply with USCG and BSEE regulations relating to prevention and control of oil spills. Onshore releases could potentially occur from construction equipment or HDD activities. All wastes generated onshore would comply with applicable state and federal regulations including the Resource Conservation and Recovery Act and the Department of Transportation Hazardous Materials regulations.") There are recent news articles expressing concerns about the WTG blades naturally eroding during operation and spreading a significant amount of microplastics as a byproduct. The PEIS should discuss the epoxy compounds shed by WTGs and if they contain toxins that could adversely impact the environment. Microplastic shedding from turbine blades commonly referred to as Leading Edge Erosion has the potential should be evaluated. The particles eroded from blades include epoxy which can be comprised of 40% Bisphenol-A (BPA) a purportedly banned endocrine disruptor and neurotoxin. (See international Journal of Medical Sciences "Int J Med Sci. 2015; 12(12): 926936 Published online 2015 Oct 30; Neurological Effects of Bisphenol A and its Analogues); the abstract of which states "The endocrine disrupting chemical bisphenol A (BPA) is widely used in the production of polycarbonate plastics and epoxy resins. The use	Potential contaminants other than accidental releases are discussed in Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative*, under the Presence of Structures IPF and Discharges/Intakes IPF. However, the project-specific, COP-level NEPA analysis will provide greater detail for each of the NY Bight lease areas.

Comment No.	Comment	Response
	of BPA-containing products in daily life makes exposure ubiquitous and the potential human health risks of this chemical are a major public health concern. Although numerous in vitro and in vivo studies have been published on the effects of BPA on biological systems there is controversy as to whether ordinary levels of exposure can have adverse effects in humans. However the increasing incidence of developmental disorders is of concern and accumulating evidence indicates that BPA has detrimental effects on neurological development. Other bisphenol analogues used as substitutes for BPA are also suspected of having a broad range of biological actions. The objective of this review is to summarize our current understanding of the neurobiological effects of BPA and its analogues and to discuss preventive strategies from a public health perspective. Academic research has shown the potential for 137 pounds of epoxy microparticles to be shed per turbine per year. The resulting annual BPA release can potentially contaminate water and impact water quality and aquatic and terrestrial life. Minimizing the shedding depends on specialized blade coatings that contain toxic ingredients from the PFAS family of "forever" chemicals which are biologically cumulative and nondegradable. These coatings likewise need replacement after a few years. PFAS is also a common ingredient in lubricants and hydraulic fluids which can leak from wind turbines. The risk of forever impacting the water surrounding nearshore communities and sensitive habitat by wind turbines should be evaluated in the PEIS.	
BOEM-2024-0001-0313-0023	Conversely there are fact sheets and reports from proponents of offshore wind and that attempt to debunk concerns by indicating that any leading edge erosion is minor however this fails to knowledge that potential adverse impacts are measures in parts per trillion so even the smallest amount of erosion especially when considering cumulatively could most certainly have an adverse environmental impact which should be discussed in the PEIS. It is also worthy of note that NYSDEC recently published information on emerging contaminant on aquatic ecosystems which should be included in the evaluation of the PEIS there are significant concerns of bioaccumulation in the food chain of contaminants in the tissues of organisms which again should be discussed in the PEIS. It is	Thank you for your comment. Through the AMMM measures WQ-1 and WQ-2, accidental releases are anticipated to be reduced or minimized. Potential contaminants other than accidental releases are discussed in Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative*, under the Presence of Structures IPF and Discharges/Intakes IPF. Derivation of bioaccumulation factors and bioaccumulative chemicals of concern are out of scope for this PEIS. The discussions in the PEIS are based on the best available science to date.

Comment No.	Comment	Response
	important that the stated objectives of human and environmental health and safety are evaluated in the PEIS. (see: https://dec.ny.gov/news/press-releases/2023/3/dec-releases-final-ambient-water-quality-guidance-values- for-pfoa-pfos-and-14-dioxane) and the NYSDEC Division of Water Technical and Operational Guidance Series (1.1.4) PROCEDURES FOR DERIVATION OF BIOACCUMULATION FACTORS document. The stated purposed of which is "PURPOSE Bioaccumulation Factors (BAFs) are needed to derive Health (Fish Consumption) and Wildlife type water quality standards and guidance values. BAFs are also used to identify Bioaccumulative Chemicals of Concern (BCCs) in Department programs. The purpose of this document is to provide detailed procedures for the derivation of such BAFs." "The purpose of this document is to describe procedures for deriving bioaccumulation factors (BAFs) to be used in the calculation of Health (Fish Consumption) and Wildlife type standards and guidance values. A subset of the human health BAFs is also used to identify the chemicals that are considered bioaccumulative chemicals of concern (BCCs). B. Bioaccumulation reflects uptake of a substance by aquatic organisms exposed to the substance through all routes (i.e. ambient water and food) as would occur in nature. Bioconcentration reflects uptake of a substance by aquatic organisms exposed to the substance only through the ambient water. Both BAFs and bioconcentration factors (BCFs) are proportionality constants that describe the relationship between the concentration of a substance in aquatic organisms and its concentration in the ambient water. The water quality regulations require BAFs rather than BCFs because they better account for the total exposure of aquatic organisms to chemicals." It is important that the seemingly flippant dismissal of deminimis impacts of microplastics and impacts from epoxy and PFAS/14-dioxane could actually be orders of magnitude more impactful based on the levels of contaminants that are considered by environmental and health agencies to be a serious environmental and human health hazard.	
BOEM-2024-0001-0313-0027	3.1-2 Affected Environment and Environmental Consequences Comment on Table 3.1-1 - Regarding the description for the impact producing factor (IPF) identified as discharges/intakes is incomplete	Thank you for your comment. Corrosion is considered in the Presence of Structures IPF.

Comment No.	Comment	Response
	and should include cleaning chemicals anti-fouling paints any discharge associated with recoating and maintenance. Is the corroded material considered a discharge in this context?	
BOEM-2024-0001-0313-0029	Section 3.4.2 Water Quality includes a discussion of the nature of releases anticipated. Based on Appendix D Table D2-3 up to about 1989065 gallons (7.5 million liters) of coolants 3895547 gallons (14.7 million liters) of oils and lubricants and 1077618 (4.1 million liters) of diesel fuel would be contained in the 737 wind turbine and substation structures for the wind energy projects within the air quality geographic analysis area. If accidental releases occur they would be most likely during construction but could occur during operations and conceptual decommissioning of offshore wind facilities. These may lead to short- term periods (hours to days) of HAPs emissions through surface evaporation. HAPs emissions would consist of VOCs which are important for O3 formation." Comment The staggering number of contaminants that could be accidentally released into the environment requires further analysis and discussion and/or inclusion of the proactive planning documents in the final PEIS to ensure that all reasonable measures are in place and immediate actions are in place prior to any incidental release for the reasons described previously in this comment letter.	Thank you for your comment. Through AMMM measures WQ-1 and WQ-2, accidental releases are anticipated to be reduced or minimized. Please see Section 3.4.2.5.1, *Impacts of One Project*, for a discussion of accidental releases and the potential impacts of the AMMM measures mentioned above.
BOEM-2024-0001-0313-0034	3.4.2 Water Quality The PEIS states "The water quality geographic analysis area as shown on Figure 3.4.2-1 includes a 10- mile (16.1-kilometer) radius around the NY Bight lease areas along with inshore waterways around representative ports that may be used for the NY Bight projects. The offshore geographic analysis area accounts for some transport of water masses due to ocean currents. The inshore geographic analysis area was chosen to capture the extent of the natural network of waterbodies that could be affected by port utilization for construction and operation activities of the NY Bight projects." Screenshot of Figure 3.4.2-1: SEE ORIGINAL COMMENT FOR FIGURE 3.4.2-1: Water quality geographic analysis area Comment The geographic boundary of the water quality impact analysis is woefully inadequate and must be extended to the shoreline to encompass all of the planned components of this project. This is particularly concerning for all of the reasons previously mentioned but some of the most sensitive ecosystems	Since the exact locations and activities for each project are not known at this programmatic stage, the project-specific, COP-level NEPA analysis will include inshore areas for each NY Bight lease area if conditions or activities are different than the analyses of representative areas and projects included in the PEIS.

Comment No.	Comment	Response
	that are dependent on water quality and health of the ecosystem are at the intertidal areas. Further it is unacceptable that water quality analysis does not include the areas proposed for "ocean dumping" and project components that absolutely have the potential to impact water quality. SEE ORIGINAL COMMENT FOR FIGURE 3.6.62- TSS. Separation zones precautionary areas and USCG proposed fairways anchorages and precautionary areas in the geographic analysis area.	
BOEM-2024-0001-0313-0035	Affected Environment and Environmental Consequences 3.4.2-3 The PEIS states "The offshore U.S. waters of the Atlantic Ocean including potential offshore export cable corridors and lease areas have little variation in salinity and temperature though a vertical variation (i.e. stratification) occurs on a seasonal basis (conductivity-temperature-depth data from the World Ocean Database 2021). Stratification typically is strongest in the summer when surface waters are warmer and somewhat less saline than bottom waters; well-mixed and more uniform vertical salinity and temperature profiles are evident in the fall. In late spring and early summer a strong thermocline develops at an approximately 20-meter depth across the entire shelf of the Mid-Atlantic Bight isolating a continuous mid- shelf cold pool of water that extends from Nantucket to Cape Hatteras (Miles et al. 2021). The cold pool holds nutrients over the shelf during the spring and summer which in turn promotes phytoplankton productivity and affects fish distributions and behavior (Lentz 2017; Miles et al. 2021; Nye et al. 2009). The Cold Pool is highly dynamic over its annual lifespan and among years (Chen and Curchitser 2020) experiencing significant changes in stratification with peak stratification occurring in summer and with weaker stratification occurring during its formation and breakdown in spring and fall (Miles et al 2021). Additionally the isolated volume of cold bottom water shifts location predominately moving southwestward along the shelf as it slowly warms through the season (Miles et al. 2021)." The PEIS also states "As one of the key drivers behind water quality change over time climate change (including warming sea temperatures rising sea levels ocean acidification etc.) can affect water quality causing changes and variability within the ecosystem. Northeast regional ocean temperatures have warmed faster than the global ocean over the last two decades according to the National Oceanic and Atmospheric	Thank you for your comment. Please see Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative, Presence of structures,* which discusses hydrodynamics, including atmospheric wakes and the Mid-Atlantic Bight Cold Pool.

Comment No.	Comment	Response
	Administration (NOAA 2021). Additionally there is some evidence indicating that the cold pool is both warming and shrinking due to the effects of climate change which will likely affect species distributions and total ecosystem productivity in the Mid-Atlantic Bight (Friedland et al. 2022)." (page 3.4.2-8) Comment There are unanswered questions based on lack of meaningful analysis in the PEIS if the OSSs will impact the ecosystem dynamic especially as it pertains to the converter stations. There are also questions regarding anticipated impact of vertical mixing from WTG installation (pile driving as well as activities associated with installation of appurtenant structures and infrastructure). Further will the construction activity impact the aforementioned thermocline and what will be the impact on the surrounding ecosystem? The short-term and long terms effects of the impacts of the proposed action should be evaluated in the PEIS as it pertains to the thermocline and Cold Pool and potential direct indirect and cumulative impacts of these changes when considering not just the NY Bight but planned offshore wind activities.	
BOEM-2024-0001-0313-0036	Affected Environment and Environmental Consequences 3.4.2-3 Page 3.4.2-3 of the PEIS states "As of 2022 the offshore U.S. waters of the Atlantic Ocean are considered attainable (i.e. meeting water quality standards/goals) per the 303(d) requirements. With increasing distance from shore oceanic circulation patterns play an increasingly larger role in dispersing and diluting anthropogenic contaminants and determining water quality. Waters are assessed as impaired when an applicable water quality standard is not being attained. The top causes of pollution associated with impairment in assessed bays and estuaries are mercury most common in fish tissue; polychlorinated biphenyls (PCBs) persisting in sediments and fish tissue; and pathogens which indicate possible fecal contamination (USEPA 2017). PCBs in sediments among other legacy chemicals (i.e. mercury dichlorodiphenyltrichloroethane and dioxin) potentially exceed water quality standards and can be resuspended in the water column during major storm events or from activities such as dredging." Comment This section raises concerns that are not evaluated in the PEIS regarding potential impacts to ocean circulation patterns as a result of the WTGs and associated	Thank you for your comment. Please see Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative, Presence of structures,* which discusses hydrodynamics, including atmospheric wakes and the Mid-Atlantic Bight Cold Pool. Please see Sections 3.4.2.4.1, *Impacts of One Project*, and 3.4.2.4.2, *Impacts of Six Projects*, for discussion on accidental releases, anchoring, cable emplacement and maintenance, and discharges/intakes. AMMM measures, including MUL-1, WQ-1 and WQ-2, and RP MUL-28, address accidental releases of both solid waste and chemicals. AMMM measures MUL-2 and NAV-3 address anchoring plans to avoid sensitive habitats. AMMM measures BEN-1, MUL-41, and OU-4 discuss infrastructure and cable emplacement during siting, construction, operation, and decommissioning phases of the project.

Comment No.	Comment	Response
	structures/infrastructure substantial disturbance and physical barriers in the water. Further this is a case in point example of why the geographic area of water quality analysis must extend to all potentially impacted areas. As the methodology for construction a resuspension of potentially contaminated sediments and suffocating benthic organisms and increasing turbidity are all serious concerns. Accidental releases anchoring cable emplacement and maintenance discharges/intakes points of interconnection all have the potential to substantially contribute to degradation of water quality which should be studied and proactive planning measures and mitigation measures should be discussed in the final PEIS as appropriate. Page 3.4.2-9 indicates that "Additionally global climate change is an ongoing and developing phenomenon in the absence of offshore wind development that causes ocean acidification warming sea temperatures rising sea levels and changes in ocean circulation patterns that can affect water quality." It is important to substantiate in the final PEIS that the proposed action does not cause an unforeseen impact to ocean circulation and water quality impacts than is worse than the no action alternative; which is why this must be evaluated in the final PEIS.	
BOEM-2024-0001-0313-0037	Affected Environment and Environmental Consequences 3.4.2-11 The PEIS states "Using the assumptions in Appendix D Table D2-3 approximately 128184 gallons (485229 liters) of coolants and 842583 gallons (3189524 liters) of fuels oils and lubricants would be involved during construction of the WTGs and OSSs for the Empire Wind 1 and 2 (OCS-0512) projects (the only planned offshore wind projects within the water quality geographic analysis area). Other chemicals including grease paints and sulfur hexafluoride would also be used at the offshore wind projects and black and grey water may be stored in vessels and at onshore facilities. BOEM's study "Environmental Risks Fate and Effects of Chemicals Associated with Wind Turbines on the Atlantic Outer Continental Shelf" presented extensive analysis and modeling to determine the probability and potential environmental consequences of a chemical spill at offshore wind facilities (Bejarano et al. 2013). The modeling effort revealed the most likely type of spill is a non-routine event and could occur from the WTGs at a volume of 90 to 440 gallons (341 to 1666 liters) at a	Thank you for your comment. Through AMMM measures WQ-1 and WQ-2, accidental releases are anticipated to be reduced or minimized. Potential contaminants other than accidental releases are discussed in Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative*, under the Presence of Structures and Discharges/Intakes IPFs. Sulfur hexafluoride is a gas, poorly soluble in water, and used in WTG switchgears in small quantities (approximately 3 kg). If there is a leak, it is more likely to affect air quality than water quality. Section 2.3 discusses design features of WTGs to accommodate extreme weather, including hurricanes.

Comment No.	Comment	Response
	rate of one time in 1 to 5 years or a diesel fuel spill of up to 2000 gallons (7571 liters) at a rate of one time in 91 years. The likelihood of a spill occurring from multiple WTGs and OSSs at the same time is very low and therefore the potential impacts from a spill larger than 2000 gallons (7571 liters) are largely discountable. BOEM anticipates that the likelihood of a non-routine catastrophic or maximum-case scenario release of all oils and chemicals to be very low (Bejarano et al. 2013). Small-volume spills could occur during OSS transformer maintenance or transfer of fluids (oils and chemicals) while low-probability small- or large-volume spills could occur due to vessel collisions allisions such as a vessel striking against a WTGs/OSS or incidents such as toppling during a storm or earthquake. The use of heavy equipment onshore could result in potential spills during use or refueling activities. Onshore construction and installation activities and associated equipment would involve fuel and lubricating and hydraulic oils." Comment DER reviewed the 5330-page document and while this is in referenced above "Environmental Risks Fate and Effects of Chemicals Associated with Wind Turbines on the Atlantic Outer Continental Shelf" again this does not include evaluation of water quality impacts of emerging contaminants and issues of concern regarding potential contaminants beyond spills and accidental releases. A more comprehensive review of all potential contamination impacts to the water body and organisms must be addressed in the final PEIS. Additionally the risks associated with sulfur hexafluoride seem to be inconsistently evaluated in the PEIS whether it will be utilized or not and thus the evaluation seems disjointed and incomplete. This section further solidifies that validity of the concerns of structural failure during an extreme storm event despite the design for a Category 5 storm there should be a contingency plan in place and evaluation of impacts if WTGs parts thereof and OSSs are destroyed during a storm and the containments and mitigation measures in place.	
BOEM-2024-0001-0313-0038	Affected Environment and Environmental Consequences 3.4.2-12The PEIS states "Cable emplacement and maintenance: The installation of array cables and offshore export cables would include site preparation activities (e.g. boulder removal) cable installation via jetting (primary method) plowing trenching and dredging which can	A statement has been added to the Final PEIS Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative*, to make clear to the reader that a project-specific, COP-level NEPA analysis will provide greater details of the specific NY Bight lease areas in regard to sediment transport models.

Comment No.	Comment	Response
	cause temporary increases in turbidity and sediment resuspension. A sediment transport analysis model was conducted for the only planned offshore wind projects within the geographic analysis area the Empire Wind 1 and 2 projects (OCS-0512) (Tetra Tech 2022). The model showed the displacement of sediments would be low and that sediments would remain suspended for a short period of time (4 hours) and typically dissipate to background levels very close to the trench. The model simulated jet plowing the primary installation method to be used for the Empire Wind projects (OCS-0512). The sediment transport model predicted that the sediment plume would typically travel between 328 feet (100 meters) and 1640 feet (500 meters) during flood and ebb conditions but could travel more than 3280 feet (1000 meters) in some areas with stronger currents. Maximum plume concentrations at 3280 feet (1000 meters) would be below 30 milligrams per liter at all stations with the exception of the two stations with strong currents. Coarse particles (medium sand and larger) would not be suspended in the water column from jet plow activities. Fine sand would settle to the bed in less than 1 minute and within 3 feet (1 meter) to 16 feet (5 meters) of the trench centerline depending on current velocities. Silts and clays would remain suspended for approximately 4 hours and would be transported farther from the trench." Comment Although these models are for Empire Wind it does make sense that similar conditions would be expected for 1 NY bight project but again this does not analyze the cumulative impacts to water quality and benthic organisms marine mammals and the entire ecosystem dynamic for the number of activities ongoing at one time. There could be synergistic and cumulative adverse impacts not only in the short term but also in terms of long-term impacts for smothering of shellfish and larvae as well as dislodging potentially contaminated sediments that would otherwise not be disturbed as a result of the proposed action. These issues should be evaluated and analyzed in the final PEIS.	Please see Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative, Discharges/Intakes* for the discussion of resuspension of contaminants.
BOEM-2024-0001-0313-0039	Affected Environment and Environmental Consequences 3.4.2-13The PEIS states "Offshore wind facilities could have impacts on atmospheric and oceanographic processes (including the cold pool) through the presence of structures and the extraction of energy from	Thank you for your comment. Please see Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative, Presence of structures,* which discusses hydrodynamics, including atmospheric wakes and the Mid-Atlantic Bight Cold Pool.

Comment No.	Comment	Response
	the wind. There has been extensive research into characterizing and modeling atmospheric wakes created by wind turbines in order to design the layout of wind facilities and hydrodynamic wake/turbulence related to predicting seabed scour. However relatively few studies have analyzed the hydrodynamic wakes coupled with the interaction of atmospheric wakes with the sea surface. Further even fewer studies have analyzed wakes and their impact on regional scale oceanographic processes (i.e. cold pool) and potential secondary changes to primary production and ecosystems. Studies on this topic have focused on ocean modeling rather than field measurement campaigns." Comment It seems apparent from the information above that there is a lack of scientific studies to understand the impact and long-term effects of a project of this size and scope. In additional to the escrow account required by the developer for decommissioning it appears that there should be funds set aside by the developer for mitigating the potential adverse impacts that may be needed so any long -term remediation and restoration of the habitat is not passed on to the taxpayers in the future.	Lessees can request that facilities remain in place in the decommissioning application submitted to BSEE (30 CFR 285.900-285.913), but BOEM approves or does not approve the request (30 CFR 585.434). Unless otherwise determined during the decommissioning application review, lessees are required to remove all facilities, installations, and other devices permanently or temporarily attached to the seabed on the OCS to a depth of 15 feet below the mudline within 2 years following the termination of a lease or grant. The Energy Policy Act also established specific financial security requirements for OCS projects and requires the lessee to provide a surety bond or other form of financial assurance. Ultimately, the sum of all the lessee's financial assurances will cover the estimated decommissioning costs of an offshore wind farm and, upon termination of the lease, this sum is returned to the lessee or grantee to be used for decommissioning. More information on decommissioning can be found in the following study: https://www.boem.gov/sites/default/files/documents/renewable-energy/state-activities/Decommissioning_WhitePaper.pdf.
BOEM-2024-0001-0313-0040	Affected Environment and Environmental Consequences 3.4.2-15 The PEIS States "The exposure of offshore wind structures which are mainly made of steel to the marine environment can result in corrosion without protective measures. Corrosion is a general problem for offshore infrastructures and corrosion protection systems are necessary to maintain their structural integrity. Protective measures for corrosion (e.g. coatings cathodic protection systems) are often in direct contact with seawater and have different potentials for emissions of metals or organic compounds into the marine environment e.g. galvanic anodes emitting metals such as aluminum zinc and indium and organic coatings releasing organic compounds due to weathering or leaching. The current understanding of chemical emissions for offshore wind structures is that emissions appear to be low suggesting a low environmental impact especially compared to other offshore activities; however these emissions may become more relevant for the marine environment with increased numbers of offshore wind projects and a better understanding of the potential long-term effects of	Additional text has been added to Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative, Presence of structures*. Additional sources—including findings from a study of sacrificial anodes (Reese et al. 2020) and further discussion of HDVC cooling systems (Middleton and Barnhart 2022)—have been included. In addition, AMMM measure WQ-1 details the mitigation measurement designed to address sacrificial anodes, and AMMM measure WQ-2 details a 17-step plan to address accidental spills.

Comment No.	Comment	Response
	corrosion protection systems (Kirchgeorg et al. 2018). Based on the current understanding of offshore wind structure corrosion effects on water quality BOEM anticipates the potential impact to be minor. The presence of structures would not be expected to appreciably contribute to the cumulative impacts on water quality." Comment To build on previous comments and concerns expressed in this letter the potential impacts to water quality are seemingly summarily dismissed without substantiation. In the above paragraph not only are concerns raised about the impacts to water quality from corrosion but also the typing of chemicals that are used in coatings which may themselves be comprised of materials that could leach into the waterbody and affect the water quality and supported marine life. It does not appear that there is meaningful and comprehensive evaluation of all potential contamination that could contribute to impairing the water body to arrive at the conclusion below especially when considering not just this project but all planned and future offshore wind projects. Suggestions of no impact are not an acceptable substitute to definitive research on this topic which again should also analyze not just this project and the other planned projects but also any synergistic effects of how these chemicals interact in the waterbody bioaccumulating factors and mitigation measures to minimize any impacts to the ecosystem.	
BOEM-2024-0001-0313-0046	Affected Environment and Environmental Consequences 3.5.2-15The PEIS states "Discharges/intakes: Increase in discharge and intake would be expected due to an increase in vessel activity within the NY Bight area waters and ports. Permitted offshore discharges would include uncontaminated bilge water ballast grey water and treated liquid wastes. It is generally expected that maritime activity including offshore development recreation and shipping would increase in the foreseeable future. Water intake can occur through planned activities such as cooling systems for power plants or other energy sources which is the case for the Sunrise Wind Farm (Woods Hole Group 2021; Middleton and Barnhart 2022). Intake of smaller volumes can also occur with some cable trenching methods. This water intake increases the likelihood of entrainment and impingement of planktonic organisms (Barnthouse 2013; Heimbuch 2007). Intake and physical contact with a barrier (screen) due to high	CWA Section 316(b) requires NPDES permits to ensure that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available to minimize adverse environmental impacts. Please see Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative, Discharges/Intakes,* which discusses the minimal impacts of the open loop cooling system. The project-specific COP-level NEPA analysis will also provide greater details.

Comment No.	Comment	Response
	intake velocity can negatively impact larval benthic invertebrates and larval fish (Barnthouse 2013; Heimbuch 2007). Benthic larvae and other planktonic organisms would experience unavoidable mortality within a small range of the activity. " Comment DER disagrees with the characterization of this activity and impact as small in general given the scope scale and magnitude of the proposed action and cumulative impacts there is relatively little if anything about this project that should be considered small. Further any unavoidable mortality should be quantified with a commensurate impact to water quality as previously discussed as well as environmental impacts to the trophic levels and subsequent environmental impact to the ecosystem as a result of the proposed action.	
BOEM-2024-0001-0313-0056	Again DER would also like to reiterate the necessity for extending the water quality geographic boundary to include this area and sphere of potential impact influence in the PEIS analysis. Are other planned developments utilizing these same disposal sites what is the cumulative impact and amount of sediment planned for disposal?	Since the exact locations and activities for each project are not known at this programmatic stage, the project-specific, COP-level NEPA analysis will include proposed disposal sites for each NY Bight lease area if the project is proposing sediment disposal.
BOEM-2024-0001-0331-0009	"Few studies have been done to understand hydrodynamics around wind energy turbines and those that exist focus on European offshore wind farms in the North Sea where conditions are different from Nantucket Shoals. Large turbines of the size planned for the Nantucket Shoals region have not been built yet in U.S. waters. Researchers have tried to model the hydrodynamic impacts of turbines but their results don't always agree with each other. There's a need for more work to compare different types of models with each other and with actual observations in the ocean to make sure that they represent key processes like tides stratification turbulence and drag correctly. The most accurate outputs will likely come from using a range of models. Oceanographers might start with models that predict what happens as water moves past a single turbine. These results then would inform models that predict the effects of an entire wind farm. Then results from wind farm- scale models would be incorporated into models that predict regional ocean circulation.	Please see Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative, Presence of structures* for the discussion on hydrodynamics. The project-specific COP-level NEPA analysis will provide further details specific to the NY Bight lease areas.
BOEM-2024-0001-0331-0038	The PEIS ignores the Deoxygenation Potential of Offshore Wind Areas. Offshore wind projects have the potential to increase sediment carbon in deeper areas of the ocean due to reduced	Thank you for your comment. Caution should be taken in extrapolating study outcomes from European wind farms to expected results in the NY Bight, as the environmental conditions

Comment No.	Comment	Response
	current velocities and negatively impact decreased dissolved oxygen within areas that currently have low oxygen concentration. In European wind farm areas there is evidence that ongoing offshore wind farm developments can have a substantial impact on the structuring of coastal marine ecosystems on basin scales. Recently Floeter et al. (Floeter J. et al. Pelagic effects of offshore wind farm foundations in the strati!ed North Sea. Prog. Oceanogr. 156 154173 (2017). provided empirical evidence for the existence of these upwelling/down-welling dipoles showing distinct structural changes in mixed layer depth and potential energy anomaly inside the wind wake area of OWFs in the summer stratified area of the southern North Sea. (Floeter J. et al. Pelagic effects of offshore wind farm foundations in the stratified North Sea. Prog. Oceanogr. 156 154173 2017) including ? An increase in sediment carbon due to the reduced velocities in the water columns and? An Increase in dissolved oxygen in the pelagic and benthic region. A first assessment of the large-scale integrated impact of atmospheric wakes from already existing OWFs on the hydrography of the southern North Sea revealed the emergence of large-scale oceanic structures with respect to currents sea surface elevation and stratification. Daewal et al. (2022) (Offshore wind farms are projected to impact primary production and bottom water deoxygenation in the North Sea. Ute Daewel et al. 2022. 3:292. https://doi.org/10.1038/s43247-022-006250 www.nature.com/commsenv studied the impacts of primary production and bottom water deoxygenation in the North Sea. The researchers examined modifications in mixing and stratification in relation to impacts with nutrient availability in the euphotic zone. Their concerns examined the ecosystem impacts for some obvious reasons: (i) Changes in nutrient concentration would start a cause-effect chain that translates into changes in primary production and effectively alters the food chain; (ii) In a dynamic system like the southern North Sea which is characterized by strong tidal and residual currents changes in the biotic and abiotic environment are exposed to advective processes; (iii) The expected changes depend strongly on the prevailing hydrodynamic conditions which makes it	are not equal. European wind farm facilities differ as they are in shallower waters with weak seasonal stratification, in sheltered areas along the coasts, and are arranged with tight spacing of turbines (Lentz 2017; Hogan et al. 2023). Please see Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative, Presence of structures*, which discusses hydrodynamics, including atmospheric wakes and the Mid-Atlantic Bight Cold Pool.

Comment No.	Comment	Response
	difficult to disentangle natural from inflicted changes. Other than a high-density suite of physical and biological observations numerical modeling studies are the only means to build BACI studies as scenarios with and without the disturbance can be simulated.	
BOEM-2024-0001-0331-0040	The PEIS Incorrectly Dismisses Impact to Cold Pool The PEIS dismisses as an alternative to minimize an important factor impacting marine habitats and migratory patterns on the midAtlantic shelf called the “Cold Pool”. This seasonal thermocline is one of the largest of its kind in the global ocean and extends from Nantucket to Cape Hatteras. Wind turbines have been shown to impact the mixing of ocean water both at the surface through their change in wind energy and at other levels through their physical structure. The PEIS on table 2-3 makes passing mention of the mid Atlantic cold pool but subsequently in the no action or the action alternatives does not present or any assessment of the impacts on it. This is a glaring omission the PEIS. The PEIS needs to provide a full assessment of the impact to the cold pool not just from this project but from all reasonably foreseeable actions including its own wind project approvals between the Hudson Shelf valley and Cape May NJ. Beyond that the impact on the Cold Pool both off the New Jersey coast and more broadly off the mid-Atlantic shelf from this project and in conjunction with the other foreseeable offshore wind projects must be carefully assessed. As mentioned in the July 22 2020 report of the Science Center for Marine Fisheries Management (a project funded by the National Science Foundation) in its critique of the BOEM Supplementary Environmental Impact Statement for the Vineyard Wind Project: “Too much attention cannot be given to the Cold Pool” and “The weakening of the Cold Pool supports the potential of generating the most catastrophic ecological event on the continental shelf the world has ever seen”. On page 3.4.2-13 of the PEIS BOEM states that offshore wind facilities could have impacts on the cold pool and admits that relatively few studies have analyzed the hydrodynamic wakes coupled with the interaction of atmospheric wakes with the sea surface. Further even fewer studies have analyzed wakes and their impact on regional scale and oceanographic process (cold pool). On page 3.5.2-29 BOEM states that few studies have evaluated the secondary impacts of atmospheric wakes the interaction with the	Thank you for your comment. Please see Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative, Presence of structures,* which discusses hydrodynamics, including atmospheric wakes and the Mid-Atlantic Bight Cold Pool. Additional text was added in the hydrodynamics discussion.

Comment No.	Comment	Response
	sea surface and the regional changes of oceanographic patterns (cold pool) and primary productivity. On page 3.5.6-49 BOEM states that changes in the cold pool dynamics resulting from future activities should they occur could conceivably result in changes in habitat suitability and fish community structure but the extend and significance of these potential effects are unknown. The potential impact of cumulative impact of the Atlantic Coast offshore wind projects including the New York Bight on the Cold Pool should be clearly understood before this or any new projects are permitted.	
BOEM-2024-0001-0331-0041	The PEIS Does Not Adequately Address the Potential Impact of Offshore Wind Projects on Freshwater Aquifer Shoreline Sinking and Potential Catastrophic Offshore Landslides. A Rutgers study on the impact of climate change (New Jersey's Rising Seas and Changing Coastal Storms: Report of the 2019 Science and Technical Advisory Panel Kopp et al 2019) identifies two major components to rising sea levels at the NJ shore global warming and the sinking shoreline. Contributors to the sinking shoreline include "glacial isostatic adjustment" (GIA) which is tied to the fresh water aquifers that underlie the continental shelf and sediment compaction which is due to increasing weight on the developed land. Another study shows the connection between the onshore aquifers and the huge deep freshwater aquifer that extends out to the edge of the continental shelf (Aquifer Systems Far Offshore on the US Atlantic Margin Gustafson et al Scientific Reports 9 article 8709 2019).	Thank you for your comment. The project-specific, COP-level NEPA analysis will provide further details.
BOEM-2024-0001-0331-0042	And a study (Overpressure and Fluid Flow in the New Jersey Continental Slope: Implications for Slope Failure and Cold Seeps authored by Dugan and Flemings and published by in Science July 14 2000) documents the instability in the NJ seabed above the deep aquifer. That study was reported in Science News July 25 2000 under the title Trapped Water Could be a Cause for Underwater Landslides Tidal Waves. The PEIS on page 3.4.2-7 states that "groundwater reservoirs underlie areas where onshore project activities could occur. Some of these reservoirs provide water supplies to communities including USEPA-designated sole source aquifers which are aquifers that supply at least 50-percent of the drinking water for an area with no other sources available if the aquifer is contaminated. Sole-source aquifers that overlap areas where	Thank you for your comment. The project-specific, COP-level NEPA analysis will provide further details specific to the NY Bight lease areas. Through AMMM measures WQ-1 and WQ-2, accidental releases are anticipated to be reduced or minimized. Please see Section 3.4.2.5.1, *Impacts of One Project,* for a discussion of accidental releases and the potential impacts of the AMMM measures mentioned above. Empire Wind (OCS-0512) is the only ongoing offshore wind project in the offshore geographic analysis area.

Comment No.	Comment	Response
	onshore project activities may occur include the New Jersey Coastal Plains aquifer system Kings/Queens Counties (Brooklyn- Queens) aquifer system and the Nassau/Suffolk Counties Long Island aquifer system. On page 3.4.2-18 BOEM states that impacts from accidental releases on water quality would result in negligible and temporary impact on surface and groundwater quality including sole source aquifers." Therefore the PEIS does not adequately address this very significant issue. BOEM in other EIS documents has stated that "Very few studies have examined the effects of substrate vibration from pile driving yet many have acknowledged that is a field of urgently needed research". Nor has there been a programmatic analysis done of the multiple projects planned off the northeast Atlantic coast to evaluate the combined potential impact on the unstable ocean floor from these massive industrial developments.	
BOEM-2024-0001-0331-0043	Atlantic Coast projects contemplate 1800+ massive 900-1300 ft tall turbines as close as 9 miles to the NJ shore which will likely have monopole bases that are each 15 meters in diameter and each weigh 2500 tons (5 million pounds). They will be pile driven up to 242 feet into the seabed with repeated hammer strokes each up to 4400 kilojoules. And these giant turbines will generate significant continuous low frequency operating vibrations that will be transmitted into the ocean floor for their entire multi - decade operating life. The public needs assurance that these massive projects will not impact our fresh water aquifers that they will not exacerbate the current sinking of the NJ shore line related to the changing pressure dynamics of the underground aquifers and that they will not trigger underwater landslides in the unstable continental shelf. Therefore this subject requires much more analysis in the PEIS and future EIS documents.	Please see the Land Disturbance discussion in Section 3.4.2.4.1, *Impacts of One Project*. The project-specific, COP-level NEPA analysis will provide further details specific to the NY Bight lease areas. Proper erosion and sedimentation controls would be maintained to prevent soil destabilization and water quality impacts during construction, protecting groundwater resources, including sole source aquifers, and minimizing land disturbance near shorelines through the use of HDD at landfall sites.
BOEM-2024-0001-0332-0012	Discharges/Intakes With regards to discharges/intakes (3.5.2-24) routine vessel discharges even within USCG regulations brings a hot topic of invasive species to the forefront. OSSs with open loop cooling systems must be prohibited due to thermal plume warming waters and loss of fish larvae. This could hurt recruitment and jeopardize the sustainability of some fisheries. The NYB the waters and substrate necessary for spawning feeding and growth to maturity. In New Jersey PSEG continues to pay compensatory	Section 3.5.5, *Finfish, Invertebrates, and EFH,* and Section 3.5.2, *Benthic Resources,* provide analysis of entrainment and impingement. Section 316(b) of the CWA requires NPDES permits to ensure that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available to minimize adverse environmental impact from impingement and entrainment of aquatic organisms. If a project

Comment No.	Comment	Response
	mitigation for the fish eggs/larvae entrained/impinged through the open loop cooling system at the Salem nuke plant. That money goes towards a host of programs that seek to offset the impact of that mortality. Given the fact that we know many important species fluke and BFT being just two spawn in those waters or where their larvae are present in waters where AC/DC substations would be needed BOEM must calculate mortality and execute an agreement to outline a plan to mitigate the impact. A mitigation fund must be set up prior to construction with payments into the fund based on the economic cost associated with their entrainment/impingement. Cold Pool Disruption. The NYB's unique cold bottom waters support our diverse fisheries and must be protected. The use of "few studies" and "fewer studies" in Section 3.4.2-13 screams stop and get the scientific work done before proceeding. "The new presence of structures and their impact on regional scale oceanographic processes and potential secondary changes to primary production and ecosystems is extremely important. Structures may reduce wind-forced mixing of surface waters whereas water flowing around the foundations may increase vertical mixing." "There has been extensive research into characterizing and modeling atmospheric wakes created by wind turbines in order to design the layout of wind facilities." Obviously their investment depends on it. Why isn't this same attention and resources dedicated to hydrodynamics?	is proposing open loop systems, the project-specific COP-level NEPA analysis can be expanded and mitigation proposed. Section 3.5.5, *Finfish, Invertebrates, and EFH,* and Section 3.5.2, *Benthic Resources,* provide analysis of hydrodynamic effects and the Mid-Atlantic Bight Cold Pool.
BOEM-2024-0001-0334-0003	Though your reviewers are adept at identifying numerous issues with the construction of offshore wind projects there are no tough stances to ensure that these issues are indeed mitigated. The result appears to be the overlooking of potential dangers. In your past two New Jersey EIS efforts the documents contain numerous MAJOR category impacts. Ocean Wind 1 FEIS contains 770 instances of the word "MAJOR" and Atlantic Shores 1 contains 366 instances. Spot-checking these instances in the PDF view reveals that most are material references to important impacts not just incidental use of the word "major. SEE ORIGINAL COMMENT FOR IMAGES OF Filed Drive of Ocean Wind 1 Offshore Wind Farm Final Environmental Impact Statement May 2023 BOEM has ignored the risks associated with the fluids and chemicals/gases (SF6) contained in offshore installations. The infographic below calculates all of the industrial	Thank you for your comment. Through AMMM measures WQ-1 and WQ-2, accidental releases are anticipated to be reduced or minimized. Please see Section 3.4.2.5.1, *Impacts of One Project*. Sulfur hexafluoride is a gas, poorly soluble in water, and used in WTG switchgears in small quantities (approximately 3 kg). If there is a leak, it is more likely to affect air quality than water quality.

Comment No.	Comment	Response
	fluids in the current U.S. offshore plans. Prior estimates for just the New Jersey 7500MW plan and 1100MW plan are 25 million gallons/2.5 million pounds of SF6 and 35 million gallons/5 million pounds of SF6 respectively. Creating such a risk which could become a nightmare on the East Coast in catastrophic storms or acts of war should be avoided. Relatedly the plans that would be implemented in the case of catastrophic spills are classified and therefore cannot be judged by the public. The public should know the completeness of the cleanup plans. SEE ORIGINAL COMMENT FOR The U.S. Plan for 86Gw of Off Shore Wind SEE ORIGINAL COMMENT FOR TABLE: Hazardous Material Risks with U.S. 2050 Offshore Wind Industrialization	
BOEM-2024-0001-0334-0006	Wrecking of marine habitat through increasing water temperature: We expect all further analyses to model increases in water temperature due to the blocking of normal water churning by the undersea installations. Furthermore for the farms further out we understand that the HVDC cooling installations will intake 8 million gallons a day of cool seawater and output that water at temperatures exceeding 90F. The creatures living in the vicinity of these installations will not survive these temperature increases. The ripple effect on the chain of life will be devastating. These behaviors contradict the assertion that offshore wind helps global climate issues. In fact it appears that they will gravely exacerbate problems. SEE ORIGINAL COMMENT FOR IMAGE: Bringing Renewable Energy to About 1.2 Million Homes and Supporting the UK Governments Strategy to Meet New Zero Greenhouse Emissions by 2050	Please see Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative, Presence of structures* for the discussion of hydrodynamics and discharges/intake for the HVDC cooling water intake.
BOEM-2024-0001-0334-0007	Poisoning of the fish in the vicinity: You do not forbid the use of sacrificial anodes as a method of protecting the undersea steel structures. So the builders will use them as the cheapest solution. We aren't supposed to use hot water from hot water tank heaters in our homes for cooking due to the sacrificial anodes contained within as they leach heavy metals into the water making it unsafe to consume. Sacrificial anodes have been used on oil rigs and boats for a long time. There has already been sensing of the heavy metal content in the North Sea from sacrificial anodes. Now New Jersey the East Coast and all of the coastal US have plans to fill the near-shore	Please see Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative, Presence of structures* for discussion on the sacrificial anodes. Additional text has been added. Please see Section 3.4.2.5, *Impacts of Alternative C (Proposed Action) – Identification of AMMM Measures at the Programmatic Stage,* for further information on WQ-1, which requires lessees to avoid using zinc sacrificial anodes.

Comment No.	Comment	Response
	waters with an explosion of structures likely using sacrificial anodes - significantly increasing the concentration of leached heavy metals.	
BOEM-2024-0001-0355-0018	My main concerns are: Contamination of our state's water resources. What are the components of the cables and their sheathing composed of and will there be a chance for any contamination of materials from these cables and sheathing or digging the trenches into our water supply?	Thank you for your comment. This will be included in the project-specific, COP-level NEPA analysis.
BOEM-2024-0001-0355-0048	The HVDC high voltage direct current converter station with required environmental containment walls is still a gamble on the Kirkwood-Cohansey aquifer which in case of a catastrophic accident could affect the drinking water in a high percentage of Jersey and all the home values along the 12.5-mile route of the cables. Once this large aquifer is compromised it will be a disaster for the State of New Jersey.	Thank you for your comment.
BOEM-2024-0001-0357-0056	Enclosure VI The Cold Pool Cumulative Impact An important factor impacting marine habitats and migratory patterns on the mid-Atlantic shelf is the "Cold Pool". This seasonal thermocline is one of the largest of its kind in the global ocean and extends from Nantucket to Cape Hatteras. Wind turbines have been shown to impact the mixing of ocean water both at the surface through their change in wind energy and at other levels through their physical structure. The Atlantic Shores draft EIS on page 3.5.54 makes passing mention of the mid Atlantic cold pool but subsequently in the no action or the action alternatives does not present or any assessment of the impacts on it. This is a glaring omission the DEIS. The Call pool with the impacted by all the projects off New Jersey and New York. Therefore this program EIS needs to provide a full assessment of the impact to the cold pool not just from this project but from all reasonably foreseeable actions including its own wind project approvals between the Hudson Shelf valley and Cape May NJ. Beyond that the impact on the Cold Pool both off the New Jersey coast and more broadly off the mid-Atlantic shelf from this project and in conjunction with the other foreseeable offshore wind projects must be carefully assessed. As mentioned in the July 22 2020 report of the Science Center for Marine Fisheries Management (a project funded by the National Science Foundation) in its critique of the BOEM Supplementary Environmental Impact Statement for the	Please see Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative, Presence of structures* for the discussion on hydrodynamics, including the Mid-Atlantic Bight Cold Pool.

	Vineyard Wind Project: "Too much attention cannot be given to the Cold Pool" and "The weakening of the Cold Pool supports the potential of generating the most catastrophic ecological event on the continental shelf the world has ever seen". The potential impact of this and other such wind projects on the Cold Pool should be clearly understood before this or any new projects are permitted.	
BOEM-2024-0001-0362-0021	BOEM should detail information related to air and water quality impacts in the region associated with potential manufacturing port activities construction and ongoing operations and maintenance.	Section 3.4.2.3.2 provides an assessment of the impacts on water quality from port utilization and possible port improvements. Port improvement projects are described in Appendix D, Section D.2.5. If the individual projects include other port improvement components, the project-specific COP-level NEPA analysis will provide further details.
BOEM-2024-0001-0469-0012	The seafloor is an important reserve for natural carbon storage known as "blue carbon" in coastal and marine environments. NOAA's early research in Marine Protected Areas ("MPA") show the critical role this environment plays in sequestering carbon though fewer studies have been conducted in non-MPAs. [Footnote 32: Sara Hutto et al Mud Matters: Understanding the Role of Ocean Sediment in Carbon Sequestration OPEN COMMC'NS FOR THE OCEAN (Feb. 13 2024) https://octogroup.org/mud-matters-understanding-the-role-of-ocean- sediments-in-storing-carbon/] Industrial development that disturbs the seafloor can displace the stored carbon which can then remineralize into aqueous carbon dioxide in the ocean. [Footnote 33: Id.; Knut Heinatz & Maike Scheffold A First Estimate of Offshore Wind Farms on Sedimentary Organic Carbon Stocks in the Southern North Sea 9 FRONTIERS IN MARINE SCI. (Jan. 16 2023) https://doi.org/10.3389/fmars.2022.1068967] Although the Draft PEIS highlights that climate change threatens the ocean's function as a carbon sink it does not compare the risk of carbon resuspension from seafloor disturbance especially accounting for BOEM's earlier projection that OSW projects in the United States are unlikely to significantly affect the global climate on their own. [Footnote 34: NEW YORK BIGHT DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT supra note 5; BUREAU OF OCEAN ENERGY MGMT. VINEYARD WIND OFFSHORE WIND FARM FINAL ENVIRONMENTAL IMPACT STATEMENT vol. 2 at A-51 (March 2021)	The project-specific COP-level NEPA analysis will provide further details on sediment resuspension specific to the NY Bight lease areas.

BOEM-2024-0001-0469-0015	Oceanographic Conditions The Mid-Atlantic cold pool is a seasonal temperature and nutrient stratification cycle that allows cold-water creatures to thrive in the North Atlantic. It results in cold water remaining trapped just above the seafloor so animals that prefer colder climates can remain further south than they otherwise would especially shellfish and the organisms that depend on them. [Footnote 44: See Travis Miles et al Could federal wind farms influence continental shelf oceanography and alter associated ecological processes? A literature review SCI. CTR. FOR MARINE FISHERIES & RUTGERS SCH. ENV'T & BIOLOGICAL SCIS. at 2-3 (Dec. 2020) https://scemfis.org/wp-content/uploads/2021/01/ColdPoolReview.pdf] In the Mid-Atlantic Bight ("MAB") "over 2 million acres of the continental shelf have been leased for offshore wind energy projects that are under development including sites that overlap with the seasonal Cold Pool". [Footnote 45: Rebecca Horowitz et al Overlap Between the Mid-Atlantic bight Cold Pool and Offshore Wind Lease Areas ICES J. MARINE SCIS. at 1 (2023) https://academic.oup.com/icesjms/advance-article/doi/10.1093/icesjms/fsad190/7462579]Many OSW studies were conducted in the North Sea because Europe already has industrial OSW installations to study. [Footnote 46: Miles et al supra note 45 at 1.] However the North Sea's cold pool is not as stratified as the Mid-Atlantic Cold Pool so the results are more representative of OSW impacts when the Cold Pool is not as stratified such as in the spring and fall. [Footnote 47: Id.] Additionally "many European lease areas use smaller capacity turbines with different spacing further adding to uncertainty about how relevant prior research is to MAB conditions". [Footnote 48: Horowitz et al supra note 46 at 2.]OSW installations could potentially change the patterns of the Cold Pool due to the structures themselves and the extraction of wind changing the naturally occurring current. [Footnote 49: Miles et al supra note 45 at 10.] "Turbines can disturb downwind wind fields by decreasing wind speed and increasing turbulence". [Footnote 50: L. Bennun et al supra note 42.] This is known as the "wind wake effect"	Thank you for your comment. Please see Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative, Presence of structures,* which discusses hydrodynamics, including atmospheric wakes and the Mid-Atlantic Bight Cold Pool.

Comment No.	Comment	Response
	and it can cause both upwelling and downwelling changing the distribution of temperature and nutrients "potentially affecting an area 10-20 times larger than the wind farm itself with possible knock-on ecosystem effects." [Footnote 51: Id.; see also Ute Daewel et al Offshore wind farms are projected to impact primary production and bottom water deoxygenation in the North Sea 3 COMMS. EARTH & ENV'T (Nov. 24 2022) https://doi.org/10.1038/s43247-022- 00625-0 (Wind wake effects can increase or decrease zooplankton productivity by up to 10%)]Moreover it is unclear if the research conducted to date fully assessed and evaluated the impacts of the high-temperature discharge from the many once-through cooling systems (discussed in Section V) planned not only for the six New York Bight lease areas but for other projects in the area. As COA outlined in our comments on the Notice of Intent to Prepare the Draft PEIS the sea surface microlayer contains distinct microbial habitats and is central to a range of global biogeochemical and climate-related processes. [Footnote 52: Oliver Wurl et al Sea Surface Microlayer in a Changing Ocean A Perspective ELEMENTA: SCI. OF THE ANTHROPOCENE (2017) https://doi.org/10.1525/elementa.228] BOEM acknowledged receiving COA's concerns about potential effects of offshore wind on the sea surface microlayer in COA's comments on the Notice of Intent to prepare the Draft PEIS. However BOEM did not provide a response to COA's comment discuss the role of the microlayer analyze the sea surface microlayer or provide a reason why they would not do so nor how the microlayer will be assessed and protected. [Footnote 53: NEW YORK BIGHT DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT supra note 5 appx. O at O-46.]The Cold Pool is an essential phenomenon for the survival of the Mid Atlantic ecosystem. The PEIS must not be finalized without a multi-year assessment study of the Cold Pool with independent scientific assessment.	
BOEM-2024-0001-0469-0016	Once-Through Cooling There is no detailed research on the projected impacts of once-through cooling systems in the six New York Bight OSW lease areas as those impacts will be evaluated during the COP NEPA review according to BOEM staff. Projects in the six Draft PEIS lease areas will likely use once- through cooling systems as it is	Thank you for your comment. CWA Section 316(b) requires NPDES permits to ensure that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available to minimize adverse environmental impacts.

Comment No.	Comment	Response
	currently the only economically feasible method of cooling HVDC systems. [Footnote 54: BUREAU OF OCEAN ENERGY MGMT. SUPPORTING NATIONAL ENVIRONMENTAL POLICY ACT DOCUMENTATION FOR OFFSHORE WIND ENERGY DEVELOPMENT RELATED TO HIGH VOLTAGE DIRECT CURRENT COOLING SYSTEMS 5 (Apr. 2022) https://www.boem.gov/sites/default/files/documents/renewable-energy/state-activities/HVDC%20Cooling%20Systems%20White%20Paper.pdf] AC power does not travel well via undersea cables further than thirty miles offshore so projects sited further from shore must convert AC to DC through an HVDC substation which requires a cooling system and produces higher electromagnetic fields which could affect electrosensitive species. [Footnote 55: Id. at 1.] The once-through cooling process involves pumping in cool ocean water; filtering small particles sand and other elements smaller than 500 microns; impinging and entraining organisms within said water; adding biocides such as sodium hypochlorite to prevent growth in the system at 10-200 parts per million; and discharging heated treated water back into the ocean. [Footnote 56: Id. at 2.]Generally without citing to any specific source BOEM writes: "The warm water discharged is generally considered to have a minimal effect as it will be absorbed by the surrounding water and returned to ambient temperatures. Entrainment of potential prey resources would be minimal given the small number of [offshore substations] proposed per project. Entrainment of marine mammals that may depredate on entrained prey is discounted due to physical impedance by intake safety screens." [Footnote 57: NEW YORK BIGHT DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT supra note 5 at 3.5.6-29.]COA opposes the use of once-through cooling systems in all industries as they have significant adverse impacts on marine ecosystems. [Footnote 58: CLEAN OCEAN ACTION POSITION PAPER ON OYSTER CREEK NUCLEAR GENERATION STATION'S COOLING WATER SYSTEM (2010) (on file with COA).] Studies conducted on once-through cooling system discharges from other power plants have shown that these discharges are several degrees warmer than surface temperature of the receiving waterbody(ies) and are	The project-specific COP-level NEPA analysis will provide further details.

Comment No.	Comment	Response
	detrimental to marine communities and fish populations. Coastal power plants with once through cooling systems have been found to entrain and impinge millions of fish and larvae within the space of two years. [Footnote 59: URS CORP. NORMANDEAU ASSOCIATES INC. CHARACTERIZATION OF THE AQUATIC RESOURCES AND IMPINGEMENT AND ENTRAINMENT AT OYSTER CREEK NUCLEAR GENERATING STATION Tables 6-9 (Sept. 2008);] Once-through cooling systems significantly change the bacterioplankton community. [Footnote 60: Meora Rajeev et al Thermal discharge-induced seawater warming alters richness community composition and interactions of bacterioplankton assemblages in a coastal ecosystem SCI. REPORTS (Aug. 30 2021) https://www.nature.com/articles/s41598-021-96969-2; Jebarathnam Prince Prakash Jebakumar et al Impact of a Coastal Power Plant Cooling System on Planktonic Diversity of a Polluted Creek System 133 MARINE POLLUTION BULLETIN 378 (Aug. 2018) https://doi.org/10.1016/j.marpolbul.2018.05.053] In one study phytoplankton population density decreased by 64% zooplankton density decreased by 93% and loss of fish larvae impacted local fisheries. [Footnote 61: Jebarathnam Prince Prakash Jebakumar et al supra note 60.] Species that prefer warmer water such as sea turtles may be attracted to the warm water surrounding the outflow area which can change the composition of the marine community. Marine life that become habituated to the warmer temperature can be killed from thermal shock in the event of a planned or emergency shutdown of the cooling system. [Footnote 62: See Oyster Creek Nuclear Generating Station Fish Kill Monitoring Report (January 2000) NRC ML#003684420; Oyster Creek 2001 Annual Environmental Operating Report (February 2002) NRC ML#020660222; A. Cradic Oyster Creek Generating Station fined for water violations and fish kills: DEP seeks compensation for Natural Resources Damages New Jersey Department of Environmental Protection news release (December 12 2002) available for viewing at http://www.state.nj.us/dep/newsrel/releases/02_0131.htm] There has never been a study in the North Atlantic offshore environment to determine what species would be impacted by once-through cooling systems through impingement or entrainment; such a study should	

Comment No.	Comment	Response
	be conducted before large-scale once-through cooling systems are built in the New York Bight lease areas. According to the PEIS specific cooling systems will be chosen and evaluated during the individual environmental review of each project's COP and other agencies are responsible for ensuring compliance with pollution discharge requirements including thermal pollution. [Footnote 63: NEW YORK BIGHT DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT supra note 5 at 3.1-2.] However this is not possible until a thorough study of the impacts of once-through cooling systems is conducted. Then with NMFS BOEM needs to incorporate more parameters related to once- through cooling in the project design envelope such as ranges for the amount of water that would be pumped through amount of biocides that would be discharged and effects on local water temperature. Additionally BOEM must reconsider its characterization of once-through cooling as having minor impacts especially as there is no scientific basis for this determination.	
BOEM-2024-0001-0474-0005	Among other reasons the action is Arbitrary because the proposed action fails to properly consider that the offshore wind projects and development of leasehold interests impair the integrity of the ocean to the detriment of citizen stakeholders and the public. 	substations in our cold bight area that are going to be constantly pumping out 90-degree water to increase the surface temperature. Has anybody considered how important the New York Bight cold bight is to global warming and what it does to cool down the Gulf Stream before it reaches the Arctic Circle.?	discusses hydrodynamics, including the Mid-Atlantic Bight Cold Pool. A discussion of the potential impacts of cooling system discharge and intake on finfish, invertebrates, and EFH is provided in Section 3.5.5.3.3. CWA Section 316(b) requires NPDES permits to ensure that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available to minimize adverse environmental impacts. The project-specific COP-level NEPA analysis will provide further details.
BOEM-2024-0001-0528r	We know from studies of existing wind farms that both increases and decreases in phytoplankton and other plankton productivity are observed around wind turbines, essentially cancelling each other out over the whole region. But opponents of offshore wind often cite the 2022 paper by Daewal and colleagues in the North Sea of Europe as reason for concern, but conveniently ignore their finding of a 12% increase in zooplankton biomass in the presence of wind turbines. The PEIS itself cites a 2020 paper by Dannheim and colleagues which found increased primary productivity at local scales around wind turbines.	Thank you for your comment. Potential impacts from offshore wind activities on primary productivity are discussed in Section 3.5.2.4. Caution should be taken in extrapolating study outcomes from European wind farms to expected results in the NY Bight, as the environmental conditions are not equal. European wind farm facilities are in shallower waters with weak seasonal stratification, are in sheltered areas along the coasts, and are arranged with tight spacing of turbines (Lentz 2017; Hogan et al. 2023). Please also see Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative; Presence of Structures*, which discusses hydrodynamic impacts in greater detail.
BOEM-2024-0001-0528z	Placement of converter stations and the use of cooling systems like the open loop cooling system mentioned on page 59, volume one of the PEIS. The cumulative impacts of these cooling systems are extremely concerning, especially if they're anything like those mentioned in sunrise wind documents which take in cool ocean water to dissipate heat produced through the A/C to D/C conversion of electricity. Each offshore cooling system will discharge up to 8,100,000 gallons of seawater daily with chlorine residuals and the temperature report per document is between 86 to 90°F per day. What happens to all the fish, larvae, phytoplankton, zoo plankton, and necessary microorganisms that end up in this wash cycle with bleaching chlorine?	Additional analysis has been added to Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative; Discharges/Intakes,* to further describe the warm water discharges. A discussion of the potential impacts of cooling system discharge and intake on finfish, invertebrates, and EFH is provided in Section 3.5.5.3.3. CWA Section 316(b) requires NPDES permits to ensure that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available to minimize adverse environmental impacts. The project-specific COP level NEPA analysis will provide further details.
BOEM-2024-0001-0528z	Before proceeding with mass construction in Hudson Canyon, home of the unique marine environment with a cold pool, BOEM should	Thank you for your comment. Hudson Canyon is outside of the six NY Bight lease areas. However, as part of the subsequent COP

Comment No.	Comment	Response
	implement a pilot project, considering the studies on this cold pool were done in the North Sea, which is a different environment. Especially since the currents around the turbines are exactly what breaks down the cold pool.	NEPA analysis, BOEM plans to coordinate with the NOAA Office of National Marine Sanctuaries regarding the proposed designation of the Hudson Canyon National Marine Sanctuary. Please also see Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative; Presence of Structures*, which discusses hydrodynamics, including the Mid-Atlantic Bight Cold Pool. Further, BOEM considered but dismissed from further consideration an alternative to build a pilot project (PEIS Chapter 2, Table 2-3). Data from sites that are constructed and operating (e.g., Block Island), as well as the pilot project in Virginia, were incorporated into this PEIS and will be incorporated into the development of project specific COPs and EISs.
BOEM-2024-0001-0529k	At the same time there are, are at least 50 power transfer stations that will discharge billions of gallons of contaminated, superheated wastewater.	Additional analysis has been added to Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative; Discharges/Intakes,* to further describe the warm water discharges. CWA Section 316(b) requires NPDES permits to ensure that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available to minimize adverse environmental impacts. The project-specific COP-level NEPA analysis will provide further details.
BOEM-2024-0001-0529n	It is unclear how many of these sites will use once through cooling stations like those mentioned in sunrise wind documents, these cooling stations, taking cool ocean water to dissipate heat produced through the AC to DC conversion of electricity. Each offshore cooling station will discharge up to 8,100,000 gallons of sea water with chlorine residuals and the temperature per BOEM's document is between 86 to 90°F. What happens to all the fish, larvae, phytoplankton, zoo plankton, necessary microorganisms that end up in this wash cycle?	Additional analysis has been added to Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative; Discharges/Intakes,* to further describe the warm water discharges. BOEM-2024-0001-0310m	There's a handful of other things over the history here that I wanted to call out. BOEM, you're not that interested in the contents of what's in these turbines and what is in all of the substations. So for the 7500 megawatt plan, all of which you will be reviewing all the	Thank you for your comment. The NY Bight lessees will prepare project-specific Spill Prevention Control and Countermeasures and Oil Spill Response Plans prior to construction that are followed throughout the life of the project and monitor for and

Comment No.	Comment	Response
	individual plans for, there's 25 million gallons of industrial fluids in all of that construction that's sitting above the water just waiting for some destruction to dump it into the water. For the 1100 megawatt plan that goes up to 35 million gallons and this poster here shows what the U.S. plan for 86 gigawatts. Now, that would be BOEM managing all those all around the country. Right? And that's 117 million gallons of fluids, which if you total it up and compare it to things we're used to, that's 156 city water towers of fluids or 21 oil tankers worth of fluids sitting out there in the ocean waiting for some kind of pollution destruction. That's not too good for clean ocean. Right?	report any environmental releases or fish kills to the appropriate authorities or agencies. The Oil Spill Response Plans will need to meet USCG and BSEE requirements, which would provide for rapid spill response, cleanup, and other measures to minimize any potential impact on affected resources from spills and accidental releases, including spills resulting from catastrophic events. According to BOEM modeling (Bejarano et al. 2013), a release of 128,000 gallons (484,533 liters) is likely to occur no more often than once per 1,000 years, and a release of 2,000 gallons (7,571 liters) or less is likely to occur every 5 to 20 years. The probability of an accidental discharge or spill occurring simultaneously from multiple WTGs is extremely low.
BOEM-2024-0001-0310n	Factor this with an unknown number of substations and offshore cooling systems that will constantly be pumping chlorinated water at 90 degrees Farenheit, killing all phytoplankton and microorganisms that get sucked in.	Additional analysis has been added to Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative; Discharges/Intakes,* to further describe the warm water discharges. A discussion of the potential impacts of cooling system discharge and intake on finfish, invertebrates, and EFH is provided in Section 3.5.5.3.3. CWA Section 316(b) requires NPDES permits to ensure that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available to minimize adverse environmental impacts. The project-specific COP-level NEPA analysis will provide further details.
BOEM-2024-0001-0310o	Sites that are more than 30 nautical miles offshore that are running HVDC will require offshore cooling systems, which are mentioned in the PEIS. And if they're like those described in Sunrise Wind's documents it's truly concerning. These cooling systems take in cool ocean water to dissipate heat produced through the AC to DC conversion of electricity. Each offshore cooling system will discharge up to 8,100,000 gallons of seawater with chlorine residuals per day and the temperature per documents is between 86 to 90 degrees Farenheit. What happens to all the fish larvae, phytoplankton, zooplankton and other necessary microorganisms that end up in this warm bleach wash cycle?	Additional analysis has been added to Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative; Discharges/Intakes,* to further describe the warm water discharges. CWA Section 316(b) requires NPDES permits to ensure that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available to minimize adverse environmental impacts. The project-specific COP-level NEPA analysis will provide further details.

Comment No.	Comment	Response
BOEM-2024-0001-0529gg	One is in response to some of the folks who testified who are concerned about the open loop cooling systems. For instance, the one being utilized by Sunrise Wind. I think it would be important for the PEIS to juxtapose, the open loop cooling system from an offshore wind farm against power plants, fossil fuel-based power plants. So, for instance, in Northport on Long Island, where I live. They kill billions, with a "b", of finfish and fish larvae, juvenile fish, horseshoe crabs, crustaceans, and other marine species. So, all offshore, all energy infrastructure has an impact on our environment. We need to do a comparative analysis, so we choose the one with the least impact. And frankly, that's offshore wind.	Thank you for your comment. Since these projects are not related to the six NY Bight projects and site-specific details are not known at this time, we cannot make direct comparisons in this PEIS. However, we appreciate the commenter pointing this out in the public commenting process.
BOEM-2024-0001-0310t	What's been going on in the North Sea has been going on for quite some time now. So there are a lot of studies that are starting to come out on the effects of microclimate, on the effects of stratification, deoxygenation, sediment deposits. There's a lot of stuff coming out. Right? The research that we need, the data that we need to make more informed decisions with how we're going to approach renewable energy.	Thank you for your comment. Caution should be taken in extrapolating study outcomes from European wind farms to expected results in the NY Bight, as the environmental conditions are not equal. European wind farm facilities are in shallower waters with weak seasonal stratification, are in sheltered areas along the coasts, and are arranged with tight spacing of turbines (Lentz 2017; Hogan et al. 2023). Please see Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative; Presence of Structures*, which describes potential hydrodynamic impacts.
BOEM-2024-0001-0310h	So might I ask what is the point? In fact, the proposed cooling stations will mimic climate change and kill off fish larvae, zooplankton, microorganisms, et cetera, by taking in cool, clean ocean water at up to 8.1 million gallons per day and mixing it with chemicals, such as bleach and discharging it back into the ocean at 86 to 90 degrees Fahrenheit.	Additional analysis has been added to Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative; Discharges/Intakes,* to further describe the warm water discharges. A discussion of the potential impacts of cooling system discharge and intake on finfish, invertebrates, and EFH is provided in Section 3.5.5.3.3. CWA Section 316(b) requires NPDES permits to ensure that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available to minimize adverse environmental impacts. The project-specific COP-level NEPA analysis will provide further details.

P.5.5 Bats

Table P.5-5. Responses to Comments on Bats

Comment No.	Comment	Response
BOEM-2024-0001-0325-0001	Bat Conservation International (BCI) wishes to provide information in response to draft programmatic environmental impact statement (PEIS) to analyze the potential impacts of wind energy development in six lease areas of the New York (NY) Bight. BCI has actively worked with the Department of Energy and energy producers to find methods that minimize bat mortality at wind turbines. Bats experience high rates of mortality as a result of collisions with land-based wind turbines with hundreds of thousands of individuals killed a wind facilities across the United States and Canada (Hein and Schirmacher 2016). Bats have been consistently observed in offshore environments across the world (Solick and Newman 2021). The reasons for bats to be active offshore are poorly understood but it is likely that some species migrate over portions of the ocean between landmasses (Ahln et al. 2009 Brabant et al. 2020) and use coastlines as migratory corridors. Coastal islands with foraging and roosting habitat are used as stopover sites for some migratory species (Tenaza 1966 Cryan and Brown 2007 Peterson et al. 2014a). Considering the risk land-based wind energy poses to some bat populations and the documented activity of bats offshore it is reasonable to assume that offshore wind energy development can contribute to declines in bat populations. Additionally offshore wind energy development has been shown to provide foraging and roosting habitat (Willmott et al. 2023) for bats and consequently might attract bats increasing the risk of mortality from collision with offshore wind energy turbines.	BOEM acknowledges the presence of bats in the offshore environment, as documented in PEIS Section 3.5.1. BOEM used the best available information to describe bat presence in the offshore environment in the PEIS. Bat presence in the offshore environment is low and represents a very small percentage of total populations onshore. Therefore, BOEM does not anticipate population-level effects from offshore wind activities. Refer to responses to comments BOEM-2024-0001-0325-0002 and BOEM-2024-0001-0325-0003 for additional information on bat presence offshore versus onshore.
BOEM-2024-0001-0325-0002	Unfortunately we feel the draft PEIS misinterprets or overlooks important aspects of the available science and therefore minimizes the potential negative impact offshore wind energy in the NY Bight region may have on bat species. While the risk of offshore wind energy to bats is largely unknown the level of observed bat activity and impact of onshore wind turbines indicates that there should be greater concern about offshore wind turbine impacts to bat populations than is currently evaluated in the draft PEIS. The	BOEM acknowledges the temporal difference between the survey data presented in Johnson (2011) and the NJDEP Ecological Baseline Studies survey data collected in 2020 and 2021 in Lease Area OCS-A 0499, to which the Johnson (2011) data is compared. However, various sources clearly indicate that bat activity levels are generally lower in the offshore environment compared to onshore, as cited in PEIS Section 3.5.1.1 (see Hein et al. 2021, Brabant et al. 2021, Stantec 2020, Dominion Energy 2022, Atlantic

Comment No.	Comment	Response
	conclusion that risk to bats is low because offshore bat activity rates are less than Johnson 2011 is flawed. The sampling in Johnson 2011 occurred in 2007 and 2008 when the Appalachian range had a rich and abundant bat community not yet impacted by White-nose Syndrome. The high level of activity and migratory activity associated with the Appalachian range leads to some of the highest recorded levels of fatality in the United States sometimes greater than 100 bats per turbine (Kunz et al. 2007). The comparison of offshore bat activity to activity rates in the Appalachian mountains is flawed both spatially and temporally.	Shores 2022, and TetraTech 2022). In addition, the DOE funded an acoustic survey of bat activity offshore and at coastal sites (onshore mainland locations on and near the shoreline) in the New England Gulf of Maine, mid-Atlantic coast, and Great Lakes regions in 2012–2014. This was a very large survey effort across a wide area that detected a total of 565,158 bat passes during a total of 17,730 detector nights. The mean number of bat passes per night in offshore open water was 4.96, while the number of bat passes per night for coastal onshore was significantly higher at 112.6. This information has been added to PEIS Section 3.5.1 and is cited as Stantec 2016. BOEM used the best available information to describe bat presence in the offshore environment in PEIS Section 3.5.1. Bat presence in the offshore environment is low and represents a very small percentage of total populations onshore.
BOEM-2024-0001-0325-0003	Recent evidence shows activity levels are not drastically different onshore and offshore although offshore may be less distributed across time (i.e. more 'clumped'). Acoustic data from the Gulf of Maine and mid-Atlantic show levels of bat activity in the offshore environment are similar to those documented in open arid land in the United States with 2.57 passes/night at offshore locations in the Gulf of Maine and mid-Atlantic (Peterson et al. 2014b Peterson 2016) and average of 1.07 bat passes per detector night within the Coastal Virginia Offshore Wind Area (Tetra Tech Inc. 2022 Table O-2-2). For comparison activity rates in pre-construction onshore wind farm surveys averaged 1.89 bat passes per detector night with a range of 0.53 to 6.27 bat passes per detector night (Solick et al. 2020). Therefore the 6.2 bat passes per detector night in Lease Area OCS-A 0499 is on the high end of bat activity at wind energy facilities not low end of activity rates. Regional average bat fatalities range from 1.11-10.87 bats/MW capacity (AWWI 2020). Arid regions have an average of 1.99 (Pacific Southwest) and 6.01 (Southwest) bats/MW (AWWI 2020).	Open arid lands in the United States are outside of the bats' geographic analysis area defined in the PEIS and consist of an environment and habitats that are very different than the terrestrial area along the United States Atlantic coast. Refer to response to comment BOEM-2024-0001-0325-0002 regarding the comparison of bat presence in the offshore environment and onshore environment in the geographic analysis area. BOEM reviewed Appendix B in the AWWI (2020) study and acknowledges the low fatality numbers cited by the commenter for the arid regions of the United States. However, BOEM notes that the Northeast region shows 8.65 fatalities per MW onshore, which indicates a higher density of bats onshore in the Northeast.
BOEM-2024-0001-0325-0004	Eastern red bats are the most commonly detected and broadly distributed bat species off the coast of North America (Sjollema et al.	BOEM acknowledges the presence of eastern red bats in the offshore environment, as documented throughout PEIS Section

Comment No.	Comment	Response
	2014 Peterson 2016). Tracking data show they can travel vast distances over short periods of time with one individual documented flying 453 km in one night likely over the Atlantic Ocean between Long Island and New Jersey (Dowling et al. 2017). They were identified in 26 of 40 published visual records from the Atlantic and made up 89.8% of echolocation calls classified to species in acoustic surveys at structures off the Gulf of Maine and mid-Atlantic (Peterson 2016 Solick and Newman 2021). They are also broadly distributed occurring at 88% of offshore structures at 75% of which they were the primary species detected.(Solick and Newman 2021) This included a buoy located 18.8 km from shore where high levels of activity (8 passes/night) were recorded over a span of nine consecutive nights in August 2012 potentially illustrating a pulse of migratory activity or indicating that they used the buoy as a roost (Peterson 2016 Solick and Newman 2021). Aerial surveys conducted off the coasts of New Jersey Delaware and Virginia in September 2012 identified 11 easter red bats from 16.9 to 41.8 km from land and a vessel-based survey documented a sighting about 44 km off the coast of Delaware (Hatch et al. 2013). Studies at the Coastal Virginia Offshore Wind Pilot Project documented eastern red hoard and silver-haired bats in the project area about 44 km offshore including acoustic recordings and observations of bats roosting on vessels (Bureau of Ocean Energy Management 2022). Acoustic monitoring at the Atlantic Shores Offshore Wind area recorded five species or species groups (Myotis) with eastern red bats being the most frequently recorded (BOEM 2023). Given the broad distribution and relatively high levels of activity of eastern red bats in the offshore environment and the high rates of mortality experienced by the species at terrestrial wind farms it is likely that offshore wind energy infrastructure will pose a high level of risk level to the species.	3.5.1 using the same information and studies referenced in the comment. However, as described in Section 3.5.1, bat presence for all species in the offshore environment is low and represents a very small percentage of total populations onshore. Therefore, the risk level to the species is low for all IPFs addressed for the offshore environment.
BOEM-2024-0001-0325-0005	Hoary bats have been regularly observed on islands in the Atlantic including the Orkney Islands (Barrett-Hamilton 1910) Iceland (Hayman 1959) Southampton Island (Hitchcock 1943) Newfoundland (Maunder 1988) and Bermuda (Allen 1923 VanGelder and Wingate 1961) with most records occurring in the fall indicating that members of this species fly considerable distances across the ocean seasonally.	BOEM acknowledges the presence of hoary bats in the offshore environment, as documented in PEIS Section 3.5.1. Offshore surveys at the Block Island Wind Farm, Coastal Virginia Offshore Wind Pilot, and Lease Area OCS-A 0499 identified hoary bat presence. However, as described in PEIS Section 3.5.1, bat presence for all species in the offshore environment is low and

Comment No.	Comment	Response
	Acoustic surveys off the northeastern coast of the continent reveal low levels of activity (4% of recordings) but broad distributions with occurrences at 88% of offshore survey locations (Solick and Newman 2021). Studies at two project areas off the coast of the US documented hoary bat activity in offshore wind call areas (BOEM 2022 BOEM 2023). Hoary bats can fly at high elevations (Peurach 2003) and at times without echolocating (Corcoran and Weller 2018 Corcoran et al. 2021) potentially causing them to be under sampled by acoustic surveys (Solick and Newman 2021). Despite apparently low levels of activity in the offshore environment given their broad distribution and high rates of fatality at terrestrial wind turbines we determined that the threat of offshore wind energy infrastructure is high for this species. With current predictions of a potential 90% reduction of the species' population by 2061 (Frick et al. 2017a) any additional threats (such as offshore wind energy) could reduce hoary bats chances at survival. The hoary bat was added to the USFWS workplan for a species status assessment in 2027.	represents a very small percentage of total populations onshore. Therefore, the risk level to the species is low for all IPFs assessed for the offshore environment.
BOEM-2024-0001-0325-0007	Collisions with wind turbines are the leading cause of mortality for several bat species and are a primary contributor to the dramatic decline of at least one species of bat in North America (Frick et al. 2017b Friedenberg and Frick 2021). While the magnitude of effect that offshore wind infrastructure will have on bats is currently unclear precautionary measures should be put in place to minimize additional take of vulnerable bat species. While additional study is needed there are clear actions that can be taken as part of the PEIS.	BOEM acknowledges the presence of several bat species in the offshore environment in the geographic analysis area. Based on best available information— including literature, studies, and offshore bat surveys documented and described in PEIS Section 3.5.1—bat presence in the offshore environment is low and represents a very small percentage of total populations onshore. As such, BOEM anticipates the risk to bat species from offshore IPFs is low. However, though there is still some level of uncertainty regarding risk to bats offshore, the analysis in the PEIS is sufficient to support sound scientific judgments and informed decision-making related to bat distribution and use of the offshore environment as well as the potential for collision risk of bats (see PEIS Appendix E). Alternative C includes several bat AMMM measures that would result in learning more about bat presence in the offshore environment and bat interactions with offshore wind infrastructure. In addition, BOEM would consider additional or different AMMM measures for project-specific environmental analyses for a given NY Bight lease area for which a COP is submitted.

P.5.6 Benthic Resources

Table P.5-6. Responses to Comments on Benthic Resources

Comment No.	Comment	Response
BOEM-2024-0001-0089-0001	The NY EIS should be discarded as submitted. There are numerous instances where knowledge gaps exist that are dismissed as inconsequential to the project. Examples include gaps in knowledge of EMF emissions impacting benthic layers and the authors suggest that ongoing studies taking place at Block Island Wind Farm which has consistently operated at a fraction of its stated capacity or not at all should suffice as evidence that the project should forge ahead. This is IRRESPONSIBLE!	The PEIS uses the best available information and, therefore, complies with the procedural requirements of NEPA to predict potential impacts on benthic resources from expected development in the NY Bight lease areas. Although knowledge gaps exist, the available information is sufficient to support sound scientific judgments to inform decision-making for the projects, as discussed in the PEIS. Text regarding EMF emissions and potential impacts has been updated with the latest science. Models are most common in understanding EMF, and published studies rarely rely on measured EMFs. Measured cable EMFs are rare, especially for offshore wind projects. Block Island Wind Farm is used because there were actual measurements from those cables and the post-construction surveys show a thriving benthic ecosystem.
BOEM-2024-0001-0217-0004	Benthic environment destruction: concern that the construction of offshore energy infrastructure could damage the seafloor habitats that support Sand Lance populations a key food source for humpback whales. Positive impact of whales on the ecosystem	Thank you for your comment. Brief text about the sand lance and associated references have been added to the PEIS. Impacts on seafloor habitats will also depend on the ambient conditions. For example, when ambient levels of suspended sediment and the degree of variation throughout the year are high, then the degree of impact from suspended sediment is likely to be less during that same year.
BOEM-2024-0001-0262-0003	The destructive impact to marine ecosystems already being caused by the preliminary surveying is being blatantly ignored by organizations such as NOAA who are supposed to be acting in the best interest of marine wildlife. I can only imagine the destruction that will ensue once actual cable installation and construction begin.	Thank you for your comment. The PEIS is based on the best available science to date. Research on marine impacts of offshore wind development will continue to grow and future contributions to the knowledge base are expected.
BOEM-2024-0001-0313-0020	Page 2-8 goes on to state "Monopile and piled jacket are anticipated to be the most likely foundation types to be used for the NY Bight projects. Monopile foundations typically consist of a single steel cylindrical pile that is embedded into the seabed and is made up of sections of rolled steel plate welded together. A transition piece is fitted over the monopile and secured via bolts or grout from where the tower is attached. Piled jacket foundations are large lattice	Thank you for your comment. Sediment dispersion modeling from other OSW projects within the NJ and NY WEAs estimated that the maximum turbidity of all sediment disturbance due to various cable installation scenarios (>100 mg/L) would not last longer than 9.1 hours and that turbidity would be below 10 mg/L within 17.7 hours. Project-specific COPs and COP NEPA analyses will address particular mitigation measures, including but not

Comment No.	Comment	Response
	structures fabricated of steel tubes welded together and typically consist of three- or four-legged structures to support WTGs and OSSs. For monopile and piled-jacket substructures the foundations would be driven to the target seabed penetration depths by hydraulic impact hammering vibratory hammering water jetting drilling or a combination of methods." Comment There are a number of concerns regarding the above statement that should be addressed during the environmental review process. There do not appear to be any indications that a turbidity curtain or other similar mitigation measures to reduce impacts from the sedimentation and impacts of increased turbidity will have on the surrounding benthic habitat - including water quality impacts.	limited to RP MUL-27, which aims to minimize sediment disturbance.
BOEM-2024-0001-0313-0042	3.5.2.1.1 Offshore Benthic Resources The PEIS states "Benthic invertebrates in the NY Bight area also include commercially viable species such as the Atlantic surfclam (Spisula solidissima) and ocean quahog (Arctica islandica) which have experienced mortality of large adults and declining recruitment (NEFSC 2017). Guida et al. (2017) found ocean quahogs and Atlantic surfclams were sparsely distributed within water depths of 98.4 feet (30 meters) with increased abundance in deeper waters reaching a maximum of 4025 quahogs per sample twice the amount of surfclam present per sample (Grothues et al. 2021; Guida et al. 2017). The shifting of increased abundance in deeper water supports the theory that warming waters in shallow offshore waters are driving these bivalves into deeper cooler waters (Grothues et al. 2021). As ocean temperatures increase the distribution and biology of Atlantic surfclam are also changing with likely effects on fishery productivity (Munroe et al. 2016). Atlantic sea scallops were absent within 98.4 feet (30 meters) water depth and sparse from 98.4 to 164 feet (30 to 50 meters) reaching the maximum near the edge of the Hudson Shelf Valley. See Section 3.6.1 Commercial Fisheries and For-Hire Recreational Fishing and Section 3.5.5 for additional information. Studies of the U.S. Atlantic coast have shown spatial shifts of benthic species in response to the warming ocean temperatures from 1990 to 2010 (Hale et al. 2017). With predicted continual temperature increases in the waters of the NY Bight area it is expected that the	BOEM agrees that filter feeders can improve water quality through filtration. Although some habitat will be lost due to the offshore infrastructure footprint, the additional hard structure can foster habitat for filter feeders as well, especially on the vertical structures.

Comment No.	Comment	Response
	shift of marine species distribution northward and to deeper waters would continue (BOEM 2021)." Comment Shellfish have been found to filter up 50 galls of water per day and are an integral biological component to improved water quality through their filtration processes. The PEIS should include an analysis of the amount of water quality benefits lost due to the extensive benthic area lost due to trench laying and the footprint of all structures.	
BOEM-2024-0001-0313-0045	Affected Environment and Environmental Consequences 3.5.2-14 "Due to the life cycles of demersal finfish and invertebrate species adverse impacts may be far-reaching (see Section 3.5.5). Elevated turbidity and sediment deposition would also impact seagrasses in inshore waters. Increased turbidity decreases the amount of light availability and may inhibit growth or recovery from disturbance (de Boer 2007; LaFrance Bartley et al. 2022)." "Cable emplacement activities in sensitive habitats such as SAV or mollusk reefs would have a greater impact and require longer periods for recovery. In areas where cable protection is added the benthic community would be permanently impacted." "Kraus and Carter (2018) studied seabed recovery following the burial of subsea cables on the continental shelf. Their results showed that water-jetted trenching methods take roughly 815 years to infill trenches depending on sediment availability mobility and water depth. They concluded that along the mid-shelf where water depths range from 98263 feet (3080 meters) recovery usually takes 2 years though it may exceed 5 years if the adjacent sediment supply is low (Kraus and Carter 2018)." Comment - Similar to the above comment the water quality impact of loss of SAV should also be reviewed in the PEIS. It is extremely concerning that permanent impacts are not comprehensively evaluated in the PEIS. The statement above regarding sediment redistribution is also concerning in that the composition of the sediment and the stratification will be different as compared to its natural state. Again the impacts to the benthic community do not appear to include the potential adverse impacts of suffocation of sensitive species the impacts from turbidity and the direct and indirect impacts to water quality.	The PEIS uses the best available information and complies with the procedural requirements of NEPA to predict potential impacts on benthic resources. The proposed cable routes and potential landing sites will be surveyed, and details will be provided in the project-specific COP. Substrates and habitats will be described in more detail at that time.

Comment No.	Comment	Response
BOEM-2024-0001-0331-0037	Theoretical scenario simulations provide evidence that the increasing amount of future OWF installations will substantially impact and restructure the marine ecosystem. Changes in mixed layer depth have been reported earlier in North Sea wind area as a consequence of offshore wind farm wakes due to the reduced wind induced mixing but also due to the upwelling and downwelling dipoles Since the dipole structure is associated with both an uplift and a depression in mixed layer depth and is variable in dependence of the wind direction. The marine ecosystem responds very clearly to the changes in the atmosphere leading to changes in ocean stratification advective processes and a systematic decrease in bottom shear stress. These changes can be expected to progress into higher trophic levels of the marine ecosystem. Additionally the estimated changes in organic sediment distribution and quantity could have an effect on the habitat quality for benthic species. Spatial distributions might change as it has been shown to depend on the available food quantity and quality as well as the prevailing bottom shear stress.	As stated in the most recent inclusive study for United States waters (National Academies of Sciences, Engineering, and Medicine 2023), "to date, few studies exist to assess the potential hydrodynamic and ecological impacts of offshore wind development, and those that do exist consist of modeling studies with limited observational data developed for wind farms in the North Sea, which have different hydrodynamic and ecosystem characteristics." This study concluded that the hydrodynamic impacts would be difficult to distinguish from natural variability and other outside forces, such as climate change.
BOEM-2024-0001-0331-0039	The PEIS should have presented the level of impacts on re-structuring of marine ecosystems on energy extraction both above and below sea level. Impacts on the regional atmosphere multiple physical biological and chemical impacts on the marine system must be identified in the project PEIS. Complicating these effects underwater structures such as foundations and piles may cause turbulent current wakes which impact circulation stratification mixing and sediment resuspension.	Refer to the response to comment BOEM-2024-0001-0331-0037.
BOEM-2024-0001-0332-0011	EMF Electro-Magnetic Field Cable Emissions With regards to EMF there MUST be a threshold level of EMF emissions that are identified as acceptable or unacceptable for the marine environment and this should change in consideration to the water depth. The same emf emissions in deep open water that fish may feel react and get up over very well may have a much more powerful effect in shallow estuaries and bays.	As stated by Hogan et al. 2023 at this time, no thresholds of the acceptable or unacceptable levels of EMF emissions have been determined for the marine environment.
BOEM-2024-0001-0346-0013	The Draft PEIS Identifies A Wide Range of Impacts from Offshore Wind Development Against Which Site-Specific Analyses Will Need to Protect Fisheries and Fishing Grounds Scallops are particularly susceptible to offshore wind development. They are sessile and exist	Thank you for your comment. Chen (2021) looked at the potential impacts of offshore wind on regional scallop settlement and stated, "The results indicate that the scallop larval settlement exhibited a significant interannual variability...The larval transport

Comment No.	Comment	Response
	at the mercy of pelagic and benthic conditions that allow for their settlement survival and growth. Among other things these conditions include bottom composition currents that bring nutrients to scallops and that cause larvae to settle and turbidity. As the PEIS explains wind farm development will change all these environmental attributes in a manner that is negative for the scallop resource. BOEM itself explained in the Draft PEIS: A synthesis of European studies by van Berkel et al. (2020) [Footnote 4:: Van Berkel et al. The Effects of Offshore Wind Farms on Hydrodynamics and Implications for Fishes Oceanography Vol. 33 Issue 4 p. 108-117 (2020). Available at https://tos.org/oceanography/assets/docs/33-4_van-berkel.pdf (last accessed on June 24 2022).] summarized the potential effects of wind turbines on hydrodynamics the wind field and fisheries. Local to a wind facility the range of potential impacts include increased turbulence downstream remobilization of sediments reduced flow inside wind farms downstream changes in stratification redistribution of water temperature and changes in nutrient upwelling and primary productivity. (3.5.6-48) . . . . In terms of the changes to currents the Draft PEIS identified at least two negative attributes of note for scallops: upwelling brings the phytoplankton that scallops eat to the surface (and away from the scallops) and forces warm surface waters detrimental to scallops' survival to the bottom. As the Draft PEIS further explains: Structures may reduce wind-forced mixing of surface waters whereas water flowing around the foundations may increase vertical mixing (Carpenter et al. 2016). During summer when water is more stratified increased mixing could increase pelagic primary productivity near the structure increasing the algal food source for zooplankton and filter feeders. Increased mixing may also result in warmer bottom temperatures increasing stress on some shellfish and fish at the southern or inshore extent of the range of suitable temperatures. (3.6.1-49) Localized turbulence and upwelling effects around the monopiles are likely to transport nutrients into the surface layer potentially increasing primary and secondary productivity. That increased productivity could be partially offset by the formation of abundant colonies of filter feeders on the monopole foundations. (3.6.1-49) While the PEIS tries to minimize	to the MAB is closely related to the intensity of the cold pool and temperature front." Miles et al. (2021) studied the potential effects of offshore wind farms on the Mid-Atlantic Bight Cold Pool. See Section 3.5.6.3.3 for further discussion. Refer to the response to comment BOEM-2024-0001-0331-0037 for a response to the general hydrodynamic changes.

Comment No.	Comment	Response
	these impacts as "localized" what BOEM really means is "local[ized] to a wind facility." (3.6.1-48) This clarification makes sense as wind turbines will only be 0.6 nautical miles apart from each other (3.6.1-49). Furthermore it is reasonable to consider the New York Bight wind lease areas as one giant facility. Four of these six areas are packed together in one unit with no particular provision made for their separation. "The overall impact on stratification is directly related to the scale of development." (3.5.2-29) Packing these six areas tightly together and developing them during the same time period can also yield "regional" changes in benthic stability and species composition. (3.5.2- 31-32) Indeed these six lease areas' concentration is a principal reason BOEM developed this Draft PEIS. None of this bodes well for the scallop settlement survival and growth especially with these lease areas being concentrated in the center of the Mid-Atlantic scallop resource.	
BOEM-2024-0001-0346-0014	The Van Berkel paper on which BOEM relies explains how broadly these hydrodynamic impacts have been observed: "Hydrodynamics play a pivotal role in controlling turbidity sedimentation salinity temperature and nutrient uptake in coastal systems." And these "hydrodynamic impacts are transferred to the ocean via two routes: (1) modification of the wind field and consequently the wave and current fields due to the direct effect of power extraction from the wind and (2) wind turbine foundations' effects on ocean currents and consequently on turbulence mixing and vertical stratification." These hydrodynamic effects were recorded to "extend 5-20 km in the downwind direction depending on weather conditions." For its part BOEM confirmed that: [B]roadscale hydrodynamic impacts could alter zooplankton distribution and abundance with impacts that may extend to tens of kilometers from structure foundations (Christiansen et al. 2022; van Berkel et al. 2020). (3.5.6-50) Further a second even more recent paper cited by BOEM also explained the impacts that offshore wind farms have on ocean hydrodynamics. The Draft PEIS reports that: Daewel et al. (2022) modeled the effects of offshore wind farm projects in the North Sea on primary productivity and found that there were areas with both increased and decreased productivity within and around the wind farms. There was a	Refer to the response to comment BOEM-2024-0001-0346-0013.

Comment No.	Comment	Response
	decrease in productivity in the center of large wind farm clusters but an increase around these clusters in the shallow near-coastal areas of the inner German Bight and Dogger Bank (Daewel et al. 2022). (3.5.6-49) Scallops generally are not found in the shallower waters of the New York Bight as can be seen from relatively lower landings in Lease Areas OCS-A 544 and OCS-A 541. (3.6.1-12) Scallops generally begin to be found at depths of 20-25 fathoms.	
BOEM-2024-0001-0346-0015	The Draft PEIS likewise soft-pedals the potential impacts from offshore wind farms to scallop larval distribution. As FSF explained in its scoping comments BOEM commissioned an exercise to model the potential wind farms' impacts on larval distribution. The modeling predicts significant impacts on scallop larval distribution but the paper then rationalized that "The results of this modeling effort indicate that at a regional fisheries management level these shifts are not considered overly relevant with regards to larval settlement." (3.5.5-34) [Footnote 5: The BOEM-funded study in question is T. Johnson et al. Hydrodynamic Modeling Particle Tracking and Agent-Based Modeling of Larvae in the U.S. Mid-Atlantic Bight OCS Study BOEM 2021-049 (June 2021). Available at https://espis.boem.gov/final reports/BOEM_2021-049.pdf (last accessed on June 24 2022).] The actual Johnson et al. modeling tells a different story. Any reasonable review of Figures 1 and 2 (below) reveals a redistribution of scallop larvae over dozens of miles. Indeed due to the projected effects of wind farms south of Martha's Vineyard scallop larvae were redistributed along an area from well east of Nantucket to well west of Montauk. SEE ORIGINAL COMMENT FOR Figure 1: Predicted differences in settled larval sea scallop density (larvae/m2) from full build-out OSW lease offshore MA- RI area 12 MW turbines (1063 towers).Source: T. Johnson et al. SEE ORIGINAL COMMENT FOR Figure 2: Predicted differences in settled larval sea scallop density (larvae/m2) from full build-out OSW lease offshore MA- RI area 15 MW turbines (1063 towers).Source: T. Johnson et al.	Refer to the response to comment BOEM-2024-0001-0346-0013.
BOEM-2024-0001-0362-0023	BOEM should analyze the benefits derived from offshore wind developers conducting appropriate benthic surveys for cable routes	Based on BOEM’s understanding of the comment, it is possible that surveys within the Lease Area could identify areas of contamination from previous sources. This information may be

Comment No.	Comment	Response
	and other activities that may exacerbate existing contamination from urban and storm runoff industry or historic use of the site.	useful for analyzing cable corridors or other infrastructure of specific wind projects during project-specific COP NEPA analyses.
BOEM-2024-0001-0447-0002	Benthic Analysis This PEIS identifies total mortality of the benthic environment from scour protection. We agree the dropping of 1000 on tons of rock will completely change the environment on the sea floor. However it's even greater at 8 acres per windmill than .51 acres per windmill. We have no understanding how the science of this document can reach the conclusion that the result in benthic impact of a windfarm is negligible to minor of this sample project!	Thank you for your comment. The impact determinations are based on the best available science. Although some habitat conversion is expected due to cable and scour protections, the additional surfaces offer opportunities for the settlement of invertebrates, some of which are commercially important species such as mussels and oysters. A newly published study on the settlement success of the European flat oyster showed that granite had the highest settlement success. Granite is often used in scour protection for offshore wind projects (ter Hofstede et al. 2024). The majority of the substrate within the NY Bight is soft sediment. The amount of soft-bottom habitat that will be affected is relatively small compared to the available habitat in the surrounding area.
BOEM-2024-0001-0469-0013	Benthic communities are the foundation of the marine ecosystem. [Footnote 35: See Jacob P. Kritzer et al The Importance of Benthic Habitats for Coastal Fisheries 66 BIOSCIENCE 274 (Mar. 29 2016) https://doi.org/10.1093/biosci/biw014] Marine mammals are certainly charismatic and generate high levels of media reporting and public concern but it is important to focus efforts on the species on which the charismatic species rely. The Draft PEIS proposes only two (2) mitigation measures designed specifically to avoid minimize mitigate and monitor impacts on benthic communities. Twenty (20) of the AMMM measures address benthic communities in addition to other resources. There has been little dedicated research on impacts to benthic communities particularly regarding how electromagnetic fields ("EMF") will affect them and the potential secondary impacts of those changes. [Footnote 36: NEW YORK BIGHT DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT appx. E at E-3.] In fact research on the ecological impact of EMF is lacking for most species and "Mid-Atlantic OSW development will expose important seasonally migrating (north south inshore offshore) finfish and elasmobranchs to EMFs as their movements will periodically cross cables". [Footnote 37: BUREAU OF OCEAN ENERGY MGMT. EFFECTS OF EMFS FROM UNDERSEA POWER CABLES ON	EMFs are discussed in Section 3.5.2.3 under cumulative impacts, as other offshore wind farms are planned within the NY Bight area. CSA and Exponent (2019) studied potential EMF effects on fish species of commercial or recreational fishing importance in southern New England and concluded, “The operation of offshore wind energy projects is not expected to negatively affect commercial and recreational fishes within the southern New England area. Negligible effects, if any, on bottom-dwelling species are anticipated. No negative effects on pelagic species are expected due to their distance from the power cables buried in the seafloor.” Newer references of studies on DC cables emitting EMF have been added, and these align with CSA and Exponent 2019. It is important to note that cable configuration and spacing could lead to differences in the risk to benthic species. Details, including cable configurations, will be provided in project-specific COPs.

Comment No.	Comment	Response
	ELASMOBRANCHS AND OTHER MARINE SPECIES 1 https://www.boem.gov/sites/default/files/environmental-stewardship/Environmental-Studies/Pacific-Region/Studies/2011-09-EMF-Effects.pdf; Zo L. Hutchison et al The Interaction Between Resource Species and Electromagnetic Fields Associated with Electricity Production by Offshore Wind Farms 33 OCEANOGRAPHY (2020) https://doi.org/10.5670/oceanog.2020.409] Quantitative risk assessments would help determine what mitigation efforts are needed to reduce EMF impacts. [Footnote 38: Annemiek Hermans et al Do electromagnetic fields from subsea power cables effect benthic elasmobranch behaviour? A risk-based approach for the Dutch Continental Shelf 346 ENV'T POLLUTION (Apr. 2024) https://doi.org/10.1016/j.envpol.2024.123570.] Though risks during embryogenic development and migration could be consequential is unclear whether or to what extent electrosensitivity will translate to behavioral or ecological change. [Footnote 39: Id.] Baseline studies are crucial as "distinguishing cable EMF effects from structure attraction or nearby fishing activity will be impossible without additional controls on the experimental setting". [Footnote 40: EFFECTS OF EMFS FROM UNDERSEA POWER CABLES ON ELASMOBRANCHS AND OTHER MARINE SPECIES supra note 38; Hutchison et al supra note 38.] BOEM must commission more study of EMF that determines the secondary effects of any behavioral responses to EMF before approving projects in the six New York Bight lease areas. Any assessment of EMF in the individual project review must include an estimate of the total area wherein EMF would be emitted accounting for all nearby OSW projects.	
BOEM-2024-0001-0469-0014	Another potential risk to benthic communities comes from an impact that is often presented as a benefit: [Footnote 41: NEW YORK BIGHT DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT supra note 5 at 3.5.5-44.] turbine foundations acting as artificial reefs. While artificial reef habitats may be beneficial for organisms that prefer those environments it is not necessarily a benefit for the naturally occurring marine wildlife and can alter the composition of the marine community and predator-prey dynamics near wind turbine installations. [Footnote 42: L. Bennun et al Biodiversity	The "reef effect" and adverse effects of habitat conversion on softbottom species and communities are addressed in Section 3.5.2.3.2., and 3.5.2.4.4. The Bennun et al. 2021 citation was added. Beneficial aspects of the reef effect have also been called out in nearby offshore wind projects, such as Empire Wind 1 and Atlantic Shores South. AMMM measure MUL-4 and RP MUL-12 incorporate ecological design elements in scour protection (e.g., using nature-based scour protection such as oyster beds or other artificial reefs) to

	Impacts Associated to Offshore Wind Power Projects INT'L UNION FOR CONSERVATION OF NATURE (2021) https://www.iucn.org/sites/default/files/2022-06/01_biodiversity_impacts_associated_to_off-shore_wind_power_projects.pdf.] New habitats could even attract and facilitate the growth of invasive species especially if they are already present in the area but no AMMM measures address invasive species. [Footnote 43: NEW YORK BIGHT DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT supra note 5 at 3.5.2-14 Appx. G.]Similar to the analysis of marine mammals BOEM concludes that these unknowns do not prevent it from choosing among the Draft PEIS alternatives. Again this is unreasonable as benthic communities and sediment carbon storage are rarely analyzed in studies and serve a vital role in the marine ecosystem.	provide suitable substrate for increasing the probability of recolonization. While these do not directly address invasive species, colonization does inhibit the growth of many sessile invasives.
BOEM-2024-0001-0529k	And of course there's the thousands, tens of thousands of miles of cables emitting electromagnetic fields, including high voltage cables known to affect marine life.	An EMF analysis is provided in Sections 3.5.5.3.3 and 3.5.5.4.1. EMF exposure levels in the built environment are not expected to reach high enough energy levels to have an impact on populations, and there is no evidence to indicate that EMFs from undersea alternating current (AC) or DC power cables negatively affect commercially and recreationally important fish species (CSA Ocean Sciences Inc. and Exponent 2019; Gill and Desender 2020; NYSERDA 2017; SEER 2022; Taormina et al. 2018). Additionally, RP MUL-39 proposes using electric shielding on underwater cables to control the intensity of EMFs.
BOEM-2024-0001-0529cc	However, the reef effect is not what you've been told. The reef effect is actually called biofouling. You've got essential environment in the mid-Atlantic Bight, and by literally putting turbines, you are creating an environment that is ripe for invasives, such as sea-squirts as the muscles which are going to…Actually, there's a study, and let me see if I can find it, and if I can't, I can't in time. The Tethys has a fouling community on turbine foundations and scour protections. They basically become magnets for anything that happens to float by, and they completely change an essential environment into a hard substrate, and the ecosystems within it.	Thank you for your comment. The "reef effect" and adverse effects of habitat conversion on softbottom species and communities are addressed in Sections 3.5.2.3.2 and 3.5.2.4.4. The Bennun et al. 2021 citation was added. Additionally, as discussed in Section 3.5.2.4.2, *Benthic Resources*, a recent study published by Li et al. (2023) found that the artificial reef effect from wind farms in the North Sea could lead to a doubling of species richness and an increase of species abundance by up to two orders of magnitude. AMMM measure MUL-4 and RP MUL-12 incorporate ecological design elements in scour protection (e.g., using nature-based

Comment No.	Comment	Response
		scour protection such as oyster beds or other artificial reefs) to provide suitable substrate for increasing the probability of recolonization. While these do not directly address invasive species, colonization does inhibit the growth of many sessile invasives. The introduction of invasive species is discussed in Section 3.5.2, *Benthic Resources*, under the accidental releases, cable emplacement and maintenance, and presence of structures IPFs.
BOEM-2024-0001-0310o	Many believe on a cumulative level we're going to warm the ocean significantly. Thousands of miles of EMF laden cables, and these aren't telecom cables that people like to mention. These are high voltage electrical cables jet trenched through our ocean floor, plowing through all these ridges and ledges that provide habitat. It's sickening to think of.	Cables associated with offshore wind projects will be buried in the ocean floor. Heat from the cables will be highly localized to the sediments within the immediate vicinity of the cables. Based on controlled experiments, Emeana and others (2016) measured > 10°C increases in sediment temperature at distances ranging from 40 centimeters to over a meter from a cable source; these temperatures varied, depending on sediment substrate type and source temperature of the cable. An EMF analysis is provided in Sections 3.5.5.3.3 and 3.5.5.4.1 of the PEIS. Additionally, RP MUL-39 proposes the electric shielding on underwater cables to control the intensity of EMF. At this time, BOEM is not aware of any studies demonstrating increases in water column temperatures and decreases in CO_2 absorption as a result of the thousands of miles of existing operational submarine electric transmission cables.
BOEM-2024-0001-0529v	The PEIS states that artificial reefs provide valuable habitats to foster the biodiversity of marine invertebrates and finfish. So, their value is acknowledged in the document, but I am concerned that the PEIS seems to present full decommissioning as the default end of life plan for the wind farms, which would require any developer that wishes to retire any portion of the project in place to jump over additional hurdles. So given that the artificial reef benefits have already been well documented on other wind farms, we want BOEM to make partial decommissioning the default. This can be done by following the renewables to reef concepts that is presented in a 2015 paper by Smith and colleagues. This leaving the scour protection in place can ensure that the artificial reef communities that become established there over	Thank you for your comment. As discussed in Section 3.5.2.4.2, *Benthic Resources*, a recent study published by Li et al. (2023) found that the artificial reef effect from wind farms in the North Sea could lead to a doubling of species richness and an increase of species abundance by up to two orders of magnitude. Lessees are required to remove all human-made structures from the seafloor unless direct approval from BSEE is determined during the lessee's decommission application review. Decommissioning is covered by BSEE under 285.902, which details the decommissioning application review and approval process, while 285.910 details removal of facilities. Additionally, 285.909 details the authorization to have facilities remain in place; specifically, 285.909.909(c) speaks to facilities that will be

Comment No.	Comment	Response
	decades of operation, can remain there in perpetuity. A 2017 paper on Sustainable Decommissioning of Wind Farms by Topham and McMillan acknowledges that there's no one size fits all solution. So the specific decommissioning plan for each project will be site specific. But as a general rule, scour should be left in situ, because marine life will have flourished around scour, protecting any element of the wind farm. So preserving these reefs could be especially consequential for recreational and subsistence fishermen, as we anticipate that these reefs will become a destination for fishing activity akin to oil rig fishing in the Gulf of Mexico. It would be nonsensical to facilitate the growth of this ecological and economic activity only to remove it later. So, we are asking BOEM to take steps as early as possible to ensure the preservation of these reefs.	toppled in place or converted to artificial reef purposes (https://www.ecfr.gov/current/title-30/chapter-II/subchapter-B/part-285/subpart-I/subject-group-ECFR73f535d05e8b5d9/section-285.909). BOEM will conduct project-specific NEPA analysis of the COP for each lease area, focusing on site- and project-specific analyses that were not already addressed by the PEIS.

P.5.7 Birds

Table P.5-7. Responses to Comments on Birds

Comment No.	Comment	Response
BOEM-2024-0001-0357-0007	Neither this draft program EIS or any project specific EIS presents a cumulative assessment of the deaths to the endangered /threatened piping plover and red knot bird as it attempts to migrate through the NJ/NY Bight area on its traditional routes. No substantive AMMM measures are presented to mitigate this risk (See Enclosure IV) .	Cumulative impact analyses for all birds collectively are addressed in PEIS Sections 3.5.3.3.3, 3.5.3.3.4, 3.5.3.4.4, 3.5.3.4.5, 3.5.3.5.4, and 3.5.3.5.5. Cumulative impacts on federally listed threatened and endangered species (including piping plover and red knot) are addressed in more detail as part of BOEM's consultation with the USFWS on a Programmatic Framework ESA Section 7 consultation, which was initiated on June 20, 2024.
BOEM-2024-0001-0357-0020	The closer in turbines will likely kill the piping plovers as they attempt to cross the wind complex to get to their nesting grounds on the island. Farther out we also have risk to the birds from the turbines in the other areas while they migrate but perhaps with more room for the bird to circumvent those complexes.	Impacts on federally listed threatened and endangered species (including piping plover) are addressed in more detail as part of BOEM's consultation with the USFWS on a Programmatic Framework ESA Section 7 consultation, which was initiated on June 20, 2024.

Comment No.	Comment	Response
BOEM-2024-0001-0357-0050	Enclosure IV Piping Plover Migration Routes Cumulative Impact The program EIS presents no meaningful AMMM measures to prevent the deaths of the piping plover and other migratory birds as they attempt to traverse the wind turbine complexes. The prior paths of the piping plover on its coastal migration are shown below. The operation of the turbines would impact the birds migrating offshore as well as those seeking to nest onshore for example at the Holgate and Barnegat Light locations on Long Beach Island NJ. SEE ORIGINAL COMMENT FOR MAP: Migratory routes of Piping Plovers Tracking stations Offshore Wind Energy Areas	Impacts on piping plover are addressed in more detail as part of BOEM's consultation with the USFWS on a Programmatic Framework ESA Section 7 consultation, which was initiated on June 20, 2024. The framework consultation includes the consideration of potential collisions with offshore wind turbines as well as impacts on nesting and AMMM measures to avoid and minimize impacts. In addition, a COP-specific BA for NY Bight lease areas that might be developed in the future would include project-specific analysis based on the most current and relevant piping plover information available at that time.
BOEM-2024-0001-0357-0051	The U.S. Fish and Wildlife Service provides monitoring and management of beach nesting birds at the Edwin B. Forsythe National Wildlife Refuge. The Refuge nesting sites both the Holgate and Little Beach Island Units provide some of the only habitat in the State closed to the public and free of human disturbance and detrimental beach management practices. The habitat at the sites is especially suitable for the State endangered piping plover as a result of optimal nesting conditions created by Superstorm Sandy and largely sustained since then through winter storms. As of the 2021 season the Refuge sites had the highest concentration of piping plovers in the state with Holgate having by far the most pairs (46). Furthermore on average in recent years Holgate has produced a higher fledgling rate than many sites in the state. The piping plover's existence is "threatened" under the Endangered Species Act (ESA) and should receive a review under that statute. About 86 plovers' nest in Holgate and Barnegat Light where they are protected others in the North Brigantine State Natural Area. It migrates offshore north-south PP1 and must cross the project area in and out from their nests. If heading toward turbines it would quite difficult for a 7-inch bird to first perceive and then avoid rotating blades with a 774-foot diameter and blade tip speeds approaching 200 miles per hour creating highly turbulent conditions. Assuming little avoidance of the entire wind complex to get to its historical nesting location as discussed below there is the potential for a high number of fatalities (PP2) estimated here at up to 31 percent per year. That is based on reference PP2 Figure 2.25 the average of the Chapin Dead Neck Avalon Stone Harbor results. It is also consistent with the percent of	Impacts on piping plover are addressed in more detail as part of BOEM's consultation with the USFWS on a Programmatic Framework ESA Section 7 consultation, which was initiated on June 20, 2024. Consultation with the USFWS occur concurrently with the NEPA process, and there is no ESA regulatory requirement to have consultation completed when the Draft PEIS is issued (although BOEM strives to complete consultation as soon as possible). On June 20, 2024, BOEM initiated consultation with the USFWS on a Programmatic Framework ESA Section 7 consultation. In addition, a COP-specific BA for NY Bight lease areas that might be developed in the future would include project-specific analysis based on the most current and relevant piping plover information available at that time. BOEM notes that many of this commenter's comments (commenter ID BOEM-2024-0001-0357) are the same comments provided on BOEM's Atlantic Shores South Draft EIS and BA. (Atlantic Shores South is stated in several of these comments.) However, BOEM understands the general concerns and has responded in the context of the NY Bight lease areas.

Comment No.	Comment	Response
	transit area blocked by rotating blades and 2 flights per bird in and out. The Atlantic Shores South draft EIS presents no assessment of the turbine collision risk to the local endangered piping plover population that nests on the Island and must now cross the wind complexes to get there and back to its offshore migration routes. It discusses the existence of a preliminary biological assessment (BA) prepared for consultation under the Endangered Species Act but presents no results of that analysis in the draft EIS. It says that the final biological assessment will be available in the final EIS but that prevents the public from reviewing and commenting on this important impact. This is another example of lack of full disclosure and lack of coordination with other environmental reviews to the fullest extent practicable. This is another impact that must be presented in a supplemental draft EIS for public review.	
BOEM-2024-0001-0357-0052	Regarding turbine collision on page 3.5.3-18 the Atlantic Shores draft EIS purports to minimize the collision risk by pointing to a study by Madsen et.al. in 2012 that showed a 99% avoidance when turbines were spaced greater than 0.6 miles. The avoidance rate used in the DEIS is not well defined but it appears to be the probability that the bird will avoid the entire wind complex this needs to be clarified. But that study was for a particular bird species (the common elder) and a much smaller wind complex that it was able to fly around which the modeling then depicted. In the case here the piping plover considering both the Ocean Wind and the Atlantic Shores projects faces a 32-mile long barrier to making landfall. In addition the turbines proposed off LBI are much more powerful and carry greater pressure changes and turbulence one cannot just take results from small turbines and assume they hold for large ones. In addition that study did not show the collision risk to those birds that entered the wind complex which is the critical issue here facing the piping plover as well as the red knot. Further that study was for much smaller turbines with much different pressure and turbulence characteristics than the larger turbines proposed here. Finally it is unclear whether the piping plover has similar avoidance traits as the elder bird. Therefore the relevance of that study to the situation facing the piping plover is highly questionable. And there are other studies as shown below that present a much different and much	The PEIS paragraphs in which the Madsen et al. (2012) paper is referenced are concerning adverse impacts of additional energy expenditure due to minor course corrections or complete avoidance of offshore wind lease areas, not collision risk; this discussion is a general one and does not focus on any one bird species in particular. Madsen et al. (2012) examined the number of birds flying through the wind farm through the spacing between turbines, not around the entire wind farm, which is clearly stated in the PEIS. Additionally, although data on only the common eider was collected, the model simulations explored permeability scenarios to account for bird species with various levels of wind farm avoidance. Although WTGs to be used in lease areas on the Atlantic OCS (including the NY Bight lease areas) are expected to be larger, may result in greater pressure changes and turbulence than smaller turbines, and may be greater in number than the wind farm from which data was collected in the Madsen et al. (2012) study, the spacing between the WTGs will also be greater. As stated in the PEIS, “The 0.6- to 1-nautical mile (1.1- to 1.9-kilometer) spacing estimated for most structures that will be proposed on the Atlantic OCS is greater than the distance at which 99 percent of the birds passed through in the model.” In addition, Vattenfall (2023) recently studied bird movements within an offshore wind farm. The study was robust in that

Comment No.	Comment	Response
	greater risk to the plover which should have been presented in the draft EIS. In either case the BOEM cannot assume a 99 percent turbine avoidance by simply referencing studies which reference other studies which in turn are based on much smaller turbines (e.g. 216-foot diameters) other bird species and different circumstances. On its face it does not seem at all realistic to expect a small bird to easily and often escape multiple rows of rotating turbine blades with diameters more than two football fields long a rotor swept area 13 times that used in previous studies and wind tip speeds approaching 200 miles an hour causing significant disruptions in air currents. Prior studies (PP2) acknowledge that the avoidance rate for the piping plover is simply not known. If the BOEM uses an avoidance percentage number it needs to provide a plausible explanation for it. Otherwise it should be conservative in its analysis. If the avoidance percentage is of the entire complex then the assumption of 99 percent avoidance is especially unfounded when we know historically that the piping plover's instincts are driving it towards its nesting ground on the Island and the direct path from its migratory routes to it is through the wind complex. There seems no basis to assume it will go tens of miles out of its way from that direct path to get there. So the avoidance rate is likely to be closer to zero than it is to 99 percent. Rather for a bird approaching these large turbines and their aerodynamics suggest otherwise. First it is not clear that the bird can even detect the rotating blades especially the outer part which are now moving at very high speeds. This causes vision blur and paradoxically is now greater with a larger turbine again because of their outward tip speeds approaching 200 miles an hour. If the bird does detect an obstacle and tries to change course there are additional difficulties. If it is approaching the turning blades against the wind it will experience a very significant pressure drop in front of the blades which will suck it in to the blade swept area. If it is approaching the turning blades with the wind behind it and seeks to change course it has the counter that wind speed which is likely to be significant during operation of the turbine. If it passes through the swept area it will experience that same pressure drop behind the blades. All of this suggests that a 99 percent avoidance through	seabirds were tracked inside the array with video cameras and radar tracks, which allowed for measuring avoidance movements with high confidence and at the species level. The study concluded that seabirds would be exposed to very low risks of collision in offshore wind farms during daylight hours. This was substantiated by the fact that no collisions or even narrow escapes were recorded in over 10,000 bird videos during the 2 years of monitoring. Refer to response to comment BOEM-2024-0001-0400-0022. Impacts on federally listed threatened and endangered birds (including piping plover) are addressed in more detail as part of BOEM's consultation with the USFWS on a Programmatic Framework ESA Section 7 consultation, which was initiated on June 20, 2024. The Programmatic Framework ESA Section 7 consultation considers collision risk for the piping plover and other ESA-listed bird species using Stochastic Collision Risk Assessment for Movement (SCRAM) models. The final report on the SCRAM model (Adams et al. 2022) is available at https://espis.boem.gov/Final%20Reports/BOEM_2022-071.pdf. SCRAM uses bird passage rates based on modeled flight paths of birds fitted with nanotag transmitters, rather than avoidance rates (Gilbert et al. 2022). Estimates of bird collisions will be part of the consultation.

Comment No.	Comment	Response
	multiple rows of such situations is completely arbitrary and the BOEM needs to go back and present something realistic.	
BOEM-2024-0001-0357-0053	It is not known if the BOEM is using the "BAND" model in its Biological Assessment (BA) to analyze collision risk as the bird goes through the wind complex. The description of the BAND model in other literature as a "static" model indicates that it scores a collision only when a bird actually hits a blade. The blades are relatively thin and the area occupied by the blades compared to the entire area swept by the rotation is very small so obviously using only that the risk of collision will be small. This does not account for the risk of injury or fatality from the extreme turbulence and pressure changes that the bird would experience as it passes through the rotor swept area and beyond it especially just downwind of the turbine. It ignores all the turbulence pressure changes and wind shear effects occurring in between and downwind of the blades which could also maim or kill a bird. Any use of the model without modification would seems especially inappropriate considering the huge 110-meter blade length and blade tip tangential speeds approaching 200 miles per hour. The BOEM needs to do a current realistic assessment of the risk of injury and fatalities here in its BA. It cannot rely on the BAND model as it did for the Vineyard Wind 1 Biological Assessment based on the model's limitations described above and other major drawbacks expressed by the U.S. Fish and Wildlife Service PP3. Collision Risk Models (CRMs): we expect that BOEM will apply CRMs to evaluate avian impacts in its BA. While limited CRMs are one of the only tools available to hypothesize potential impacts to birds from collision in the offshore environment. As such CRMs provide a mechanism for testing outcomes (e.g. observed collision rates) against the model predictions (e.g. expected collision rates) and BOEM must address the need to collect the data necessary to test these hypotheses. The DEIS should include a CRM-driven collision risk analysis for all species of conservation obligation which may occur within 20 km of the Atlantic Shores footprint and for which a current CRM would be appropriate even if the species has not been documented within the footprint. This should include a recent stochastic derivation of the Band model such as the McGregor (2018) version [Footnote 1: McGregor RM King S Donovan CR Caneco B	Collision risk for the piping plover, red knot, and roseate tern is addressed using the SCRAM model as part of the Programmatic Framework ESA Section 7 consultation that BOEM initiated with USFWS on June 20, 2024. The SCRAM model is specific to offshore wind on the U.S. Atlantic Ocean developed collaboratively between the USFWS, BOEM, University of Rhode Island, and Biodiversity Research Institute. Descriptions of the SCRAM model and limitations can be found in the final report on the model (Adams et al. 2022), which is available at https://espis.boem.gov/Final%20Reports/BOEM_2022-071.pdf. For all non-ESA listed bird species, BOEM anticipates NY Bight lessees would submit bird risk assessment information similar to that used for previous COP-specific NEPA reviews. The PEIS references two such documents from previous and adjacent lease areas—Empire Wind OCS-A 0512 and Ocean Wind 1 OCS-A 0498. As stated in the PEIS Section 3.5.3.4.1, the majority of the bird species identified in the impact assessments for these two lease areas are expected to have “minimal” to “low” overall exposure risk. Further, coastal birds are considered to have minimal exposure (occurrence) within the NY Bight lease areas because they are far enough offshore to be beyond the range of most breeding terrestrial or coastal bird species. Regarding Collision Risk Model daytime and nighttime flight patterns, SCRAM indirectly accounts for daytime and nighttime activity by using monthly averages of wind speed and turbine operation as inputs. If there was sufficient information about the timing of bird migration and what the turbines are doing during the same time frame, then the results would more directly reflect bird behavior with the operation of the wind farm. For instance, if most of the birds migrate between one hour before sunset and two hours after sunset, then BOEM would need information of what the turbines are likely to be doing during that time.

Comment No.	Comment	Response
	Webb A. 2018. A Stochastic Collision Risk Model for Seabirds in Flight:61. https://tethys.pnnl.gov/sites/default/files/publications/McGregor-2018-Stochastic.pdf.]. BOEM must be transparent in its CRM application. These models are extremely sensitive to the input parameters. A study by Cook et al. (2014) found that estimations of avoidance and collision risk from Band models were highly sensitive to the flux rate (total number of birds passing through the wind farm) corpse detection rate rotor speed and bird speed. Factors such as weather (i.e. wind speed and visibility) and habitat use would also affect the accuracy of these estimates as such factors would greatly influence avian flight patterns and behavior [Footnote 2: Cook ASCP Humphreys EM Masden EA Burton NHK. 2014. The Avoidance Rates of Collision Between Birds and Offshore Turbines. Scottish Marine and Freshwater Science 5:263. 62]. Therefore the Draft EIS must provide the inputs used in its analysis for public comment and transparency. Providing CRM results without transparency to the inputs and analytical process would never be acceptable from a scientific perspective and therefore should not be acceptable from BOEM. Providing inputs would show whether BOEM followed the guidance provided by Band in assessing collision risk. These details regarding inputs should include but not be limited to avoidance behavior flight height flight activity flux rate corpse detection rate rotor speed bird speed and collision risk. Additionally CRMs should consider differences in daytime and nighttime flight patterns. As Band himself stipulates: For some species typical flight heights are dependent on the season and in such a case it will be best to use seasonally dependent typical flight heights in assessing collision risk for each month rather than average flight heights across the year...Flight activity estimates should allow both for daytime and night-time activity. Daytime activity should be based on field surveys. Night-time flight activity should be based if possible on nighttime survey; if not on expert assessment of likely levels of nocturnal activity...collision model[s] should take both day and night flights into account. Where there is no night-time survey data available or other records of nocturnal activity for the species in question (or for other sites if not at this site) it should be assumed	

Comment No.	Comment	Response
	that the Garthe and Hppop/ King et al. 1-5 rankings apply. These rankings should then be translated to levels of activity at night which are respectively 0% 25% 50% 75% and 100% of daytime activity. These percentages are a simple way of quantifying the rankings for use in collision modelling and they may to some extent be precautionary [Footnote 3: Band B. 2012. Using a collision risk model to assess bird collision risks for offshore windfarms. SOSS report for The Crown Estate Norway. https://www.bto.org/sites/default/files/u28/downloads/Projects/Final_Report_SOSS02_Band1ModelGuidan ce.pdf.]. There are new derivations of the Band model under development namely the 3-D CRM for seabirds by the Shatz Energy Research Center [Footnote 4: Seabird Distribution in 3D: Assessing Risk from Offshore Wind Energy Generation Shatz Energy Research Center (2020) https://schatzcenter.org/2020/04/seabird3dstudy/.] and stochastic CRM specific to ESA-listed species in southern New England from the University of Rhode Island [Footnote 5: Transparent Modeling of Collision Risk for Three Federally-Listed Bird Species to Offshore Wind Development US Fish and Wildlife Service with University of Rhode Island (Oct. 29 2020) https://www.boem.gov/sites/default/files/documents/environment/environmental-studies/Transparentmodeling-of-collisionrisk-for-three-federally-listed-bird-species-to-offshore-wind-development_1.pdf.].	
BOEM-2024-0001-0357-0054	BOEM Cannot Assume that Larger Turbines Further Apart Reduces Risks to Birds There is no substantial evidence to suggest that larger turbines spaced farther apart reduces risks to birds and it should be a goal of BOEM to understand the effects of displacement and mortality relative to turbine size and spacing. The size of turbines has grown substantially over the past decade and this trend is expected to continue. In its Vineyard Wind 1 project Vineyard Wind plans to use GE's 12 MW Haliade-X turbine which has a 220-meter rotor swept zone and is estimated to reach a maximum height of 260 meters above sea level. University of Virginia is currently developing 200-meter-long blades to power a 50-mw turbine with a potential rotor swept zone of approximately 400 meters. Given that the tower height would need to be more than 200 meters in height to	As stated in the PEIS, the effects of offshore wind farms on bird movement ultimately depends on the bird species, size of the offshore wind farm, spacing of turbines, and extent of extra energy costs incurred by the displacement of flying birds (relative to normal flight costs pre-construction) and their ability to compensate for this degree of added energy expenditure. Little quantitative information is available on how offshore wind farms may act as a barrier to movement, but there are some studies that provide information on bird movement through offshore wind farms. One study cited in the PEIS is Madsen et al. (2012), which found that increased turbine spacing coincided with increased numbers of birds flying through the wind farm. Further, Vattenfall (2023) recently conducted a robust study of bird

Comment No.	Comment	Response
	accommodate rotor blades of this size turbines could soon reach heights greater than 400 meters above sea level. Studies Karas (2009) [Footnote 6: Smallwood KS Karas B. 2009. Avian and Bat Fatality Rates at Old-Generation and Repowered Wind Turbines in California. The Journal of Wildlife Management 73:10621071.] and Johnston et al. (2014) [Footnote 7: Johnston A. A.S.C.P. Cook L.J. Wright E.M. Humphreys and N.H.K. Burton. 2014. Modeling Flight Heights of Marine Birds to More Accurately Assess Collision Risk with Offshore Wind Turbines. Journal of Applied Ecology 51 31-41.] which suggest that fewer larger turbines reduce avian collision risk are based on turbines less than 5 mw. As turbines increase in size they are more likely to encroach on airspace occupied by nocturnal migrants [Footnote 8: Id. 64 bird species.] while not necessarily avoiding airspace occupied by relatively lower flying foraging marine. Conversely studies by Loss et al. (2013) Choi et al. (2020) and Huso et al. (2020) find that bird deaths not only increase with turbine size but also suggest that the number of bird deaths from collision with wind turbines is proportional to the number of mw produced in a wind farm. Turbulence above and below the rotor swept zone can affect flight performance. If this should make birds more susceptible to physical interactions with turbines then larger turbines would only increase that risk. Additionally limiting risk evaluations to the rotor swept zone neglects the risk of collision from the tower itself and turbulence around the rotor swept zone. Suggestions that increased spacing (1 nm) between turbines would reduce risks to birds from both collision and displacement is unfounded as offshore wind farms in Europe do not provide this level of spacing and therefore there is no operational comparison to be made. Instead increased spacing means fewer turbines and less energy production within the footprint of the project so more projects (and more space) will be necessary to meet state and national energy goals. Furthermore greater space between turbines may increase collision risk if species vulnerable to collision end up using the wind farm more frequently. Unfortunately these are all unknowns and BOEM will need to fund studies to answer these questions. The Draft EIS should have included a risk assessment considering the full range of the potential rotor swept zone provided in the COP to assess 1) impacts from	movements within an existing offshore wind farm. The study tracked seabirds inside the array with actual video cameras and radar tracks, which allowed for measuring avoidance movements with high confidence and at the species level. The study concluded that seabirds would be exposed to very low risks of collision in offshore wind farms during daylight hours. This was substantiated by the fact that no collisions or even narrow escapes were recorded in over 10,000 bird videos during the 2 years of monitoring. Refer to response to comment BOEM-2024-0001-0400-0022. Aside from the few studies that are available on this matter, BOEM still maintains that bird presence on the Atlantic OCS is low based on the literature, studies, and other information documented and described in PEIS Section 3.5.3. As such, BOEM anticipates the risk to birds from any offshore IPF is low (even accounting for turbine spacing and size). For risk to federally listed threatened and endangered birds from offshore wind turbines, refer to responses to comments BOEM-2024-0001-0357-0051 and BOEM-2024-0001-0357-0053. Regarding unknowns and data gaps on birds' use of the of offshore environment, refer to response to comment BOEM-2024-0001-0400-0003. The lessees would need to comply with the Migratory Bird Treaty Act.

Comment No.	Comment	Response
	collision and barrier effects to migrating birds including the piping plover and 2) potential increased habitat loss that may need to occur. Similarly the federally threatened and State endangered red knot is likely crossing the lease area as well and a similar analysis should be done for it. It has a critical habitat in the Holgate and North Brigantine areas during its fall migration (PP4). The results of all Atlantic Shore's Phase 1 and subsequent studies of its migration routes should have been included in the DEIS. The list of project authorizations should also include compliance with the Migratory Bird Protection Act and the criteria used to determine that.	
BOEM-2024-0001-0423-0012	Birds/Bats The Draft PEIS notes the stressors that birds are experiencing including vulnerability to sea level rise and the increasing frequency of strong storms resulting from global climate change (page 3.5.3-11) and commercial fisheries by-catch (page 3.5.3-2 notes that approximately 2600 seabirds are killed annually on the Atlantic through commercial fishing activities). In addition to these stressors climate change is causing more intense droughts increasingly frequent wildfires mismatches between food supplies and migration times which impact bird habitat and migrations. The Draft PEIS meaningfully understates the beneficial effects from the six NY Bight projects since birds would benefit from the resulting reduction in climate change impacts that would occur when the six projects are in operation and producing renewable energy. This benefit may be difficult to quantify but qualitatively it would be expected and should be noted. The Draft PEIS states that [italicized: "potential impacts on birds within the NY Bight lease areas under six projects is not anticipated to be different compared to a single NY Bight project"] (Section 3.5.3.5.2 page 3.5.3-28) and that [italicized: "the incremental impacts contributed by Alternative C to the cumulative impacts on birds would be almost undetectable"] (Section 3.5.3.5.5 page 3.5.3-29). Yet the AMMMs for birds would still require extensive monitoring and reporting burdens with open- ended requirements for plan revisions. These AMMMs are duplicative as bird and bat monitoring requirements will come out of the ESA Section 7 consultation process	As stated in PEIS Section 3.3.2, some impacts of the NY Bight projects may not be measurable at the programmatic level, such as the beneficial impacts on climate change due to a reduction in greenhouse gas emissions. Beneficial impacts on climate change may be addressed in the COP-specific NEPA review document. The minimal difference in bird impacts under six projects and one project—and the impacts anticipated to be undetectable in the context of cumulative impacts—is primarily based on the current understanding that bird presence in the offshore environment is low. If bird presence is low, then there is unlikely to be any notable difference between one project and six projects because neither would have notable effects on bird populations. However, AMMM measures are still implemented by BOEM because there still is some level of uncertainty on the distribution and habitat use of birds in the offshore environment (refer to response to comment BOEM-2024-0001-0400-0003), and implementation of AMMM measures will improve the understanding of bird interactions with offshore wind farms and help inform the assessment of potential impacts on birds from construction and operation of offshore wind farms.

Comment No.	Comment	Response
	during the project-specific NEPA reviews. A PEIS that requires such monitoring frameworks in a COP puts the cart before the horse.	
BOEM-2024-0001-0450-0004	Avian Recommendations- Integrated Monitoring Systems: BOEM should require the deployment of integrated multi- sensor systems at project substations and selected turbines to improve avian impact detection and identification. This would enhance monitoring capabilities and allow for better estimation of collision and avoidance rates.- Adaptive Monitoring Plans: BOEM should require comprehensive monitoring plans that adapt to new information and technology. This includes reporting requirements to enable adjustments to monitoring approaches and consideration of new technologies or additional monitoring periods ensuring the effectiveness of mitigation measures.- Cumulative Impacts Assessment: BOEM should conduct a thorough assessment of cumulative impacts on marine and migratory birds across multiple spatial scales. This would involve considering non-Endangered Species Act (ESA) listed bird species in tracking studies focusing on larger-bodied species for large-scale assessments and transparently discussing poorly- understood areas of avian risk.	BOEM recognizes that monitoring and reporting after construction may be necessary. Based on COP approvals to date, BOEM anticipates monitoring and reporting may be part of the terms and conditions of future COP approval for any of the NY Bight lease areas, as well as adaptive management if impacts deviate substantially from the impact analysis in the EIS. BOEM anticipates that there will be technical innovations to sensor systems in the near future. The PEIS addresses cumulative impacts for the No Action Alternative, Alternative B, and Alternative C (see PEIS Sections 3.5.3.3.3, 3.5.3.3.4, 3.5.3.4.4, 3.5.3.4.5, 3.5.3.5.4, and 3.5.3.5.5). These assessments are based on the best available information regarding bird use on the Atlantic OCS and potential risk from offshore wind projects, as documented in PEIS Section 3.5.3. BOEM understands there are data gaps, uncertainties, and incomplete and unavailable information. However, as stated in PEIS Appendix E, BOEM concludes the PEIS is sufficient to support sound scientific judgments and informed decision-making and does not believe that there is incomplete or unavailable information on birds that is essential to making a reasoned choice among alternatives (refer to response to comment BOEM-2024-0001-0400-0003 and PEIS Appendix E for more information on this matter). In addition, COP specific NEPA documents for NY Bight lease areas that might be developed in the future would include project-specific bird information and cumulative effects analyses based on the most current and relevant bird information available at that time. Tracking studies of large-bodied birds for large scale assessments is something BOEM will consider.
BOEM-2024-0001-0450-0020	Avian Cumulative Impacts Analysis The cumulative impacts must be assessed with great care and focused purpose. This is especially true for marine birds and offshore migrating bats as their year-round ecological needs and conservation risks are fundamentally transboundary in nature. *[Footnote 84: Jodice PGR Suryan RM. 2010. The transboundary nature of seabird ecology. In: Trombulak SC*	Refer to response to comment BOEM-2024-0001-0450-0004. In addition, the PEIS cumulative effects analysis accounts for all anticipated offshore wind projects along the Atlantic OCS that are in the geographic analysis area for birds (with an estimated 2,459 WTGs), and not just in lease areas adjacent to the NY Bight lease areas (see all wind projects in PEIS Figure 3.5.3-1), as well as other planned non-offshore-wind activities that may affect birds

Comment No.	Comment	Response
	Baldwin RF (eds) Landscape- scale conservation planning. Springer Dordrecht pp 139165.] Whereas the mitigation and monitoring approaches in many instances are responsive to wildlife concerns in the NY Bight PEIS we believe the attention devoted to cumulative impacts should be improved. The six lease areas in the NY Bight are configured such that at least three spatial scales would need a cumulative impacts analysis for birds. These include (1) the impacts of each individual lease area relative to the most proximate or adjacent lease area(s) (e.g. OCS-A 0541 and OCS-A 0542); (2) the contribution of each cluster of lease areas to each other (e.g. OCS-A 0541/0542/0539/0538 and OCS-A 0512/0544); and (3) the contribution of any individual lease and all six new lease areas to other adjacent wind areas spread along the Atlantic seaboard of the U.S. In each case the cumulative impacts of the NY Bight PEIS should address marine and migrant birds as well as bats within a hierarchical multi-scale framework. *[Footnote 85: This approach should be similar to that used by Garthe S Schwemmer H Peschko V Markones N Mller S Schwemmer P Mercker M. 2023. Large-scale effects of offshore wind farms on seabirds of high conservation concern. Scientific Reports 13: 4779. In that study cumulative impacts were examined for loons (Gavia stellata G. arctica) in a large area of the North Sea consisting of 14 offshore wind farms organized into 5 wind farm clusters. Displacement impacts were examined at multiple scales including within the wind farms out to 1 km zones and out to 10 km zones.]* For cumulative effects analyses it is especially important to consider widespread non-ESA listed bird species in potential tracking studies to detect how avoidance attraction collision risk and displacement may occur for birds throughout the NY Bight PEIS project and adjoining lease areas. The focus for species selection might rely on project-site surveys in aggregate or the MDAT data but preferably both. Cross- project tracking studies could build on previous work that identifies the most susceptible species of marine birds *[Footnote 86: Marques AT Batalha H Bernardino J. 2021. Bird displacement by wind turbines: assessing current knowledge and recommendations*	(see PEIS Appendix D for a description of planned activities). As stated in PEIS Section 3.5.3, given that the abundance of bird species that overlap with wind energy facilities on the Atlantic OCS is relatively small (see PEIS Figure 3.5.3-2), offshore wind activities would not appreciably contribute to impacts on bird populations.

Comment No.	Comment	Response
	for future studies. Birds 2:460475.] ones that are also sufficiently widespread throughout the NY Bight. Larger-bodied species of birds can make superior focal subjects for large-scale cumulative impacts assessment *[Footnote 87: Garthe et al. 2023.]* and for determining optimal locations to monitor and mitigate bird populations affected by offshore wind in a regional context. Other avian candidates for monitoring objectives in cumulative impacts assessments can be selected from species designated as having higher exposure scores or higher collision vulnerabilities from offshore wind projects along the Atlantic seaboard. *[Footnote 88: Robinson Willmott JC Forcey G Kent A. 2013. The Relative Vulnerability of Migratory Bird Species to Offshore Wind Energy Projects on the Atlantic Outer Continental Shelf: An Assessment Method and Database. Final Report to the U.S. Department of the Interior Bureau of Ocean Energy Management Office of Renewable Energy Programs. OCS Study BOEM 2013-207. 275 pp.]* Finally we strongly recommend more transparent discussion of poorly-understood subject areas where minimal risk to birds is now assumed based merely on limited knowledge or high uncertainties. This includes effects of low frequency sound (infrasound) during turbine operations a factor that could potentially interfere with avian navigation. *[Footnote 89: Patrick SC Assink JD Basille M Clusella-Trullas S Clay TA den Ouden OF Joo R Zeyl JN Benhamou S Christensen-Dalsgaard J Evers LG. 2021. Infrasound as a cue for seabird navigation. Frontiers in Ecology and Evolution 9:812.]* Indirect effects to marine birds from prey redistribution should be incorporated into adaptive monitoring frameworks. Removal of existing hard and/or soft bottom substrates or replacing them with vertical structures that act as artificial reefs could lead to ecosystem-scale alterations to fish and invertebrate prey resources *[Footnote 90: Methratta ET Dardick WR. 2019. Meta-analysis of finfish abundance at offshore wind farms. Reviews in Fisheries Science & Aquaculture 27:242260; Perry RL Heyman WD. 2020. Considerations for offshore wind energy development effects on fish and fisheries in the United States. Oceanography 33:2837.]* thereby influencing avian habitat use and energetics around wind farms. *[Footnote 91: Ronconi*

P.5.8 Coastal Habitat and Fauna

Table P.5-8. Responses to Comments on Coastal Habitat and Fauna

Comment No.	Comment	Response
BOEM-2024-0001-0063-0001	Environmental Disruption: The installation and operation of turbines in the New York Bight will disrupt the marine ecosystem potentially harming habitats and affecting the behavior of marine life.	Thank you for your comment.
BOEM-2024-0001-0122-0002	Additionally ecological changes and alterations to the local marine ecosystem raise environmental concerns that necessitate careful consideration. The devasting impact this will have on bird and bat mortality as well as the visual and noise impact on residents further contribute to the argument against wind turbines in the region. These concerns coupled with the possible negative effects on property values. Offshore wind turbines will have a negative impact on ecosystems industries and communities. We must not allow this to move forward!	Thank you for your comment. Impacts on birds and bats are analyzed in Sections 3.5.3 and 3.5.1, respectively. The visual impacts are analyzed in Section 3.6.9.
BOEM-2024-0001-0313-0048	Affected Environment and Environmental Consequences 3.5.4-14 The PEIS states "Temporary construction impacts on coastal fauna would be limited (see noise and traffic IPFs) as most individuals would avoid the construction areas (Goodwin and Shriver 2010). Land disturbance that does occur especially on shoreline parcels could cause short-term erosion and sedimentation impacts in coastal habitat. Altering dune and beach habitat could increase erosion and sedimentation because dune habitat serves as a crucial buffer zone against flooding. Federal and state agencies work with Atlantic coastal towns and other land managers to develop site-specific Beach Management Plans for the protection of federally and state-listed threatened and endangered species. The COP NEPA analysis	The project-specific COP-level NEPA analysis will coordinate with local towns and beach managers once the landing locations are identified to ensure consistency with relevant local management plans.

Comment No.	Comment	Response
	will coordinate with local beach managers once the landing locations are identified to ensure concurrence with local Beach Management Plans. Overall impacts from land disturbance on coastal habitat and fauna are expected to be minor." Comment DER is unaware of the existence of the aforementioned Beach Management Plan or the Federal and State government efforts to provide resources regarding same further it is all but certain that any plans for TOBAY Beach did not have any considerations for the impacts from offshore wind. Further any impediments to the shore as referenced above should be completely avoided where feasible especially where it could impact access to the Town's beachfront community and enjoyment of local resources and could impede environmental improvement measures regularly deployed by the Town such as dune grass planting.	
BOEM-2024-0001-0394-0003	Many forms of aquatic marine life have evolved to be highly dependent on sound because vision underwater is only useful for perceiving very short distances. Many forms of aquatic ocean life are only able to understand perceive or 'image' their environment using sound. The effects of sound on marine organisms is not receiving a proper examination. For most marine organisms use of and response to sound is necessary for the execution of essential life processes. For some vibration. The U.S. Offshore Wind program will make profound modifications to a very large portion of the ocean habitat on the outer continental shelf. The examination performed by BOEM and NOAA Fisheries has largely been focused on whether sounds expected to be generated by offshore wind activity are expected to be loud enough to cause permanent hearing losses. The scope so narrow that it will not be able to capture the environmental effects of this project that are reasonably likely to occur.	Noise is an IPF analyzed throughout the PEIS. The impacts of noise on coastal fauna are discussed for all alternatives in Section 3.5.4. The behavioral impacts of noise on species are further discussed in the corresponding sections for marine mammals, sea turtles, birds, bats, benthic resources, and finfish and invertebrates.

P.5.9 Finfish, Invertebrates, and Essential Fish Habitat

Table P.5-9. Responses to Comments on Finfish, Invertebrates, and Essential Fish Habitat

Comment No.	Comment	Response
BOEM-2024-0001-0071-0002	Through noise pollution (I was part of a study that tested noise levels at VW construction as loud as 181dbs WAY TOO LOUD) through EMFs (we'll literally be putting radiant heat in our ocean floors) through the substations that will suck up 8000000 gallons of water each and heat it up to as high as 93*F cooking and killing plankton microbes and fish larvae through oil spills and through endangering migrating birds and bats. We will be endangering our natural food supply.	BOEM is analyzing several AMMM measures under Alternative C, including measures to reduce decibel (dB) levels using attenuation devices and shut-off protocols when animals are within the vicinity of sound sources. The design, location, construction, and capacity of the cooling water intake structures shall reflect the best technology available for minimizing adverse environmental impacts from the impingement and entrainment of all life stages of fish (e.g., eggs, larvae, juveniles, and adults) by the cooling water intake structures. Examples of RPs for noise include MUL-5, MUL-6, and MUL-7, including implementation of lowest noise practices for equipment, WTG installation methods, and adherence to International Maritime Organization (IMO) guidelines on vessel noise, which would reduce impacts from noise on finfish, invertebrates, and EFH.
BOEM-2024-0001-0093-0002	I believe that the wind turbines will encourage new habitats for fish life.	Thank you for your comment. You can read more about the reef effect in the Presence of Structures subheadings within Sections 3.5 and 3.6.
BOEM-2024-0001-0122-0004	Marine Ecosystem Disruption: The installation of offshore wind turbines will disturb marine ecosystems. Construction activities such as pile driving will create noise and vibrations that affect marine life and the presence of underwater structures can alter the behavior of marine species.	The impact of pile-driving on multiple species is discussed in Table 2.4 and Section 3.5. Acoustic thresholds are analyzed for multiple species. There are several AMMM measures that can be applied during pile-driving activities to address underwater noise.
BOEM-2024-0001-0176-0002	This push for Offshore Wind is nothing more than a massive experiment on our ocean and the entire marine ecosystem. Cooling systems taking in cool ocean water at up to 8100000 gallons per day and mixing it with chemicals such as bleach to keep the pipes clean and then dumping it back into the ocean at temp. between 86-90 degrees F. this will certainly mimic climate change kill off fish larvae zooplankton etc.	The analysis of warm water discharges from the offshore substations is included in Section 3.4.2. Warm water discharged from the offshore substations will have a minimal effect because it will be mixed by the surrounding water and returned to ambient temperatures. The overall impacts are expected to be minimal with no degradation of water quality. CWA Section 316(b) requires project-specific NPDES permits to ensure that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available to minimize adverse environmental impacts. The design, location, construction, and capacity of the cooling water intake structures

Comment No.	Comment	Response
		will incorporate the best technology available for minimizing adverse environmental impacts from the impingement and entrainment of all life stages of fish (e.g., eggs, larvae, juveniles, and adults).
BOEM-2024-0001-0308-0001	The construction of wind turbines in the New York Bight poses a significant threat to the marine ecosystem particularly affecting numerous whale and fish species that frequent this area as reported by Gotham Whales. This includes several endangered species highlighting the critical nature of the threat.	BOEM has previously required developers to use protective measures—such as protective species observers, exclusion zones, and independent reporting,—to avoid whales and other protected species during project activities. A full list of measures aimed at protecting finfish, invertebrates, and EFH can be found in Table 3.5.5-8. Measures protecting marine mammals and sea turtles can be found in Tables 3.5.6-11 and 3.5.7-8, respectively.
BOEM-2024-0001-0313-0019	There are numerous concerns with the potential impacts of the open loop system mentioned above including the intake of phytoplankton and larvae that form a basis for the ocean food chain and the cascade of potential adverse effects. Again the concern and analysis should not be limited to just the NY Bight Area but the impact of the loss of the organisms and food supply in terms of the cumulative impacts for this technology for all the planned and future offshore wind projects in the sphere of ecological influence. Even the PEIS makes note on page 3.4.2-3 that "Phytoplankton is the foundation of the marine food web and their associated growth rates depend on nutrient (e.g. nitrogen phosphorus and carbon plus calcium and silicon are various micronutrients) availability in the water." Thus the impact to other trophic levels given the potential impact to the foundational structure of the marine food web should be analyzed.	Section 316(b) of the Clean Water Act requires NPDES permits to ensure that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available to minimize adverse environmental impact from impingement and entrainment of aquatic organisms. Impacts of entrainment and impingement on finfish and invertebrates at HVDC converter intakes would be limited to the immediate area of the offshore substations and to intake volumes. Project design and specific intake volumes will be assessed in the NEPA analysis of each project-specific COP.
BOEM-2024-0001-0313-0044	Further there should be a quantification of the cumulative impacts of all project impacts to loss of filter feeding organism in terms of not just loss to commercial harvesting but in terms of water quality benefits correlated to the societal economic impact to decreased water quality as result of the proposed action. Estimating the dollar value of water quality benefits currently provided in the no action alternative as compared to the proposed action requires a multidisciplinary approach. A new study estimates that oyster and clam aquaculture provides $2.85.8 million in services that remove excess nitrogen from the coastal waters of Greenwich Connecticut. The study was conducted by shellfish biologists economists and	Section 3.6.1.5.1 provides an assessment of shellfish, including AMMM measure COMFIS-3, which proposes the development of a Fisheries and Benthic Monitoring Plan, which would include surfclam and scallops and would be compatible with other regional data collection methods. This measure, if applied, would increase data and knowledge about the surfclam and scallop fishery, potentially resulting in the future development of other mitigation measures that may benefit those or other commercial or for-hire recreational fisheries.

Comment No.	Comment	Response
	modelers from NOAA Fisheries NOAA National Centers for Coastal Ocean Science and Stony Brook University. It was recently published in Environmental Science & Technology. Researchers used a "transferable replacement cost methodology" to estimate the ecological and economic value of nitrogen reduction that results from oyster and clam aquaculture in this coastal community. The replacement cost method puts a dollar value on ecosystem services by estimating what it would cost for humans to provide those services." (Source: NOAA Fisheries "How Much Is A Clam Worth To A Coastal Community?" April 05 2021). As the proposed action has the significant potential to dramatically reduce the filter feeding capacity of destroyed filter feeding organisms this should be analyzed and a compensation package and/ mitigation measures and plan for restoring what is lost should be provided if warranted in the PEIS.	
BOEM-2024-0001-0313-0047	Affected Environment and Environmental Consequences 3.5.2-15 The PEIS states "Electric and magnetic fields and cable heat: EMF would result from ongoing and planned transmission or communication cables. DC cables placed on the seafloor would generate a static magnetic field changing the natural geomagnetic field. Cables carrying AC which produce low-frequency EMF are the most commonly used in offshore wind farms to date. EMF effects from offshore wind cables on benthic habitats would vary in extent and significance depending on overall cable length the proportion of buried versus exposed cable segments and project-specific transmission design (e.g. HVAC or HVDC transmission voltage). The EMF intensity diminishes rapidly with distance but is considered a long-term impact as it is expected to be present in the environment for the life of the project. The maximum magnetic field expected for an offshore wind energy project's export cable EMF is about 165 milligausses) (16.5 microteslas) dropping to 40 milligausses (4.0 microteslas) 3.26 feet (1 meter) above the cable a decrease in field strength of 76 percent (CSA and Exponent 2019). To put these values in perspective the strength of the Earth's DC magnetic field is approximately 516 milligausses (51.6 microteslas) along the southern New England Coast (CSA and Exponent 2019) and normal values of the Earth's geomagnetic field can range from 200 to 750 milligausses (20 to 75 microteslas) depending on the geographical location (Diez-	The Final PEIS considers the best available data and information that reflect the state of the science at the time of publication of the PEIS. An acknowledgment of uncertainty about the impacts of EMFs is included in Appendix E, *Analysis of Incomplete or Unavailable Information*. Future research about EMF exposure on benthic marine organisms may be incorporated into future project-specific COP NEPA analyses as information becomes available.

Comment No.	Comment	Response
	Caballero et al. 2022). At this time no thresholds of the acceptable or unacceptable levels of EMF emissions have been determined for the marine environment (Hogan et al. 2023). The impact of EMF on benthic habitats is an emerging field of study; as a result there is a high degree of uncertainty regarding the nature and magnitude of the effects on all potential receptors (Gill and Desender 2020). Recent reviews by Bilinski (2021) Gill and Desender (2020) Albert et al." Comment It is concerning that there is an admitted lack of scientific studies and evidence documenting the potential impacts to benthic organisms and the ecosystem as a result of EMF and cable heat. It would also stand to reason that the assumption should not be that there is no impact but should conversely be an assumption that there is an impact until proven otherwise in an abundance of caution to protect the environment.	
BOEM-2024-0001-0313-0058 and BOEM-2024-0001-0313-0059	Further, based on DER past experience, and comments from NYSDEC and responses from AECOM (source: Response to Comments Letter Dated: March 4, 2022 Technical Comment Letter South Brooklyn Marine Terminal – Port Infrastructure Improvements Project DEC ID: 2-6102-00120). • Protected Species Time of Year Restrictions (TOYRs) -The narrative recognizes the need for compliance with the TOYRs however TOYR dates are not specified. TOYRs also will apply for in-water work associated with bulkhead/wharf improvements (such any in-water vibratory pile driving). To avoid impacts to federal-and state-protected species including migrating Atlantic sturgeon and spawning winter flounder no in-water activity shall occur between: a. December 15 and March 1 in waters less than 20 feet; and b. March 1 and June 30 and between October 1 and November 30 in waters of any depth. ○ Response 2: Thank you for providing the TOYRs. The project will comply with these restrictions. • Protected Species Protection Measures -Please indicate the size of the buffer zone that would trigger a shut down if a protected species is observed (as discussed in Section 8.1 of the Permit Information Packet). Additionally please also include the	The PEIS will not result in the approval of any activities in the NY Bight lease areas. Each lessee has the exclusive right to develop and submit a COP as outlined under 30 CFR 585.628. BOEM will then conduct project-specific COP NEPA analysis for each lease area that will focus on providing site- and project-specific analyses. Specific time of year restrictions for each project will depend on the proposed project activities and will be negotiated as part of the project permits.

Comment No.	Comment	Response
	Protected Species Shut Down buffer zone as a Best Management Practice to be implemented. ○ Response 3: As described in the JPA the likelihood that protected species would be present in the Project Area during in-water construction activities is extremely low. Based upon review of the NOAA Fisheries Final Biological Opinion for the New Jersey Wind Port dated February 25 2022 which required no buffer zone for similar in-water work and implementation of other conflict- minimizing Best Management Practices pile installation (e.g. operator will begin pile driving with soft start 'warning taps' piles will be vibrated in for the majority of the installation and then driven the remainder of the way) the Applicant believes that a shutdown buffer zone is not necessary. Based on prior experience with pile driving operations these BMPs would cause any protected species present to leave the action area prior to the production of maximum noise levels reducing the risk of injury. Pile driving at the start of each day would commence with an initial set of three strikes with the hammer operating at 40% power. After a one-minute pause two more sets of three strikes separated by a one-minute pause would be performed with the hammer operating at 40% power. After a third and final one-minute pause normal hammer operations would commence. Further pile installation will be limited to dates outside of sturgeon TOYR lessening the likelihood of potential impacts to sturgeon species." It is unclear if these restrictions will be in place for this project and if they have been factored in the construction schedule projections or if a waiver/permitting restriction relief will be sought from NYSDEC and what the consequences of same would be to the environment. AS this has the potential to impacts numerous project considerations this should be evaluated in the Final PEIS.	
BOEM-2024-0001-0332-0008	EFH Essential Fish Habitat The NYB leases are in the middle of the 20/30/40 fm midshore offshore fishing grounds which is some of the most productive	Impacts on sand lances and other fish are acknowledged in Section 3.5.5.1.4, *Essential Fish Habitat*. The addition of scour protection would result in short-term to permanent impacts on

Comment No.	Comment	Response
	fishing grounds and also home to a number of prominent/historic wreck sites. The area's sand ridges are home to abundant colonies of sand lance aka sandeels which are a quintessential link in the food web. They are not only forage to ground fish and pelagic species but also whales and sea birds. Anyone who has fished these waters in the summertime knows the show is better than Sea World! Based on documents which detail [Embedded Hyperlink: https://www.researchgate.net/publication/262875861_Short-_and_long-term_effects_of_an_offshore_wind_farm_on_three_species_of_sandeel_and_their_sand_habitat] the strong association of sand eels to sandy sediment sand eels will most likely be negatively affected by the radical change in habitats when hundreds of turbines and thousands of tons of rock scour protection are added around the turbine and substation bases. If and when sand eels leave so too do all of the other species.	softbottom habitat within the project area and would impart minor impacts on finfish, including the sand lance, though localized impacts would likely be greater. Habitat conditions would be unaffected after construction is complete. Impacts from six NY Bight projects would therefore remain negligible to major.
BOEM-2024-0001-0332-0009	How can it be that no HAPC (habitat areas of particular concern) are designated within the NYB yet summer flounder spawn in the winters on the OCS and use the areas during all four stages of their life cycle (egg larvae juveniles and adults)? Many other coastal species rely on the Chicken Canyon and Hudson Canyon during one or more life stages and use the NYB's lease areas. Also mako sharks should be of concern as they spend a lot of time in this area. As of 7/5/2022 U.S. fishermen may not land or retain Atlantic short fin mako sharks; however these water used to be prime shark fishing grounds. It seems many of these are conveniently overlooked. A lot of these ecologically sensitive area (what I would call HAPC) and fishing hot spots were detailed in the very basic early work of Buchanan at the NJDEP in 2010 NJ's Area of Interest Wind Power On The OCS. Was any of this really basic stuff even considered?	Habitat Areas of Particular Concern (HAPCs) are discrete subsets of EFH designated by the regional fishery management councils and represent high priority areas for conservation, management, or research, and they are necessary for healthy ecosystems and sustainable fisheries. The HAPCs for the study area are shown on Figure 3.5.5-2, along with the NY Bight lease areas. No designated HAPCs are located within the NY Bight lease areas; however, Section 3.5.5 discusses that summer flounder HAPCs may overlap with potential NY Bight offshore export cable corridors and vessel routes to the identified representative ports (see Chapter 2, *Alternatives*).
BOEM-2024-0001-0334-0005	Damage to the shoreline: Our fishermen are aware of catastrophic losses of sea scallop populations in the vicinity of sonar work. It has killed them. This outcome is unacceptable and BOEM has allowed it to happen.	AMMM measure COMFIS-3 is aimed to benefit the scallop fishery by focusing on increasing data and knowledge about the scallop fishery. See Table 3.6.1-20.
BOEM-2024-0001-0345-0012	CCE also makes the following suggestions for inclusion in the final document: Benefits of Offsetting Fossil Fuel Plants In addition to the benefits listed in the PEIS [Bold Italics: CCE urges BOEM to consider	Thank you for your comment. Assessment of impingement from the cooling systems of two existing onshore fossil fuel plants is outside the scope of this NEPA analysis.

Comment No.	Comment	Response
	the potential benefits of offsetting the need for the Northport Port Jefferson and E.F. Barrett power plants which are legacy fossil fuel power plants on Long Island.] During previous public meetings concerns were raised about the impact that the open-loop cooling systems of offshore wind farms will have on fish populations particularly Atlantic Cod. The Northport power plant which discharges directly into a marine environment (Long Island Sound) is responsible for the entrainment of almost 8.5 billion larvae and impingement of over 125000 fish each year. It is important for BOEM to note not only the potential adverse impacts of an offshore wind open loop system but to compare those impacts to the existing fossil fuel plants particularly the Northport and Barrett Plants that this project would reduce the need for.	
BOEM-2024-0001-0352-0010	In the finfish and EFH section Atlantic cod is referenced as a species that could benefit from increased hard bottom habitat resulting from project development. While we agree that it is important to ensure suitable habitats exist for Atlantic cod the New York Bight is not an important area for this species and the creation of new structures in this region may not confer a noticeable benefit. We remain concerned about the possible negative impacts of offshore wind construction on this species and we appreciate that acoustic impacts on cod and other fishes are discussed in this section. We are concerned that the discussion of open loop cooling systems underestimates potential effects on plankton including fish eggs and larvae (Section 3.5.2.4.1). For example the draft PEIS notes that discharge water for the South Coast project was predicted to reach 90F which is quite high. This was modeled to result in a 1.4 F increase up to 155 feet from the discharge point and was expected to result in mortality for many types of plankton. Impacts are described as negligible given that they are highly localized even when considered across all six New York Bight projects. It may not be appropriate to draw these conclusions without further consideration of the specific locations of these cooling systems within each lease area. We recommend a more detailed evaluation of this topic in the final PEIS and subsequent project-specific analysis.	Thank you for your comment. The estimated temperature and distribution of the discharge water provided from the predicted model developed by TetraTech and Normandeau Associates, Inc. in 2023 represents the current best available science. The Final PEIS considers the best available data and information that reflect the state of the science at the time of publication of the PEIS. An acknowledgement of uncertainty about the impacts of EMFs has been added to Appendix E, *Analysis of Incomplete or Unavailable Information*. Additional citations and clarifying text have been added to Final PEIS Section 3.5.5, *Impacts of the Proposed Action on Benthic Resources*, under *Presence of Structures*.

Comment No.	Comment	Response
	The draft PEIS seems dismissive of EMF impacts (Section 3.5.2.4.1). Given that large scale offshore wind projects are just now being installed off the East Coast this issue requires further study. We are also concerned that the draft PEIS downplays the potential for wind projects in these lease areas to result in expanding species distributions through the "steppingstone effect." The PEIS notes that wind projects in these lease areas may not notably contribute to the steppingstone effect given the existing network of artificial reefs off New York and New Jersey (Section 3.5.2.4.1). However the document fails to acknowledge that the six New York Bight lease areas are much further offshore than the existing artificial reefs. Fully built out along the East Coast offshore wind will result in a very large increase in artificial structures offshore that run from the seabed through the entire water column. Blue mussels for example may be demonstrating a steppingstone effect in the Block Island Wind Farm (Hogan et. al 2023[Footnote 2: Hogan F. B. Hooker B. Jensen L. Johnston A. Lipsky E. Methratta A. Silva and A. Hawkins (2023). Fisheries and Offshore Wind Interactions: Synthesis of the Science. 383p. https://repository.library.noaa.gov/view/noaa/49151] Section 1.1. and references therein).	
BOEM-2024-0001-0362-0026	Environmental Protection The draft PEIS reviews potential environmental impact from offshore wind development in the New York Bight and measures that could avoid minimize mitigate and monitor those impacts. The analysis explores potential impacts to bats benthic resources birds fish marine mammals sea turtles and wetlands. Environmental protection is a key requirement under the Outer Continental Shelf Lands Act (OCSLA) and NEPA and rigorous plans must be in place for offshore wind projects to comply with various state and federal statutes that projects are subject to. Offshore wind energy must be developed in an environmentally responsible manner that avoids minimizes and mitigates impacts to marine life and ocean users meaningfully engages stakeholders from the start and uses the best available science and data to ensure science- based and stakeholder-informed decision making. The PEIS should analyze potential cumulative impacts; benefits of mitigation measures; and adaptive management strategies. The analysis should include all relevant data and acknowledge relevant scientific	Thank you for your comment. The continuation of all other ongoing and reasonably foreseeable future activities described in Appendix D, *Planned Activities Scenario,* without the NY Bight projects, serves as the baseline for the evaluation of cumulative impacts. In Chapter 2, the impact of No Action Alternative; Alternative B, No Identification of AMMM Measures at the Programmatic Stage; and Alternative C, Identification of AMMM Measures at the Programmatic Stage, are discussed in light of the best available information. Incomplete or unavailable information (Data gaps) is described in Appendix Section E.1.7.

Comment No.	Comment	Response
	disagreements and data gaps. Avoiding sensitive habitat areas requiring strong measures to protect wildlife throughout each state of the development process and comprehensive monitoring of wildlife and habitat before during and after construction are all essential for the responsible development of offshore wind energy. The combination of alternatives should be chosen that ensures communities wildlife and the environment are protected while maximizing the creation of quality high-paying jobs and economic benefits.	
BOEM-2024-0001-0528x	The first article is “Offshore Wind Farms Are Projected to Impact Primary Production and Bottom Water Deoxygenation in the North Sea”, which is from *Communications, Earth and Environment*. Volume 3. Article number 292 by Ute Daewel, Naveed Akhtar, Nils Christiansen, and Corinna Schrum where they determine that associated wind wakes in the North Sea provoke large scale changes in annual primary production with local changes of up to plus or minus 10%. Not only at the offshore wind farm clusters, but also distributed over a wider region. The model also projects an increase in sediment, carbon, and deepen areas of the sor - of the Southern North Sea, due to reduced current velocities and decreased, dissolved oxygen inside area with already low oxygen concentration. Their results provide evidence that ongoing offshore wind farm developments can have a substantial impact on the structuring of coastal marines ecosystems on basin scales, and as one of the other previous speakers, it said, yes, there is an increase in some areas, however, the response quote the response in phytoplankton biomass is relatively small on average, but below 1%, both inside and outshore offshore wind farm cluster but can reach up to 10% locally, and that annual net, prime primary production changes in response to offshore wind wake effects in the southern North Sea areas both show areas with a decrease in areas with an increase for annual net primary production of up to 10 percent. Most obvious is the decrease in the center of the large offshore wind clusters in the inner German Bight, and at Dogger bank, which are both clearly situated in highly productive frontal areas and an increase in areas around these clusters in shallow near-coastal areas of the German Bight and at Dogger Bank. The second article is from *Frontiers in Marine Science*,	Thank you for your comment. Caution should be taken in extrapolating study outcomes from European wind farms to expected results in the NY Bight, as the environmental conditions are not equal. European wind farm facilities differ, as they are in shallower waters with weak seasonal stratification, in sheltered areas along the coasts, and arranged with tight spacing of turbines (Lentz 2017; Hogan et al. 2023). Please see Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative; Presence of Structures*, which discusses hydrodynamics, including atmospheric wakes and the Mid-Atlantic Bight Cold Pool. Discussion of the two other references requested by the commenter—Christiansen et al. 2022 and Stoelinga et al. 2022 (ArcVera Renewables)—has been added to Appendix B.

Comment No.	Comment	Response
	February 2022. "The Emergence of Large-Scale Hydrodynamic Structures Due to Atmospheric Offshore Wind Farm Wakes" again by Christiansen and Daewel with Bughsin, Djath and Corrina Schrum. It talks about the large-scale surface heating up of up to .1 Celsius, imitating the effects of climate change in which an increase in sea surface temperature is also to be expected as a result of warming of the earth's atmosphere. Then ArcVera had recent study - ArcVera Renewables in August, 16 20, 16th 2022, which confirmed that severe under-prediction of long range wake losses by engineering wake loss models in common use and investigated long range wake loss potentials at the New York Bight offshore development sites, velocity deficits has high as Velocity deficits as high as one meter per second or 10% persist for up to persists for up to, or greater than 60 miles downwind of large or offshore arrays leading to long range energy deficits much greater than expected by most subjects experts using the weather research forecasting model, a firmly established high fidelity, numerical prediction model along with the Wind Farm parameters. Sorry, hard to sell this parameterization which was added to the model to account for the effects. We do feel the PEIS should be analyzing this ArcVera methodology as it relates the wind lease areas, cumulative wind lease areas and COPs and records of decision that have been submitted to the Atlantic Ocean to date.	
BOEM-2024-0001-0528aa	Marine food sources, such as planktons, mollusks, bivalves. The primary sources are affected by abnormal frequencies. Fish are affected by abnormal sounds and vibrations. Each species has its different vulnerability index, which is a critical component of all the overall risk assessment but it's not discussed, and that's quoted from your fine book there. The amount of marine real estate used for these turbine arrays will push natural-recurring feeding, breeding, migration, and navigation out of its natural areas.	The Final PEIS considers the best available data and information that reflect the state of the science at the time of publication of the PEIS. Acoustic thresholds are analyzed for multiple species. There are several AMMM measures that can be applied during pile-driving activities to address underwater noise as well. Additionally, examples of RPs for noise include MUL-5, MUL-6, and MUL-7. These include implementation of lowest noise practices for equipment, WTG installation methods, and direction to follow IMO guidelines on vessel noise, which would reduce impacts from noise on finfish, invertebrates, and EFH. A discussion regarding uncertainty about the impacts of underwater noise is included in Appendix E, *Analysis of Incomplete or Unavailable Information*. Future research will be

Comment No.	Comment	Response
		incorporated into subsequent COP NEPA analyses as information becomes available.
BOEM-2024-0001-0310a	And one of the impacts of the EMF on -- one of the questions was what are the impact of EMF on species. They directed me to a specific page in which I read and it said EMF will affect all species of sharks, skates, electric eels, and the mating of flounder. And that was just one page and there was way too much in a 1400-page document to go on.	An EMF analysis is provided in Section 3.5.5.3.3 and 3.5.5.4.1. EMF exposure levels in the built environment are not expected to reach high enough energy levels to result in impacts on populations, and there is no evidence to indicate that EMFs from undersea AC or DC power cables negatively affect commercially and recreationally important fish species (CSA Ocean Sciences Inc. and Exponent 2019; Gill and Desender 2020; NYSERDA 2017; SEER 2022; Taormina et al. 2018). Additionally, RP MUL-39 proposes the electric shielding on underwater cables to control the intensity of EMF. The Final PEIS considers the best available data and information that reflect the state of the science at the time of publication of the PEIS. An acknowledgment of uncertainty about the impacts of EMFs is included in Appendix E, *Analysis of Incomplete or Unavailable Information*. Future research about EMF exposure on benthic marine organisms may be incorporated into future project-specific COP NEPA analyses as information becomes available.
BOEM-2024-0001-0529cc	Offshore wind will increase climate change by increasing sea surface temperature and will decrease the upwelling and downwelling of the ocean, which decreases the productivity of all marine food webs. The loss of current, and will increase the loss of productivity, and will extend according to ArcVera's studies, up to 60 miles leeward of where the lease area is. Basically, the wind acts as a block, and as such the sea surface, where current comes from will have less wind, and will actually warm the ocean, mimicking climate change and increasing the issues of climate change. The ocean is our carbon sink. Especially in the mid-Atlantic, we have something called the Mid Atlantic Cold Pool, which Rutgers did study on in 2021, and they are extremely concerned because it has been considered basically our safety mechanism, a large pool of cold water toward the bottom. By pile driving and jet plowing the ocean floor, and then creating this lack of upwelling and downwelling, we risk losing the protective	Thank you for your comment. Section 3.4.1.4.3 and Appendix B, Section B.1.4 discuss potential impacts of WTGs on ocean temperatures. A discussion of the ArcVera study has been added in Appendix B. Please see Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative, Presence of Structures*, which discusses hydrodynamics, including atmospheric wakes and the Mid-Atlantic Bight Cold Pool.

Comment No.	Comment	Response
	nature of the cold pool itself, which would literally put climate change on steroids.	
BOEM-2024-0001-0310o	Putting these monstrosities in Hudson Canyon, the home of hundreds of species of fish and protected marine mammals is unthinkable. This area has a unique cold pool which attracts these marine inhabitants. The currents around the turbines are exactly what breaks down the cold pool and ultimately because of the wind wake effect extending for up to 60 miles past a turbine zone, we believe it will decrease the upwelling and downwelling of the ocean and it will increase the sea surface temperature.	Avoidance of major OCS features was part of BOEM's planning process to identify lease areas (Section 1.2, Table 1-1, *History of BOEM planning and leasing activities in the NY Bight*), and none of the NY Bight lease areas are in the Hudson Canyon. Please see Section 3.4.2.3.2, *Cumulative Impacts of the No Action Alternative, Presence of Structures,* which discusses hydrodynamics, including atmospheric wakes and the Mid-Atlantic Bight Cold Pool.

P.5.10 Marine Mammals

Table P.5-10. Responses to Comments on Marine Mammals

Comment No.	Comment	Response
BOEM-2024-0001-0063-0005	Noise and Vibrations: Noise and vibrations from offshore wind turbines will have adverse effects on marine life disrupting the natural behaviors and communication patterns of marine mammals and fish.	Thank you for your comment. The potential acoustic impacts on marine mammals due to operational turbine noise is discussed in detail in Section 3.5.6.3.3, and the effects on fish are discussed in Section 3.5.5.3.3.
BOEM-2024-0001-0071-0005	83 whales wash up on our shores last year never mind the dolphins horseshoe crab and other marine life. These deaths are strongly correlated with the beginning of construction and sonar mapping for offshore wind. Why are we still moving forward with these projects?	To date, no whale mortality has been attributed to offshore wind activities. The scientific consensus is that offshore wind activity is not a cause of these marine mammal mortalities. Instead, the three declared UMEs for whales in 2016 and 2017 were primarily determined to be caused by non-wind vessel strikes and fishing gear entanglements (and infectious disease for the minke whales). These UMEs began prior to any offshore wind activities in the Atlantic Ocean. NOAA, academic institutions (e.g., Rutgers University, University of Rhode Island, Yale), environmental organizations (e.g., Sierra Club, Natural Resources Defense Council), BOEM, and the DOE have all issued official statements that no marine mammal mortality has been attributed to offshore wind activities. Furthermore, the Marine Mammal Commission—an independent federal agency whose purpose is the protection of marine mammals—has stated in a letter,

Comment No.	Comment	Response
		"Despite several reports in the media, there is no evidence to link these strandings to offshore wind energy development. For more information on offshore energy development and whales, please see this fact sheet produced by the Bureau of Ocean Energy Management."
BOEM-2024-0001-0176-0003	The unprecedented uptick in Whale and Dolphin deaths in the past 14 months is devastating and all of them while offshore wind vessels were surveying nearby. While you deny any connection between offshore wind and the deaths no full necropsies have been released meaning there is no evidence that there is not a connection. The Incidental Harassment Authorization is evidence! Level B Take- disrupting behavioral patterns including but no limited to migration breathing nursing breeding feeding or sheltering Level A Take- an act of annoyance pursuit torment that has the potential to injure a marine mammal or marine mammal stock in the wild. Read that again it's certain death and an invasion of THEIR ocean!	There is no causal connection between recent offshore wind development and large whale mortality, and such an assumption is contrary to the scientific consensus. The overwhelming scientific consensus is that offshore wind activity is not a cause of these marine mammal mortalities. Instead, the scientific community has determined the three declared UMEs for whales in 2016 and 2017 were primarily caused by non-wind vessel strikes and fishing gear entanglements (and infectious disease for the minke whales). NOAA, the Marine Mammal Commission, academic institutions (e.g., Rutgers University, University of Rhode Island, Yale), environmental organizations (e.g., Sierra Club, Natural Resources Defense Council), BOEM, and the DOE have all issued official statements that no marine mammal mortality has been attributed to offshore wind activities.
BOEM-2024-0001-0180-0002	Marine mammals are being threatened harmed and even killed with the full support of both BOEM and NOAA both proponents of the "incidental take" of potentially over 1000 marine mammals many protected by the Endangered Species Act. BOEM is being completely dismissive of the fact that shellfish and finfish stocks will be significantly harmed and commercial catch is already significantly down and often no longer viable where offshore wind farms are located. Thousands of birds and bats are being destroyed worldwide with the potential result of species extinction.	"Take" of a marine mammal is a term that is specifically defined under the Marine Mammal Protection Act (MMPA) and the ESA. While the PEIS analyzes impacts on ESA-listed species, the "taking" of a marine mammal is not determined through NEPA but through the MMPA and/or ESA. For clarity, BOEM does not authorize any permits or takes. Only the NMFS has this authority through the ESA or MMPA. To date, offshore wind developers have not applied for, and NMFS has not approved, any authorization to kill any marine mammals incidental to offshore wind site characterization surveys or construction activities. Authorized takes during construction in finalized authorizations have been limited to Level A and Level B takes by acoustic harassment. Additionally, authorized takes are based on modeling and are therefore likely proportional to but not the actual number of takes that will occur during activities. Authorized takes mean that the project may not exceed the authorized number of takes

Comment No.	Comment	Response
		within the given time period of the issued permit. Consideration of takes that occur as a result of these projects is better characterized by protected species observer (PSO) reports. For example, from the published high-resolution geophysical (HRG) survey PSO reports from multiple offshore wind development projects within the U.S. Atlantic Ocean, professional PSOs recorded 2,696 large whale detections; of these, only 68 (2.5%) were detections that met Level B exposure criteria (animal distance and source operations). Consideration of other stressors that have resulted in mortality or injury of marine mammals (e.g., fisheries interactions, vessel strikes) are unrelated to the offshore wind projects considered part of the Proposed Action of this PEIS and are outside the scope of this assessment. Please see Tables P.6.13, P.6.5 and P.6.7 for responses regarding fisheries resources and bird and bat resources.
BOEM-2024-0001-0217-0001	Lack of impact studies: The total impact of these projects on endangered species and their prey has not been adequately studied. This raises concerns about potential habitat degradation and disruption of critical ecological relationships and the fact there are no studies on what the overall impacts would be were the whole 100megawatts be built out along the several hundred mile swath that is the whale migratory pathway.	Substantial scientific data exist for offshore wind development that allow for an assessment of impacts. All available information regarding long-term, regional impacts of offshore wind projects has been considered in this PEIS.
BOEM-2024-0001-0217-0003	The potential benefits for the ecosystem through whale foraging needs further research. For instance one adult humpback whale sequesters as much carbon as 70 sq miles of Forest in one year yet there's no studies to what will happen if the whales abandon these offshore areas due to the acoustic vibrations and electromagnetic fields that risk whale habitat.	Thank you for your comment. Long-term impacts of marine mammal responses to the presence of these projects are considered in Section 3.5.6.3.3, specifically the WTG Operations subsection, the Presence of Structures subsection, and the Electric and Magnetic Fields and Cable Heat subsection. Because the locations of the six proposed NYB projects do not overlap with any critical habitat or BIAs, because no barriers to migration or movement would be expected, and based on all available information, no habitat abandonment due to these offshore wind projects is expected to occur.
BOEM-2024-0001-0217-0004	Benthic environment destruction: concern that the construction of offshore energy infrastructure could damage the seafloor habitats	Benthic impacts due to construction of offshore windfarm projects were considered in this PEIS. Based on the most recent data available, effects on the seafloor habitats would be limited

Comment No.	Comment	Response
	that support Sand Lance populations a key food source for humpback whales. Positive impact of whales on the ecosystem	to short-term disturbances. Therefore, no long-term effects on marine mammal prey species or marine mammal foraging are expected.
BOEM-2024-0001-0217-0005	Improved ecology: the positive ecological impact of humpback whales in the region through their foraging activities have contributed to a thriving Sand Lance population and overall ecosystem health.	Thank you for your comment. The impact assessment of the Proposed Action (Alternative C) considered mitigation that would reduce impacts to the extent possible for whale species such that no population-level effects or long-term foraging behavior effects would be realized for humpback whales.
BOEM-2024-0001-0217-0006	Increased wildlife presence: Despite rising sea temperatures and despite current scientific understanding the author observes an increase in whales tuna and sharks in the area potentially benefiting from the improved ecosystem due to increased whale activity precisely in the areas where the wind turbines are planned and endangered the whale habitat.	The most recent PAM data, visual observation studies, and density models include these observed shifts in marine mammal distribution. Additionally, offshore wind farms are expected to have long-term benefits for climate change impacts that are driving these changes in distribution, which would subsequently benefit marine life.
BOEM-2024-0001-0217-0007	Call for further research and caution:* Data lacking: Halt further installation until research to document the positive effects of whales and quantify the potential impacts of offshore energy projects before making decisions.* Urgency and caution: Fisherman and ecologists urge the government to approach offshore energy development with caution and prioritize protecting the benthic environment crucial for whale survival. Overall there is valid concerns about the potential negative impacts of offshore energy projects on marine ecosystems and calls for a more comprehensive approach that considers the broader ecological implications before implementing these initiatives.	Thank you for your comment. BOEM used the best available science to address impacts on marine mammals in the PEIS. Substantial scientific data exist for offshore wind development that allow assessment of impacts. All available information regarding long-term, regional impacts of offshore wind projects has been considered in this PEIS.
BOEM-2024-0001-0217-0008	Additional points to consider:* The excerpt focuses on the specific case of humpback whales and Sand Lance in the western Atlantic. The impacts of offshore energy projects on other species and ecosystems may vary depending on the location and specific technologies used.* Balancing energy needs with environmental protection is a complex challenge and finding sustainable solutions requires careful consideration of all stakeholders and potential outcomes.* Ongoing research and monitoring are crucial to understanding the potential impacts of offshore energy projects and adapting strategies to minimize harm to marine life.	The discussions in the PEIS are based on the best available science to date. Substantial scientific data exist for offshore wind development that allow assessment of impacts. All available information regarding long-term, regional impacts of offshore wind projects has been considered in this PEIS.

Comment No.	Comment	Response
BOEM-2024-0001-0224-0002	I would like to draw attention to several facts that raise environmental apprehensions in relation to the proposed action: Ecological Impact: The construction and operation of wind turbines in the NY Bight will disrupt the delicate balance of marine ecosystems impacting marine life migratory patterns and overall biodiversity.	The discussions in the PEIS are based on the best available science to date. Substantial scientific data exist for offshore wind development that allow assessment of impacts. All available information regarding long-term, regional impacts of offshore wind projects has been considered in this PEIS.
BOEM-2024-0001-0255-0001	Marine mammals such as whales during these months. It might be prudent to conduct the powerful survey work during the cold months off NJ. The survey work may be what is killing the whales. Also remember that a large percent of those shipwrecks occurred during the 19th century on the shoreline.	Thank you for your comment. Seasonal restrictions are implemented for several offshore wind activities as a protection measure for certain species. There is no causal connection between offshore wind surveys and large whale mortality. The overwhelming scientific consensus is that offshore wind activity is not a cause of these marine mammal mortalities.
BOEM-2024-0001-0284-0002	There has been a dramatic uptick in the number of deaths of whales and dolphins since the surveying started for these OSW projects. It has been more than a year since necropsies were first performed on the deceased marine life found in our ocean and on our shores. Why have we not seen any results? Why would these OSW projects be pushed along if the cause of death of these whales and dolphins have not been narrowed down?	The scientific community has determined that large whale mortality is primarily caused by non-wind vessel strikes and fishing gear entanglements (and infectious disease for the minke whales). These determinations are based, in part, on published necropsy results. Please see the NMFS Marine Mammal Unusual Mortality Events page for the most recent necropsy information.
BOEM-2024-0001-0308-0002	The use of sonar for seabed mapping in the region generates noise levels up to 226 decibels at the source falling into the low-frequency range (LFI) which is within the hearing range of many whale and dolphin species. Analysis of NOAA data reveals a stronger correlation between the recent surge in whale mortalities and sonar mapping activities than with cargo ship traffic challenging the notion that increased ship traffic is the primary cause of these deaths. Statistical evidence further supports this argument. From 2020 to 2021 despite an 18.46% increase in ship traffic whale deaths astonishingly fell by 92.31%. The following year saw a 25.15% rise in ship traffic yet whale deaths still decreased by 53.85%. However a pivotal shift occurred from 2022 to 2023; ship traffic declined by 18.56% but whale deaths skyrocketed by 216.67%. This period coincides with a fourfold increase in surveying activities related to wind farm development leading to an alarming spike in whale fatalities in the New York/New Jersey area. Specifically 21 humpback whales perished which according to Gotham Whales' August 2022 count of 280 humpbacks	Most sonar used for HRG surveys is actually outside the low-frequency hearing group (see Ruppel et al. 2022). There is no causal connection between recent offshore wind development and large whale mortality, and such an assumption is contrary to the scientific consensus. The overwhelming scientific consensus is that offshore wind activity is not a cause of these marine mammal mortalities. Instead, the scientific community has determined the three declared UMEs for whales in 2016 and 2017 were primarily caused by non-wind vessel strikes and fishing gear entanglements (and infectious disease for the minke whales). NOAA, the Marine Mammal Commission, academic institutions (e.g., Rutgers University, University of Rhode Island, Yale), environmental organizations (e.g., Sierra Club, Natural Resources Defense Council), BOEM, and the DOE have all issued official statements that no marine mammal mortality has been attributed to offshore wind activities.

Comment No.	Comment	Response
	in the region represents a significant loss of 7.5% of the population. Moreover NOAA's estimation that only one-third of whale deaths are detected suggests the actual impact could be even more devastating. These findings starkly contradict the argument that increased ship traffic is to blame for the rise in whale deaths. Instead they implicate the intensification of surveying traffic linked to wind farm development as a significant factor. Given that a substantial 7.5% of the humpback whale population in this region was lost in a single year and considering NOAA's admission that we may only be observing a fraction of the true number of fatalities it's clear that the environmental implications of proceeding with wind turbine construction in this sensitive area are profound. This data mandates immediate comprehensive research and a cautious approach by both the Bureau of Ocean Energy Management (BOEM) and NOAA before any further development is considered.	
BOEM-2024-0001-0309-0006	Further BOEM's haste in approving the PEIS is in direct opposition to a longstanding federal protection program and in danger of disrupting a protected species that the federal government spent all this time and money to save from endangerment: the North Atlantic Right Whale protections. The North Atlantic Right Whale has been the subject of significant concern and federal protection. Since the U.S. government has spent close to $10M of taxpayer money to protect this endangered species why is this PEIS Project comprising six wind farm lease areas adjacent to the other projects already smack in the center of this federally endangered whale migration zone only nine miles from the Brigantine shore? [Footnote 19: See BOEM 2023-0030.] The cumulative effects of the vessel traffic and noise from BOEM's own PEIS is admittedly missing comparison with the mitigation effects and missing data such as NOAA takes [Footnote 20: See PEIS at D2-D2.9.1 at D-14; see also C-6 C-7.] and old outdated studies. [Footnote 21: Id. at D2-1; The Conservation November 15 2023 "As the US begins to build offshore wind farms scientists say many questions remain about impacts on the oceans and marine life." https://theconversation.com/as-the-us-begins-to-build-offshore-wind-farms-scientists-say-many-questions-remain-about-impacts-on-the-oceans-and-marine-life-216330 .] Therefore	The discussions in the PEIS are based on the best available science to date. Substantial scientific data exist for offshore wind development that allow assessment of impacts. All available information regarding long-term, regional impacts of offshore wind projects has been considered in this PEIS. Vessel strike risk is still considered as part of the No Action Alternative but is driven largely by non-offshore wind vessels, which are outside the scope of this PEIS.

Comment No.	Comment	Response
	the mitigation measures fail - yet another reason for a No Action ruling.	
BOEM-2024-0001-0313-0049	Affected Environment and Environmental Consequences 3.5.6-70 The PEIS states "Noise: Under six NY Bight projects noise generated from pile-driving will increase due to the substantial increase in the number of foundations to be installed in the NY Bight area. If project construction is staggered for all six NY Bight projects such that only one is being constructed at any given time then the total sound produced would be the same as in the one NY Bight project scenario for a given time. However if there is overlap in construction for all six NY Bight projects such that multiple projects are being constructed simultaneously within a proximal geographic area then the total sound produced could greatly increase the ensonified region within which marine mammals must forage travel and communicate. The impact of unmitigated pile-driving noise on marine mammals would remain major for the NARW as there is a reasonable likelihood that auditory injury would occur and therefore population-level impacts affecting the viability of the species cannot be ruled out. Impacts remain moderate for all other mysticetes odontocetes and pinnipeds as auditory injury could result in population-level effects for some species but the long-term viability of populations would not be affected. These impacts are expected to result from impact pile-driving whereas vibratory pile-driving would result in only minor impacts on all marine mammals including NARWs." Comment Concerns exist about the cumulative impacts of noise and the synergistic and potential cacophonous auditory impacts from multiple ongoing activities. Similar to comment expressed about air quality impacts there is a potential for a concentrated and greater adverse impact to sound and impacts to organisms in the waterbody to humans and our quality of life. The analytical structure of the PEIS to examine the impact of one representative NY Bight Project does not account for the logarithmic nature of noise impacts for all 6 lease projects nor the quantified evaluation of a likely scenario where this activity could be happening all at once and have a greater deleterious impact	Substantial scientific data exist for offshore wind development that allow assessment of impacts. All available information regarding long-term, regional impacts of offshore wind projects has been considered in this PEIS. Project and site-specific noise exposure modeling will be conducted during the COP-level NEPA stage for individual projects. The assessment in this PEIS is intentionally qualitative because local environmental and project-specific conditions will affect noise production. Cumulative effects from multiple projects were considered in Section 3.5.6.3.3, and this information was carried forward in Section 3.5.6.5 during the assessment of Alternative C. Furthermore, the Proposed Action in this PEIS (Alternative C) analyzes the use of mitigation measures, which would not allow unmitigated pile driving.

BOEM-2024-0001-0326-0001	There has not been enough study on the impacts on the marine life that the windmills will cause. We are already seeing a large increase in mammal fatalities. Directly coinciding with sonar mapping of the ocean floor.	Offshore wind turbines have been in operation and have been the topic of many biological studies in Europe since the 1990s, and approximately 116 offshore wind farms operate in 12 European countries (more outside of Europe). Therefore, while this may be a newer industry in the United States, it is not one that is unstudied or that has unknown impacts. In regard to the marine mammal mortalities, there is no causal connection between recent offshore wind development and large whale mortality, and such an assumption is contrary to the scientific consensus. The overwhelming scientific consensus is that offshore wind activity is not a cause of these marine mammal mortalities. Instead, the scientific community has determined the three declared UMEs for whales in 2016 and 2017 were primarily caused by non-wind vessel strikes and fishing gear entanglements (and infectious disease for the minke whales). NOAA, the Marine Mammal Commission, academic institutions (e.g., Rutgers University, University of Rhode Island, Yale), environmental organizations (e.g., Sierra Club, Natural Resources Defense Council), BOEM, and the DOE have all issued official statements that no marine mammal mortality has been attributed to offshore wind activities.
BOEM-2024-0001-0328-0001	Please stop the development of wind farms- there needs to be unbiased studies of the whale's navigating system within their inner ear and the effects of sonar exploration and pile driving.	Thank you for your comment. Substantial scientific data exist for offshore wind development that allow assessment of impacts. All available information regarding potential impacts from offshore wind projects on marine mammals has been considered in this PEIS.
BOEM-2024-0001-0331-0004	the failure to coordinate and disclose results of other key environmental reviews e.g. the rulemaking proceeding under the Marine Mammal Protection Act and the overall level of obfuscation is unprecedented.	The results of all other environmental reviews of offshore wind projects conducted by BOEM (available to date) are published on its website, and all MMPA consultations conducted by NMFS for offshore wind projects available to date are available on its website. Additionally, NMFS is a cooperating agency for this PEIS and has reviewed/provided comments pertaining to its roles enforcing the MMPA and ESA. No specific NMFS ESA or MMPA consultations have been performed for this PEIS, given the programmatic nature of this evaluation, but coordination is ongoing with NMFS on a Programmatic Framework BA. Future

Comment No.	Comment	Response
		project-specific consultations will be conducted, and the results of those assessments will be similarly published as they are finalized.
BOEM-2024-0001-0331-0008	According to Scientists who participated in the National Academies of Sciences Engineering and Medicine examination of how constructing offshore wind farms in the Nantucket Shoals region southeast of Massachusetts could affect critically endangered North Atlantic right whales the concluded that there are knowledge gaps in understanding the impact of offshore wind.	Thank you for your comment. The NASEM (2023) report has been reviewed and incorporated into the PEIS to consider potential effects of offshore wind farms in this region.
BOEM-2024-0001-0331-0010	There are also a lot of knowledge gaps on the biology side including questions about what species of zooplankton are in the Nantucket Shoals region where they come from and what makes them aggregate into patches that are dense enough for right whales to eat. Right whale feeding in the Nantucket Shoals region isn't well understood so scientists need observations to determine which zooplankton types are targeted by right whales and where and when the whales feed." The PEIS is another example of BOEM's lack of relevant and rigorous scientific studies to use for the huge scope of these projects. The BOEM reports lack baseline data overall from offshore wind development from this region. There is a growing interest and evidence of how ocean sediments and marine mammals are useful to sequester carbon. However this has not been studied or assessed thoroughly yet and this proposed massive industrialization will cause more harm. The issue of Electromagnetic fields effects has not been scaled. There is a lack of rigorous and relevant research on pile driving impacts on marine mammals specifically baleen whales and the response of large whale species to extensive networks of wind turbines.	Thank you for your comment. Substantial scientific data exist for offshore wind development that allow assessment of impacts. All available information regarding potential impacts from offshore wind projects on marine mammals has been considered in this PEIS. The NASEM (2023) report information has been incorporated into the PEIS.
BOEM-2024-0001-0331-0019	The disturbance of marine life during the surveying construction and operation of the NY/NJ projects will be significant. The number of Level B Harassment Takes on the Atlantic Coast during the 2024-25 time period alone totals 249503 and the number of Level A Injury Takes during the 2024-25 time period totals 761. The total number of Level B takes of endangered species totals 920 and Level A Injury endangered species Takes total 9. This includes IHA Permits for 26 offshore projects from Massachusetts to South Carolina. The total	Authorized takes are based on modeling and are therefore likely proportional to but not the actual number of takes that *will* occur during activities. Authorized takes mean that the project may not exceed the number of takes authorized within the given time period of the issued permit. For example, from the published HRG survey PSO reports from multiple offshore wind development projects within the U.S. Atlantic Ocean, professional PSOs recorded 2,696 large whale detections; of these, only 68

Comment No.	Comment	Response
	number of Level B Harassment Takes for Atlantic Shores project permits alone will total 10998 during the time period including 35 takes for endangered species. (See Appendix A). The authorization of this cumulative level of takes is irresponsible and reckless.	(2.5%) were detections that met Level B exposure criteria (animal distance and source operations).
BOEM-2024-0001-0331-0023	PEIS Lacks Sufficient Information and Mitigation for Noise Impacts Noise impacts from pre-construction construction operations and maintenance and decommissioning will impact marine mammals and other marine life for entire life cycle of the projects in the 6 lease areas. Potential and unknown impacts include noise electromagnetic fields navigational safety changes to benthic and pelagic habitats behavioral changes in wildlife alternations to food webs invasive species concerns and pollution from increased vessel traffic heat and onshore and offshore infrastructure. We are attaching a Report and Congressional Testimony from Dr. Bob Stern of Save LBI as part of our comments to add to our public comment record (see Appendix B). Unless BOEM addresses the issues outlined in his report EIS will be inaccurate and misleading. There is a lack of basic research of the impacts of OSW energy development on large whale species in U.S. waters particularly in the mid-Atlantic region. It is reckless to move forward without the scientific baseline assessments for what harm may or could occur to whales before issuing any permits and authorizations including IHAs ITRs and associated LOAs including the failure to include crucial scientific assessments and consultations as follows:	Thank you for your comment. Substantial scientific data exist for offshore wind development that allow assessment of impacts. All available information regarding potential impacts from offshore wind projects on marine mammals has been considered in this PEIS. Additionally, given the programmatic nature of this assessment, BOEM expects project-specific analyses of noise and other effects will be conducted during future project NEPA stages, which will further address specific, quantitative effects from offshore wind development of these projects.
BOEM-2024-0001-0331-0024	In a May 2022 letter obtained under the Freedom of Information Act by Bloomberg Law Dr. Sean Hayes PhD Chief of Protected Species NOAA NEFSC clearly documents and confirms the NARW's fragile hold on existence. First the Chief of Protected Species notes that there are less than 350 remaining NARW animals. (Letter from Sean A. Hayes PhD Chief of Protected Species NOAA NEFSC to Brian R. Hooker Lead Biologist Bureau of Ocean Energy Management Office of Renewable Energy Programs dated May 13 2022.) Again we note the Draft North Atlantic Right Whale and Offshore Wind Strategy states that not one animal can be lost. In regard to the development phases of offshore wind Dr. Hayes states in his letter: "The development of offshore wind poses risks to these species which is	Thank you for your comment. The information contained in the Hayes (2022) letter has been included in this PEIS, and all consideration of effects is based on the best available science to date. Effects on the NARW population being driven by non-offshore wind-related activities (e.g., non-offshore wind vessel traffic, fisheries interactions) are outside the scope of this PEIS. These stressors are discussed in the PEIS as baseline information for comparison to the Proposed Action.

Comment No.	Comment	Response
	magnified in southern New England waters due to species abundance and distribution. These risks occur at varying stages including construction and development and include increased noise vessel traffic habitat modifications water withdrawals associated with certain sub-stations and resultant impingement/entrainment of zooplankton changes in fishing effort and related potential increased entanglement risk and oceanographic changes that may disrupt the distribution abundance and availability of typical right whale food (e.g. Dorrell et al 2022)." It is clear that any further disturbance of the NARW species will have an impact on this critically endangered species. Some scientists estimate that the species will go extinct within 20 years with current threats. (Pennisi Elizabeth. "The North Atlantic right whole faces extinction." Science November 7 2017 https://www.science.org/content/article/north-atlantic-right-whale-faces- extinction.	
BOEM-2024-0001-0331-0026	According to statistical analysis and independent research by Apostolos Gerasoulis Professor of Computer Science at Rutgers University the construction of wind turbines in the New York Bight poses a significant threat to the marine ecosystem particularly affecting numerous whale and fish species that frequent this area as reported by Gotham Whales. This includes several endangered species highlighting the critical nature of the threat. The use of sonar for seabed mapping in the region generates noise levels up to 226 decibels at the source falling into the low- frequency range (LFI) which is within the hearing range of many whale and dolphin species. Analysis of NOAA data reveals a stronger correlation between the recent surge in whale mortalities and sonar mapping activities than with cargo ship traffic challenging the notion that increased ship traffic is the primary cause of these deaths. According to Gerasoulis statistical evidence further supports this argument. From 2020 to 2021 despite an 18.46% increase in ship traffic whale deaths astonishingly fell by 92.31%. The following year saw a 25.15% rise in ship traffic yet whale deaths still decreased by 53.85%. However a pivotal shift occurred from 2022 to 2023; ship traffic declined by 18.56% but whale deaths skyrocketed by 216.67%. This period coincides with a fourfold increase in surveying activities	Most sonar used for HRG surveys is actually outside the low-frequency hearing group range (see Ruppel et al. 2022). There is no causal connection between recent offshore wind development and large whale mortality, and such an assumption is contrary to the scientific consensus. The overwhelming scientific consensus is that offshore wind activity is not a cause of these marine mammal mortalities. Instead, the scientific community has determined the three declared UMEs for whales in 2016 and 2017 were primarily caused by non-wind vessel strikes and fishing gear entanglements (and infectious disease for the minke whales). The NOAA, the Marine Mammal Commission, academic institutions (e.g., Rutgers University, University of Rhode Island, Yale), environmental organizations (e.g., Sierra Club, Natural Resources Defense Council), BOEM, and the DOE have all issued official statements that no marine mammal mortality has been attributed to offshore wind activities.

Comment No.	Comment	Response
	related to wind farm development leading to an alarming spike in whale fatalities in the New York/New Jersey area. Specifically 21 humpback whales perished which according to Gotham Whales' August 2022 count of 280 humpbacks in the region represents a significant loss of 7.5% of the population. Moreover NOAA's estimation that only one-third of whale deaths are detected suggests the actual impact could be even more devastating.	
BOEM-2024-0001-0331-0027	We agree with Dr. Gerasoulis' belief that these findings starkly contradict the argument that increased ship traffic is to blame for the rise in whale deaths. Instead they implicate the intensification of surveying traffic linked to wind farm development as a significant factor. Given that a substantial 7.5% of the humpback whale population in this region was lost in a single year and considering NOAA's admission that we may only be observing a fraction of the true number of fatalities it's clear that the environmental implications of proceeding with wind turbine construction in this sensitive area are profound. This data mandates immediate comprehensive research and a cautious approach by both the Bureau of Ocean Energy Management (BOEM) and NOAA before any further development is considered. SEE ORIGINAL COMMENT FOR GRAPH: Humpback Whale Deaths per Year in Polygon includes NYNJRI new	The scientific community has determined that large whale mortality is primarily caused by non-wind vessel strikes and fishing gear entanglements (and infectious disease for the minke whales).
BOEM-2024-0001-0331-0045	I would like to focus on just one topic noise to whales and to we humans from these wind energy activities. The whales rely on noise for everything including communication. navigation sensing danger and finding food. If loud enough a noise can directly damage the whale's hearing at lower levels it disturbs their behavior. Disturbance may not sound so bad but it too can lead indirectly to serious harm and fatality for example through separation of a mother and calf because their communications are overridden or by a whale surfacing to lessen the noise while losing its ability to detect and avoid oncoming ships. Since December there have been nine whale strandings on the New Jersey coast. This is very unusual given that the annual average is seven. Of the nine four have been identified as possibly due to vessel strike and noise may be a contributing factor there with the remaining causes so far unresolved. The only recent	There is no causal connection between recent offshore wind development and large whale mortality, and such an assumption is contrary to the scientific consensus. The overwhelming scientific consensus is that offshore wind activity is not a cause of these marine mammal mortalities. Instead, the scientific community has determined the three declared UMEs for whales in 2016 and 2017 were primarily caused by non-wind vessel strikes and fishing gear entanglements (and infectious disease for the minke whales). NOAA, the Marine Mammal Commission, academic institutions (e.g., Rutgers University, University of Rhode Island, Yale), environmental organizations (e.g., Sierra Club, Natural Resources Defense Council), BOEM, and the DOE have all issued official statements that no marine mammal mortality has been attributed to offshore wind activities.

Comment No.	Comment	Response
	difference offshore that we are aware of are the multiple wind energy vessels using high intensity noise devices to characterize the seabed. We commented a year ago to the National Marine Fisheries Service that the noise source number they were using for the strongest device was too low and the noise dissipation assumed too high and therefore the affected distance was significantly underestimated. With proper assumptions as shown in Table 1 the elevated noise from that device extends quite far and could affect a significant number of animals. Given the vessel presence and the noise levels there is ample reason to suspect that the surveys are a plausible cause of the recent deaths. At a minimum a thorough objective transparent investigation is warranted- that is not asking for much. Unfortunately the vessel surveys are just the beginning of the noise problems the whales will face. The noise from pile driving 49-foot diameter steel foundations into the seabed will be intense and require many strikes over a period of several years. Here again we find an underestimation of impacts as shown in Table 2. In our view the worst noise problem of all will come from the operation of the much larger turbines proposed today. We hired a respected acoustics engineering company to assess the noise levels generated from the full wind project proposed off LBI. Based on their results in Figure 1 the noise levels that baleen whales would avoid extend at least 93 miles from shore. With the critically endangered North Atlantic right whale migrating historically within 86 miles this project could potentially block its migration and seal its fate. This operational noise problem is not being addressed by the agencies and that is one reason why we sent a detailed letter to President Biden asking for his personal intervention (Attachment).	
BOEM-2024-0001-0331-0047	So where do we go from here? We recommend creation of a Science Board within NOAA with sufficient authority to initially conduct a thorough vessel survey investigation and then to establish protocols for government-wide use in predicting marine animal impact from noise. Beyond that this program cries out for some common-sense turbine siting criteria e.g. a turbine exclusion zone from shore and excluding turbines from primary whale migration corridors.	Thank you for your comment. BOEM will take your comment into consideration as it administers its program.

Comment No.	Comment	Response
BOEM-2024-0001-0334-0004	We cannot simply accept at face value that you are operating truthfully about the effects of sonar on marine mammals. The increase in ocean mammal deaths is now commonly understood to result from the aftermath of exposure to sonar and other sonic surveying. Expect that the assertion that "there is no evidence that sonar is killing the whales and dolphins" (much like the tobacco industry's "there's no evidence that cigarette smoking causes cancer") will have to pivot to proving to the public that the dead mammals found have no issues in their navigational tissues. Further evidence is emerging every week with more compelling correlations between whale deaths and recent sonar boat activity. If the evidence mounts sufficiently to sway a (fair) court of law you might expect to be instructed to rescind your take authorizations and the ability to grant any further ones will end. It is not lost on me and many others that take authorizations are legal for U.S. companies only yet foreign companies are using a thin veil of U.S. shell companies to skirt this and that is. SEE ORIGINAL COMMENT FOR GRAPH: Whale Deaths/Offshore Wind Survey Vessels NJ/NY	There is no causal connection between recent offshore wind development and large whale mortality, and such an assumption is contrary to the scientific consensus. The overwhelming scientific consensus is that offshore wind activity is not a cause of these marine mammal mortalities. Instead, the scientific community has determined the three declared UMEs for whales in 2016 and 2017 were primarily caused by non-wind vessel strikes and fishing gear entanglements (and infectious disease for the minke whales). NOAA, the Marine Mammal Commission, academic institutions (e.g., Rutgers University, University of Rhode Island, Yale), environmental organizations (e.g., Sierra Club, Natural Resources Defense Council), BOEM, and the DOE have all issued official statements that no marine mammal mortality has been attributed to offshore wind activities.
BOEM-2024-0001-0345-0015	Whale Death Analysis There has been a great deal of misconception around the impact offshore wind will have on whales and other marine mammals. This myth was raised frequently during the public comment period for this PEIS. CCE thanks BOEM as well as NOAA for their proactive approach in putting out public factsheets and up-to-date information explaining that the increase in whale strandings and fatalities is not linked to offshore wind activity. However the misconception still remains that wind surveys are responsible for whale mortality events and that the "authorized takes" allowed by offshore wind companies could be killing whales. It would be helpful for the final PEIS and for the individual projects' DEIS moving forward to better clarify the difference between a "Level A" and "Level B" take and what direct impacts including nuisance impacts are actually being authorized to occur during construction and operation of these turbines. [Underline: CCE also recommends BOEM include more detailed information on not only the ongoing rigorous studies and data being collected to minimize impacts to whales to the greatest extent	Thank you for your comment. BOEM agrees with all points made about the misconceptions regarding offshore wind activities and the whale strandings and appreciates your feedback. Regarding the comment about including this as a discussion in future NEPA documents, BOEM will take this into consideration as it administers its program. Due to the programmatic nature of this assessment, MMPA consultation will not be conducted. However, MMPA consultations are expected for the individual projects included in this PEIS, and BOEM will consider including clarification of Level A and Level B impacts in future NEPA documents. Individual project MMPA authorizations will have PSO reports on the NMFS MMPA authorization website for each project.

Comment No.	Comment	Response
	possible and but also to include data on what is actually causing the unusual mortality events. In the absence of facts myths spread.] It is important to note that the increase in whale mortality events started in 2016 far before any offshore wind development was occurring off our shores. That in fact there is no evidence that offshore wind is a contributing factor to any of these strandings or deaths. Necropsies have been performed on approximately half of the 181 whales that died through February 2023. The results showed that 40% had evidence of either entanglement in fishing gear or a ship strike. This is consistent with studies across the country and the globe which identify ship strikes and fishing gear as the greatest human threats to these species. Since the Covid pandemic there is a 35% increase in the volume of shipping to NY and NJ ports since 2019. Furthermore approximately 40% of these cargo ships are carrying oil an impact that could be offset by reliance on local renewable energy like offshore wind. In addition marine mammal scientists have identified that not only do we have more whales in the New York Bight but they are staying in this region longer due to increased food supply. As offshore wind projects move forward offshore wind companies are conducting regular survey work. Each offshore wind vessel is mandated to have an independent protected species observer (PSO) onboard who collects valuable data about marine mammal activity in the survey area. The information from offshore wind surveys and PSOs should be collected by BOEM and made publicly available on a regular basis to aid other vessels and commercial fishing operations in avoiding areas with whale sightings. [Underline: The positive impacts of reducing our reliance on oil cargo ships and the potential benefits of the in-depth whale monitoring data collected by the offshore wind companies should be considered by BOEM in the PEIS.] Thank you for your consideration of our comments.	
BOEM-2024-0001-0350-0001	The greatest concern is that the combined excessive noise created by these six projects will severely harm whales and other protected species. This is especially true for the incredibly loud clangor made from driving the monstrous monopiles that hold up the enormous wind turbines into the waterbody's floor. Construction of all six	The discussions in the PEIS are based on the best available science to date. The PEIS serves as a relevant review of the existing knowledge for future wind development projects and scientific researchers to consider. Additionally, project and site-specific noise exposure modeling will be conducted during the COP-level NEPA stage for these projects. The assessment in this

Comment No.	Comment	Response
	projects may occur simultaneously further exacerbating the cacophony.	PEIS is intentionally qualitative because local environmental and project-specific conditions will affect noise production. Cumulative effects from multiple projects were considered in Section 3.5.6.3.3, and this information was carried forward in Section 3.5.6.5 during the assessment of Alternative C.
BOEM-2024-0001-0350-0003	On this matter the PEIS is absolutely absurd. It is structured like a project environmental impact statement (EIS) so the pile-driving impacts are supposedly addressed in a technical appendix on "acoustics;" in this case it is "Appendix J: Introduction to Sound and Acoustic Assessment." The operative word in the appendix title is "Introduction" as it is basically an academic treatise. In fact it starts off by explaining at length how underwater sound is measured. We do finally get to the Bight but that is about as far as the discussion goes. What we find instead is a regurgitation of an academic paper that bears no resemblance to the six projects this assessment is supposed to be addressing To begin with the draft uses just two theoretical sites with a mere 60 turbines each for a total of 120 turbines. BOEM says these six real sites are expected to develop up to 7000 MW of generating capacity and recent site designs use 13 MW turbines which would require approximately 540 turbines or almost five times as many as discussed in the draft. Furthermore the PEIS study uses noise levels from small 6 MW turbines. At that size we are discussing a sum closer to 1200 turbines or roughly ten times as many as are considered. The potential impact of 120 turbines is clearly not helpful in assessing 1200. To make matters worse the pile driving noise level referenced in the study is for driving a roughly 20-foot diameter pile which is very small by present and future standards. Today's 13 to 15 MW turbines use piles closer to 40 feet in diameter. Moreover gigantic 20 MW turbines have just been introduced which might take 60-foot diameter piles. The noise level is based on the energy of the pile-driving hammer and bigger piles require a greater amount of energy to drive so there is a significantly greater amount of noise realistically that what is accounted for in the draft.. One wonders why BOEM did not measure the noise from the much bigger piles that were being driven back in July just off Rhode Island? The answer seems to be that BOEM did not want to put any	The discussions in the PEIS are based on the best available science to date. The PEIS serves as a relevant review of the existing knowledge for future wind development projects and scientific researchers to consider. The PEIS does not assess impacts from individual projects, which will be analyzed in their own COP-level NEPA analysis and tier off this analysis. Additionally, project and site-specific noise exposure modeling will be conducted during the COP-level NEPA stage for these projects. The assessment in this PEIS is intentionally qualitative because local environmental and project-specific conditions will affect noise production. Cumulative effects from multiple projects were considered in Section 3.5.6.3.3, and this information was carried forward in Section 3.5.6.5 during the assessment of Alternative C. Additionally, the two offshore wind projects that were recently installed or are being installed offshore Rhode Island and Massachusetts did include acoustic measurements of pile driving noise. However, given the timing of these activities, the reports are not yet available for incorporation into this PEIS. BOEM will incorporate this information into future reports when available.

Comment No.	Comment	Response
	serious work into this PEIS. In short the academic acoustic case considered in the PEIS tells us absolutely nothing about the potentially immense noise impact of the six projects supposedly being assessed. There is quite literally no environmental impact assessment here. This vacuum seems to hold for virtually the entire PEIS with no real assessment of the six projects. There is certainly nothing of substance on noise. As environmental impact statements go this one is essentially useless.	
BOEM-2024-0001-0354-0015	POINT VI The approval of the within NY Bight Industrial Wind Turbine Project without independent peer reviewed scientific research on the negative impacts upon marine mammals and in particular the North American Right Whale is violative of the Endangered Species Act and NEPA.	Thank you for your comment. The discussions in the PEIS are based on the best available science to date.
BOEM-2024-0001-0354-0016	An even more appalling aspect of the within proposal can be seen in the lack of scientific method and any good faith attempt at a complex economic evaluation to be applied to the critically threatened North American Right Whales. This species is in dire jeopardy due to this specific proposal and the threat of pollution generating windfarms proposed to be constructed directly in the right Whales' primary and sole migratory waterways off the New Jersey Coast. With approximately three hundred fifty (350) North Atlantic Right Whales left in the entire world the DEiS barely touches the surface as to the potentially devastating if not terminating impact of this vast industrial project itself and numerous ongoing adverse impacts presented. From a noise perspective pollution generating standpoint and otherwise the construction operation and totally ignored dismantling and decommissioning process of the gigantic wind turbines themselves has insufficiently been addressed. Moreover the Draft Environmental Statement does not recognize the legal and moral standing of such an invaluable threatened species whose inspirational value beauty and potential worth as to biodiversity for our planet and to life itself cannot be overstated. How outrageous is it that this entire species of the North Atlantic Right Whales in all likelihood is being condemned to extinction by this juggernaut of industrial windfarm construction in this treasured creature's only habitat and migratory living pathways. What	Thank you for your comment. Substantial scientific data exist for offshore wind development that allow assessment of impacts. All available information regarding potential impacts from offshore wind projects on marine mammals has been considered in this PEIS. However, an economic evaluation of NARW is outside the scope of this PEIS.

Comment No.	Comment	Response
	arrogance and true ignorance of science has been presented!. What is the value of this species now being wiped off the face of the earth?	
BOEM-2024-0001-0355-0001	With the proposed OSW projects I see a whole list of negatives and no positives at all. The list of negatives include: Marine/Mammal Deaths the evidence exists that there IS a correlation with survey vessels driving pilings with whale deaths and other mammals and disruption of the ecosystem. The marine life and ecosystem in our oceans will undergo significant transformations potentially leading to the extinction of some marine mammals. (BOEM reference material on Marine Life)	There is no evidence of death or serious injury from offshore wind preconstruction surveys or from offshore wind pile driving or offshore wind vessel strike. The greatest transformational threat to the marine ecosystem is climate change. There is no causal connection between recent offshore wind development and large whale mortality, and such an assumption is contrary to the scientific consensus. The overwhelming scientific consensus is that offshore wind activity is not a cause of these marine mammal mortalities. Instead, the scientific community has determined the three declared UMEs for whales in 2016 and 2017 were primarily caused by non-wind vessel strikes and fishing gear entanglements (and infectious disease for the minke whales). NOAA, the Marine Mammal Commission, academic institutions (e.g., Rutgers University, University of Rhode Island, Yale), environmental organizations (e.g., Sierra Club, Natural Resources Defense Council), BOEM, and the DOE have all issued official statements that no marine mammal mortality has been attributed to offshore wind activities.
BOEM-2024-0001-0355-0023	With the proposed OSW projects I see a whole list of negatives and no positives at all. The list of negatives include: - Marine/Mammal Deaths the evidence exists that there IS a correlation with survey vessels driving pilings with whale deaths and other mammals and disruption of the ecosystem. The marine life and ecosystem in our oceans will undergo significant transformations potentially leading to the extinction of some marine mammals. (BOEM reference material on Marine Life)	Duplicate comment. Refer to response to comment BOEM-2024-0001-0355-0001.
BOEM-2024-0001-0355-0051	From the BOEMRE-2011-09 report: "Many fundamental questions about sensory system mechanisms and life functions supported by these senses [Bold Underline: have not been resolved.] Just a small fraction of marine species have been directly studied for magnetic or electric senses." I also want to call your attention to the attached article. This is just one of many of the RISKS of these HIGH VOLTAGE underground cables. Again [Bold: more time and studies are needed before you can approve these permits]. There are SO MANY	The discussions in the PEIS are based on the best available science to date. Available data suggest marine mammals are minimally magneto-sensitive and, as discussed in the PEIS, impacts would be limited to effects on prey. However, the inherent cable protections built into subsea cables are expected to mitigate EMFs produced, and additional mitigation measures considered under Alternative C would further reduce the risk of

Comment No.	Comment	Response
	UNANSWERED questions actually more questions than answers. This must not be approved until more information is available and the DEP can make an informed confident decision. For your reference this is one of many instances where BOEM supplies no evidence despite the data that is there and make empty non-validated claims. There is clear data to support the opposite of what they say. See Evidence Video.	effects from the expected development in the NY Bight lease areas.
BOEM-2024-0001-0356-0002	The first of which is the outdated permissible decibel level used by NOAA for Incidental Takes. Recent Congressional testimony by Rand Accoustics showed that the geotechnical survey levels are actually in certain cases 16 decibels louder than what is permitted. With this updated independent information the NOAA proxy numbers used in this EIS are incorrect and need to be re-addressed at the very least. Researchers have repeatedly brought this information before BOEM and NOAA many times and both BOEM and NOAA refuse to acknowledge that the original decibel levels are far from correct. See the attached document referenced from Rand Accoustics.	The methods used to estimate acoustic ranges and the regulatory thresholds used to assess effects are considered the best available science and are used consistently and correctly in the permitting literature.
BOEM-2024-0001-0357-0001	The six New York Bight areas are shown in Exhibit 1 along with the nearby New Jersey wind energy area. Wind energy development off the New Jersey coast is unique with regard to all other US projects because it proposes development both close to shore and father from shore in fact impacting the entire 50-mile-wide historic migration corridor of the critically endangered North Atlantic right whale.	Thank you for your comments. The discussions in the PEIS are based on the best available science to date regarding existing environmental conditions and marine mammal distribution, such that effects from projects in this region are sufficiently covered in the PEIS.
BOEM-2024-0001-0357-0005	Need to Consider Full Real Area Impact for Project Decisions in the NJ/NY Area. Off the New Jersey coast the BOEM uniquely proposes energy projects both close to shore and farther out. As presented below there are many environmental impacts from those projects that have significant cumulative effects on the offshore New Jersey and New York Bight areas. Neither this draft program EIS or any project specific EIS provides a cumulative impact analysis of turbine operation from all these projects on the whale. Such an assessment of the impact of concurrent turbine operation from all projects on the migration of the North Atlantic right whale (NARW) is provided here in Enclosure II. It can be seen that concurrent turbine operation of the projects in the New Jersey area and the New York Bight areas	Thank you for your comments. The discussions in the PEIS are based on the best available science to date regarding existing environmental conditions and marine mammal distribution, such that effects from projects in this region are sufficiently covered in the PEIS.

Comment No.	Comment	Response
	leaves no viable path for the North Atlantic right whale to migrate. Therefore with respect to AMMM measures this program EIS or a project-specific EIS should include alternatives among projects and options within projects such as lesser turbine powers greater spacing the use of direct drive versus gearbox turbines turbine exclusions zones in the lease areas away from the whale's migratory paths and other initiatives to allow for migration of the whale (see Enclosure I).	
BOEM-2024-0001-0357-0010	Neither this draft program EIS or any project specific EIS presents a cumulative assessment of the marine mammal takes from concurrent project vessel surveys using high intensity noise devices to characterize the seabed. Such vessel surveys have been implicated in spikes of recent whale deaths along the New Jersey and New York coasts. But no AMMM measures are provided to address this problem such as reducing vessel survey areas and establishing a cooperative data sharing program to minimize the number of vessels needed and this sounds like you're not seeing. (see Enclosure VII).	Cumulative impacts for marine mammals of the proposed alternatives are assessed in Sections 3.5.6.5.2 and 3.5.6.5.4 of the PEIS. AMMM measures in the PEIS may be applied to all projects within the six NY Bight lease areas. However, these measures do not reflect additional measures that could be required for each individual project, or potential measures developed for future data sharing opportunities.
BOEM-2024-0001-0357-0015	To the NARW: Once BOEM does that it would find for example with the respect to the cumulative impacts of [Bold: operational] turbine noise on the migration of the North Atlantic right whale as presented in Enclosure II that one critical avoidance measure is to choose between close in and farther out projects. Wind projects in both the close-in Atlantic Shores lease area and the farther out NY Bight areas leave no path for the right whale to migrate past New Jersey dooming it. The BOEM must chose one it cannot have both. Once it reaches that inescapable conclusion the choice should among projects should be obvious.	Thank you for your comment. BOEM will take your comment into consideration as it administers its program. This PEIS does not approve or disapprove any projects; that will occur at the project-specific COP-level NEPA analysis level. However, the discussions in the PEIS are based on the best available science to date. The potential acoustic impacts on marine mammals from operational turbine noise and potential behavioral disturbances from the presence of structures are discussed in detail in Section 3.5.6.3.3. Results of this assessment concluded that migratory pathways may be altered but would not be fully blocked for any marine mammal species.
BOEM-2024-0001-0357-0016	With the close-in Atlantic Shores project we have the blocking off an historic primary 12-mile- wide migration corridor of the right whale adjacent to that project area. Farther out we would still have obstruction of the whales migration from those areas as well.	Thank you for your comment. BOEM will take your comment into consideration as it administers its program. This PEIS does not approve or disapprove any projects; that will occur during the project-specific COP-level NEPA analysis.
BOEM-2024-0001-0357-0021	So if an offshore wind energy program proceeds that choice to protect the right whale should be obvious. The Atlantic Shores project must be terminated to preserve the New Jersey shore experience and leave a path for the right whale to migrate.	Thank you for your comment. BOEM will take your comment into consideration as it administers its program. This comment is addressing Atlantic Shores not the NY Bight. The NY Bight PEIS does not approve or disapprove any projects; that will occur during the project-specific COP-level NEPA analysis.

Comment No.	Comment	Response
BOEM-2024-0001-0357-0034	Within the above framework the following AMMM measures should be considered in the EIS: With the respect to the cumulative impacts of construction [Bold: and operational] noise on the migration of the North Atlantic right whale discussed in Enclosure II: 1.One critical avoidance measure Is to choose between close in and farther out projects. Wind projects in both the close-in Atlantic Shores lease area and the farther out NY Bight areas leave no path for the right whale to migrate past New Jersey the federal agency must chose one it cannot have both. Once it reaches that inescapable conclusion the choice should be obvious.	Thank you for your comment. BOEM will take your comment into consideration as it administers its program. This PEIS does not approve or disapprove any projects; that will occur during the project-specific COP-level NEPA analysis.
BOEM-2024-0001-0357-0036	With the close-in Atlantic Shores project we have the blocking off an historic primary 12-mile- wide migration corridor of the right whale adjacent to that project area. Farther out we would still have obstruction of the whales migration from those areas as well.	Thank you for your comment. BOEM will take your comment into consideration as it administers its program. This PEIS does not approve or disapprove any projects; that will occur during the project-specific COP-level NEPA analysis.
BOEM-2024-0001-0357-0049	Effect on Whales & other Marine Mammals. Compunding this problem the synergistic impact of the vessel traffic change and the operational noise impact from the larger turbines will have a significant impact on the migration of the North Atlantic right whale and other marine mammals. As discussed in Enclosure the strip between the Atlantic Shores lease area and the Hudson South area has been a primary migration corridor for the North Atlantic right whale. That same strip has been proposed by the U. S Coast Guard as a deep. deep draft vessel corridor. Also as shown in Enclosure II the noise levels in that corridor from turbine operation will be above that that will disrupt the whale's migration and disturb and disorient any whale attempting to migrate through it. Worsening the situation further are experimental results showing that one reaction of the right whale to such noise is to surface to lessen the noise which would make it more susceptible to strike from those deep draft and other vessels in the corridor. Therefore the synergistic effect of the concentrated vessel traffic and whale migration in the same narrow corridor the disorienting effect on the whale from turbine operational noise and the tendency of whales to surface to avoid that noise could have a devastating effect on marine mammals off the coast of New Jersey. The BOEM the Coast Guard	Thank you for your comment. BOEM will take your comment into consideration as it administers its program. This PEIS does not approve or disapprove any projects; that will occur during the project-specific COP-level NEPA analysis. However, the discussions in the PEIS are based on the best available science to date. The potential acoustic impacts on marine mammals from operational turbine noise and potential behavioral disturbances from the presence of structures are discussed in detail in Section 3.5.6.3.3. Results of this assessment concluded that migratory pathways may be altered but would not be blocked for any marine mammal species.

Comment No.	Comment	Response
	and NOAA should immediately convene to assess that synergistic affect and at a minimum provide analysis of it in this NY Bight EIS.	
BOEM-2024-0001-0357-0058	The cumulative impact of the vessel surveys it's not just a matter of adding the take estimates from each survey. It needs to correct the NMFS practice of using unsupported low noise source levels from a surrogate device rather than higher levels from measurements of the devices being used. It needs to correct the NMFS practice of using the 20 dB loss factor for spherical spreading beyond the range where such optimistic spreading occurs. The combined impact of those significantly reduces the actual distance where noise above 160 dB exists from one and a half miles using proper assumptions to 0.1 miles using the erroneous ones. With proper source levels and transmission losses it can be shown that there are numerous scenarios for example a survey vessel traveling parallel to and overtaking a whale where the threshold for permanent hearing loss will be exceeded and many other cases where the threshold for temporary hearing threshold loss will be exceeded. The cumulative impact analysis should address those scenarios and visibly show its modeling assumptions not relegate them to an opaque computer model on it was survey table to learn from group that time by a number of another name are: well these days or more users will block or use a know where the need for new hires or am	Based on the scientific literature (e.g., Ruppel et al. 2022) the 20 log (i.e. not 20 dB) transmission loss coefficient is the correct spreading loss to use for calculations. Several in situ field measurements support this transmission loss coefficient for HRG surveys.
BOEM-2024-0001-0357-0063	The agencies provide no specific noise source attenuation system that would achieve this reduction. Nor do they provide technical justification for the assumed 10 dB attenuation upon which they relies heavily for certain calculations and conclusions. Without that specific proposal and justification the assumption appears to be arbitrary and designed to artificially keep the level A take number from direct injury according to the current calculations below the biological removal rate for the right whale. Regarding source attenuation it should be noted first that the use of bubble curtains or other systems that are placed immediately around the pile are inherently limited because they cannot attenuate ground-borne re-radiated sound. Therefore appreciable attenuation is not achieved for the sound that resonates through the ground into the far field. More of the sound emitted during impact pile driving resonates from	Thank you for the comment. Noise attenuation technology continues to evolve, and there are many options available today, either a single solution or a combination of solutions, that can reach 10 dB or more of noise attenuation from the unmitigated case (Bellmann et al. 2020). Examples of the growing number of noise attenuation solutions include the IHC-Noise Mitigation Screen, OffNoise Solutions GmbH's Hydro-Sound Damper, the big bubble curtain or double bubble curtains (available from several suppliers), and the Grout Annulus Bubble Curtain. In addition, there are alternative hammer designs (e.g., IQIP-Pulse and Menck Noise Reduction Unit) that can be used to reduce the noise associated with impact pile driving over traditional methods. As the commenter points out, near-field resonate systems can be tuned to target the

Comment No.	Comment	Response
	the ground than through the water column (Caltrans. 2015. Technical guidance for assessment and mitigation of the hydro acoustic effects of pile driving on fish State of California Department of Transportation Sacramento California) and such sound is also of lower frequency impacting LFC's such as the right whale. In the NMFS proposed rule under the MMPA the Level A take number for the right whale shown in Table 24 of less than one is critically dependent on the January through April exclusion timeframe (should also include December) and the assumed 10 dB attenuation of the pile driving noise source. However regarding the assumed attenuation at the source there is only a general reference to the use of bubble curtains in Section 11.2.12 with no specifics as to how it will be achieved in practice. That section also refers to prior measurements of noise attenuation systems that are reasonably expected to achieve greater than a 10 dB broadband attenuation. However there is no reference provided for those measurements and that assurance and it is unlikely that any prior measurements would be relevant to these new large diameter monopiles and jacket foundations. The discussion of sound attenuation methods in the rule's Appendix B Section 2.4 also does not inspire confidence regarding achieving a 10 dB attenuation. It does mention the difficulties encountered with needing larger bubbles for lower frequencies as discussed further below. According to the references provided the single bubble systems appear limited to piles less than 8 meters in diameter even though these piles could be as large as 15 meters. The Bellman reference states that noise attenuation systems for jacket foundations are limited yet the Tables in the project's MMPA Application include 10 dB and higher attenuations for construction schedule 2 involving jacket foundations. The references indicate that for monopile foundations double bubble curtains or other auxiliary systems will be necessary but it's not clear that those will be successful for these diameters. In short much of the discussion is not relevant to the large diameter monopile foundations here or the jacket foundations. There is no specific proposal made that would be expected to achieve a 10 dB attenuation in the context of this project.	reduction of sound at specific frequencies. This is an active field of research, and the technology is continually evolving. The commenter is referred to the Bellmann et al. 2020 technical report entitled, “Underwater noise during percussive pile driving: influencing factors on pile-driving noise and technical possibilities to comply with noise mitigation values” for details on the proven effectiveness of these systems alone or in combination with other systems.

Comment No.	Comment	Response
BOEM-2024-0001-0357-0064	Absent evidence to the contrary assumptions regarding broadband noise attenuation from air bubble curtains should be less than 5 dB as recommended in Buehler 2015 titled Technical Guidance for Assessment and Mitigation of the Hydro acoustic effects of Pile Driving on Fish (see page 410). On page 218 Buehler (2015) cites actual project results of 0 to 5 dB of attenuation. Measured noise levels in the report titled Underwater Sound Levels associated with Driving Steel Piles at the Vashon Ferry Terminal Laughlin April 2010 show in Table 2 the effect of bubbles on root mean square (rms) noise values to be 1 dB. The report titled Underwater Reduction of Marine Pile Driving using a Double Pile Reinhall December 2015 shows a maximum 5.5 dB reduction in rms levels for a bubble curtain. The Caltrans 2015 study cited above has also stated that even in the near field an assumed source level reduction should be limited to 5 dB because of the uncertainties associated with the degree of attenuation that would be provided by a bubble curtain. Thus achieving a 10 dB reduction would require an auxiliary system such as a double wall pile. However as discussed below even that would not address the problem of achieving reductions at the lower frequencies relevant to the right whale's hearing range. We have seen no written enforceable commitment from the Atlantic Shores management to achieve a 10 dB broadband attenuation. Also as shown below there are significant technical problems in achieving such a large attenuation for the lower whale-hearing frequencies needed to protect right whales. In addition since noise source levels are not presented there is no way of measuring the noise level and verifying that a 10 dB attenuation is achieved in practice. Therefore the BOEM and the NMFS should not assume more than a 5 dB broadband attenuation. With that even using the questionable small exposure ranges and takes estimates critiicized in Save LBI's comments on the prposed rule the rule document admits that the project would cause Level A noise takes of the right whale absent mitigation. But as discussed below even that 5 dB is not applicable to the lower frequency situations involving the right whale and other LFC's.	Thank you for the comment. A section introducing some of the noise attenuation technologies has been added to the acoustic appendix for the final PEIS. Noise attenuation technology continues to evolve, and there are many options available today, either a single solution or a combination of solutions, that can reach 10 dB or more of noise attenuation from the unmitigated case (Bellmann et al. 2020). Examples of the growing number of noise attenuation solutions include the IHC-Noise Mitigation Screen, OffNoise Solutions GmbH’s Hydro-Sound Damper, the big bubble curtain or double bubble curtains (available from several suppliers), and the Grout Annulus Bubble Curtain. In addition, there are alternative hammer designs (e.g., IQIP-Pulse and Menck Noise Reduction Unit) that can be used to reduce the noise associated with impact pile driving over traditional methods. The commenter is referred to the Bellmann et al. 2020 technical report entitled, “Underwater noise during percussive pile driving: influencing factors on pile-driving noise and technical possibilities to comply with noise mitigation values” for details on the proven effectiveness of these systems alone or in combination with other systems.

Comment No.	Comment	Response
BOEM-2024-0001-0357-0065	Noise Source- Low Frequency Attenuation. Regarding pile driving the proposed MMPA rule project Application and the NMFS Biological Opinion are incomplete and flawed because they do not address attenuation in the most relevant frequency range for the right whale and other LFC's. In that regard it is not broadband attenuation that is critical here but attenuation of noise levels in the frequency range less than 1000 Hertz as this is the range that overlaps right whale hearing. Attenuating the sound at lower frequencies requires larger bubbles; and practical problems have been raised regarding the control of bubble size distribution and the production of a sufficient number of large bubbles (several centimeters) that are necessary to achieve efficacy at low frequencies (see Measurements of Construction Noise during Pile Driving of Offshore Research Platforms and Wind Farms Rainier Matuschek and Klaus Betke NAG/DAGA 2009 Rotterdam). More specifically in the study titled Underwater Noise Emission Due to Offshore Pile Installation: A Review Article in Energies June 2020 DOI: 10.3390/en13123037 by Tsouvalas of Delft University of Technology it was stated that "For piles with diameters larger than 6 meters that are used as foundation piles of offshore wind turbines the acoustic energy is radiated at frequencies between 100 and 400 Hz (Section 4.3). At such low frequencies the desired bubble radii to stimulate resonance range between 8 mm and 32 mm near the surface are between 14 mm (1.4 cm) and 50 mm (5 cm) at a water depth of 30 meters. The creation of bubbles of such large radii is rather difficult especially in the harsh offshore environment. Thus despite the role that resonance phenomena may play in sound absorption the wave reflection caused by the impedance mismatch between the seawater and the air bubble curtain seems to be the single most significant mechanism leading to noise reduction". As discussed above achieving a 10 dB attenuation would require an additional auxiliary system such as a double walled pile. Such a system was employed and measured in the Vashon Ferry Terminal report cited above. However a frequency analysis of the noise reductions between the unmitigated piled driving and the double wall pile shows e.g. in Figures 9c and 11a very little noise attenuation	Thank you for the comment. At the present time, there is no MMPA application for the PEIS. Noise attenuation technology continues to evolve, and there are many options available today, either a single solution or a combination of solutions, that can reach 10 dB or more of noise attenuation from the unmitigated case (Bellmann et al. 2020). Examples of the growing number of noise attenuation solutions include the IHC-Noise Mitigation Screen, OffNoise Solutions GmbH’s Hydro-Sound Damper, the big bubble curtain or double bubble curtains (available from several suppliers), and the Grout Annulus Bubble Curtain. In addition, there are alternative hammer designs (e.g., IQIP-Pulse and Menck Noise Reduction Unit) that can be used to reduce the noise associated with impact pile driving over traditional methods. As the commenter points out, near-field resonate systems can be tuned to target the reduction of sound at specific frequencies. This is an active field of research and the technology is continually evolving. The commenter is referred to the Bellmann et al. 2020 technical report entitled, “Underwater noise during percussive pile driving: influencing factors on pile-driving noise and technical possibilities to comply with noise mitigation values” for details on the proven effectiveness of these systems alone or in combination with other systems.

Comment No.	Comment	Response
	occurring below 1000 Hz in the right whale's primary hearing range and the addition of bubble curtains in Figure 11d does not change that. This was not unexpected because as discussed above much of that low frequency sound was re-radiated from the seabed and not affected by the double pile or the close to source bubble curtains. Therefore even such auxiliary systems will not provide significant attenuation in the low frequency range nor will bubble curtains.	
BOEM-2024-0001-0357-0066	[Bold: Consequently the BOEM and NMFS should assume no source attenuation in their calculations of exposure ranges and take estimates for the right whale and other low frequency cetaceans.] For higher hearing frequencies they should assume more realistic attenuation numbers less than 5 dB with technical justification for them. In light of all these noise attenuation limitations it would be irresponsible for the BOEM and the NMFS to simply accept the applicant's assurances that a 10 dB can or will be achieved and proceed based in large part on such a broad (frequency-wise) tenuous and unsupported assumption. [Bold: Many of the agency's positive conclusions have depended on that assumption. Therefore those conclusions in the project EIS's the MMPA rulemaking and the Biological Opinion need to be revisited.]	Thank you for the comment. A section introducing some of the noise attenuation technologies has been added to the acoustic appendix for the final PEIS. Noise attenuation technology continues to evolve, and there are many options available today, either a single solution or a combination of solutions, that can reach 10 dB or more of noise attenuation from the unmitigated case (Bellmann et al. 2020). Examples of the growing number of noise attenuation solutions include the IHC-Noise Mitigation Screen, OffNoise Solutions GmbH’s Hydro-Sound Damper, the big bubble curtain or double bubble curtains (available from several suppliers), and the Grout Annulus Bubble Curtain. In addition, there are alternative hammer designs (e.g., IQIP-Pulse and Menck Noise Reduction Unit) that can be used to reduce the noise associated with impact pile driving over traditional methods. BOEM-2024-0001-0368-0001	I have grave concerns about many aspects of the installation of dozens if not hundreds of offshore wind turbines. Since your area of concern is the environmental impact of these projects I will restrict my comments to that. Regarding sonar which can be deadly I was presented with information that many tests have been performed and that any sonar being deployed is within "safe" parameters. I am not a scientist and I cannot dispute your findings but I think any reasonably thinking person can look at the vast increase in numbers	Thank you for your comment and your concern. The sonar implicated in any marine mammal injury (primarily long distance anti-warfare sonar) is not the same sonar being used for offshore wind surveys, which consists only of three types: 1) *Bathymetric mapping* uses multibeam echosounders to map the depth and shape of the seafloor and backscatter to interpret density of the top few centimeters of the seabed. All modern nautical and navigation charts depend on bathymetric mapping,

Comment No.	Comment	Response
	of dead sea mammals along the Jersey shore that occurred during increased use of sonar at the same time and make a logical correlation between the two. I simply cannot believe your argument.	which is conducted frequently (sometimes as much as annually in high traffic commercial passages) to ensure navigation data are accurate. Bathymetric mapping is also a key component in dredging, beach renourishment, and post-storm surveying to certify navigable waters. 2) Seafloor Imaging is another method of seafloor shape characterization; it typically uses side scan sonar for high-definition detail of the seafloor. This method is used in many applications, including underwater archaeology, coral reef mapping, wreck mapping, and hazard identification. For offshore wind applications, seafloor imaging is required by BOEM to identify all potential archaeological sites (e.g., shipwrecks), fish habitats such as hard bottom communities or sand ridges, and other sensitive habitats that cannot be disturbed as part of the offshore wind development. 3) *Sub bottom profiling* not only acquires data for the surface of the seafloor but also penetrates several meters into the seafloor for a picture of subsurface materials and geology. Sub bottom profiling is used regularly for sand source identification and characterization for beach renourishment and restoration activities along the entire Eastern seaboard. Identification and monitoring of these sand resources through sub bottom profiling is critical to maintain ongoing sand resources for coastal resilience, particularly after storms such as Hurricane Sandy. Sub bottom profilers include CHIRP Sonar (which is the same type of sonar method used in the “fish finders” common on commercial and recreational fishing vessels). There is no causal connection between recent offshore wind development and large whale mortality, and such an assumption is contrary to the scientific consensus. The overwhelming scientific consensus is that offshore wind activity is not a cause of these marine mammal mortalities. Instead, the scientific community has determined the three declared UMEs for whales in 2016 and 2017 were primarily caused by non-wind vessel strikes and fishing gear entanglements (and infectious disease for the minke whales). NOAA, the Marine Mammal Commission, academic institutions (e.g., Rutgers

Comment No.	Comment	Response
		University, University of Rhode Island, Yale), environmental organizations (e.g., Sierra Club, Natural Resources Defense Council), BOEM, and the DOE have all issued official statements that no marine mammal mortality has been attributed to offshore wind activities.
BOEM-2024-0001-0381-0002	What will the underwater cables noise/vibrations ships etc. do to the marine life all along the eastern seaboard?	Underwater noise effects on marine mammals from various noise sources, including vessel and cable laying activities, are discussed in detail in Section 3.5.6.3.3 of the PEIS.
BOEM-2024-0001-0394-0002	The findings of federal scientists at NOAA-Fisheries (National Marine Fisheries Service) were that the project represented a threat to the continued existence of the North Atlantic Right Whale. The agency wrote a letter in May of 2022 to BOEM recommending for harm mitigation a buffer zone bounded on the east by the depth line where the Nantucket shoals depth measures 30 m and extending southwest for 20 km (12 mi). There was a big expos by Bloomberg News in November of 2022 that BOEM was not heeding the federal government's own scientists at NOAA-Fisheries. The Mayflower DEIS reveals that BOEM ruled out doing this because it considers the power purchase agreement to have irretrievably committed whatever portion of the lease area is necessary for power production outlined in the agreement which was formed in 2020 three years before conclusion of the environmental inquiry as to the project's effects. This means the decision as to whether to commit ocean resources to any specific purpose is being made ahead of the environmental review which examines what the environmental consequences will be. This runs counter to the intent of the environmental law.	Thank you for your comment. BOEM will take your comment into consideration as it administers its program. This PEIS does not approve or disapprove any projects; that will occur during the project-specific COP-level NEPA analysis. Additionally, the findings of the Hayes (2022) memo were included in the impact assessment discussion of this PEIS.
BOEM-2024-0001-0394-0004	We also found examination of effects on migratory birds in the DEIS to be inadequate. Many birds use infrasound for essential migration timing ensuring that energy expenditure does not exceed energy reserves and that deadly storms are avoided. There have been 3 dead right whale calves this year showing NOAA's lack of care towards whale populations and reducing speed limits for recreational vehicles jet skis and tourist whale watching vehicles. Many states (with the exception of Massachusetts) have not updated their recreational sea vehicle speed limits at all. Moreover unlike in	There have been no reported vessel strikes from offshore wind vessels during any preconstruction or construction activities to date. Vessel transits are monitored electronically and by on-board observers, and all sightings of ESA-listed whales must be reported regardless of whether any strike avoidance was required. There is no causal connection between recent offshore wind development and large whale mortality, and such assumption is contrary to the scientific consensus. The overwhelming scientific consensus is that offshore wind activity is

Comment No.	Comment	Response
	Europe the NOAA does not provide fishermen free gear and tackle to reduce risks to whales. Instead they impose burdens on fishermen who continue to try to make a living despite increasingly crowded waters and now wind turbines that don't work. Wind turbine parts cannot be recycled. Their cable causes whale entanglements and death. Their blasting also causes whale death in addition to school confusion and changed migration patterns. If you develop these wind turbines you will be signing the death warrant of the right whale.	not a cause of these marine mammal mortalities. Instead, the scientific community has determined the three declared UMEs for whales in 2016 and 2017 were primarily caused by non-wind vessel strikes and fishing gear entanglements (and infectious disease for the minke whales). NOAA, the Marine Mammal Commission, academic institutions (e.g., Rutgers University, University of Rhode Island, Yale), environmental organizations (e.g., Sierra Club, Natural Resources Defense Council), BOEM, and the DOE have all issued official statements that no marine mammal mortality has been attributed to offshore wind activities. Additionally, effects of cable emplacement and maintenance, UXO detonations, and decommissioning from the proposed NYB projects are considered in this PEIS both without mitigation (Section 3.5.6.4) and with mitigation (Section 3.5.6.5).
BOEM-2024-0001-0425-0006	The approval of the within NY Bight Industrial Wind Turbine Project without independent peer reviewed scientific research on the negative impacts upon marine mammals and in particular the North American Right Whale is violative of the Endangered Species Act and NEPA. True science involves constantly emerging new evidence and findings along with the everchanging challenges imposed as to prior conclusions. As such contrary to the non-scientific "group think" and massive amounts of money driven public relations press releases behind the current wind turbine projects such sentiment ignores scientific methods of ongoing experimenting at the very least through realistic peer reviewed scientific pilot projects. True science involves constantly emerging new evidence and findings. This process necessarily continually involves the ongoing application of extensive scientific research which is then applied to the previously accepted theories. Such a true application of peer reviewed science especially applied to growingly obsolete wind turbine construction would support the revision if not rejection of prior dogma as to allegedly "settled science". As I have testified previously only from a partially facetious standpoint the rush to judgment approach as to this specific proposal to construct massive windfarms off New Jersey represents non-scientific "group think" with the devastating	Thank you for your comment. BOEM used the best available science to address impacts in the PEIS, but will take this comment into consideration as it administers its program. This PEIS does not approve or disapprove any projects; that will occur during the project-specific COP-level NEPA analysis.

Comment No.	Comment	Response
	potential to trample upon scientific inquiry and research. Such immense pressure from those supporting such colossal development of this offshore industrial site off of the precious New Jersey Coast unfortunately has facilitated many knee-jerk feel-good reactions which totally ignore the required economic and scientific vetting process. During a prior era particularly relevant to the coast of New Jersey our town and I were subjected to enormous pressures exerted by those supporting ocean dumping generated by a foreign corporation's pipeline off our beautiful and incalculably valuable portion of the New Jersey shore. Similar subconscious and actual influences are once again being exerted in favor of a foreign corporation looking to create another potential ocean dumping site off New Jersey's shoreline. I would truly beseech BOEM officials to rise above the narrow bureaucratic rubber-stamping of the within proposal in favor of the true application of scientific method to the entire cumulative and indirect impacts of the current project as well to windfarms off of New Jersey's Coast in general. Just as one heartfelt objector testified in a virtual hearing as to the threats proposed by foreign corporations to our country's national symbol the bald eagle these threats are very real whether proposed by a non-American entity or a corporation based in our own country. An even more appalling aspect of the within proposal can be seen in the lack of scientific method and any good faith attempt at a complex economic evaluation to be applied to the critically threatened North American Right Whales. This species is in dire jeopardy due to this specific proposal and the threat of pollution generating windfarms proposed to be constructed directly in the right Whales' primary and sole migratory waterways off the New Jersey Coast. With approximately three hundred fifty (350) North Atlantic Right Whales left in the entire world the DEIS barely touches the surface as to the potentially devastating if not terminating impact of this vast industrial project itself and numerous ongoing adverse impacts presented. From a noise perspective pollution generating standpoint and otherwise the construction operation and totally ignored dismantling and decommissioning process of the gigantic wind turbines themselves has insufficiently been addressed. Moreover the	

Comment No.	Comment	Response
	Draft Environmental Statement does not recognize the legal and moral standing of such an invaluable threatened species whose inspirational value beauty and potential worth as to biodiversity for our planet and to life itself cannot be overstated. How outrageous is it that this entire species of the North Atlantic Right Whales in all likelihood is being condemned to extinction by this juggernaut of industrial windfarm construction in this treasured creature's only habitat and migratory living pathways. What arrogance and true ignorance of science has been presented! What is the value of this species now being wiped off the face of the earth?	
BOEM-2024-0001-0469-0009	In the Draft PEIS section on marine mammals BOEM states that impacts from the presence of structures would likely be minor for non-North Atlantic right whale mysticetes and odontocetes but the appendix on incomplete and unavailable information indicates that it is unclear how large marine mammals will respond to the presence of "extensive networks of new structures" in their environment. [Footnote 20: NEW YORK BIGHT DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT appx. E at E-6.] For the North Atlantic right whale ("NARW") BOEM discusses the precarious status of the species and risks OSW presents such as stress response from vessel noise auditory masking and vessel strikes. [Footnote 21: NEW YORK BIGHT DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT supra note 5 at ES-11 3.5.6-24-25.] BOEM projects that impacts to the North Atlantic right whale could be as high as "major" because the population's high mortality rate low fecundity and small size make it so that "all human-caused mortalities have the potential to impact their population status". [Footnote 22: Id. at 3.5.6-10.] Given the dire status of the North Atlantic right whale any impacts to the species are unacceptable.	Thank you for your comment. BOEM used the best available science to address impacts and assign impact-level determinations in the PEIS.
BOEM-2024-0001-0469-0010	Because marine mammal hearing is difficult to study animals are often grouped based on anatomy rather than studying the hearing of specific species and how they may be impacted by surveying activities and construction noise. [Footnote 23: Id. at 3.5.5-9.] There is a particularly glaring data gap regarding baleen whale hearing. [Footnote 24: Takes of Marine Mammals Incidental to Specified Activities; Taking Marine Mammals Incidental to Marine Site	Thank you for your comment. BOEM acknowledges data gaps in marine mammal hearing studies in Section 3.5.6.1.3 of the PEIS, and the marine mammal hearing groups used throughout follow the scientific recommendations from NMFS (2018) and Southall et al. (2019), which incorporate the best available data on marine mammal hearing to date.

Comment No.	Comment	Response
	Characterization Surveys Off New York New Jersey Delaware and Maryland 89 FR 753 761 (Jan. 5 2024) ("no direct measurements of hearing ability have been successfully completed for mysticetes").] A 2015 University of Santa Cruz study indicated that pinnipeds were more sensitive to high-frequency noise than was previously predicted. [Footnote 25: Kane Cunningham Pinniped Hearing in a Changing Acoustic Environment U.C.S.C. ESCHOLARSHIP (2015) https://escholarship.org/uc/item/737223k8] The same study outlined a myriad of factors that could affect how noise travels in the marine environment suggesting that frequency is far from the whole story of how noise reaches and affects pinnipeds. [Footnote 26: Id.] In section 3.5.6.1.3 of the Draft PEIS the majority of the references are to studies that are more than ten (10) years old; some date as far back as 1985. [Footnote 27: NEW YORK BIGHT DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT supra note 5 at 3.5.6-13-21.] This speaks to how little is currently understood especially given that proposed OSW development has increased exponentially in the New York Bight in a short amount of time. Changes to a population or species can happen quickly so if BOEM has an underdeveloped understanding of marine mammal species' current status the agency cannot accurately plan for future protections and mitigation of potential impacts. This makes it even more concerning that New York Bight projects are expected to have "major" impacts to scientific research surveys. [Footnote 28: Id. at ES-12.] NOAA has reported that this will increase uncertainty in assessments for fisheries and endangered species consultation: "By disrupting NOAA Fisheries survey programs and the advice that depends upon them regional wind development will result in major adverse impacts on U.S. fisheries stakeholders including fishermen and fishing communities and the American public who consume American seafood and who also expect the recovery and conservation of endangered species and marine mammals." [Footnote 29: NOAA Technical Memorandum NMFS-NE-291 Fisheries and Offshore Wind Interactions: Synthesis of Science at 184 (March 2023)	

Comment No.	Comment	Response
	https://repository.library.noaa.gov/view/noaa/49151/noaa_49151_DS1.pdf]	
BOEM-2024-0001-0469-0011	Moreover marine mammals have been stranding off the coast of New York and New Jersey in larger numbers than normal since December 2022 remaining elevated through March 2023 and spiking again in summer 2023. [Footnote 30: MARINE MAMMAL STRANDING CENTER Current Cetacean Data https://mmsc.org/current-cetacean-data (last visited Mar. 12 2024); Alexandra George Why Have So Many Dead Whales Washed Ashore Along the New Jersey New York Coasts in 2023? ABC EYEWITNESS NEWS (Sept. 1 2023) https://abc7ny.com/climate-change-dead- whale-beached-tri-state-area/12901186/.] This correlates in time to OSW pre-construction activities but it is unclear what role the OSW activities may have played if any because there was no independent region-specific study commissioned on marine mammals in the New York Bight despite COA and many concerned citizens and elected officials calling for one. Whatever the cause of the increased marine mammal mortalities it is clear that the marine environment is already experiencing stress which makes it even more important to use the precautionary principle proving no harm before moving forward with an activity before adding more stressors in the form of surveying and construction noise vessel traffic and new networks of structures. BOEM concluded that the data gaps do not impede its ability to make a reasoned choice between the Draft PEIS alternatives despite also indicating that adverse impacts including injury or death to marine mammals and sea turtles could still occur because of the data gaps outlined in Appendix E. [Footnote 31: NEW YORK BIGHT DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT supra note 5 at 4.2-3.] The agency's conclusion is unreasonable on its face and especially so given the amount of other unanswered research questions and known risks arising from OSW energy development.	There is no causal connection between recent offshore wind development and large whale mortality, and such an assumption is contrary to the scientific consensus. The overwhelming scientific consensus is that offshore wind activity is not a cause of these marine mammal mortalities. Instead, the scientific community has determined the three declared UMEs for whales in 2016 and 2017 were primarily caused by non-wind vessel strikes and fishing gear entanglements (and infectious disease for the minke whales). NOAA, the Marine Mammal Commission, academic institutions (e.g., Rutgers University, University of Rhode Island, Yale), environmental organizations (e.g., Sierra Club, Natural Resources Defense Council), BOEM, and the DOE have all issued official statements that no marine mammal mortality has been attributed to offshore wind activities.
BOEM-2024-0001-0473-0001	Please consider the following from RODA regarding offshore wind development: "There are opportunities for mutual wins however offshore wind development is an ocean use that directly conflicts with fishing and primary food production while imposing significant impacts on marine habitats biodiversity and physical oceanography."	Thank you for your comment. BOEM will take your comment into consideration as it administers its program.

Comment No.	Comment	Response
	As marine mammal deaths continue BOEM and NOAA have failed to "Thoroughly assess cumulative impacts of OSW to whales and other protected resources including all project phases and components and impacts to migration and food availability". Offshore wind is being advanced via excessive Incidental Harassment Authorizations and disregard for the MMPA and ESA. The Synthesis in Science report indicates "major gaps" in knowledge regarding the adverse impacts across nearly all manner of topics affected by offshore wind development. Environmental impact statements show connections between survey activity and an increase in vessel strikes and deaths due to construction activity yet agencies still profess there is no connection. There are contradictions across agencies and documents. Wind turbine failures and adverse impacts are finally coming to light around the world. I'm implore those with authority and integrity to halt further progress until assessments can be made of the damage already done since the installation of Block Island. I fully support the comments from Clean Ocean Action Save LBI and the plethora of other individuals and groups supplying data against further wind development.	
BOEM-2024-0001-0512-0001	I am commenting because I strongly oppose the proposed offshore wind lease areas in the New York Bight. As a concerned citizen of New Jersey I believe that these projects could have severe negative impacts on our communities and the surrounding environment. One of my primary concerns is the threat posed to endangered species such as the Atlantic Right Whales and other marine life. The construction and operation of offshore wind farms have the potential to disrupt crucial habitats and migration routes causing irreversible harm to what is an already vulnerable species. This ecological disruption would have far-reaching consequences for the delicate balance of our marine ecosystems.	Thank you for your comment. The PEIS discusses any potential impacts associated with the development of offshore wind within the NY Bight to protected species and the marine environment.
BOEM-2024-0001-0524-0001	The construction of wind turbines in the New York Bight poses a significant threat to the marine ecosystem particularly affecting numerous whale and fish species that frequent this area as reported by Gotham Whales. This includes several endangered species highlighting the critical nature of the threat. The use of sonar for seabed mapping in the region generates noise levels up to 226	There have been no reported vessel strikes from offshore wind vessels during any preconstruction or construction activities to date. Vessel transits are monitored electronically and by on-board observers, and all sightings of ESA-listed whales must be reported regardless of whether any strike avoidance was required. There is no causal connection between recent offshore

Comment No.	Comment	Response
	decibels at the source falling into the low-frequency range (LFI) which is within the hearing range of many whale and dolphin species. Analysis of NOAA data reveals a stronger correlation between the recent surge in whale mortalities and sonar mapping activities than with cargo ship traffic challenging the notion that increased ship traffic is the primary cause of these deaths. Statistical evidence further supports this argument. From 2020 to 2021 despite an 18.46% increase in ship traffic whale deaths astonishingly fell by 92.31%. The following year saw a 25.15% rise in ship traffic yet whale deaths still decreased by 53.85%. However a pivotal shift occurred from 2022 to 2023; ship traffic declined by 18.56% but whale deaths skyrocketed by 216.67%. This period coincides with a fourfold increase in surveying activities related to wind farm development leading to an alarming spike in whale fatalities in the New York/New Jersey area. Specifically 21 humpback whales perished which according to Gotham Whales' August 2022 count of 280 humpbacks in the region represents a significant loss of 7.5% of the population. Moreover NOAA's estimation that only one-third of whale deaths are detected suggests the actual impact could be even more devastating. These findings starkly contradict the argument that increased ship traffic is to blame for the rise in whale deaths. Instead they implicate the intensification of surveying traffic linked to wind farm development as a significant factor. Given that a substantial 7.5% of the humpback whale population in this region was lost in a single year and considering NOAA's admission that we may only be observing a fraction of the true number of fatalities it's clear that the environmental implications of proceeding with wind turbine construction in this sensitive area are profound. In addition each turbine will need:187 gallons of grease40 gallons hydraulic oil106 gallons of gear oil1585 gallons of dielectric fluid793 gallons of diesel fuel243 lbs of sulfur hexafluoride357 gallons Propylene glycol48 gallons Ethylene glycol This is not clean energy! This data mandates immediate comprehensive research and a cautious approach by both the Bureau of Ocean Energy Management (BOEM) and NOAA before any further development is considered.	wind development and large whale mortality, and such an assumption is contrary to the scientific consensus. The overwhelming scientific consensus is that offshore wind activity is not a cause of these marine mammal mortalities. Instead, the scientific community has determined the three declared UMEs for whales in 2016 and 2017 were primarily caused by non-wind vessel strikes and fishing gear entanglements (and infectious disease for the minke whales). NOAA, the Marine Mammal Commission, academic institutions (e.g., Rutgers University, University of Rhode Island, Yale), environmental organizations (e.g., Sierra Club, Natural Resources Defense Council), BOEM, and the DOE have all issued official statements that no marine mammal mortality has been attributed to offshore wind activities. The fluids and amounts required for turbine operation are provided in the PEIS.

Comment No.	Comment	Response
BOEM-2024-0001-0547-0007	Further BOEM's haste in approving the PEIS is in direct opposition to a longstanding federal protection program and in danger of disrupting a protected species that the federal government spent all this time and money to save from endangerment: the North Atlantic Right Whale protections. The North Atlantic Right Whale has been the subject of significant concern and federal protection. Since the U.S. government has spent close to $10M of taxpayer money to protect this endangered species why is this PEIS Project comprising six wind farm lease areas adjacent to the other projects already smack in the center of this federally endangered whale migration zone only nine miles from the Brigantine shore? [Footnote 19: See BOEM 2023-0030.] The cumulative effects of the vessel traffic and noise from BOEM's own PEIS is admittedly missing comparison with the mitigation effects and missing data such as NOAA takes [Footnote 20: See PEIS at D2-2; D2.9.1 at D-14; see also C-6 C-7.] and old outdated studies. [Footnote 21: Id. at D2-1; The Conservation November 15 2023 "As the US begins to build offshore wind farms scientists say many questions remain about impacts on the oceans and marine life." https://theconversation.com/as-the-us-begins-to-build-offshore-wind-farms-scientists-say-many-questions-remain-about-impacts-on-the-oceans-and-marine-life-216330 .] Therefore the mitigation measures fail - yet another reason for a No Action ruling.	See response to comment BOEM-2024-0001-0309-0006.
BOEM-2024-0001-0530c	Nobody listens to us. What about the effects of the survey areas? We've seen massive reductions in our fish populations and fish stock assessments since the surveying of the areas happened. This fall, all's we caught was dead scallops and dead clams and dead horseshoes in the areas that were once lively thresholds for all sorts of black sea bass, scup, summer flounder. And these things, whenever a survey vessel would show up, would disappear. The animals that couldn't get out of the way like the scallops, clams, and horseshoe crabs all died. And you're going to tell us that these vessels have nothing to do with the massive amount of whales and mammals that have washed ashore in the last year?	Potential impacts on scientific research and surveys are covered in detail in Section 3.6.7. NMFS and BOEM have prepared a Federal Survey Mitigation Implementation Strategy for the Northeast U.S. region (Hare et al. 2022) that describes impacts on fishery participants and on the conservation and recovery of protected species. This implementation strategy also defines stakeholders, partners, and other ocean users that will be engaged throughout the process and identifies potential resources for successful implementation through the duration of wind energy development in the Northeast U.S. region. BOEM is committed to working with NOAA toward a long-term regional solution to account for changes in survey methodologies as a result of offshore wind farms.

		Please refer to response to comment BOEM-2024-0001-0528f regarding recent marine mammal strandings.
BOEM-2024-0001-0528f	What kinds of sound decisions can be made if this monitoring cannot be completed prior to construction of one of the many projects along our coast? In this document BOEM listed potential for negligible to major impacts to whales. That is the full possible range of impact, confirming that the impact of our mammals is not in a fully known.	Thank you for your comment. Substantial scientific data exist for offshore wind development that allow assessment of impacts. All available information regarding potential impacts from offshore wind projects on marine mammals has been considered in this PEIS. Additionally, given the programmatic nature of this assessment, BOEM expects project-specific analyses of noise and other effects will be conducted during subsequent project NEPA stages that will further address specific, quantitative effects from offshore wind development of these projects. Further, the Final PEIS analyzes AMMM measure MM-3, which would require lessees to conduct long-term PAM or contribute to a research fund to support PAM on the lease area for 1 year before construction through at least 3 years but no more than 10 years of operations. If MM-3 were adopted as a COP T&C, then this data could be used to support additional analysis on noise impacts on marine mammals.
BOEM-2024-0001-0528f	Agencies that claim there's no evidence leaking these deaths to offshore wind have not provided evidence otherwise, or any scientific support for such a statement. The lack of due diligence in investigating cetacean deaths and transparency is alarming, to say the least. Without this long-term baseline data we cannot begin to determine causality from marine mammal deaths or other environmental impacts we are bound to see.	There is no causal connection between recent offshore wind development and large whale mortality. This assumption is contrary to the overwhelming scientific consensus that offshore wind activity is not a cause of these marine mammal mortalities. Instead, the scientific community has determined the three declared UMEs for whales in 2016 and 2017 were primarily caused by non-wind vessel strikes and fishing gear entanglements (and infectious disease for the minke whales). These determinations are based, in part, on published necropsy results. NOAA, the Marine Mammal Commission, academic institutions (e.g., Rutgers University, University of Rhode Island, Yale), environmental organizations (e.g., Sierra Club, Natural Resources Defense Council), BOEM, and the DOE have all issued official statements that no marine mammal mortality has been attributed to offshore wind activities. For additional information on these UMEs, see https://www.fisheries.noaa.gov/national/marine-life-distress/active-and-closed-unusual-mortality-events.

Comment No.	Comment	Response
BOEM-2024-0001-0528w	In the required appendix on incomplete and and unavailable information, the P.EIS shows multiple concerning data gaps. Data on the distribution of multiple species of whales and dolphins is lacking. The effects of electromagnet magnetic fields on benefit communities, sea turtles, and marine mammals are not well understood. For baleen whales, BOEM is extrapolating the effect of the effect of pile driving noise from studies on responses to air guns, and little research at all has been conducted on sea turtle hearing. Scientists do not know how marine mammals will will respond to the presence of artificial structures in their environment. A pilot project would have been the only way to determine this beforehand, which is why COA has long advocated for a pilot project before full scale development.	Thank you for your comment. The Final PEIS uses the best available information and complies with the procedural requirements of NEPA to predict potential impacts on marine mammals. An acknowledgment of uncertainty about the impacts of EMFs is included in Appendix E, *Analysis of Incomplete or Unavailable Information*. Future research about EMF exposure on marine organisms may be incorporated into future project-specific COP NEPA analyses as information becomes available. Further, BOEM considered but dismissed from further consideration an alternative to build a pilot project (PEIS Chapter 2, Table 2-3). Data from sites that are constructed and operating (e.g., Block Island) as well as the pilot project in Virginia were incorporated into this PEIS and will be incorporated into the development of project-specific COPs and EISs.
BOEM-2024-0001-0528w	At the in-person meeting in New Jersey we learned that BOEM made compromises on the amount of baseline, passive, acoustic monitoring it would require to accommodate the expeditious timeframe of offshore wind development.	Thank you for your comment. BOEM believes that a 1-year baseline is sufficient for the NY Bight region because there are ongoing PAM efforts already underway in NY Bight that could provide more than a 1-year baseline. Additionally, the Final PEIS analyzes AMMM measure MM-3, which would require lessees to conduct long-term PAM or contribute to a research fund to support PAM on the lease area for 1 year before construction through at least 3 years but no more than 10 years of operations. The requirements in this AMMM measure are consistent with previously applied COP T&Cs.
BOEM-2024-0001-0529f	My other point of view is, why does BOEM need to give, take charts or provide take charts to these wind companies? New York wind companies, allowing them to kill so many marine life. In the beginning, NOAA said wind development, sonar testing or the wind turbines would not affect the whales. Now they come out and say, oh, yes, they will affect the whales, they will harm the whales or harass the whales, but they will not kill the whales. But if you talk to any marine biologists, they will tell you a harmed whale, or harassed whale is a dead whale. These whales that you want to show that are	Thank you for your comment. There is no evidence of death or serious injury from offshore wind pre-construction surveys or from offshore wind pile driving or offshore wind vessel strike. The greatest transformational threat to the marine ecosystem is climate change. Please refer to response to comment BOEM-2024-0001-0528f for more information on recent marine mammal strandings. As documented in Section 3.5.3, presence of birds in the offshore environment is low; therefore, BOEM anticipates that the risk to birds from offshore wind development and operations would be

Comment No.	Comment	Response
	struck by something, are struck by boats and other marine things because they are fleeing for their lives from the noise that the wind farms are creating. Let's start telling the America the truth about what wind turbines will do to our ocean floor and our fishing industry. So please start telling America the truth. Stop giving, take charts. You gave take charts out in out, in, out in the inland and said they could kill so many birds, and they're far surpassing the amount of birds that they were supposed to kill. And now these wind farms are being fined for it. Same thing is going to happen to our whales. 68 dead whales, is on your hands.	low. Potential collisions and disruption of behavior and flight patterns are addressed in Section 3.5.3. Potential impacts on federally threatened and endangered birds are addressed through the ESA Section 7 requirements.
BOEM-2024-0001-0528ee	I'm a conservation biologist, and I'm very concerned about offshore wind development, especially regarding its impact on whale populations. We have seen an unprecedented increase in whale strandings in the New York and New Jersey area over the past 14 months which directly corresponds with offshore wind vessel activities in our area. So, while many say that there's no evidence linking offshore wind to the recent whale deaths, no one is at the same time, no one is providing evidence that offshore wind activity is not a contributing factor to these strandings. So, we, I feel we definitely need to have more studies on the potential impact that offshore wind will have not just on marine mammals, but on all marine life prior to construction of these wind turbines. As it stands right now, scientists really do not know how the construction of thousands of wind turbines will impact the marine ecosystem.	Thank you for your comment. Please refer to response to comment BOEM-2024-0001-0528f regarding recent marine mammal strandings.
BOEM-2024-0001-0529n	According to 3.5.7-33 PES New York Bight, glauconitic sands may be present in New York Bight lease areas depending on the classification of the glauconitic sands present, there could be challenges associated with potential offshore wind development in these areas. Specifically. Specifically, some glauconitic sands are difficult or even impossible to drill through and cause high friction and increase noise during pile driving. Developers discovered glauconitic sands during construction installation, noise levels will likely increase as they determine if the	Thank you for your comment. The Final PEIS acknowledges the possibility for glauconite soils to be present in the NY Bight lease areas and identifies potential impacts associated with glauconite. Specifically, text within Section 3.5.5.5.1 (page 3.5.5-42) has been enhanced to discuss the correlation between the presence of glauconite sand and the potential need to use an increased level of hammer strike energy during pile driving operations for WTG installation. Additional details will be addressed at the COP-specific NEPA stage.

Comment No.	Comment	Response
	glauconitic is possible. We need to know if glauconitic exists before any construction begins. Developers need to be required to disclose this prior to any IHAs being issued, considering sound may be much louder, leading to higher mortality.	
BOEM-2024-0001-0529o	For example, in this document, BOEM lists the potential for negligible to major impacts to whales. That is the full possible range of impact. Confirming the impact to marine mammals is not fully known. Even assuming a moderate cumulative impact will cause more harm than the species can handle. So how do you gauge and plan monitoring mitigation efforts when you don't know what to expect?	Thank you for your comment. Substantial scientific data exist for offshore wind development that allow assessment of impacts. All available information regarding potential impacts from offshore wind projects on marine mammals has been considered in this PEIS. Additionally, given the programmatic nature of this assessment, BOEM expects project-specific analyses of noise and other effects will be conducted during subsequent project NEPA stages, which will further address specific, quantitative effects from offshore wind development of these projects.
BOEM-2024-0001-0529o	Over the past 13 months, 99 cetaceans, including 38 whales and 61 dolphins and porpoise have died just in the New York New Jersey Bight that we know of. That does not include the countless others outside the Bight or the ones we could not locate records for, or that never washed ashore. Agencies that claim that there is no evidence linking the deaths to offshore wind have not provided any scientific support. The lack of due diligence in investigating the cetacean deaths and transparency is alarming, to say the least. COA is concerned that these grim headlines can be more common without proper investigations into how the construction and operation of these concrete and steel jungles in the ocean will affect marine habitats and behavioral responses, such as feeding, mating, and migration patterns. We owe it to the many vulnerable and endangered species of marine mammals, sea turtles and fish to understand the inevitable repercussions of building an obstacle course in their home. The ocean is without boundaries, and the increased noise, vessel traffic, and potential, chemical and electromagnetic field exposure that come with offshore wind infrastructure need to be investigated cumulatively to understand the total impact to a species.	Thank you for your comment. Please refer to response to comment BOEM-2024-0001-0528f regarding recent marine mammal strandings.
BOEM-2024-0001-0529p	I personally added up the IHAs. There are over 1 million takes on marine mammals for offshore wind, dating back to 2014. Why is anyone saying that offshore wind doesn't cause harm to whales	Authorized takes are based on modeling and are therefore likely proportional to but not the actual number of takes that *will* occur during activities. Authorized takes mean that the project may not

Comment No.	Comment	Response
	when we have legal documentation of offshore wind corporations requesting to cause harm to whales? What is this delusion? Is there some sort of miraculous plan to build offshore whale without vessels and pile driving? Are offshore, is offshore wind somehow different than the other vessels that are killing North Atlantic right whales?	exceed the authorized number of takes within the given time period of the issued permit. For example, from the published HRG survey PSO reports from multiple offshore wind development projects within the U.S. Atlantic Ocean, PSOs recorded 2,696 large whale detections; of these, only 68 (2.5%) were detections that met Level B exposure criteria (animal distance and source operations). Please refer to response to comment BOEM-2024-0001-0528f regarding recent marine mammal strandings.
BOEM-2024-0001-0529t	In the required appendix on incomplete and unavailable information, the PEIS shows there are significant gaps in scientific knowledge of how the offshore wind industry will affect marine wildlife. Example, data on the distribution of multiple species of whales and dolphins is lacking. The effects of electromagnetic magnetic fields affect the communities, sea turtles and marine mammals are not well understood. For Baleen whales, BOEM is extrapolating the effect of pile, the effect of pile driving noise from studies on response to air guns, which is a different technology, and little research has been conducted at all on sea turtle hearing. Scientists don't know how marine mammals will respond to the presence of artificial structures in their environment. And outside of the PEIS, scientific research has also outlined multiple ways in which offshore wind poses risks to marine life. Increased vessel activity, noise, and in this particular geographic area, potentially changing the patterns of the North Atlantic Cold Pool, a unique seasonal temperature cycle that allows cold water creatures to thrive here.	Thank you for your comment. The Final PEIS uses the best available information and complies with the procedural requirements of NEPA to predict potential impacts on marine mammals. An acknowledgment of uncertainty about the impacts of EMFs is included in Appendix E, *Analysis of Incomplete or Unavailable Information*. Future research about EMF exposure on marine organisms may be incorporated into future project-specific COP NEPA analyses as information becomes available.
BOEM-2024-0001-0529t	Clean Ocean Action is not claiming, but there is definitive proof that offshore winds is the cause of the spike in whale deaths, but we also cannot rule out, offshore wind is a potential factor either because of the data gaps. This is why Clean Ocean Action has been calling for an independent peer reviewed scientific study. We need to conclusively determine why so many whales have been dying in the New York Bight.	Thank you for your comment. Please refer to response to comment BOEM-2024-0001-0528f regarding recent marine mammal strandings.

Comment No.	Comment	Response
BOEM-2024-0001-0310c	So if fluke disappear what's -- where do they go? It's not going to be because of industrial offshore wind. They won't have the evidence to support that. We've seen that with the whale killings.	Thank you for your comment. Please refer to response to comment BOEM-2024-0001-0528f regarding recent marine mammal strandings.
BOEM-2024-0001-0310g	The last thing I would like, I'd like to add, BOEM, President Biden, Governor Murphy, the whales and dolphins sadly have been the canary in our coal mine. And I'm sorry it gets me choked up, but they are warning us of the coming dangers of what's going to happen to our ocean environment. I ask that you heed those warnings and stop offshore wind.	Thank you for your comment. Please refer to response to comment BOEM-2024-0001-0528f regarding recent marine mammal strandings.
BOEM-2024-0001-0310h	The unprecedented uptick in whale and dolphin deaths in the past 14 months is devastating, and all of them while offshore wind vessels were surveying nearby. While you deny any connection between offshore wind and the deaths, no full necropsies have been released meaning there is no evidence that there is not a connection. The Incidental Harassment Authorization is evidence. Level B harassment refers to acts that have the potential to disturb a marine mammal or marine mammal stock in the wild by disrupting behavioral patterns, including but not limited to migration, breathing, nursing, breeding, feeding, or sheltering. Level A harassment means any act of annoyance, pursuit, torment that has the potential to injure a marine mammal or marine mammal stock in the wild. It is certain death and it is an invasion of their ocean.	There is no causal connection between recent offshore wind development and large whale mortality. This assumption is contrary to the overwhelming scientific consensus that offshore wind activity is not a cause of these marine mammal mortalities. Instead, the scientific community has determined the three declared UMEs for whales in 2016 and 2017 are primarily caused by non-wind vessel strikes and fishing gear entanglements (and infectious disease for the minke whales). NOAA, the Marine Mammal Commission, academic institutions (e.g., Rutgers University, University of Rhode Island, Yale), environmental organizations (e.g., Sierra Club, Natural Resources Defense Council), BOEM, and the DOE have all issued official statements that no marine mammal mortality has been attributed to offshore wind activities.
BOEM-2024-0001-0310j	I am here representing those without a voice, our whales. I am very concerned about the impact that the proposed offshore wind projects will have on our humpback whale population in the New York and New Jersey waters. Over the last 20 years, from 2002 to 2022, the average number of humpback whale strandings in New Jersey is 1.47 per year. Now that suddenly changed in the last 12 months. From December 2022 to December 2023, there were 11 dead humpback whales off New Jersey, and ten humpback whales dying off New York waters. In New Jersey, that's a 750 percent increase in the number of dead whales in one year. Just think about that for a second. 750 percent increase. This major increase in the number of whale deaths doesn't just happen by accident. Many people, myself included, do not think	Thank you for your comment. Please refer to response to comment BOEM-2024-0001-0528f regarding recent marine mammal strandings.

Comment No.	Comment	Response
	that it's a coincidence that the whales started dying off New York and New Jersey waters when offshore wind surveying activity in our ocean was at its highest. We hear from NOAA all the time that there is "no evidence that offshore wind activity has contributed to the recent uptick in whale deaths," but this really isn't a scientific response and it's not good enough. Is there evidence that offshore wind activity is not causing these whale deaths? That is really the question we need to have answered. It's imperative that we find out what is causing this massive increase in whale deaths before any more projects are approved. Humpback whales like all whales are protected under the Marine Mammal Protection Act. Because of the alarming and unprecedented increase in whale deaths, all activity that can potentially be contributing to these deaths must be halted until a full and thorough investigation can be completed. There also needs to be baseline studies of the current humpback whale population in the New York and New Jersey waters conducted along with a pilot study to determine the environmental impact prior to offshore wind construction.	
BOEM-2024-0001-0310m	Give us time to -- give us more time, because we'd like to take away your take authorizations	“Take” of a marine mammal is a term that is specifically defined under the MMPA and the ESA. While the PEIS analyzes impacts on ESA-listed species, the “taking” of a marine mammal is not determined through NEPA but through the MMPA or ESA. For clarity, BOEM does not authorize any permits or takes. Only the NMFS has this authority through the ESA or MMPA. To date, offshore wind developers have not applied for, and NMFS has not approved, any authorization to kill any marine mammals incidental to offshore wind site characterization surveys or construction activities. Authorized takes during construction in finalized authorizations have been limited to Level A and Level B takes by acoustic harassment.
BOEM-2024-0001-0310n	We have been fed lies about an "unusual mortality event" that started in 2016 and how it's unrelated to the offshore wind activity because "construction wasn't even started yet." We were fishing when surveying activity started in late 2015 and has increased dramatically from a few survey vessels occasionally surveying to	Thank you for your comment. The scientific community has determined that the three declared UMEs for whales in 2016 and 2017 were primarily caused by non-wind vessel strikes and fishing gear entanglements (and infectious disease for the minke whales).

Comment No.	Comment	Response
	dozens of survey vessels working around the clock in the past year and a half. We see our fishing grounds disturbed and our stocks leave the area as soon as the survey vessels show up. We are catching an unprecedented amount of dead clams, scallops, horseshoe crabs and other shellfish in areas that have been surveyed.	
BOEM-2024-0001-0529gg	Also, some are saying, we have never seen whales die, and I think it's very important that the PEIS, identify when the unusual whale mortality event started, which was in 2017, way prior to any offshore wind exploration ever occurred.	Thank you for your comment. The scientific community has determined that the three declared UMEs for whales in 2016 and 2017 were primarily caused by non-wind vessel strikes and fishing gear entanglements (and infectious disease for the minke whales).
BOEM-2024-0001-0310s	Just -- just seeing over the past year the amount of mortality that's happened because of this preconstruction. They're not even building the things yet, you know. Sound can do a lot of things to creatures on this planet. And, you know, what happens when they start pounding these pilings in, you know? That's even worse from what I'm seeing. All the research that I've been looking at on computers and books and libraries, I get to it and at the very end there's 12, 15 pages of where they got their information from. Did they actually go out and do anything? No. They took somebody's report, put it into another report. Look what I got, you know.	Thank you for your comment. Please refer to response to comment BOEM-2024-0001-0528f regarding recent marine mammal strandings.
BOEM-2024-0001-0310s	What's happening with the sonars, they're putting sounds in the water that they don't recognize, which I guess puts them in a panic and sorry it's not a direct correlation, but interferes with their migration. Their, you know, everything that they live for, and it maybe it causes a boat strike, but it wouldn't have happened if that noise wasn't there and they didn't recognize it, you know. It's like somebody coming up and bashing you on the side of the head, you know.	Most sonar used for HRG surveys are actually outside the low-frequency hearing group (Ruppel et al. 2022). There is no causal connection between recent offshore wind development and large whale mortality. This assumption is contrary to the overwhelming scientific consensus that offshore wind activity is not a cause of these marine mammal mortalities. Instead, the scientific community has determined that the three declared UMEs for whales in 2016 and 2017 were primarily caused by non-wind vessel strikes and fishing gear entanglements (and infectious disease for the minke whales). NOAA, the Marine Mammal Commission, academic institutions (e.g., Rutgers University, University of Rhode Island, Yale), environmental organizations (e.g., Sierra Club, Natural Resources Defense Council), BOEM, and the DOE have all issued official statements that no marine

Comment No.	Comment	Response
		mammal mortality has been attributed to offshore wind activities.
BOEM-2024-0001-0310u	For heaven's sake, do an investigation on the whales. You know, what the heck. What's the, you know, what is the problem? Do an investigation. You haven't provided the evidence. We don't have evidence that it did, but we are -- we think it's plausible.	Thank you for your comment. Please refer to response to comment BOEM-2024-0001-0528f regarding recent marine mammal strandings.
BOEM-2024-0001-0529jj	Since 2017, NOAA Fisheries has permitted, or is considered, or is considering permitting 108 vessels to conduct geophysical survey activities over more than 10,000 survey days, resulting in more than 113,000 instances of harassment, level B takes of marine mammals. And we all know that these, this type that was from NRDC themselves, and in a letter to BOEM. And we all know that takes our harassment. You can, everybody knows that a deaf whale is a dead whale, and if a whale loses its calf, they search for each other for eternity. What you're doing is an atrocity, and it needs to stop.	Authorized takes are based on modeling and are therefore likely proportional to but not the actual number of takes that will occur during activities. Authorized takes mean that the project may not exceed the authorized number of takes within the given time period of the issued permit. Consideration of takes that occur as a result of these projects is better characterized by PSO reports. For example, from the published HRG survey PSO reports from multiple offshore wind development projects within the U.S. Atlantic Ocean, PSOs recorded 2,696 large whale detections; of these, only 68 (2.5%) were detections that met Level B exposure criteria (animal distance and source operations).
BOEM-2024-0001-0529kk	I can tell you that for decades, I have followed the Center for Coastal Studies out of Cape Cod and they do whale research. And they, major killers of whales are ship strikes and entanglement in fishing gear. And that is not new. That is decades and if we don't address climate change, we don't have to worry about the whales, we have to worry about anything because we're unleashing chaos.	Thank you for your comment. Please refer to response to comment BOEM-2024-0001-0528f regarding recent marine mammal strandings.

P.5.11 Sea Turtles

Table P.5-11. Responses to Comments on Sea Turtles

Comment No.	Comment	Response
BOEM-2024-0001-0175-0003	[Bold: Cable Emplacement:] According to the NY Bight Draft PEIS 3.5.7-38 [Underline: Severe injury or mortality for sea turtles] "Cable emplacement and maintenance: Under six NY Bight projects the total area of seafloor disturbance would increase due to the substantial increase in the number of cables installed and maintained in the NY Bight area. Additionally construction of six NY Bight projects would increase the amount of dredging equipment and activities used during installation of the cables. As discussed in Sections 3.5.7.3.3 and 3.5.7.4.1 direct impacts from dredging particularly entrainment typically result in severe injury or mortality for sea turtles". How is this protecting the ocean's environment and sea life?	Thank you for your comment. The text in Section 3.5.7.4.2 referenced in this comment is specific to Alternative B, which assesses the risk of impacts without the AMMM measures. The Proposed Action in this PEIS is Alternative C, which includes the application of AMMM measures to reduce potential adverse effects on sea turtles from the NY Bight projects. Additionally, this PEIS does not approve or disapprove any projects; this would occur during the project-specific COP-level NEPA analysis.

P.5.12 Wetlands

Table P.5-12. Responses to Comments on Wetlands

Comment No.	Comment	Response
BOEM-2024-0001-0313-0050	5.8.5.1 Impacts of One Project The PEIS states "Requiring developers to consider how to adjust project design to minimize impacts on environmental resources such as by siting onshore infrastructure to avoid wetlands or using HDD to pass underneath sensitive wetlands could reduce overall wetland impacts (MUL-23). The site selection of the onshore landfall and substation locations and the onshore cable routes would have the highest influence on the magnitude of impacts on wetlands. Impacts of Alternative C could be less than those of Alternative B on wetlands due to potentially less disturbance to wetlands; however the AMMM measures do not eliminate the potential for more substantial wetland impacts. Additionally compliance with federal state and local wetland regulations which would apply to any alternative would also require the avoidance and minimization of wetlands impacts. Therefore Alternative C is not anticipated to have a meaningful change in	All proposed NY Bight projects will be required to demonstrate compliance with the NEPA process along with other applicable environmental laws, such as Section 404(b)(1) Guidelines of the CWA. A thorough analysis of potential impacts on wetlands resulting from alternatives would be evaluated once projects are identified. BOEM anticipates that onshore infrastructure components would be intentionally located in disturbed or developed areas (e.g., along existing roadways and ROW) to avoid and minimize potential impacts on wetlands. In addition, the onshore interconnection cables would likely be installed underground using trenchless construction techniques such as jack-and-bore and HDD at wetland and waterbody crossings, where feasible, to further avoid impacts on these resources. All activities would be required to comply with federal, state, and local regulations

Comment No.	Comment	Response
	impacts compared to Alternative B. The impacts for the land disturbance IPF under Alternative C would not be different than for Alternative B which would range from negligible to moderate due to the unknown locations of onshore project components and extent of wetland impacts those project components would incur. MUL-18 involves the use of shared transmission infrastructure among the NY Bight lessees and is therefore only applicable to the analysis of six NY Bight projects." Comment It is concerning that there is no meaningful analysis of potential impacts to wetlands and that it appears to be segmented from the environmental review by being deferred to the COP which based on multiple reference in the PEIS is not a required document though it appears that the potential adverse impacts should be part of the PEIS in terms of the larger plan of scale. Further this mitigation measure is very vague and thus prevents consideration of impacts and comments for consideration. Affected Environment and Environmental Consequences 3.6.2-7	related to the protection of wetlands by avoiding or minimizing impacts. If impacts would not be entirely avoided, mitigation would be anticipated to compensate for wetland loss. Applicants would identify compensatory wetland and stream mitigation based on the requirements of USACE, the New York State Department of Environmental Conservation (NYSDEC), and/or NJDEP as part of the Section 404 permitting process. MUL-23, which proposes developers consider how to avoid or reduce potential impacts on important environmental resources by adjusting project design, is currently an RP for consideration.

P.5.13 Commercial Fisheries and For-Hire Recreational Fishing

Table P.5-13. Responses to Comments on Commercial Fisheries and For-Hire Recreational Fishing

Comment No.	Comment	Response
BOEM-2024-0001-0063-0002	Impact on Fishing: The New York Bight is a vital area for commercial and recreational fishing. The presence of wind turbines will restrict fishing activities leading to economic losses for the local fishing industry. It will DESTROY our fishing industry!	Thank you for your comment.
BOEM-2024-0001-0089-0002	Other problems include the referencing of work submitted by organizations that have benefitted directly from Orsted such as Montclair State University Woods Hole Oceanographic Institute and others. There are numerous insta where impacts that would result in most any commercial endeavor taking place in the ocean waters in the case of this EIS for offshore wind have been dismissed as negative or minimal impact.	The Final PEIS considers the best available data and information that reflect the state of the science at the time of publication of the PEIS. Future research conducted may be incorporated into future project-specific COP-level NEPA analyses as information becomes available.
BOEM-2024-0001-0122-0001	I am opposed to offshore wind and here is why! A primary issue revolves around the anticipated disruption to the local fishing industry where the displacement of traditional fishing grounds and	Thank you for your comment. The NY Bight lease areas were designed to avoid certain commercial fishing activities, based on stakeholder input and task force meetings held from 2017 to 2021.

Comment No.	Comment	Response
	the creation of physical barriers could significantly impact the livelihoods of fishermen.	
BOEM-2024-0001-0122-0003	Impact on Fisheries: Offshore wind farms will disrupt traditional fishing grounds leading to the displacement of fishing activities. The construction and operation of wind turbines will interfere with established fishing routes impacting the livelihoods of fishermen.	Thank you for your comment. The NY Bight lease areas were designed to avoid certain commercial fishing activities, based on stakeholder input and task force meetings held from 2017 to 2021.
BOEM-2024-0001-0331-0007	Many officials have been warning us of the risks of rushing thought the approval and construction of the offshore wind projects. BOEM has approved projects despite repeated warnings from the National Marine Fisheries Service about damage to the environment and fishing industry. NMFS has stated that "we are building the ship while sailing it. " The NJ Department of Environmental Projection Official has stated " We are learning as we go."	Thank you for your comment.
BOEM-2024-0001-0331-0016	The New York Bight covers 488000 acres in addition to the 423184 acres of the other offshore wind projects in the NY/NJ area. This is a total of almost a million acres of wind development activity destruction of our ocean and marine life. According to BOEM's table D-2 there will be 1103 wind turbines in the New York Bight which will be next to another 713 in contiguous lease areas. That is a total of 1816 wind turbines! There will also be a total of 6333 miles of export and interarray cables in the ocean for all projects. The cumulative impacts of the New York Bight as well as the other contiguous offshore wind projects will devastate the fishing industry and destroy a sustainable food source.	Thank you for your comment. There are several mitigation measures in place to reduce the cumulative impacts of the anticipated development in the six NY Bight lease areas. The identified AMMM measures applicable to commercial fisheries and for-hire recreational fishing are presented in Table 3.6.1-20.
BOEM-2024-0001-0331-0034	The PEIS Does Not Sufficiently Address Fishing Industry Impact and Proposed Mitigation Will Not Save the Industry The fishing industry has grave concerns over the impact of the project. Ed Baxter a commercial fishman with the Fishermen's Dock Cooperative in Point Pleasant Beach NJ claims "what we're really worried about is the cabling. It's death." According to Baxter "The offshore power cables and export cables coming ashore could potentially shut mobile gear fisheries like scallop dredging out of those routes if fishermen can't be safe that their gear won't snag on the cables." This is especially concerning because the Orsted Block Island Wind Farm of five turbines has had problems maintaining adequate sediment coverage over its cables. Problems with maintaining cable depth have been	Scallop dredge gear has penetration depths of 1–15 centimeters in sand and 1–35 centimeters in mud (Eigaard et al. 2016; Paschen et al. 2000). The minimum cable burial depth is 3 feet (over 90 centimeters), with a target depth of 6 feet, as outlined in Table ES -1. AMMM measure MUL-19 would require periodic post-installation cable monitoring, and protocols for cable maintenance are in place. The NY Bight lease areas were designed to avoid certain commercial fishing activity, based on stakeholder input and task force meetings held from 2017 to 2021. In Section 3.5.2-24, BOEM suggests the maximum temperature of discharge water from an HVDC converter OSS would be 90°F

Comment No.	Comment	Response
	reported with the ongoing Vineyard Wind project too according to Baxter. The New York Bight cable routes could run near an area called Mud Hole a shallow trench between the ship traffic lanes should of New York Harbor which is a very productive fishing area. Fishing in this area can all be endangered by offshore wind development. Fisherman are concerned too with future offshore substations and their cooling water systems which handle water at 86-90 degrees F along with a lack of transparency about anti-fouling chemicals that may be in the water systems. Seawater life pumps can accelerate the maturing process for larvae disrupt the natural process and can lead to high mortality rates and fish defects. Offshore wind structures will have their own SWLP capable of generating an average of 4-5.3 million gallons of water flow per day. This extreme power brings water and anything small enough to fit through the steel bar filters to the surface in minutes. BOEM has yet to document the temperature of the discharge water by the cooling systems although it claims that warm water effects on surrounding ocean are "likely to be extremely minimal". But there is no research to support this claim. Mitigation includes banking on engineering advancements but there is no confirmation on the effects. The entrainment of ichthyoplankton during operation is based on outdated NOAA National Centers of Environmental Information (NCEI) electronic database. Estimates are from NOAA's Marine Resource Monitoring Assessment and Prediction (MARMAP) program from 1977 to 1987 and by the Ecosystem Monitoring program from 1995 through 2017 throughout the North Atlantic region. Based on BOEM reporting on entrainment the mortality for plankton is assumed to be 100%. Higher water temperatures typically accelerate species' lifecycles including but not limited to lobser egg production cod egg development pollack spawning monkfish egg disintegration and haddock eggs.	(32°C), which was modeled to result in a 1.4°F (1°C) water temperature increase up to 155 feet (47 meters) from the discharge point (TetraTech and Normandeau Associates, Inc. 2023). In Section 2-7, BOEM acknowledges chemicals such as bleach (sodium hypochlorite) may be used in order to prevent growth in the system and keep pipes clean (Middleton and Barnhart 2022). The entrainment mortality assumes 100% of any organism entrained, not the number of organisms within the region.
BOEM-2024-0001-0331-0035	The Point Pleasant Fishing co-op claims that the tallies listed in the PEIS for the value of landings from the six lease areas between 2008-2021 are understated. The table was modeled using Vessel Trip Report and vessel logbook data to estimate catch and landings based on the percentage of a trip that overlapped with each lease area according to BOEM documents. According to Point Pleasant co-op	Thank you for your comment. BOEM uses the best available data from our partner agencies. Vessel Trip Reports are used, as they focus on the landings, value, and the ports used. The Final PEIS considers the best available data and information that reflect the state of the science at the time of publication of the PEIS, including the most recent available landing data from
