New York Bight Final Programmatic Environmental Impact Statement

October 2024

Volume II: Appendices A-P

BOEM
BUREAU OF OCEAN ENERGY MANAGEMENT

This page was intentionally left blank.

Appendix A: Consultation and Coordination

A.1 Introduction

This appendix discusses public, agency, and tribal involvement leading up to the preparation and publication of the New York Bight (NY Bight) Final Programmatic Environmental Impact Statement (PEIS), including formal consultations, cooperating and participating agency and Cooperating Tribal Government exchanges, the public scoping comment period, and other correspondence. Interagency consultation, coordination, and correspondence throughout the development of the Final PEIS occurred primarily through virtual meetings, teleconferences, and written communications (including email).

A.2 Consultations

A.2.1 Endangered Species Act

Section 7(a)(2) of the Endangered Species Act of 1973 (ESA), as amended (16 United States Code [U.S.C.] 1531 et seq.), requires that each federal agency ensure that any action authorized, funded, or carried out by the agency is not likely to jeopardize the continued existence of any endangered or threatened species or result in the destruction or adverse modification of critical habitat of those species. When the action of a federal agency could affect a protected species or its critical habitat, that agency is required to consult with either the National Marine Fisheries Service (NMFS) or U.S. Fish and Wildlife Service (USFWS), depending upon the jurisdiction of the services. Pursuant to 50 Code of Federal Regulations (CFR) 402.07, the Bureau of Ocean Energy Management (BOEM) has accepted designation as the lead federal agency for the purposes of fulfilling interagency consultation under Section 7 of the ESA for listed species. On June 20, 2024, BOEM initiated consultation with the USFWS on a Programmatic Framework ESA Section 7 consultation.

A.2.2 Tribal Consultation

Executive Order 13175 commits federal agencies to engage in government-to-government consultation with Tribal Nations when federal actions have tribal implications. A June 29, 2018, memorandum outlines BOEM's current tribal consultation policy (BOEM 2018). This memorandum states that "consultation is a deliberative process that aims to create effective collaboration and informed federal decision-making" and is in keeping with the spirit and intent of Executive Order 13175 (BOEM 2018). BOEM implements tribal consultation policies through formal government-to-government consultation, informal dialogue, collaboration, and other engagement.

On November 30, 2022, in conjunction with a White House Tribal Summit held at the Department of the Interior, the Biden-Harris administration issued several directives and updates on Tribal policies including: Presidential Memorandum on Uniform Standards for Tribal Consultation (November 30, 2022); Department of the Interior Policy on Consultation with Indian Tribes (November 30, 2022); Department of the Interior Procedures for Consulting with Indian Tribes (November 30, 2022);

Department of the Interior Policy on Consultation with Alaska Native Claims Settlement Act Corporations (November 30, 2022); Department of the Interior Procedures for Consultation with Alaska Native Claims Settlement Act Corporations (November 30, 2022); Best Practices for Identifying and Protecting Tribal Treaty Rights, Reserved Rights and Other Similar Rights in Federal Regulatory Actions and Federal Decision-Making (Draft September 2022); Guidance for Federal Departments and Agencies on Indigenous Knowledge (November 30, 2022); Memorandum on Implementation of Guidance for Federal Departments and Agencies on Indigenous Knowledge (November 30, 2022); Collaborative and Cooperative Stewardship with Tribes and the Native Hawaiian Community Chapter 1: Policy and Responsibilities (November 30, 2022); and Collaborative and Cooperative Stewardship with Tribes and the Native Hawaiian Community Chapter 2: Committee on Collaborative and Cooperative Stewardship (November 30, 2022). Finally, on April 21, 2023, President Biden issued Executive Order 14096, Revitalizing Our Nation's Commitment to Environmental Justice for All, which includes coverage for Tribal Nations.[1]

On July 7, 2022, BOEM informed tribal leaders via email of the purpose of and anticipated publication date for the Notice of Intent (NOI) to prepare a PEIS for the six NY Bight lease areas. On July 15, 2022, BOEM sent individual letters via email to tribal leaders with the Absentee-Shawnee Tribe of Indians of Oklahoma, The Delaware Nation, Delaware Tribe of Indians, Eastern Shawnee Tribe of Oklahoma, Mashpee Wampanoag Tribe, Mashantucket (Western) Pequot Tribal Nation, Mohegan Tribe of Connecticut, Shawnee Tribe, Stockbridge-Munsee Community Band of Mohican Indians, The Narragansett Indian Tribe, The Shinnecock Indian Nation, and the Wampanoag Tribe of Gay Head (Aquinnah). These letters notified them that the NOI to prepare a PEIS for the NY Bight lease areas was issued that day and noted that the scoping comment period was open until August 15, 2022. Additionally, the letters initiated formal consultation with twelve Tribes under the National Historic Preservation Act (NHPA) and invited them to be NHPA Section 106 consulting parties and Cooperating Tribal Governments for the PEIS. One tribal leader initially responded that they would not like to participate in discussions related to the NY Bight PEIS: the Mashantucket (Western) Pequot Tribal Nation. As of April 19, 2023, Michael Kickingbear Johnson, Mashantucket Pequot (Western) Tribal Historic Preservation Officer (THPO) informed BOEM that the Mashantucket (Western) Pequot Tribal Nation, "are again revising [their] areas of interest by expanding them." BOEM has established a Cooperating Tribal Government relationship with the Tribe and has added them to the NHPA Consultation list. The Stockbridge-Munsee Community Band of Mohican Indians have also agreed to be a Cooperating Tribal Government on the NY Bight PEIS.

On September 21, 2022, a virtual meeting was held with Delaware Tribe of Indians, Stockbridge-Munsee Community Band of Mohican Indians, and Shinnecock Indian Nation distinguishing the NY Bight, Empire Wind, and Atlantic Shores lease areas. During that meeting, they requested a geophysical map, location(s) of trenches for transmission lines, key observation points (KOPs), as well as information on radiant heat from cables, how turbines may affect surface ocean temperatures, and how build out may

[1] Executive Order 14096 further embeds "environmental justice agenda into the work of federal agencies to achieve real, measurable progress that communities can count on." This executive order and subsequent guidance has been incorporated into the Final PEIS.

affect migration patterns of keystone species, marine mammals, and ESA-listed species. A draft list of KOPs for the NY Bight lease areas was shared with all Section 106 consulting parties, which includes all invited Tribal Nations who did not decline the invitation to consult. Information regarding transmission lines for the NY Bight lease areas is currently unknown and will be shared at the project-specific stage.

Additionally, the following Tribes were invited to participate in quarterly Environmental Justice Forums, beginning in October 2022: the Mashpee Wampanoag, Aquinnah Wampanoag, Mohegan, Stockbridge-Munsee Community Band of Mohican Indians, Delaware Tribe of Indians, The Delaware Nation, The Narragansett Indian Tribe, Shinnecock Indian Nation, Shawnee Nation, Eastern Shawnee Tribe of Oklahoma, and Absentee-Shawnee Tribe of Indians of Oklahoma. Impacts from noise on marine mammals was discussed during the Environmental Justice Forums, and supporting resources were also shared with participants. See Section 3.6.4.1.6, *Environmental Justice Engagement,* for more information on the Environmental Justice Forums.

On November 2, 2022, the NY Bight PEIS was discussed on the Atlantic Quarterly meeting tribal call with BOEM Director Amanda Lefton. On January 10, 2023, BOEM held a virtual meeting to share the location of the NY Bight lease areas including a map of the bathymetry, areas of cultural significance for consideration as KOPs, a field opportunity to Block Island, Native American history, and their connection to the shipwrecks. The following representatives attended: Carissa Speck, Delaware Nation Historic Preservation Director; Katelyn Lucas, Delaware Nation Historic Preservation Assistant; Jeff Bendremer, Registered Professional Archaeologist, Stockbridge-Munsee THPO; Susan Bachor, Delaware Tribe THPO and Archaeologist; Kevin Devine, Aquinnah Wampanoag Tribal Council; Jeremy Dennis, Shinnecock Indian Nation Assistant THPO; Kelly Dennis, Shinnecock Council of Trustees Secretary (and Secretary's Tribal Advisory Committee member); and Kelsey Leonard, Shinnecock Tribal Member (and Committee on Offshore Science and Assessment member). On April 27, 2023, Erin Paden, Shawnee Tribe THPO asked to be taken off all NY Bight related correspondence. Several Tribes requested staff level government-to-government meetings with BOEM to discuss the NY Bight PEIS. BOEM met with the Stockbridge-Munsee Community Band of Mohican Indians on January 29, 2024, The Delaware Nation on February 26, 2024, and the Mashantucket (Western) Pequot Tribal Nation on February 29, 2024. As of August 2024, no Tribes have requested formal government-to-government consultation on the NY Bight PEIS.

A.2.3 National Historic Preservation Act

Section 106 of the NHPA (54 U.S.C. 306108) and its implementing regulations (36 CFR part 800) require federal agencies to consider the effects of their undertakings on historic properties and afford the Advisory Council on Historic Preservation (ACHP) an opportunity to comment. In anticipation of the project-level review of Construction and Operations Plans (COPs) for each of the NY Bight lease areas, BOEM has identified an opportunity to engage the appropriate federally recognized Tribes, State Historic Preservation Offices (SHPO) and consulting parties to develop a Programmatic Agreement that outlines the project-level review process; identifies avoidance, minimization, mitigation, and monitoring (AMMM) measures; and provides templates for key documents that may be required in the course of project-level Section 106 consultation. Appendix I, *NHPA Section 106 Summary*, of the Final PEIS contains a summary of BOEM's Section 106 programmatic review, including a description and summary of BOEM's consultation so far.

On July 15, 2022, BOEM contacted representatives of other federal agencies, federally recognized Tribes, state and local governments, preservation organizations, lessees of the six NY Bight lease areas and other potentially interested parties to determine their interest in participating in the programmatic Section 106 review as consulting parties. Invitations were extended to additional organizations as they were identified. Those parties that have confirmed their desire to participate in the programmatic Section 106 review of the NY Bight as of May 27, 2024, are listed in Table A1.

BOEM conducted Section 106 early coordination meetings with ACHP on September 7, 2022, and with the New Jersey and New York SHPOs and ACHP on September 21, 2022, and January 10, 2023. BOEM conducted a Section 106 consultation meeting with consulting parties on March 13, 2023 to introduce the objectives for the NY Bight programmatic Section 106 review and solicit input on the development of the Programmatic Agreement. BOEM conducted a second Section 106 consultation meeting on August 3, 2023 to present an introduction to BOEM's analysis of impacts on scenic and visual resources including a preview of the development of photo simulations of development scenarios for the NY Bight lease areas and to provide an overview of BOEM's progress on the development of the Programmatic Agreement. BOEM conducted a third Section 106 consultation meeting on February 15, 2024, to present the responses to consulting party comments and the revised Programmatic Agreement. A fourth Section 106 consultation meeting was held on June 20, 2024, to present the third version of the Programmatic Agreement and discuss responses to consulting party comments.

In the course of consultation activities, BOEM has identified additional organizations or agencies that may have an interest in the effects of offshore wind development on cultural resources and has continued to invite such parties to participate in the programmatic Section 106 review. BOEM will continue consulting with federally recognized Tribes, New Jersey SHPO, New York SHPO, ACHP, and other consulting parties regarding the project-level review procedures and the development of programmatic AMMM measures that could be adopted at the COP stage to resolve adverse effects on historic properties.

Table A1. Participating consulting parties for the NY Bight Programmatic Agreement

Organization Type	Participating Consulting Parties
Federal Government	U.S. Advisory Council on Historic Preservation
Federal Government	U.S. Army Corps of Engineers
Federal Government	U.S. Bureau of Safety and Environmental Enforcement
Federal Government	U.S. Department of the Navy
Federal Government	U.S. Environmental Protection Agency
Federal Government	U.S. National Park Service
Federally Recognized Tribe	Absentee-Shawnee Tribe of Indians of Oklahoma
Federally Recognized Tribe	Delaware Tribe of Indians
Federally Recognized Tribe	Eastern Shawnee Tribe of Oklahoma
Federally Recognized Tribe	Mashantucket (Western) Pequot Tribal Nation
Federally Recognized Tribe	Mashpee Wampanoag Tribe

Organization Type	Participating Consulting Parties
Federally Recognized Tribe	Mohegan Tribe of Connecticut
Federally Recognized Tribe	Stockbridge-Munsee Community Band of Mohican Indians
Federally Recognized Tribe	The Delaware Nation
Federally Recognized Tribe	The Narragansett Indian Tribe
Federally Recognized Tribe	The Shinnecock Indian Nation
Federally Recognized Tribe	Tuscarora Nation
Federally Recognized Tribe	Wampanoag Tribe of Gay Head (Aquinnah)
Lessee	Atlantic Shores Offshore Wind Bight (OCS-A 0541)
Lessee	Attentive Energy (OCS-A 0538)
Lessee	Bluepoint Wind (OCS-A 0537)
Lessee	Community Offshore Wind (OCS-A 0539)
Lessee	Invenergy (OCS-A 0542)
Lessee	Vineyard Mid-Atlantic Offshore Wind (OCS-A 0544)
Local Government	Atlantic County
Local Government	Avon-by-the-Sea Borough
Local Government	Borough of Beach Haven
Local Government	Borough of Highlands
Local Government	Borough of Point Pleasant Beach
Local Government	Borough of Sea Bright
Local Government	Borough of Seaside Park
Local Government	Borough of Spring Lake
Local Government	Cape May County
Local Government	City of Absecon
Local Government	City of Asbury Park
Local Government	City of Hoboken
Local Government	City of North Wildwood
Local Government	Monmouth County
Local Government	Monmouth County Park System
Local Government	Nassau County
Local Government	Neptune City
Local Government	Suffolk County
Local Government	Town of Babylon
Local Government	Town of Islip
Local Government	Town of Oyster Bay
Local Government	Township of Brick
Local Government	Township of Hamilton
Local Government	Township of Middletown
Local Government	Township of Stafford
Local Government	Village of Bellport
Local Government	Village of Patchogue
Other Potentially Interested Parties	Green-Wood Cemetery
Other Potentially Interested Parties	Hempstead Harbor Protection Committee

Organization Type	Participating Consulting Parties
Other Potentially Interested Parties	Point O'Woods Association
Preservation Organization	Bay Shore Historical Society
Preservation Organization	Greater Cape May Historical Society
Preservation Organization	Historic Districts Council
Preservation Organization	Historical Society of Highlands
Preservation Organization	Ocean City Historical Museum
Preservation Organization	Preservation Alliance of Spring Lake
Preservation Organization	Romer Shoal Light
Preservation Organization	Save Long Island Beach Inc.
Preservation Organization	The Noyes Museum of Art
Preservation Organization	West Bank Lighthouse
State Government	New Jersey State Museum
State Government	New York State Parks, Recreation & Historic Preservation, Long Island State Parks Region 9
State Government	New York State Parks, Recreation and Historic Preservation
State Government (SHPO)	New Jersey Department of Environmental Protection, Historic Preservation Office
State Government (SHPO)	New York State Historic Preservation Office
State Recognized Tribe	Lenape Indian Tribe of Delaware

A.2.4 Magnuson-Stevens Fishery Conservation and Management Act

Pursuant to Section 305(b) of the Magnuson-Stevens Fishery Conservation and Management Act (MSA), federal agencies are required to consult with NMFS on any action that may result in adverse effects on Essential Fish Habitat (EFH). NMFS regulations implementing the EFH provisions of the MSA can be found at 50 CFR part 600. As provided for in 50 CFR 600.920(b), BOEM has accepted designation as the lead agency for the purposes of fulfilling EFH consultation obligations under Section 305(b) of the MSA. Certain Outer Continental Shelf (OCS) activities authorized by BOEM may result in adverse effects on EFH and, therefore, require consultation with NMFS. At this programmatic stage, an EFH Assessment and consultation are not being undertaken. Project-specific EFH Assessments will be prepared for each offshore wind project during the COP-specific NEPA process.

A.3 Development of Final Environmental Impact Statement

This section provides an overview of the development of the Final PEIS, including public scoping, cooperating agency involvement, and distribution of the Draft PEIS for public review and comment.

A.3.1 Scoping

On July 15, 2022, BOEM issued a NOI to prepare a PEIS consistent with National Environmental Policy Act (NEPA) regulations (42 U.S.C. 4321 et seq.) to assess the potential impacts of the Proposed Action and alternatives [87 *Federal Register* 42495]. The NOI commenced a public scoping process for identifying issues and potential alternatives for consideration in the PEIS. The formal scoping period was from July 15, 2022, through August 15, 2022, but was extended until August 30, 2022. BOEM held three virtual public scoping meetings on July 28, 2022, August 2, 2022, and August 4, 2022, to share information, solicit feedback, and to answer questions. Throughout the scoping period, federal agencies, Tribal Nations, and state and local governments, and the general public had the opportunity to help BOEM identify potentially significant resources and issues, impact-producing factors (IPFs), reasonable alternatives, and potential mitigation measures to analyze in the PEIS, as well as provide additional information. BOEM also used the NEPA scoping process to initiate the Section 106 consultation process under the NHPA (54 U.S.C. 300101 et seq.), as permitted by 36 CFR 800.2(d)(3), which requires federal agencies to assess the effects of projects on historic properties. The NOI requested comments from the public in written form, delivered by hand or by mail, or through the regulations.gov web portal.

BOEM received a total of 43 comments during the scoping period. BOEM reviewed and considered all scoping comments in the development of the Draft PEIS. A scoping summary report summarizing the submissions received and the methods for analyzing them is available in Appendix O, *Scoping Report*, of the PEIS. In addition, all public scoping comments received can be viewed online at http://www.regulations.gov by typing "BOEM-2022-0034" in the search field. As detailed in the scoping summary report, the resource areas or NEPA topics most referenced in the scoping comments were the Purpose and Need, the Proposed Action, Public Engagement, Commercial Fisheries and For-Hire Recreational Fishing, Marine Mammals, Navigation and Vessel Traffic, and Scenic and Visual Resources.

A.3.2 Cooperating and Participating Agencies and Cooperating Tribal Governments

BOEM invited other federal agencies, Tribal Nations, and state and local governments to consider becoming cooperating agencies in the preparation of the PEIS. According to Council of Environmental Quality (CEQ) guidelines, qualified agencies and governments are those with "jurisdiction by law or special expertise" (CEQ 1981). BOEM also invited agencies that do not have jurisdiction by law or special expertise but that have a vested interest in the PEIS to engage as participating agencies. Agreeing to engage as a cooperating or participating agency allowed agencies the opportunity to participate in discussions and contribute to the development of the PEIS.

BOEM held interagency meetings with cooperating and participating agencies on September 12, 2022, December 2, 2022, August 7, 2023, and June 27, 2024, to discuss the environmental review process, schedule, responsibilities, consultation, potential alternatives, and the changes from Draft to Final following the public comment period. BOEM also met individually and in small groups with cooperating and participating agencies who requested additional discussion on the PEIS at various times throughout development of the PEIS.

The following federal agencies, Tribal Nations, and state and local governments have supported preparation of the Draft PEIS as cooperating and participating agencies and Cooperating Tribal Governments:

Cooperating Agencies

- Bureau of Safety and Environmental Enforcement
- U.S. Coast Guard
- U.S. Environmental Protection Agency
- New Jersey Department of Environmental Protection
- National Park Service
- New Bedford Port Authority
- U.S. Fish and Wildlife Service
- National Marine Fisheries Service
- U.S. Army Corps of Engineers
- New York State Department of State
- Massachusetts Office of Coastal Zone Management
- New York State Department of Environmental Conservation
- New Jersey Board of Public Utilities

Cooperating Tribal Governments

- Mashantucket (Western) Pequot Tribal Nation
- Stockbridge-Munsee Community, Band of Mohican Indians

Participating Agencies

- New York City Mayor's Office of Environmental Coordination

A.3.3 Distribution of the Draft Programmatic Environmental Impact Statement for Review and Comment

On January 12, 2024, BOEM published a Notice of Availability (NOA) for the Draft PEIS. The Draft PEIS was made available in electronic format for public viewing at https://www.boem.gov/renewable-energy/state-activities/new-york-bight. Notification was provided as indicated in Appendix N, *Distribution List,* and hard copies of the Draft PEIS were delivered to entities as requested. Publication of the Draft PEIS initiated a 45-day comment period. On February 29, 2024, BOEM announced an extension to the comment period, which concluded on March 13, 2024. BOEM held five public meetings to solicit feedback and identify issues for consideration in preparing the Final PEIS. Three in-person meetings were held in North Dartmouth, Massachusetts; Stony Brook, New York; and Toms River, New Jersey on February 5, 7, and 8, 2024, respectively. Two virtual meetings were held on January 31 and February 13, 2024. Throughout the public review period, government agencies, members of the public, and interested stakeholders had the opportunity to provide comments on the Draft PEIS in any of the following ways:

- In hard copy form, delivered by mail, enclosed in an envelope labeled "NY BIGHT PEIS" and addressed to Chief, Division of Environmental Assessment, Office of Environmental Programs, Bureau of Ocean Energy Management, 45600 Woodland Road (VAM-OEP), Sterling, Virginia 20166.
- Through the regulations.gov web portal by navigating to https://www.regulations.gov/ and searching for docket number "BOEM-2024-0001."
- By attending one of the public meetings on the dates listed in the NOA and providing written or verbal comments.

BOEM reviewed and considered all 1,568 comments in the development of the Final PEIS. BOEM's evaluation of public submissions focused on those comments within the submissions that were identified as substantive. Final PEIS Appendix P, *Responses to Comments on the Draft Programmatic Environmental Impact Statement*, describes the public comment processing methodology and includes comment responses. All public comment submissions received on the Draft PEIS can be viewed online at https://www.regulations.gov/ by typing "BOEM-2024-0001" in the search field.

A.3.4 Distribution of the Final Environmental Impact Statement

The Final PEIS is available in electronic format for public viewing at https://www.boem.gov/renewable-energy/state-activities/new-york-bight. Hard copies and digital copies of the Final PEIS can be requested by contacting BOEM, Office of Environmental Programs in Sterling, Virginia, at (703) 787-1703. Publication of the Final PEIS initiates a minimum 30-day mandatory waiting period, during which BOEM is required to pause before issuing a Record of Decision (ROD). Notification will be provided as indicated in Appendix N, *Distribution List,* of the Final PEIS.

Appendix B: Supplemental Information and Additional Figures and Tables

B.1 Climate and Meteorology

Conditions that affect the weather and climate in an area include wind speed and direction, air temperature, and precipitation. Long-term averages of these conditions produce the regional climate. Extreme meteorological conditions are produced in the Mid-Atlantic region of the United States during tropical and extra-tropical storms. Over the open ocean, meteorological characteristics are fundamentally influenced by oceanographic conditions and are therefore sometimes jointly discussed as "metocean" conditions. In temperate regions such as the Mid-Atlantic, several metocean conditions are highly seasonal and driven by both atmospheric and oceanic circulation patterns. Daily variability in meteorological conditions will drive fluctuations in wind farm power production and associated stresses on the wind turbine generators (WTGs), while long-term performance may be estimated based on the climatic conditions.

B.1.1 Regional Climate Overview

The Atlantic seaboard is classified as a mid-latitude climate zone based on the Köppen Climate Classification System. This larger region, which encompasses the Mid-Atlantic region, is characterized by mostly moist subtropical conditions, generally warm and humid in the summer with relatively mild winters (BOEM 2021a). Prevailing winds at the middle latitudes over North America occur mostly west to east ("westerlies") and contribute to seasonal variability along the Atlantic seaboard (NJDEP 2010).

The New York Bight (NY Bight) region is an offshore area existing within the larger Mid-Atlantic region and extending generally northeast from Cape May in New Jersey to Montauk Point on the eastern tip of Long Island, New York (BOEM 2021b). However, the lease areas identified for the Programmatic Environmental Impact Statement (PEIS) extend generally northeast from Atlantic City, New Jersey, to the southern end of Long Island, New York (BOEM 2021b). Thus, the NY Bight lease areas span only part of the full NY Bight region and include areas offshore of the states of New Jersey and New York.

The six NY Bight lease areas identified in the PEIS, listed from north to south, include Lease Areas OCS-A-0544, -0537, -0538, -0539, -0541, and -0542. The northernmost NY Bight lease area, OCS-A-0544, is adjacent to the Empire Wind lease area, which is identified as OCS-A-0512. Similarly, the southernmost NY Bight Lease Areas OCS-A-0541 and OCS-A-0542 are approximately 30 miles northeast of the Ocean Wind 1 lease area, which is identified as OCS-A-0498. As such, climatic conditions reported for the Empire Wind lease area (OCS-A-0512) are representative of the northern portion of the six NY Bight lease areas, and climatic conditions reported for the Ocean Wind 1 lease area (OCS-A-0498) are representative of the southern portion of the six NY Bight lease areas. Together, the climatic conditions of the Empire Wind and Ocean Wind 1 lease areas are representative of the climatic conditions in the six NY Bight lease areas (referred to hereafter as NY Bight lease areas).

Consistent with the larger Mid-Atlantic region, the climate across New York State can be described as humid and continental (New York State Climate Action Council 2010). The climate across New Jersey State varies, with greater humidity near the coastal and southern part of the state than in the inland and northern regions (NJDEP 2010). The NY Bight region along the New York and New Jersey coasts experiences four distinct seasons with cold air temperatures during the winter months. Coastal areas along the NY Bight are especially prone to coastal storms and their associated effects, including heavy precipitation, high winds, and coastal flooding (New York State Climate Action Council 2010). Coastal storms are common in the vicinity of the NY Bight lease areas and include hurricanes and tropical storms during the warmer months (July to September), and northeasters or "nor'easters" (extratropical storms in which the winds in coastal areas blow from the northeast) during the cooler months (October to April). Extreme rainfall and flooding associated with storm events contribute to erosion of coastal wetland areas and inland areas adjacent to the shoreline (NJDEP 2010; New York State Climate Action Council 2010).

The North Atlantic Oscillation (NAO) also affects climate in the Northwest Atlantic on the scale of decades (NJDEP 2010; Townsend et al. 2004). The NAO is calculated as the wintertime pressure difference between the high-pressure system over the Azores Islands and the low-pressure system over Iceland (NJDEP 2010; Townsend et al. 2004). Shifts in the ratio of these pressures contribute to warmer or cooler average winters in the Northwest Atlantic, which through icing, fog, and other weather events can affect offshore construction and operational conditions for wind energy development. Since the late 1970s, warmer NAO conditions have persisted on average (NJDEP 2010; Townsend et al. 2004). The NAO may be influenced by the El Niño-Southern Oscillation, which is a large-scale, multi-year fluctuation in sea surface temperatures, referred to as sea surface temperature anomalies, in the Pacific Ocean (NJDEP 2010). The NAO may also be correlated with an 11-year solar cycle (IPCC 2021).[1]

The United States Northeast region is currently subject to climate changes associated with global warming that are primarily attributed to human activities, especially the production of heat-trapping gases (i.e., greenhouse gases [GHG]) (Dupigny-Giroux et al. 2018; Hayhoe et al. 2018; IPCC 2021). These regional changes include an average winter-spring increase in air temperature of 1.67 degrees Fahrenheit (°F) (increase of 0.93 degrees Celsius [°C]) between 1940 and 2014. By 2035, the Northeast region is expected to be 3.6°F (2°C) warmer on average than during the pre-industrial era (Dupigny-Giroux et al. 2018). The Northeast region has also seen a 55 percent increase in the number of heaviest 1-percent precipitation events between 1958 and 2016 (Dupigny-Giroux et al. 2018). Severe storms have become more frequent and more intense. Storm flood heights driven by hurricanes in New York City have increased by more than 3.9 feet (1.2 meters) over the last thousand years (Dupigny-Giroux et al. 2018). Due to predicted increases in average global temperatures, the frequency and intensity of extreme regional weather events such as heat waves, strong winds, and heavy precipitation are

[1] Some modeling studies suggest that changes in the level of ultraviolet radiation from the sun affect the temperatures in the stratosphere. These changes are hypothesized to affect large-scale wind patterns that in turn affect the difference of atmospheric pressure at sea level between the Icelandic Low and the Azores High (Kuroda et al. 2022). This pressure difference constitutes the NAO, which has a major effect on climate patterns on both sides of the North Atlantic.

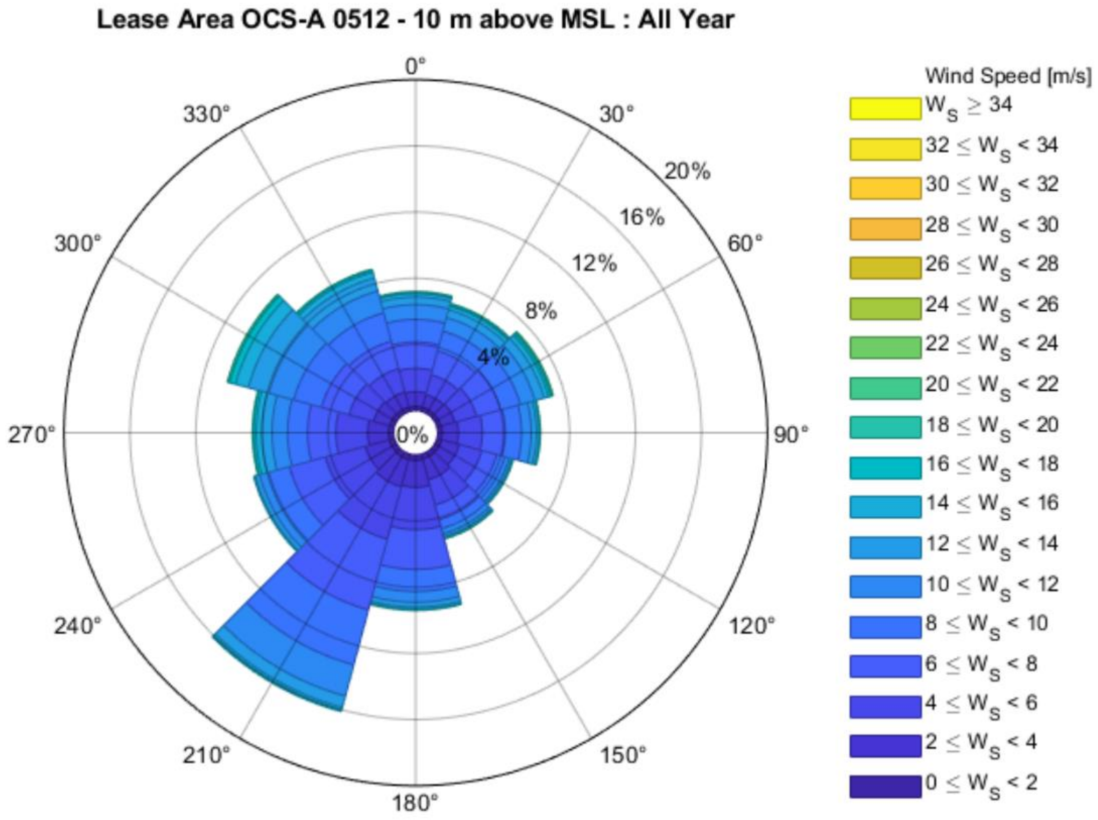
expected to increase in the coming decades (New York State Climate Action Council 2010; Dupigny-Giroux et al. 2018). In addition, the Northeast region has experienced some of the highest rates of sea level rise and ocean warming in the United States, and these exceptional increases relative to other regions are projected to continue through the end of the century (Dupigny-Giroux et al. 2018). Of note, since the retreat of the late Pleistocene glaciers after approximately 20,000 years before present, the New York and New Jersey coastline has been progressively inundated (BOEM 2012). At 21,000 years before present, sea level in the NY Bight area was approximately 394 feet (120 meters) below present levels, and at 14,400 years before present, the sea level was 256 feet (78 meters) lower (BOEM 2012; Wright et al. 2009). Studies have estimated that sea levels in the region were 43 feet (13 meters) lower than today at 6,000 years before present and 33 feet (10 meters) lower at 4,000 years before present (BOEM 2012; Miller et al. 2009). Refer to Section B.1.3 for additional information regarding projected future climate changes in the NY Bight area.

B.1.2 Current Meteorology and Climate Trends

B.1.2.1 Winds

Winds during the summer are typically from the southwest and flow parallel to the shore, while winds in the winter are typically from the northwest and flow perpendicular to the shore. Spring and fall are more variable, with wind currents from either the southwest or northeast (Schofield et al. 2008). Due to the large geographic region of the NY Bight, wind conditions are expected to vary throughout the region. As such, wind conditions of the northern and southern portions of the NY Bight are provided herein as representative wind conditions of the region encompassed by the NY Bight lease areas.

In the northern portion of the NY Bight, Empire Offshore Wind, LLC (Empire) has been collecting wind data, along with other directional wave and meteorological condition information, from a floating metocean buoy for 2 years. This metocean data will be used to inform final siting and design of the Empire Wind projects (OCS-A 0512) (Empire 2022a). Empire has also performed a preliminary metocean analysis using data from 2000 through 2020, which provides representative wind data for the northern portion of the NY Bight area. Winds measured in the northern portion of the NY Bight area are predominantly from the south to southwest and the northwest (Empire 2022a) as depicted on Figure B.1-1.



Source: Empire 2022a

Figure B.1-1. All-year wind rose at 33 feet (10 meters) AMSL for the Empire Wind lease area for 2002–2020

In addition to the wind data presented above, representative data for wind speed and wind direction are publicly available from NOAA's National Data Buoy Center for the Long Island buoy (Buoy No. 44025) (NOAA 2021a) and the New York Harbor Entrance buoy (Buoy No. 44065) (NOAA 2021b). The Long Island buoy is within the Empire Wind lease area at latitude 40.251, longitude -73.164 and is 30 nautical miles south of Islip, New York. The New York Harbor Entrance buoy is approximately 8 miles west of the Empire Wind lease area at latitude 40.369, longitude -73.703.

The most recent data available from the New York Harbor Entrance buoy are for January 2015 through December 2020. The maximum wind speed[2] recorded during this period was 47.4 miles per hour (mph) (21.2 meters per second [m/s]) in 2018, with average wind speeds from 11.2 to 15.7 mph (5 to 7 m/s) across these 6 years (Table B.1-1). Using 2017 as an example year to consider seasonal averages, the maximum wind speed was recorded in the spring of 2017 at 47.0 mph (21 m/s), although the highest average seasonal wind speed of 16.8 mph (7.5 m/s) occurred in the winter of 2017 (Table B.1-2). The average wind direction for all seasons between 2015 and 2020 was from the southwest. In other years, higher maximum wind speeds have occurred in summer and fall months due to tropical cyclones. For

[2] NOAA buoy measurements for wind speed are averaged over an 8-minute period. Higher speeds are recorded for 5- to 8-second gusts.

example, a maximum sustained wind speed of 51.4 mph (23.0 m/s) and gusts up to 70.5 mph (31.5 m/s) were recorded at the New York Harbor Entrance buoy on August 4, 2020, in association with Hurricane Isaias (NOAA 2021b).

Table B.1-1. Annual average and maximum wind speed and direction at New York Harbor Entrance buoy (Buoy No. 44065) from January 2015 to December 2020

Year	Average Wind Speed mph	Average Wind Speed m/s	Maximum Wind Speed mph	Maximum Wind Speed m/s	Average Wind Direction Degrees from True North
2015	14.1	6.3	41.6	18.6	202 (Southwest)
2016	14.5	6.5	45.0	20.1	200 (Southwest)
2017	14.3	6.4	47.0	21.0	198 (Southwest)
2018	14.1	6.3	47.4	21.2	191 (Southwest)
2019	14.1	6.3	42.9	19.2	192 (Southwest)
2020	13.9	6.2	51.4	23.0	196 (Southwest)

Source: NOAA 2021b.
Note: NOAA buoy measurements for wind speed are averaged over an 8-minute period.

Table B.1-2. Seasonal average and maximum wind speed and direction at New York Harbor Entrance buoy (Buoy No. 44065) in 2017

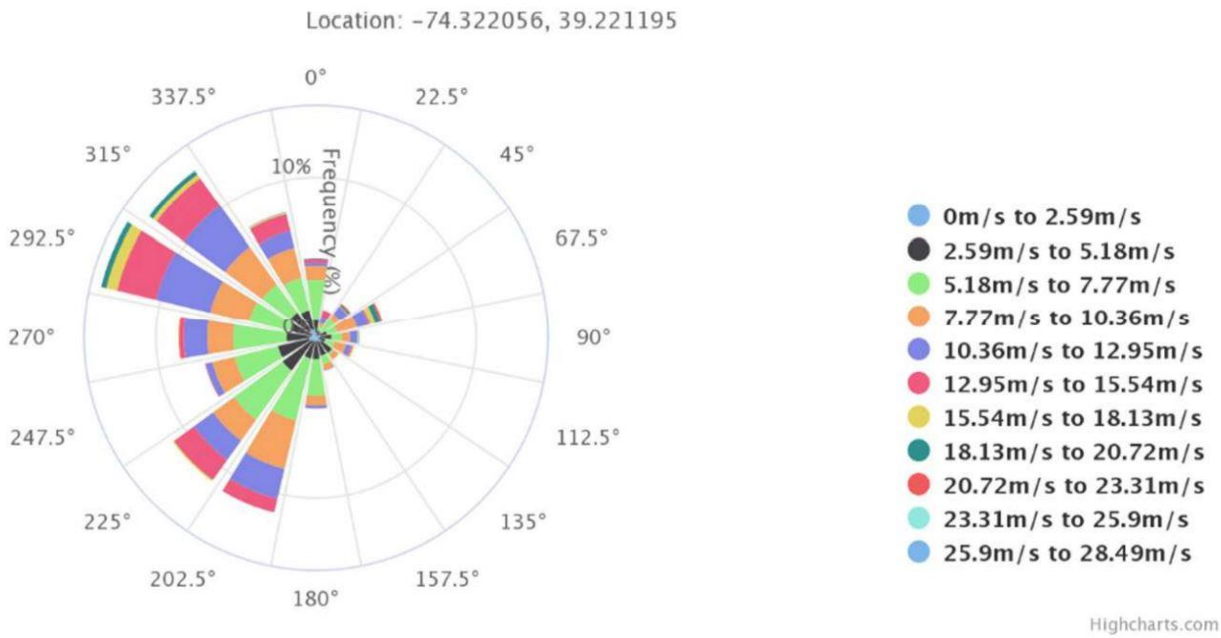
Season	Average Wind Speed mph	Average Wind Speed m/s	Maximum Wind Speed mph	Maximum Wind Speed m/s	Average Wind Direction Degrees from True North
Winter	16.8	7.5	44.3	19.8	223.9 (Southwest)
Spring	14.5	6.5	47.0	21.0	187.0 (South)
Summer	11.4	5.1	30.4	13.6	183.5 (South)
Fall	15.2	6.8	39.1	17.5	197.8 (Southwest)

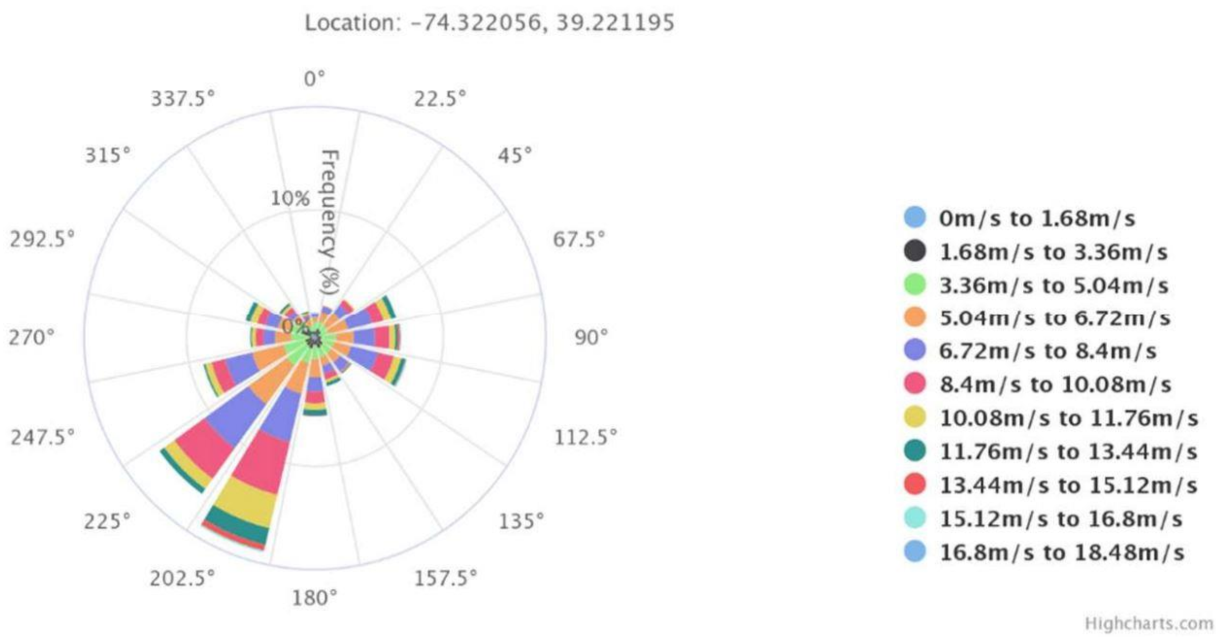
Source: NOAA 2021b.
Note: NOAA buoy measurements for wind speed are averaged over an 8-minute period.

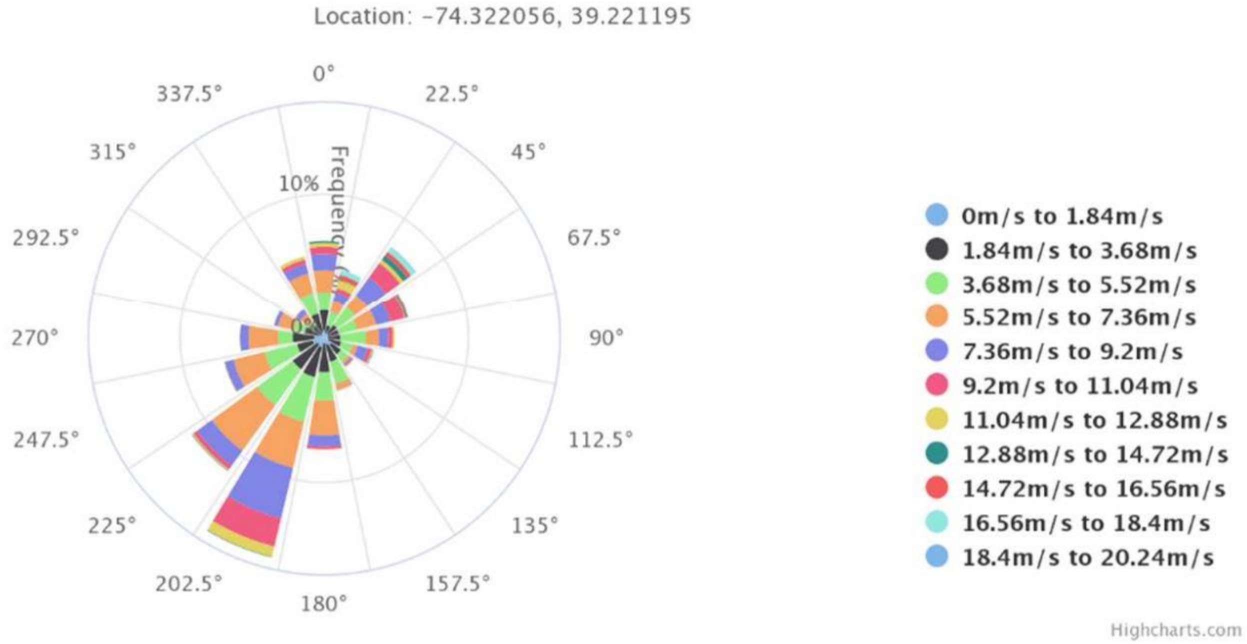
Data from the Long Island buoy (Buoy No. 44025) are available for October 1975 through December 2008. The Long Island buoy measured similar conditions as the New York Harbor Entrance buoy with a maximum wind speed of 51.0 mph (22.8 m/s) in 1991 and average wind speeds from 11.2 to 18.9 mph (5.0 to 8.4 m/s) across the 34 years recorded (NOAA 2021a).

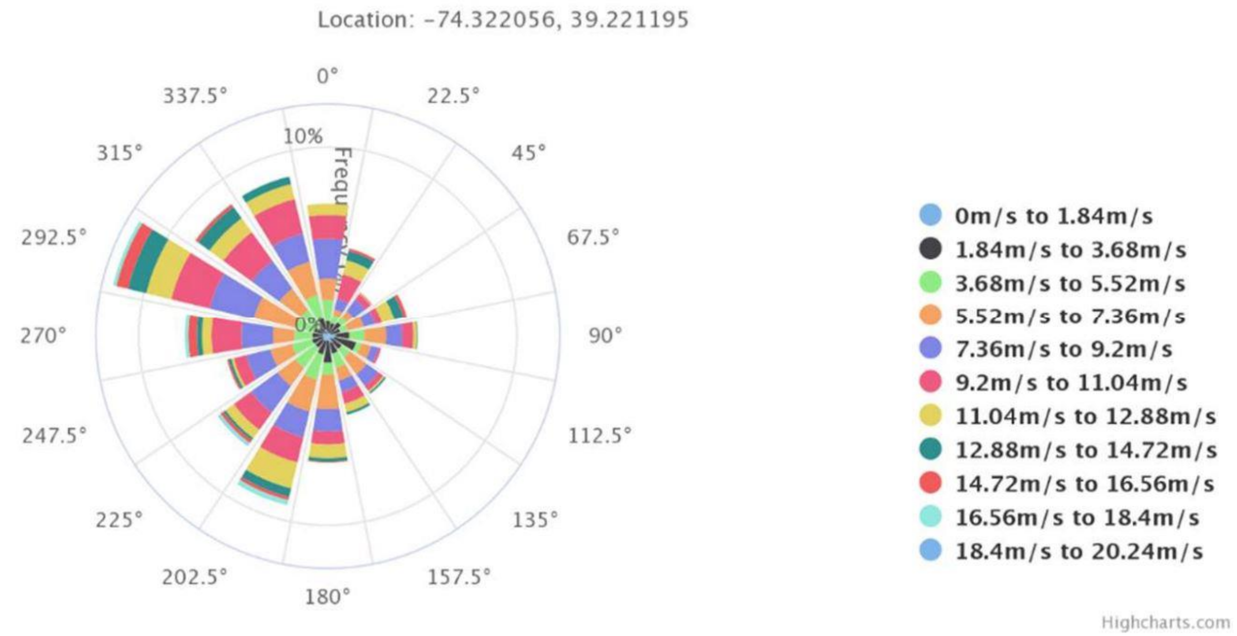
At the southern end of the NY Bight, Ocean Wind has been collecting wind and wave data from two stations in the Ocean Wind 1 lease area (OCS-A 0498): stations F220 and F230. In addition, the Metocean Data Portal, maintained by the Danish Hydrological Institute, provides wind data for the entire United States East Coast that has been generated through numerical models (Danish Hydrological Institute 2018). Data for the Ocean Wind 1 lease area were generated using a location within the Ocean Wind 1 lease area. Data from 2017 indicate wind speeds reached 63.8 mph (28.5 m/s). The highest-frequency wind directions generally were from south-southwest to northwest. Throughout the year, wind direction is variable. However, seasonal wind directions are primarily from the west/northwest during the winter months (December through February) and from the south/southwest during the summer months (June through August). Figure B.1-2 shows 3-month wind roses for January through June 2017 and July through December 2017, respectively, for a location within the Ocean Wind 1 lease area (-74.322056, 39.221195). Top wind speeds within the Ocean Wind 1 lease area peaked between January and March at 40.6 to 46.3 mph (18.1 to 20.7 m/s) from the northwest.

Extreme wind conditions on the United States East Coast are influenced by both winter storms and tropical systems. Several nor'easters occur each winter season, while hurricanes are rarer but potentially more extreme. The tropical systems therefore define the wind farm design, based on extreme wind speeds (those with recurrence periods of 50 years and beyond). Wind roses developed from the Metocean Data Portal are provided below in Figure B.1-2 (Danish Hydrological Institute 2018).









Source: Danish Hydrological Institute 2018.
Note: Wind roses identified from top to bottom: January through March 2017 (first row); April through June 2017 (second row); July through September 2017 (third row); October through December 2017 (fourth row).

Figure B.1-2. Wind rose graphs for the Ocean Wind 1 lease area

Table B.1-3 summarizes wind conditions in the region. This table shows the monthly average wind speeds, monthly average peak wind gusts, and hourly peak wind gusts for each individual month. Data from 1984 through 2008 show that monthly mean wind speeds range from a low of 10.9 mph (17.6 kilometers per hour [kph]) in July to a high of 17.4 mph (28.0 kph) in January. The monthly wind mean peak gusts reach a maximum during January at 24.1 mph (38.7 kph). The 1-hour average wind gusts reach a maximum during September at 63.3 mph (101.9 kph) (NOAA 2018). The data provided in Table B.1-3 represent wind speed data at the National Data Buoy Center buoy station No. 44009, located southeast of Cape May, New Jersey, the southern end of the NY Bight region.

Table B.1-3. Wind speed data for southeast of Cape May, New Jersey (buoy No. 44009)

Month	Monthly Average Wind Speed		Monthly Average of Hourly Peak Gust		Monthly Maximum Hourly Peak Gust	
	mph	kph	mph	kph	mph	kph
January	17.4	28.0	24.1	38.7	61.6	99.1
February	16.2	26.1	21.9	35.2	56.8	91.5
March	15.5	25.0	20.5	33.0	57.5	92.6
April	14.0	22.6	19.0	30.6	56.8	91.5
May	12.7	20.4	16.2	26.1	60.2	96.9

B.1.2.2 Air Temperature

NOAA's National Centers for Environmental Information, formerly the National Climatic Data Center, defines distinct climatological divisions to represent areas that are nearly climatically homogeneous. Locations within the same climatic division are considered to share the same overall climatic features and influences. The NY Bight region spans the New York coastal division or New York Climate Division 4, and the New Jersey coastal division or New Jersey Climate Division 3 (NOAA National Centers for Environmental Information 2021a).

The mean average annual air temperature in the coastal division of New York was 51.4°F (10.8°C) between 1895 and 2021 (NOAA National Centers for Environmental Information 2021b). The seasonal mean ranged from 31.9°F (-0.1°C) in winter (December through February) to 70.8°F (21.6°C) in summer (June through August) (NOAA National Centers for Environmental Information 2021b).

A summary of monthly and annual mean temperature data collected for the New York coastal division between 1895 and 2021 is presented in Table B.1-4. This data is representative of the ambient air temperatures in the northern portion of the NY Bight lease areas.

Table B.1-4. Mean temperatures for New York coastal division, 1895 to 2021

Month	Average Mean Temperature		Maximum Mean Temperature		Minimum Mean Temperature	
	°F	°C	°F	°C	°F	°C
January	30.3	-0.9	38.0	3.3	22.6	-5.2
February	30.8	-0.7	38.7	3.7	22.8	-5.1
March	38.4	3.6	46.6	8.1	30.1	-1.1
April	47.9	8.8	57.0	13.9	38.8	3.8
May	58.1	14.5	67.6	19.8	48.7	9.3
June	67.4	19.7	76.6	24.8	58.2	14.6
July	73.1	22.8	81.9	27.7	64.3	17.9
August	71.8	22.1	80.3	26.8	63.2	17.3
September	65.3	18.5	74.2	23.4	56.4	13.6
October	54.8	12.7	63.8	17.7	45.7	7.6
November	44.4	6.9	52.4	11.3	36.3	2.4
December	34.6	1.4	42.0	5.6	27.1	-2.7
Annual	**51.4**	**10.8**	**59.9**	**15.5**	**42.9**	**6.0**

Source: NOAA National Centers for Environmental Information 2021b.

Representative air temperature information for the northern portion of the NY Bight lease areas is also available from NOAA's National Data Buoy Center Long Island buoy (Buoy No. 44025) and New York Harbor Entrance buoy (Buoy No. 44065). This information is presented in Table B.1-5 and shows air temperatures ranging from 35°F to 75°F (1.67°C to 23.90°C), with the higher temperatures during the summer months (Empire 2022b, 2022c). Minimum, mean, and maximum air temperatures occurring over the region at 6.6 feet (2 meters) AMSL from the period between 2002 and 2019 are shown graphically on Figure B.1-3.

Table B.1-5. Average air temperature at NOAA buoys in the Empire Wind study area

Month	Average Air Temperature in °F (°C)	
	Buoy No. 44065 (2008–2018)	Buoy No. 44025 (2007–2018)
January	35.01 (1.67)	37.98 (3.32)
February	36.66 (2.59)	38.70 (3.72)
March	39.58 (4.21)	41.49 (5.27)
April	46.65 (8.14)	47.03 (8.35)
May	56.71 (13.73)	55.33 (12.96)
June	66.04 (18.91)	65.46 (18.59)
July	73.92 (23.29)	73.29 (22.94)
August	75.02 (23.90)	73.98 (23.32)
September	69.69 (20.94)	68.61 (20.34)
October	59.94 (15.52)	60.53 (15.85)
November	49.10 (9.50)	51.06 (10.59)
December	42.13 (5.63)	43.77 (6.54)

Figure B.1-3. Minimum, mean, and maximum air temperature at 6.6 feet (2 meters) AMSL at Lease Area OCS-A 0512

Ambient air temperature data at locations representative of the southern portion of the NY Bight lease areas are generally moderate and similar to those collected at the northern portion of the NY Bight lease areas. The mean average annual air temperature in the coastal division of New Jersey was 53.1°F (11.8°C) between 1895 and 2021 (NOAA National Centers for Environmental Information 2021b). Air temperature data collected from the Office of the New Jersey State Climatologist, Rutgers University, which averaged the annual, seasonal, and monthly means in southern and coastal areas of New Jersey for 1985–2009, similarly indicate that the annual mean air temperature was 53.2°F (11.8°C) (NJDEP 2010). The mean seasonal air temperature between 1985 and 2010 during the winter ranged from approximately 32–43°F (0–6°C) and in the spring from 54–64°F (12–18°C). The mean seasonal air temperature during the summer ranged from approximately 68–75°F (20–24°C) and during the fall from 53–65°F (12–18°C). The lowest average air temperatures occur in January and the highest in July (NJDEP 2010; NCDC 2021a). Recent offshore air temperature data were downloaded from NOAA buoys near the NY Bight lease areas. Data between 2014 and 2018 were downloaded from Atlantic City, New Jersey (Buoy No. ACYN4), which is located near the southern portion of the NY Bight lease areas. Table B.1-6 summarizes average temperatures at the Atlantic City buoy.

Table B.1-6. Representative temperature data for the Ocean Wind 1 project area

NOAA Station	Year	Annual Average °F/°C	No. of Observations
Atlantic City Buoy (No. ACYN4)	2014	53.8/12.1	86,432
	2015	55.4/13.0	86,357
	2016	55.6/13.1	81,252
	2017	55.9/13.3	85,557
	2018	52.9/11.6	63,856

Source: Ocean Wind 2022.

Given the cold air temperatures experienced during many Mid-Atlantic winters, there is potential for icing of equipment and vessels above the water line in the NY Bight area. Cook and Chatterton (2008) analyzed icing events in Delaware Bay for winters from 1997 to 2007 and found that icing events are a common occurrence during January, February, and March. The worst winter, as far as icing is concerned, experienced by the Delaware Bay region from 1997 through 2007, was in 2002/2003, during which 21 icing events occurred. Delaware Bay experiences approximately eight events annually where the variables favoring icing are consistent for 3 or more hours.

In addition, the occurrence of fog in the Mid-Atlantic states is driven by regional-scale weather patterns and local topographic and surface conditions. The interaction between various weather systems and the physical state of the local conditions is complex. Ward and Croft (2008) found that high-pressure systems result in heavy fog over the Delaware Bay and nearby Atlantic coastal areas. During the 2006/2007 winter season (December–February), Delaware Coastal Airport (Georgetown, Delaware) reported 45 fog events, 4 of which were described as dense fog (Ward and Croft 2008).

B.1.2.3 Precipitation

In the northern portion of the NY Bight lease areas, precipitation in the New York coastal region primarily takes the form of rain and snow. The mean annual precipitation for the coastal region of New York between 1895 and 2021 was 44.89 inches (114.0 centimeters) (NOAA National Centers for Environmental Information 2021c). During the same period, the mean monthly precipitation ranged from 3.40 inches (8.6 centimeters) in February to 4.19 inches (10.6 centimeters) in March (NOAA National Centers for Environmental Information 2021c). A summary of monthly and annual mean precipitation data collected for the New York coastal division between 1895 and 2021 is presented in Table B.1-7.

Table B.1-7. Mean precipitation for New York coastal division, 1895 to 2021

	Total Mean Precipitation	
Month	Inches	Centimeters
January	3.6	9.1
February	3.4	8.6
March	4.2	10.7
April	3.9	9.9
May	3.8	9.7
June	3.5	8.9
July	3.7	9.4

Month	Total Mean Precipitation	
	Inches	Centimeters
August	4.1	10.4
September	3.6	9.1
October	3.6	9.1
November	3.8	9.7
December	4.0	10.2
Annual	**44.9**	**114.0**

Source: NOAA National Centers for Environmental Information 2021c.

Similarly, in the southern portion of the NY Bight lease areas, precipitation in the New Jersey coastal region primarily takes the form of rain and snow (NJDEP 2010). Average monthly precipitation data from the National Climatic Data Center are presented in Table B.1-8.

Table B.1-8. Mean precipitation in the New Jersey coastal division[1]

Month	Precipitation (inches/centimeters)	
	Atlantic City Marina, New Jersey	Brant Beach, Beach Haven, New Jersey
January	3.08/7.82	3.25/8.26
February	2.87/7.29	2.86/7.26
March	4.02/10.21	3.97/10.08
April	3.39/8.61	3.26/8.28
May	3.22/8.18	2.78/7.06
June	2.68/6.81	3.05/7.75
July	3.31/8.41	3.92/9.96
August	3.92/9.96	3.71/9.42
September	3.08/7.82	2.78/7.06
October	3.47/8.81	3.65/9.27
November	3.35/8.51	2.91/7.39
December	3.62/9.19	3.36/8.53
Annual Average	**3.33/8.47**	**3.29/8.36**

Sources: NCDC 2021a, 2021b.
[1] Precipitation is recorded in melted inches (snow and ice are melted to determine monthly equivalent).

Snowfall amounts can vary quite drastically within small distances. Data from Lewes, Delaware, approximately 60 miles southwest of Atlantic City, New Jersey, show that the annual snowfall average is approximately 12 inches (30.5 centimeters), and the month with the highest snowfall is January, averaging around 4 inches (10.2 centimeters) (WRCC 2022).

B.1.2.4 Extreme Storm Events

Strong weather events in the NY Bight area include, but are not limited to, hurricanes and tropical storms in the warmer months and nor'easters during the winter months. The number of tropical storms, including hurricanes, generally reaches a peak during the period from August to early October at the northern end of the NY Bight area (Empire 2022a). This is consistent with the peak period for tropical cyclones throughout the North Atlantic basin (Figure B.1-4) (McAdie et al. 2009). Most hurricane events within the Atlantic generally occur from mid-August to late October, with the majority of all events occurring in September (Donnelly et al. 2004). At the southern end of the NY Bight area along the New Jersey coast, hurricanes occur every 3 to 4 years within 90 to 170 miles of the coast, on average (NJDEP 2010). Such storms that travel along the coastline of the eastern United States have the potential to affect the NY Bight lease areas and adjacent coastal communities with high winds and severe flooding.

Figure B.1-5 identifies the hurricane tracks surrounding the NY Bight area between 1950 and 2019 (NOAA 2021c). The category for each storm is designated by a color for each segment of its track on Figure B.1-5. Table B.1-9 lists each of the hurricanes affecting the NY Bight area and the corresponding maximum storm categories while the hurricane was within approximately 200 nautical miles (370 kilometers) of the NY Bight lease areas for the corresponding period (NOAA 2021c). The 200-nautical mile (370-kilometer) radius circle was centered upon the approximate center point of the NY Bight lease areas within Lease Area OCS-A-0538, located at latitude 39.68, longitude -73.12. Most historical hurricanes affecting the NY Bight area are Category 1, but storms as powerful as Category 5 hurricanes have passed nearby the NY Bight lease areas. The New York State ClimAID assessment determined that intense hurricanes are likely to increase in frequency over the 21st century for New York City and Long Island (New York State Climate Action Council 2010).

Source: NOAA 2021c.
Notes: The NY Bight lease areas were represented by a point with the following coordinates: latitude 39.68, longitude -73.12. Hurricane categories are identified as 1 through 5 based on the Saffir-Simpson scale.

Hurricane Sandy, which occurred in 2012, provides an example of extreme storm conditions that have occurred in the region. In coastal New Jersey, Hurricane Sandy caused the highest storm surges and greatest inundation on land. The storm surge and large waves from the Atlantic Ocean meeting up with rising waters from back bays such as Barnegat Bay and Little Egg Harbor caused barrier islands to be completely inundated (Blake et al. 2013). In Atlantic City and Cape May, tide gauges measured storm surges of 5.8 and 5.2 feet (1.8 and 1.6 meters), respectively (Blake et al. 2013). Marine observations at the Cape May National Ocean Service (CMAN4) recorded sustained wind speeds at 52 knots (60 mph; 27 m/s) and an estimated inundation of 3.5 feet (1.1 meters) (Blake et al. 2013).

In coastal New York, the storm surge created by Hurricane Sandy was more severe than a 100-year extreme event (Empire 2022). In Bergen Point West Reach on the northern side of Staten Island, tide gauges measured a storm surge of 9.56 feet (2.91 meters) and estimated inundation of 9.53 feet (2.9 meters). At the Battery on the southern tip of Manhattan, tide gauges measured storm surges of 9.40 feet (2.87 meters) and estimated inundation of 9.00 feet (2.7 meters) (Blake et al. 2013). Marine observations at NOAA Buoy No. 44025 and NOAA Buoy No. 44065 recorded maximum sustained wind speeds of 49 knots (56.4 mph; 25.2 m/s) and 48 knots (55.2 mph; 24.7 m/s), respectively (Blake et al. 2013).

B.1.3 Projected Future Climate

Projected future climate conditions include changes to the above metocean characteristics as well as other climate characteristics, including ocean warming, ocean acidification, and sea level rise. Uncertainty in the magnitude of such climate changes exists due to the uncertainty of future GHG emissions rates—which are directly related to the rate of climate change—and the inherent uncertainty of climate modeling methods. Future climate change projections are categorized by GHG emissions scenarios ranging from low global GHG emissions scenarios to high global GHG emissions scenarios. Low global GHG emissions scenarios imply less change to climate conditions, while high global GHG scenarios imply greater change to climate conditions. The subsections below describe the expected changes to climate conditions in the NY Bight area under the U.S. Environmental Protection Agency (USEPA) (2017) lower (Representation Concentration Pathways [RCP] 4.5) and higher (RCP 8.5) GHG emissions scenarios, unless noted otherwise.[3] Future projected changes to wind conditions in the NY Bight area are not included, as such changes are not explicitly characterized by available studies.

B.1.3.1 Air Temperature

In the Northeast United States between 1940 and 2014, the average winter-spring air temperature has risen 1.67°F (increase of 0.93°C) (Dupigny-Giroux et al. 2018). By 2035, under both lower and higher GHG emissions scenarios, the Northeast region is expected to be 3.6°F (2°C) warmer on average than during the pre-industrial era (Dupigny-Giroux et al. 2018). This would be the largest increase in the contiguous United States and would occur as much as two decades before global average temperatures reach a similar milestone (Dupigny-Giroux et al. 2018). By 2050, in New Jersey, temperatures are expected to increase by 4.1 to 5.7°F (2.3 to 3.2°C) based on the lower and higher GHG emissions scenarios, respectively (NJDEP 2020; Horton et al. 2015). Similarly, in New York State, under the lower and higher GHG emissions scenarios, average annual temperatures are projected to increase by 2.0 to 3.4°F by the 2020s, 4.1 to 6.8°F by the 2050s, and 5.3 to 10.1°F by the 2080s (Horton et al. 2014). According to the New York State Department of Conservation, the annual statewide average temperature in New York has warmed 3°F (1.7°C) since 1970 (NYSDEC 2023).

B.1.3.2 Precipitation

The recent dominant trend in precipitation throughout the Northeast United States has been toward increases in rainfall intensity, with recent increases in intensity exceeding those in other regions in the contiguous United States (Dupigny-Giroux et al. 2018). The Northeast region has seen a 55 percent increase in the number of heaviest 1 percent precipitation events between 1958 and 2016 (Dupigny-Giroux et al. 2018). Severe storms have become more frequent and more intense. Further increases in rainfall intensity are expected, with increases in precipitation expected during the winter and spring with little change in the summer (Dupigny-Giroux et al. 2018). The proportion of winter precipitation falling as rain has already increased and will likely continue to do so in response to a northward shift in

---

[3] The RCPs are identified by their approximate total radiative forcing (not emissions) in the year 2100, relative to 1750: 2.6 watts per meter squared (RCP 2.6), 4.5 watts per meter squared (RCP 4.5), and 8.5 watts per meter squared (RCP 8.5) (USEPA 2017).

the snow-rain transition zone projected under both lower and higher climate change scenarios (Dupigny-Giroux et al. 2018). The northward shifts are about 2° latitude under the lower emissions scenario and 4° latitude under the higher emissions scenario (Ning and Bradley 2015). By 2100, in New Jersey, heavy precipitation events are projected to occur two to five times more often and with more intensity than the 20th century under a low emissions scenario (RCP 2.6) versus the higher emissions scenario (RCP 8.5) (Walsh et al. 2014; NJDEP 2020). Small decreases in the amount of precipitation may occur in New Jersey in the summer months, resulting in greater potential for more frequent and prolonged droughts (NJDEP 2020). Regional precipitation across New York State is projected to increase by approximately 1 to 8 percent by the 2020s, 3 to 12 percent by the 2050s, and 4 to 15 percent by the 2080s under the lower and higher emissions scenarios (Horton et al. 2014).

B.1.3.3 Extreme Storm Events

Storm flood heights driven by hurricanes in New York City have increased by more than 3.9 feet (1.2 meters) over the last thousand years (Dupigny-Giroux et al. 2018). Due to predicted increases in average global temperatures, the frequency and intensity of extreme regional weather events such as heat waves, strong winds, and heavy precipitation are expected to increase in the coming decades (New York State Climate Action Council 2010; Dupigny-Giroux et al. 2018). The strongest hurricanes are anticipated to become both more frequent and more intense in the future, with greater amounts of precipitation (Dupigny-Giroux et al. 2018). More than 80 percent of open-coast north and Mid-Atlantic beaches are predicted to overwash during a Category 4 hurricane (Dupigny-Giroux et al. 2018). Additionally, 32 percent of open-coast north and Mid-Atlantic beaches are predicted to overwash during an intense future nor'easter type storm (Dupigny-Giroux et al. 2018).

B.1.3.4 Ocean Warming

Ocean and coastal temperatures along the Northeast United States Continental Shelf have increased by 0.06°F (0.033°C) per year from 1982 to 2016, which is three times faster than the global average rate of 0.018°F (0.01°C) per year (Dupigny-Giroux et al. 2018). From 2007 to 2016, the regional warming rate was four times faster than the trend from 1982 to 2016 at a warming rate of 0.25°F (0.14°C) per year (Dupigny-Giroux et al. 2018). Climate projections indicate that in the future the ocean over the Northeast United States Continental Shelf will experience more warming than most other ocean regions around the world (Dupigny-Giroux et al. 2018).

B.1.3.5 Ocean Acidification

Coastal waters in the Northeast United States region are sensitive to the effects of ocean acidification because they have low capacity for maintaining stable pH levels (Dupigny-Giroux et al. 2018). These waters are particularly vulnerable to acidification due to hypoxia (low-oxygen conditions) induced by eutrophication, and freshwater inputs, which are expected to increase as climate change progresses (Dupigny-Giroux et al. 2018). Since the industrial age, pH levels have declined by 0.1 pH units, from a global average of 8.2 to 8.1, which represents a 30 percent increase in acidity due to the logarithmic scale in which pH is measured (NJDEP 2020). If GHG emissions continue at current rates, ocean pH levels are expected to fall another 0.3 to 0.4 pH units by the end of the century, representing another 120 percent increase in acidity and creating an ocean that is more acidic than has been seen for the past 20 million years (NJDEP 2020).

Fisheries and aquaculture rely on shell-forming organisms that can suffer in more acidic conditions (Dupigny-Giroux et al. 2018). Many coastal communities in the Northeast United States region also have strong social and cultural ties to marine fisheries; in some communities, fisheries represent an important economic activity as well (Dupigny-Giroux et al. 2018). Future ocean warming and acidification, which are expected under all scenarios considered, would affect fish stocks and fishing opportunities available to coastal communities (Dupigny-Giroux et al. 2018).

B.1.3.6 Sea Level Rise

Along the Mid-Atlantic coast (from Cape Hatteras, North Carolina to Cape Cod, Massachusetts), several decades of tide gauge data through 2009 have shown that sea level rise rates were three to four times higher than the global average rate (Dupigny-Giroux et al. 2018). The region's sea level rise rates are increased by land subsidence, changes in the Gulf Stream, and geologic influences related to the loss of the North American ice sheet, all of which contribute to a higher sea level relative to land elevation (Dupigny-Giroux et al. 2018; NJDEP 2020). Projections for the Northeast United States region suggest that sea level rise will be greater than the global average of approximately 0.12 inches (3 millimeters) per year (Dupigny-Giroux et al. 2018). Two probable sea level rise scenarios project sea level rise of 2 and 4.5 feet (0.6 and 1.4 meters) on average in the region by 2100 (Dupigny-Giroux et al. 2018). By 2050, New Jersey will likely experience at least a 0.9- to 2.1-foot increase (above the levels in 2000), 1.4- to 3.1-foot increase by 2070, and potentially a 2.0- to 5.1-foot increase by 2100 (NJDEP 2020). Increases in sea level will exacerbate flooding in the coastal area caused by more intense rain events and storms (NJDEP 2020). In addition, low-lying coastal areas in New Jersey are already experiencing tidal flooding, even on sunny days in the absence of precipitation events (NJDEP 2020). Along the New York State coastline, sea level is projected to rise by 3 to 8 inches by the 2020s, 9 to 21 inches by the 2050s, and 14 to 39 inches by the 2080s (Horton et al. 2014). According to the New York State Department of Conservation, sea levels along New York's coast and in the Hudson River have already risen more than a foot since the year 1900 (about 1.2 inches per decade) (NYSDEC 2023).

B.1.4 Potential General Impacts of Offshore Wind Facilities on Meteorological Conditions

A known impact of offshore wind facilities on meteorological conditions is the "wake effect" (Christiansen and Hasager 2005). A WTG extracts energy from the free flow of wind, creating turbulence downstream of the WTG. The resulting wake effect is the aggregated influence of the WTGs for the entire wind farm on the available wind resource and the energy production potential of any facility downstream. Christiansen and Hasager (2005) observed offshore wake effects from existing facilities via satellite with synthetic aperture radar to last anywhere from 1.2 to 12.4 miles (2 to 20 kilometers) depending on ambient wind speed, direction, degree of atmospheric stability, and the number of turbines within a facility. During stable atmospheric conditions, these offshore wakes can be longer than 43.5 miles (70 kilometers).

Stoelinga et al. (2022) modeled the potential for a hypothetical large wind project to create wake impacts in the NY Bight lease areas. The modeling scenario used a set of meteorological conditions likely to result in the maximum wake impact on potential projects in the lease areas. The selected meteorology consisted of a sample of 16 days that had the greatest occurrence of southwest winds (from the 190°–240° sector) and speeds in the range of 13–25 mph (6–11 m/s). The modeling predicted a reduction in wind speed at hub height of 7 percent at up to 100 km away from the upwind project, with greater speed reductions at shorter distances. Annual average reductions in wind speed due to WTG wake would be less. The authors conclude that potential wake impacts of WTGs should be accounted for in planning of wind farms.

Under certain conditions, offshore wind farms can also affect atmospheric temperature and moisture downwind of the facilities. For example, from September 2016 to October 2017, a study using aircraft observations accompanied by mesoscale simulations examined the spatial dimensions of micrometeorological impacts from a wind energy facility in the North Sea (Siedersleben et al. 2018). Measurements and associated modeling indicated that measurable redistribution of moisture and heat were possible up to 62 miles (100 kilometers) downwind of the wind farm. However, this occurred only when (1) there was a strong, sustained temperature inversion at or below hub height and (2) wind speeds were greater than approximately 13.4 mph (6 m/s) (Siedersleben et al. 2018). Typically, air temperature will decrease with height above the sea surface in the lower atmosphere (i.e., the troposphere), and air will freely rise and disperse up to a “mixing height” (Holzworth 1972; Ramaswamy et al. 2006). A temperature inversion occurs when a warmer overlying air mass causes temperatures to increase with height; a strong inversion inhibits the further rise of cooler surface air masses, thus limiting the mixing height (Ramaswamy et al. 2006). Therefore, the North Sea study suggests that rapidly spinning turbines with hub heights at or above a strong inversion may induce mixing between air masses that would otherwise remain separated, which can significantly affect temperature and humidity downwind of a wind farm.

The mixing height over open waters of the North Atlantic Ocean is typically greater than 1,640 feet (500 meters) AMSL, except over areas of upwelling, where the mixing height may be closer to the sea surface (Holzworth 1972; Fuhlbrügge et al. 2013). Table B.1-10 presents atmospheric mixing height data from the nearest measurement location to the NY Bight area (Atlantic City, New Jersey). As shown in the table, the minimum average mixing height is 1,279 feet (390 meters), while the maximum average mixing height is 3,996 feet (1,218 meters).

Table B.1-10. Representative seasonal mixing height data

Season	Data Hours Included[1]	Atlantic City, New Jersey Average Mixing Height (feet/meters)
Winter (December, January, February)	Morning: No-Precipitation Hours	2,047/624
	Morning: All Hours	2,024/617
	Afternoon: No-Precipitation Hours	2,539/774
	Afternoon: All Hours	1,280/390
Spring (March, April, May)	Morning: No-Precipitation Hours	1,788/545
	Morning: All Hours	2,100/640
	Afternoon: No-Precipitation Hours	3,924/1,196
	Afternoon: All Hours	1,637/499
Summer (June, July, August)	Morning: No-Precipitation Hours	1,677/511
	Morning: All Hours	1,857/566
	Afternoon: No-Precipitation Hours	3,996/1,218
	Afternoon: All Hours	2,280/695
Fall (September, October, November)	Morning: No-Precipitation Hours	1,588/484
	Morning: All Hours	2,129/649
	Afternoon: No-Precipitation Hours	3,241/988
	Afternoon: All Hours	1,562/476
Annual Average	Morning: No-Precipitation Hours	1,768/539
	Morning: All Hours	2,034/620
	Afternoon: No-Precipitation Hours	3,451/1,052
	Afternoon: All Hours	1,667/508

[1] Missing values are not included.

Díaz et al. (2019) reported that measurements over the Atlantic Ocean between 1981 and 2010 indicated a trend of decreasing strength and thickness of inversion layers, accompanied by a general increase in the mixing height, which is correlated with an increase in sea surface temperatures. Therefore, WTG hub heights are expected to remain well below the typical mixing height and associated temperature inversions over the open ocean in the Mid-Atlantic region. As such, the redistribution of moisture and heat due to rotor-induced vertical mixing, and any associated shifts to the microclimate, would be limited to the immediate vicinity of a wind facility in this region.

Additionally, mixing height affects air quality by acting as a lid on the height to which air pollutants can vertically disperse. Lower mixing heights allow less air volume for pollutant dispersion and lead to higher ground-level pollutant concentrations than do higher mixing heights.

Modeling studies suggest that the atmospheric wake from wind farms also can affect sea surface temperature, horizontal and vertical ocean currents, and vertical stratification. Christiansen et al. (2022) estimated that "[sea] surface temperature primarily increases in the vicinity of offshore wind farms" due to the wind farm wake effect and that the resulting "large-scale surface heating of up to 0.18 °F (0.1 °C) imitates the effects of climate change" though the wake-related changes are about one order of magnitude smaller than the average variations due to climate change.

B.1.5 Air Quality Standards

Air quality is measured in comparison to the NAAQS, which are standards established by the USEPA pursuant to the Clean Air Act (42 USC 7409) for several common air pollutants, known as criteria pollutants, to protect human health and welfare. Primary standards are set at levels to protect human health with a margin of safety. Secondary standards are set at levels to protect public welfare including plants, animals, ecosystems, and materials. The criteria pollutants are CO, lead, NO_2, O_3, PM_{10}, $PM_{2.5}$, and SO_2. New Jersey and New York have established ambient air quality standards that are similar to the NAAQS. Table B.1-11 shows the NAAQS as well as the state ambient air quality standards for New Jersey and New York for the criteria pollutants.

Table B.1-11. National and state ambient air quality standards

Pollutant	Averaging Period	National Ambient Air Quality Standards (µg/m³)		New Jersey Ambient Air Quality Standards (µg/m³)		New York Ambient Air Quality Standards (µg/m³)	
		Primary	Secondary	Primary	Secondary	Primary	Secondary

B.2 Birds

NYSERDA conducted aerial digital surveys for avian and marine wildlife between 2018 and 2019 in the NY Bight area (NYSERDA 2022). The aerial data provides coverage for all of four NY Bight lease areas (OCS-A 0537, OCS-A 0538, OCS-A 0539, and OCS-A 0544), a portion of OCS-A 0542, and none of OCS-A 0541. Table B.2-1 identifies the number of observations by species and by lease area, and Figure B.2-1 shows the geographic distribution of the observations.

Table B.2-1. NYSERDA aerial avian survey species observations

Figure B.2-1. NYSERDA species observation

Datasets from the Northeast Ocean Data Portal show fine-scale use and movement patterns from three species of diving bird—red-throated loon (*Gavia stellata*), surf scooter (*Melanitta perspicillata*), and northern gannet (*Morus bassanus*)—over the course of 5 years. The data were collected throughout the Mid-Atlantic United States waters and represent the probability that an animal will occur within a specific area during a specified time of year, i.e., utilization distributions. As shown on Figure B.2-2 and Figure B.2-3, red-throated loon and surf scoter are less active within the geographic analysis area during fall migration and overwinter distribution, but heavily utilize the Atlantic Flyway during spring migration. In contrast, the northern gannet uses the Mid-Atlantic Flyway and passes through the geographic analysis area year-round for foraging and migration (Figure B.2-4).

B.4 Demographics, Employment, and Economics

The analysis presented in Section 3.6.3, *Demographics, Employment, and Economics*, is based on the data included in the tables provided in this appendix. The data have all been downloaded from publicly available sources at the United States Census Bureau and the National Oceanic and Atmospheric Administration. The tables include information from coastal counties in New York and New Jersey within the geographic analysis area.

Table B.4-1. Population and trends within the demographics, employment, and economic geographic analysis area (2000, 2010, and 2020)

Jurisdiction	Population Density (persons/ square mile)	Population (2000)	Population (2010)	Population (2020)	% Change (2000–2020)	% Change (2010–2020)
New York Counties						
Albany County	602	295,106	304,086	314,368	6.5	3.4
Kings County	39,438	2,467,006	2,509,828	2,727,393	10.6	8.7
Nassau County	4,905	1,336,713	1,341,669	1,393,978	4.3	3.9

*"Suppressed" data are those that, although included in summation data, NOAA is withholding because there are few enough respondents in a data category for it to be possible to extract personally (or corporate/ business) identifiable data, e.g., if there is only one marine construction firm in a county, its revenue/employment data is not included in the county total but is included in the state total.

B.5 Environmental Justice

The following subsections describe demographic, economic, environmental, and social characteristics for each of the counties in the geographic analysis area exceeding environmental justice thresholds as identified in Section 3.6.4, *Environmental Justice*.

B.5.1 Atlantic County, New Jersey

Atlantic County has a population of 265,000 residents with 45 percent of the population identifying as minority in 2020 (U.S. Census Bureau 2020). All households reported English as their primary language (DataUSA 2023a). This information does not reflect that households may have multi-lingual residents or limited English proficiency. Rather, it is the self-reported language spoken by all members of the household.

The median property value in the county was $216,600 and the homeownership rate was 67 percent. The Atlantic County economy employs 125,000 people with the largest industries being health care and social assistance, accommodation and food service, and retail trade. Relevant to ports or offshore wind services, the employment sectors reported for residents of Atlantic County are 6.3 percent in construction, 4.5 percent in manufacturing, and 3.6 percent in transportation and warehousing (DataUSA 2023a).

The largest demographic living in poverty in Atlantic County is females aged 25–34, followed by females 18–24, and females 55–64. The most common race living below the poverty line is White, followed by Hispanic, and then Black. Of children living in Atlantic County in 2021, 15.4 percent were living in poverty, with the rate decreasing over time since 2015 (DataUSA 2023a). Atlantic County has one of the highest percentages of children in New Jersey under 5 years of age living in poverty (New Jersey Department of Health 2023). Food insecurity also has trended downward with 11 percent of the population reported as food insecure in 2021. This is a 5 percent reduction from 2015 (DataUSA 2023a). In 2020, Atlantic County reported a hospitalization rate for asthma of 5.2 cases per 10,000 county residents compared to the state average of 3.8 cases (New Jersey Department of Health 2023).

B.5.2 Camden County, New Jersey

Camden County has a population of 507,000 people with 47 percent identifying as minority in 2020 (US Census Bureau 2020). All households reported English as their primary language (DataUSA 2023b). The median property value in the county was $204,400 and the homeownership rate was 66 percent. More residents drive alone or carpool than take public transportation. Only 6.6 percent rely on public transportation and overall resident commutes average 29 minutes (DataUSA 2023b). The Camden County economy employs 249,000 people with the largest employment for residents being management, education instruction and library, and business and financial operations. Relevant to ports or offshore wind services, the employment sectors reported for residents of Camden County are 4.3 percent in transportation and 4.2 percent in construction and extraction (DataUSA 2023b). The employment rate for Camden County residents declined less than 1 percent from 2019 to 2020 (DataUSA 2023b).

The largest demographic living in poverty in Camden County is females aged 25–34, followed by females 35–44, and females 45–54. The most common race living below the poverty line is White, followed by Hispanic, and then Black. Of children living in Camden County in 2021, 15.3 percent were living in poverty with the rate having decreased slowly from 22 percent since 2015 (DataUSA 2023b). Food insecurity is currently an issue for 10.3 percent of the population, down from over 14 percent in 2015 (DataUSA 2023b). In 2020, Camden County reported a hospitalization rate for asthma of 7.6 cases per 10,000 county residents, double the state average of 3.8 cases (New Jersey Department of Health 2023).

Table B.5-2. Camden County environmental indicators

B.5.3 Cumberland County, New Jersey

Cumberland County has a population of 150,000 people with 57 percent identifying as minority in 2020 (US Census Bureau 2020). All households reported English as their primary language (DataUSA 2023c). The median property value in the county was $166,400 and the homeownership rate was 66 percent. The Camden County economy employs 60,400 people with the largest employment for residents being office and administrative support services, sales and related occupations, and production occupations. Relevant to ports or offshore wind services, the employment sectors reported for residents of Cumberland County are 6.0 percent in construction and extraction occupations and 4.9 percent in transportation (DataUSA 2023c). The employment rate for Cumberland County residents declined nearly 2 percent from 2019 to 2020 (DataUSA 2023c).

In Cumberland County, 16 percent of the population lives below the poverty line. The largest demographic living in poverty is females aged 25–34, followed by females 45–54, and females 35–44. The most common race living below the poverty line is White, followed by Hispanic, and then Black. Of children living in Cumberland County in 2021, 19.5 percent were living in poverty with the rate having decreased slowly from 25 percent since 2014 (DataUSA 2023c). Food insecurity is currently an issue for 12.6 percent of the population (DataUSA 2023c). In 2020, Cumberland County reported a hospitalization rate for asthma of 9.2 cases per 10,000 county residents. This is the highest county rate in the state and is more than double the state average (New Jersey Department of Health 2023).

B.5.4 Essex County, New Jersey

Essex County is the third-most populous and second-most densely populated county in New Jersey. The county also has the most Black or African Americans within its boundaries (New Jersey Department of Children and Families 2020). Essex County has a population of 799,000 residents with 72.8 percent of the population identifying as minority in 2020 (U.S. Census Bureau 2020). All households reported English as their primary shared language (DataUSA 2022a). The median property value in the county was $395,900 and the homeowner rate was 44 percent. Over 20 percent of the population relies on public transportation with resident commute times averaging 35 minutes (DataUSA 2022a). The Essex County economy employs 380,000 people with the largest industries being health care and social assistance, retail trade, and educational services. Relevant to ports or offshore wind services, the employment sectors reported for residents of Essex County are 7.4 percent in transportation and warehousing, 6.7 percent in manufacturing, and 6.0 percent in construction (DataUSA 2022a). The employment rate for Essex County grew less than 0.5 percent from 2019 to 2020 (DataUSA 2022a). The wealth of the county is not evenly distributed, with the majority of low-income residents residing in the east, closest to the ports.

In Essex County 15 percent of the population lives in poverty. The largest community within the county, the City of Newark, has over a 35 percent poverty rate and has one of the highest homeless rates in the state (New Jersey Department of Health 2023). The largest demographic living in poverty is females aged 25–34, followed by females 35–44, and females 45–54. The most common race living below the poverty line is Black, followed by Hispanic, and then White. Of children living in Essex County in 2021, 18.4 percent were living in poverty with the rate having decreased slowly from 25 percent since 2015 (DataUSA 2022a). Essex County has one of the highest percentages of children in New Jersey under 5 years of age living in poverty (NJ Dept of Health 2023). In 2020, Essex County reported a hospitalization rate for asthma of 6.7 cases per 10,000 county residents compared to the state average of 3.8 cases (New Jersey Department of Health 2023). Food insecurity is currently an issue for 12.7 percent of the population, down from nearly 20 percent in 2014 (DataUSA 2022a).

Table B.5-4. Essex environmental indicators

Selected Variables	Value	State Average	Percentile in State	USA Average	Percentile In USA

B.5.5 Hudson County, New Jersey

Hudson County is the most densely populated county in New Jersey with a population of 672,000 people with 71.5 percent identifying as minority in 2020 (US Census Bureau 2020). All households reported English as their primary language (DataUSA 2023d). The median property value in the county was $400,800 and the homeownership rate was 32 percent. Nearly 40 percent of residents use public transportation to get to work, with an average commute time of 36 minutes. The Hudson County economy employs 360,000 people with the largest employment for residents being management occupations, office and administrative support services, and sales and related occupations. Relevant to ports or offshore wind services, the employment sectors reported for residents of Hudson County are 6.0 percent in transportation and 4 percent in construction and extraction occupations (DataUSA 2023d). The employment rate for Hudson County residents grew almost 1 percent from 2019 to 2020 (DataUSA 2023d).

In Hudson County 14 percent of the population lives in poverty. The largest demographic living in poverty is females aged 25–34, followed by females 35–44, and males 25–34. The most common race living below the poverty line is Hispanic, followed by White, and then Other. Of children living in Hudson County in 2021, 20 percent were living in poverty with the rate having decreased slowly from 30 percent since 2015 (DataUSA 2023d). Food insecurity was an issue for 12.5 percent of the population in 2017 (DataUSA 2023d). In 2020, Hudson County reported a hospitalization rate for asthma of 3.8 cases per 10,000 county residents, the same as the state average (New Jersey Department of Health 2023).

B.5.6 Middlesex County, New Jersey

Middlesex County has a population of 863,000 residents with over 61 percent of the population identifying as minority in 2020 (U.S. Census Bureau 2020). All households reported English as their primary shared language (DataUSA 2022b). The median property value was $351,400 and the homeownership rate was 34 percent. Only 9.2 percent of residents rely on public transportation to get to their place of work and average commutes for residents are 34 minutes. Over 7 percent have “super commutes,” which are commutes over 90 minutes (DataUSA 2022b). The Middlesex County economy employs 408,000 people with the largest industries being health care and social assistance; professional, scientific, and technical services; and retail trade. Relevant to ports or offshore wind services, the employment sectors reported for residents of Essex County are 8.7 percent in manufacturing, 7.4 percent in transportation and warehousing, and 5.1 percent in construction (DataUSA 2022b). The employment rate in Middlesex County rose 0.3 percent from 2019 to 2020.

In Middlesex County 8.7 percent of the population lives in poverty. The largest demographic living in poverty is females aged 25–34, followed by males 18–24, and females 35–44. The most common race living below the poverty line is White, followed by Hispanic, and then Asian. Of children living in Middlesex County in 2021, 11 percent were living in poverty with the rate having decreased slowly from

13 percent since 2014 (DataUSA 2022b). Food insecurity was an issue for 9.6 percent of the population in 2017 (DataUSA 2022b). In 2020, Middlesex County reported a hospitalization rate for asthma of 3.1 cases per 10,000 county residents, which is below the state average (New Jersey Department of Health 2023).

B.5.7 Union County, New Jersey

Union County has a population of 555,200 residents with over 63 percent of the population identifying as minority in 2020 (U.S. Census Bureau 2020). All households reported English as their primary shared language (DataUSA 2023e). The median property value was $378,700 and the homeownership rate was 59 percent. Over 11 percent of residents rely on public transportation to get to their place of work and average commutes for residents are 31 minutes. Nearly 5 percent have “super commutes,” which are commutes over 90 minutes (DataUSA 2023e). The Union County economy employs 283,000 people with the largest industries being health care and social assistance, retail trade, and transportation and warehousing. Relevant to ports or offshore wind services, the employment sectors reported for residents of Union County are 5.9 percent in transportation occupations, 4.9 percent in construction and extraction occupations, and 4.6 percent in production occupations (DataUSA 2023e). The employment rate in Union County rose 0.3 percent from 2019 to 2020.

In Union County 8.8 percent of the population lives in poverty. The largest demographic living in poverty is females aged 25–34, followed by females 35-44, and females 55–64. The most common race living below the poverty line is Hispanic, followed by White, and then Black. Of children living in Union County in 2021, 12 percent were living in poverty. This rate is an increase from 11 percent in 2020 and a decrease from a high of 16 percent in 2014 (DataUSA 2023e). Food insecurity was an issue for 11.4 percent of the population in 2017 (DataUSA 2023e). In 2020, Union County reported a hospitalization rate for asthma of 3.6 cases per 10,000 county residents, which is below the state average (New Jersey Department of Health 2023).

B.5.8 Kings County, New York

Kings County has a population of 2.6 million residents with 64 percent of the population identified as minority in 2020 (U.S. Census Bureau 2020). All households reported English as their primary shared language (DataUSA 2022c). The median property value in Kings County was $734,800 and the homeownership rate was 30 percent. Most residents travel by public transit to work (58 percent) with an overall county average commute time of 43 minutes. The Kings County economy employs 1.22 million people with the largest industries being health care and social assistance; professional, scientific, and technical services; and educational services. Relevant to ports or offshore wind services, the employment sectors reported for residents of Kings County are 6.3 percent in transportation and warehousing, 4.9 percent in construction, and 3.9 percent in manufacturing (DataUSA 2022c). The employment rate in Kings County declined 0.8 percent from 2019 to 2020.

In Kings County 19 percent of the population lives in poverty. The largest demographic living in poverty is females aged 25–34, followed by females 35–44, and males 25–34. The most common race living below the poverty line is White, followed by Black, and then Hispanic. Of children living in Kings County in 2021, 25 percent were living in poverty. This rate is a decrease from 34 percent in 2014 (DataUSA

2022c). Food insecurity was an issue for 14 percent of the population in 2017, the second-highest rate in New York (DataUSA 2022c). For 2017–2019, Kings County reported a hospitalization rate for asthma of 12.6 cases per 10,000 county residents, which is above the state average of 10.2 (New York State Department of Health 2023).

B.5.9 New York County, New York

New York County has a population of 1.6 million residents with 53 percent of the population identified as minority in 2020 (U.S. Census Bureau 2020). All households reported English as their primary shared language (DataUSA 2023f). The median property value in New York County was $1.2 million and the homeownership rate was 24 percent. Most residents travel by public transit to work (55 percent) with an overall county average commute time of 32 minutes. The New York County economy employs 894,000 people with the largest industries being professional, scientific, and technical services; health care and social assistance; and financial and insurance occupations. Relevant to ports or offshore wind services, the employment sectors reported for residents of New York County are only 1.8 percent in transportation occupations, and 1.3 percent in production (DataUSA 2023f). The employment rate in New York County declined 1.25 percent from 2019 to 2020.

In New York County 16 percent of the population lives in poverty. The largest demographic living in poverty is females aged 25–34, followed by females 18–24, and females 55–64. The most common race living below the poverty line is Hispanic, followed by White, and then Black. Of children living in New

York County in 2021, 17 percent were living in poverty, a decrease from 27 percent in 2014 (DataUSA 2023f). Food insecurity was an issue for 15 percent of the population in 2017 (DataUSA 2023f). For 2017–2019, New York County reported a hospitalization rate for asthma of 12.5 cases per 10,000 county residents, which is above the state average of 10.2 (New York State Department of Health 2023).

B.5.10 Queens County, New York

Queens County has a population of 2.4 million residents with over 77 percent of the population identified as a minority in 2020 (U.S. Census Bureau 2020). All households reported English as their primary shared language. The median property value in Queens County was $575,600 and the homeownership rate was 45 percent (DataUSA 2022d). Most residents (48 percent) travel by public transit to work with an average commute time of 44 minutes for all county residents. The economy of Queens County employs 1.12 million people with the largest industries being health care and social assistance; retail trade, and accommodation and food services. Relevant to ports or offshore wind services, the employment sectors reported for residents of Queens County are 8.1 percent in transportation and warehousing, 7.3 percent in construction, and 3.4 percent in manufacturing (DataUSA 2022d).

In Queens County 12 percent of the population lives in poverty. The largest demographic living in poverty is females aged 25–34, followed by females 35–44, and females 55–64. The most common race living below the poverty line is Hispanic, followed by White, and then Asian. Of children living in Queens County in 2021, 14 percent were living in poverty, a decrease from 24 percent in 2014 (DataUSA 2022d). Food insecurity was an issue for 13 percent of the population in 2017 (DataUSA 2022d). For 2017–2019, Queens County reported a hospitalization rate for asthma of 11.6 cases per 10,000 county residents, which is above the state average of 10.2 (New York State Department of Health 2023).

B.6 Recreation and Tourism

The following subsections characterize recreational resources within each county in the recreation and tourism geographic analysis area.

B.6.1 Kings County, New York

Kings County comprises a total of 97 square miles (250 square kilometers), of which 71 square miles (183 square kilometers) are land and 26 square miles (67 square kilometers) are water. Kings County is located at the far western tip of Long Island and contains the New York City borough of Brooklyn. Kings County has 10 nature preserves and parks (New York City Department of Parks and Recreation 2023; New York State Office of Parks, Recreation and Historic Preservation 2023) that include the Brooklyn Botanic Garden; Prospect Park; Coney Island; Floyd Bennett Field and Jamaica Bay Wildlife Refuge, which are shared with Queens County; and the first municipal airport in New York City that is now part of the National Park System. There are seven marinas serving Kings County (New York City Department of Parks and Recreation 2023), with one county-operated marina.

There were 3,720 tourism and recreation establishments in the county that supported just under 34,000 employees in 2019. Tourism and recreation generated just under $980 million in annual payroll and provided the state with a GDP of $2,081,896,633 (NOEP 2022).

B.6.2 Queens County, New York

Queens County comprises a total of 178 square miles (460 square kilometers), of which 108 square miles (280 square kilometers) are land and 70 square miles (180 square kilometers) are water. Queens County has numerous parks and recreation areas (New York City Department of Parks and Recreation 2023), including national parks (Breezy Point, Canarsie Pier, Floyd Bennett Field, Fort Tilden, Jacob Riis Park, and the Jamaica Bay Wildlife Refuge) and State of New York Parks (Bayswater Point State Park and Gantry Plaza State Park). There are two marinas serving Queens County (New York City Department of Parks and Recreation 2023), with one marina operated by the county.

There were 1,390 tourism and recreation establishments in the county that supported just under nearly 12,000 employees in 2019. Tourism and recreation generated just under $235 million in annual payroll and provided the state with a GDP of $545,211,625 (NOEP 2022).

B.6.3 Richmond County, New York

Richmond County, better known as Staten Island, comprises a total of 103 square miles (265 square kilometers), of which 59 square miles (152 square kilometers) are land and 44 square miles (114 square kilometers) are water. Staten Island is home to 24 nature preserves, of which 22 have freshwater wetland or salt marsh habitat (New York City Department of Parks and Recreation 2023). There are two marinas serving Richmond County (New York City Department of Parks and Recreation 2023), with one county-operated marina. The East Shore of Staten Island is home to the 2.5-mile F.D.R. Boardwalk, the fourth-longest in the world.

There were 846 tourism and recreation establishments in the county that supported just under 7,397 employees in 2019. Tourism and recreation generated nearly $179 million in annual payroll and provided the state with a GDP just over $360 million (NOEP 2022).

B.6.4 Suffolk County, New York

Suffolk County encompasses 2,373 square miles (6,150 square kilometers)—of which 912 square miles (2,360 square kilometers) are land and 1,461 square miles (3,780 square kilometers) are water—and has about 1,000 miles of coastline. Recreational areas in Suffolk County include national wildlife refuges, national seashore, state parks and forests, and tidal wetland areas. Notable coastal recreational resources include Montauk Point State Park, Robert Moses State Park, Captree State Park, Fire Island National Seashore, and Gilgo State Park. Suffolk County has the most lighthouses of any county in the United States, and includes the Fire Island Lighthouse, which was an important landmark for trans-Atlantic ships entering the New York Harbor in the early 20th century. Captree State Park, located on the eastern tip of Jones Island, is home to the largest public fishing fleet on Long Island. Open and charter boats are available for saltwater fishing, sightseeing excursions, and scuba diving trips. Popular spots for surf fishing in Suffolk County include Camp Hero State Park and Montauk Point State Park (New York State Office of Parks, Recreation and Historic Preservation 2023). The Suffolk County Parks Department has several full-service watercraft facilities, including four marinas and two boat ramps/launches. There are dozens of marinas serving Suffolk County (CountyOffice.org 2023a).

There were 4,016 accommodation and food service establishments in the county in 2019. Together, these generated over $1.3 billion in annual payroll. There were 937 arts, entertainment, and recreation establishments in Suffolk County, which bring in approximately $354 million in annual payroll (U.S. Census Bureau 2021a, 2021b).

B.6.5 Nassau County, New York

Nassau County comprises a total of 453 square miles (1,174 square kilometers), of which 285 square miles (737 square kilometers) are land and 168 square miles (436 square kilometers) are water. Nassau County is a densely populated county on western Long Island. Recreational areas include Bethpage State Park, Hempstead Lake State Park, Oyster Bay National Wildlife Refuge, Lido Beach Wildlife Management Area, and Jones Beach State Park. Jones Beach State Park is one of the most heavily visited beaches on the East Coast, with an estimated 8.5 million visitors in 2018 (New York State Office of Parks, Recreation and Historic Preservation 2022). Visitors to Jones Beach can swim; enjoy the boardwalk; fish; dine; visit the WildPlay Adventure Park; play miniature golf, shuffleboard, basketball, corn hole, paddle tennis, table tennis, and pickleball; and attend concerts at Northwell Health Theatre. For recreational fishing, Jones Beach offers fishing piers, a bait and tackle shop, and a boat basin that allows boaters day use of the park throughout the boating season. The county operates boat launches at four county parks (Nassau County 2023).

There were 3,812 accommodation and food service establishments in the county in 2019. Together, these generated over $1.3 billion in annual payroll. There were 928 arts, entertainment, and recreation establishments in Nassau County, which bring in approximately $559 million in annual payroll (U.S. Census Bureau 2021a, 2021b).

B.6.6 Monmouth County, New Jersey

Monmouth County encompasses 472 square miles (1,223 square kilometers) of land, including 27 miles (44 kilometers) of Atlantic coastline and 26 miles (42 kilometers) of Raritan Bay coastline. There are 30 parks in Monmouth County, many of which have campgrounds, and bays, ponds, creeks, reservoirs, and lakes for fishing. There are 148 miles (238 kilometers) of trails for walkers, runners, cyclists, and equestrians (Monmouth County Park System 2022), and there are eight wildlife management areas in the county, the largest of which is Assunpink (6,393 acres [2,587 hectares]) (NJDEP 2021). The county is home to 21 museums and many local breweries, distilleries, wineries, and golf courses. Popular tourist attractions include the annual Belmar Seafood Festival, jazz festivals, county fairs, and beach movie viewings (Monmouth County Park System 2022). It is home to 12 boardwalks, such as the Asbury Park Boardwalk, which is lined with music venues, food establishments, and shops (Monmouth County Park

System 2022). The 1,655-acre (670-hectare) Sandy Hook Peninsula, which is a unit of the Gateway National Recreation Area, is a very popular tourist destination and is frequented by two million tourists every year (National Park Service 2022). It is home to two landmarks, Fort Hancock and the Sandy Hook Lighthouse, and is popular among bird watchers, as it is used by over 300 species of birds (NJDEP 2022).

The county has 17 public beaches that are heavily frequented by tourists during the summer months for swimming, boating, fishing, and scuba diving. The county has three public beachfront areas: Seven Presidents Oceanfront Park in Long Branch, Bayshore Waterfront Park in Port Monmouth, and Fisherman's Cove Conservation Area in Manasquan, and it is home to 34 marinas, including the Monmouth Cove Marina (CountyOffice.org 2023b).

There were 1,870 accommodation and food service establishments in the county in 2019. Together, these generated over $576 million in annual payroll. There were 488 arts, entertainment, and recreation establishments in Monmouth County, which brought in approximately $197 million in annual payroll (U.S. Census Bureau 2021a, 2021b).

B.6.7 Ocean County, New Jersey

Ocean County is in the center of the Jersey Shore region, with approximately 629 square miles (1,792 square kilometers) of land. The county provides an array of recreational beaches, boardwalks, marinas, and wildlife areas. Popular activities include fishing, hiking, biking, kayaking, golfing, and sightseeing (Ocean County 2022). Ocean County has 27 parks and conservation areas, with over 4,000 acres (1,619 hectares) of preserved land. Sixteen wildlife management areas fall within Ocean County, including Greenwood Forest (32,353 acres [13,093 hectares]), which is partly in Burlington County (NJDEP 2021). Popular coastal attractions include lighthouses, the Tuckerton Seaport, Jenkinson's Boardwalk, and annual seafood and music festivals (Ocean County 2022).

The Edwin B. Forsythe National Wildlife Refuge consists of more than 47,000 acres (19,020 hectares) of coastal habitats and provides wildlife viewing and nature trails. The Barnegat Lighthouse State Park is located on the northern tip of Long Beach Island and provides panoramic views of Barnegat Inlet as well as trails through maritime forests, birding sites for waterfowl, fishing sites, and nature walks.

There were 1,292 accommodation and food service establishments in the county in 2019. Together, these generated over $342 million in annual payroll. There were 272 arts, entertainment, and recreation establishments in Ocean County, which bring in approximately $116 million in annual payroll. Approximately 6.4 percent of all housing units in Ocean County are for seasonal, occupational, or occasional use (U.S. Census Bureau 2021a; 2021b).

B.6.8 Atlantic County, New Jersey

Atlantic County lies in the southern peninsula of New Jersey and encompasses approximately 556 square miles (1,440 square kilometers) of land. Most of the Tuckahoe-Corbin City Fish and Wildlife Management Area is within Atlantic County and consists of approximately 17,500 acres (7,082 hectares) of tidal marsh, woodlands, fields, and impoundments (NJDEP 2018). Ten wildlife management areas totaling 55,360 acres (22,403 hectares) also fall within or partially within Atlantic County: Absecon (3,946 acres [1,597 hectares]), Cedar Lake (360 acres [146 hectares]), Great Egg Harbor River (7,552 acres [3,056 hectares]), Hammonton Creek (5,720 acres [2,315 hectares]), Makepeace Lake (11,737 acres [4,750 hectares]), Malibu Beach (257 acres [104 hectares]), Maple Lake (4,789 acres [1,938 hectares]), Pork Island (868 acres [351 hectares]), Port Republic (1,471 acres [595 hectares]), and Tuckahoe (18,660 acres [7,551 hectares]) (NJDEP 2021).

The county is known for its boardwalk along the beach of Atlantic City, with its nine casinos with restaurants, nightclubs, and game rooms (Stockton University 2021). The county has nine beaches, which collectively total 14 miles (23 kilometers), and 5.75 miles (9.25 kilometers) of boardwalk (Atlantic City 2021). There are several boat launches and marinas in the county, which have small recreational boat rentals. Recreational fishing is permitted on the beaches, outside of guarded areas, and from the jetties. There are also multiple fishing piers available to the public.

There were 827 accommodation and food service establishments in the county in 2019. Together, these generated over $1.2 billion in annual payroll. There were 113 arts, entertainment, and recreation establishments in Atlantic County, which bring in approximately $41 million in annual payroll. Approximately 13.4 percent of all housing units in Atlantic County are for seasonal, occupational, or occasional use (U.S. Census Bureau 2021a, 2021b).

B.6.9 Cape May County, New Jersey

Cape May is New Jersey's southernmost county and encompasses 251.5 square miles of land. There are many parks, state forests, and wildlife management areas in Cape May County. The Cape May National Wildlife Refuge encompasses 11,500 acres (4,654 hectares) of grasslands, saltmarshes, and beachfront (Friends of Cape May National Wildlife Refuge n.d.). The Cape May Coastal Wetlands Wildlife Management Area extends along the coast of Cape May County and occupies approximately 17,842 acres (7,220 hectares) (NJDEP 2021).

Cape May County is considered one of the premier beach destinations along the Mid-Atlantic coast. The Ocean City Boardwalk is more than 2 miles (3 kilometers) long and is lined with shops and amusement park rides. The Wildwood Boardwalk runs from Wildwood into North Wildwood and is home to many amusement attractions (Cape May County 2022). Recreational fishing occurs along the back bays and from the surf, piers, and boats along the Jersey Cape (Cape May County 2022).

There were 917 accommodation and food service establishments in the county in 2019. Together, these generated over $240 million in annual payroll. There were 143 arts, entertainment, and recreation establishments in Cape May County, which brought in approximately $50 million in annual payroll. Approximately 50.9 percent of all housing units in Cape May County are for seasonal, occupational, or occasional use (U.S. Census Bureau 2021a, 2021b).

B.7 Offshore Wind Vessel Types

Over 25 different types of vessels are expected to be used to construct, operate, and maintain an offshore wind project. The vessels shown in Table B.7-1 are expected to be representative of the vessels used for the NY Bight projects (ACP 2021). Multiple vessels will be needed for each offshore wind project, but the exact number and types will be dependent on project size, distance from shore, environmental conditions, and other factors. The majority of these vessels will be coastwise qualified (i.e., United States-flagged vessels with American crews that are built in the United States).

Different types of vessels are projected to be needed during the different offshore wind project stages, including Surveying, Cable Lay, Component Transfer, Turbine Installation, Development, Construction, Decommissioning, and Operations and Maintenance (O&M). As outlined in Table B.7-1, Service Operation Vessels (SOVs) and Crew Transfer Vessels (CTVs) will be the primary vessel used by the offshore wind industry. These vessels would be coastwise qualified vessels and used across the lifetime of each project in both the construction and O&M phases. Additionally, there are a large variety of vessels that could be used during the 2–3-year construction and surveying stages, many of which will be coastwise qualified. The number of coastwise qualified vessels used during construction are anticipated to grow as factories and supply chains are built in the United States. The number of vessels estimated for each class of vessel in Table B.7-1 is for a typical 800-megawatt offshore wind project. However, the number and type of vessels used will vary greatly between projects, depending on the selected installation techniques, distance from shore, the rate of construction of the domestic supply chain, and other factors.

Table B.7-1. Vessels used throughout the 35-year lifetime of a typical offshore wind project, including both construction and O&M

Vessel Type	Approximate Number of Vessels	Vessel Activities Conducted
Project Lifetime		
Crew Transfer Vessel (CTV)	Construction: 1–4 Vessels O&M: 0–3 Vessels	CTVs transfer personnel and light equipment in support of construction and O&M. During construction, both the developer and turbine manufacturer are likely to hire two CTVs, respectively. For nearshore projects (less than ~1.5 hours from port) CTVs will be primary for O&M; further offshore projects will use SOVs.
Service Operation Vessel (SOV)/Walk to Work/ Commissioning Support Vessel	Construction: 0–2 Vessels O&M: 0–3 Vessels	These vessels are equipped with motion compensated gangway allowing turbine technicians to “walk to work” directly from the vessel to the turbine. Use of SOVs or CTVs depends mostly on distance of the project from shore. Most, but not all, projects will utilize SOVs. During construction, SOVs assist with wind turbine installation and commissioning (bringing turbine and cables online). Developers and turbine manufacturers are likely to hire one SOV each. During O&M, SOVs would be used for turbine servicing and operation.

Vessel Type	Approximate Number of Vessels	Vessel Activities Conducted
Surveying		
Environmental Survey	2–4 Vessels	Environmental survey vessels conduct fisheries and benthic surveys on export cable routes and in the lease area. They are also used to place LIDAR buoys for various environmental assessments. A variety of vessels do this work: nearshore work tends to be smaller vessels, and offshore work uses larger vessels.
Geotechnical Survey	1–6 Vessels	Geotechnical survey vessels conduct physical sampling and testing of seabed characteristics to optimally place turbines and cables, typically by conducting borings or sampling to specific depths below the mean seabed.
Geophysical Survey	1–6 Vessels	Geophysical survey vessels acoustically map seabed features, surface, and sub surface within a lease area and potential Export Cable Routes. Detects and charts unexploded ordinances (UXO).
Cable Laying		
Export Cable Laying Vessel	1–2 Vessels	Export Cable Laying Vessels are large, specialist cable installation vessel equipped with 1–2 high-capacity carousels capable of reeling long lengths of large diameter export cables, exporting from cable manufacturing facility and installation on wind farm sites. Typically, a dynamic positioning vessel is used for installation in water depths greater than 32.8 feet (10 meters). These vessels will also physically sample and test seabed characteristics to optimally place cables, typically by conducting borings or sampling to specific depths below the mean seabed. These vessels also have the potential to include cable burial spread.
Shallow Water Export Cable Lay Vessel	1–2 Vessels	These vessels are flat-bottomed vessels/barges equipped with medium to large carousel(s) and anchor handling spreads for cable installation in water depths ranging from 0 feet/meters (beached) to approximately 32.8 feet (10 meters). The vessels would handle cable installation from cable landing/Horizontal Directional Drilling (HDD) sites to water depths for typical dynamic positioning vessel. These vessels also have the potential to include cable burial spread.
Nearshore Export Cable Landing Support Barge	1–2 Vessels	These are vessels used for landfall and nearshore support works, support for HDD and landfall pull-in operation of export cable.
Export and Array Cable Support Vessels	2–6 Vessels	A variety of ancillary cable installation support vessels will be used during construction: cable jointing/splicing cables, multiact shallow water anchor handling, spud leg pontoon, lift-boat/jack up for shallow water operations, Pre-lay Grapnel Run vessel, and fisheries support vessels. During O&M, these vessels will be used for cable subsea inspection and repairs.
Cable Crossing Construction Vessel	1–2 Vessels	Cable Crossing Construction vessels are used for installation of cable protection structures (mattresses, rock bags, grout bags) in a range of water depths from nearshore (shallow) to offshore wind farm site (deepwater).

Vessel Type	Approximate Number of Vessels	Vessel Activities Conducted
Array Cable Laying Vessel	1–3 Vessels	These vessels are used for cable installation between turbines and from turbines to offshore substations. Typically installed with crew transfer facilities and cable pull in equipment for cable installation into each turbine. These vessels also have the potential to include cable burial spread.
Anchor Handling Vessels	2–6 Vessels	These vessels are used to support multi-anchor cable installation. Cable installation barges can have 8–12 anchors in shallow water.
Cable Trenching Vessel	1–2 Vessels	These vessels create trenches in the seafloor to lay cable. These can be nearshore (shallow water) or offshore (deepwater) vessels equipped with cable pre- or post-lay burial tool, typically A-Frame launched seabed trencher – remotely operated vehicle Jetter/Cutter, Cable plow, Jetting sled. These vessels have the potential to require bollard pull (cable plow).
Development, Construction, & Decommissioning		
Floating Heavy Lift Foundation Vessel	1–2 Vessels	These vessels are utilized in substation, transition piece, and foundation installation, including pile-driving. Most are floating, but sometimes a jack up vessel is used.
Wind Turbine Installation Vessel	1–2 Vessels	During construction, these vessels are utilized in turbine installation. During O&M, these vessels are utilized for main component exchange, such as replacing nacelles, generators, gear boxes. If not coastwise qualified, they would be paired with a feedering spread.
Feedering Spread: Barges and Ocean-Going Tugs	2–3 Vessels	Feedering spreads are a newer installation concept in the offshore wind industry. Feeder barges supply components to installation vessels from port in compliance with the Jones Act. These vessels are likely to vary depending on the experience of the initial offshore wind projects in the United States. Feedering spreads include coastwise concepts such as: towed barges, self-propelled vessels, or ultra large lift boats. The number of vessels will depend on the feedering concept and the number of wind turbine installation vessels. A towed barge spread would likely include large deck barges with motion compensation systems, offshore tugs for station keeping, transit tugs towing barges from port to offshore locations, and port tugs for marshalling/port movements. Zero feedering spreads are required with a coastwise qualified wind turbine installation vessel. These vessels are only for installation, and not transportation between ports.
Supply Chain Transportation	2–3 Vessels	All vessels will need to be coastwise qualified vessels in order to move components between the United States manufacturing sites and marshalling areas.
Rock Dumping/Scour Protection Vessel	1–2 Vessels	These vessels are used to install protective rock for seabed infrastructure (such as cables and foundations), and are utilized in multiple phases (e.g., site preparation, scour rock around monopile, application of rock scour on top of cables, etc.).

Vessel Type	Approximate Number of Vessels	Vessel Activities Conducted
Dredging Vessels	2–4 Vessels	Dredging vessels are used to level or lower the seafloor in preparation for construction of cables and turbines. Dredging vessels include Trailing Suction Hoppers, Cutter Suction Hoppers, and Grab Hoppers.
Safety/Scout Vessel	1–4 Vessels	Safety/Scout vessels are used during Surveying and Construction, and ensure operational safety with ongoing marine traffic, look out for fixed fishing gear, and interface with fishing vessels.
Noise Mitigation Vessel	1 Vessel	These vessels are used to create a bubble curtain to mitigate noise from pile-driving.
Accommodation Vessel	0–2 Vessels	Accommodation vessels house the turbine technicians, and other crew during favorable weather windows, such as the summer months.
Construction Support Vessel	5–25 Vessels	These vessels carry fuel, supplies, and other support equipment to construction vessels.

B.8 Commercial Fisheries and For-Hire Recreational Fishing

B.8.1 Vessel Monitoring System Data

Using Vessel Monitoring System (VMS) data conveyed in individual position reports (pings) from January 2014 to December 2021, the Bureau of Ocean Energy Management (BOEM) compiled information about fishing activities in the NY Bight lease areas (NMFS 2021). Figure 3.6.1-2 through Figure 3.6.1-19 in Section 3.6.1, *Commercial Fisheries and For-Hire Recreational Fishing*, cover all fishing activities (transiting and active fishing) for VMS fisheries. Data on non-VMS fisheries are presented here. Figure B.8-1 to Figure B.8-6 provide the histograms for non-VMS fisheries.[4] The larger bars in the polar histograms represent a greater number of position reports showing fishing vessels moving in a certain direction in the NY Bight lease areas. The polar histograms differ with respect to their scales. Non-VMS vessels operated in an east–west direction in OCS-A 0537, while vessels in OCS-A 0538 operated in a northwest–southeast direction. Non-VMS vessels in the remaining lease areas generally operated in a northeast–southwest direction.

[4] VMS coverage is not universal for all fisheries. Non-VMS data have been declared as out of fishery, meaning they have been declared out of a fishery managed by days-at-sea effort controls (i.e., scallops, northeast multispecies, and monkfish).

B.8.2 Percentage of Revenue by Permit

To characterize differences in the economic importance of fishing grounds in the Wind Energy Areas (WEAs) across the commercial fishing fleet, NMFS analyzed the percentage of each permit's total commercial fishing revenue attributed to catch. The distributions of the vessel-level annual revenue percentages from 2008 to 2022 for the New York Bight lease areas are provided in the boxplots in Figure B.8-7 through Figure B.8-12. The boxplot begins at the first quartile, or the value beneath which 25 percent of all vessel-level revenue percentages fall. A thick line within the box identifies the median, the observation that 50 percent of vessel-level revenue percentages are above or beneath. The box ends at the third quartile, or the vessel-level revenue percentage beneath which 75 percent of observations fall. The "whiskers" (dashed line terminating in a vertical line) that jut out from each side of the box represent the minimum and maximum non-outlier range. In the context of this analysis, an outlier is a vessel that derived an exceptionally high proportion of its annual revenue from the WEA in comparison to other vessels that fished in the area. Although outliers derived a high proportion of their annual revenue from the WEAs in comparison to other vessels that fished in the area, in any given year, the revenue percentage for the majority of outliers was below 5 percent. Therefore, while some vessels depended heavily on the WEAs their commercial fishing revenue, most derived a small percentage of their total annual revenue from the area.

Figure B.8-12. Percentage of revenue harvested from the OCS-A 0544 lease area from 2008 to 2022

B.9 Use of New and Emerging Technologies – Recommended Practice MUL-21

BOEM is evaluating the potential for new and emerging technologies to reduce environmental impacts from the NY Bight projects under the Recommended Practice MUL-21 (see Appendix G, *Mitigation and Monitoring*, for full text of the measure). As part of this measure, BOEM encourages lessees to explore new technologies that may avoid or reduce impacts during construction, O&M, and decommissioning compared to more conventional methods. This section describes five examples of new and emerging technologies that could be evaluated for deployment for the NY Bight projects. This list of new and emerging technologies is not exhaustive, and lessees may identify other technologies that could be implemented to avoid or reduce impacts as part of MUL-21. The technological readiness of each of the following technologies varies and commercial application may not be feasible for the NY Bight leases depending on the timing of the proposed development schedule for each lease area. The description of the technologies is largely based on research conducted by the National Renewable Energy Laboratory (NREL) (NREL 2023). As these technologies are new and largely untested in the offshore wind industry, not all have been subject to detailed study, and additional information about the specific design and deployment of these technologies would be needed to fully assess impacts.

Closed-loop cooling: Some offshore wind projects may use high-voltage direct current (HVDC) offshore converter stations that would convert alternating current to direct current before transmission to onshore project components. These HVDC systems are typically cooled by an open-loop system that intakes cool sea water and discharges warmer water back into the ocean, resulting in the potential for impingement and entrainment of organisms and thermal plumes (for a detailed description of these impacts, refer to Section 3.4.2, *Water Quality*, Section 3.5.2, *Benthic Resources*, Section 3.5.5, *Finfish, Invertebrates, and Essential Fish Habitat*, Section 3.5.6, *Marine Mammals*, and Section 3.5.7, *Sea Turtles*). A subsea cooler is an example of a closed-loop cooling technology that has been successfully used for commercial subsea gas production. Subsea cooler technology does not yet have demonstrated commercial application for offshore wind, but it is an emerging technology that could become viable on the timeline of the NY Bight projects (NREL 2023). As opposed to a topside cooling system that intakes seawater on an offshore HVDC converter station as analyzed under Alternative B, a subsea cooler would be located on the seabed by the HVDC converter platform and would reject heat directly to the surrounding ocean, relying on ambient ocean flows and passive thermal convection to circulate seawater past the submerged cooling tubes. Because the system does not intake or discharge seawater, there would be no impingement/entrainment impacts and no discharge of sodium hypochlorite anti-fouling solution. While there would be no discharge of warmer water, passive cooling would be expected to result in some warming of the surrounding ocean.

This technology could minimize impacts associated with discharges/intakes impact-producing factor (IPF) for the following resources: water quality; benthic resources; finfish, invertebrates, and essential fish habitat (EFH); marine mammals; and sea turtles.

Quieter monopile installation: Alternate quieter pile-driving methods include seawater hammers, vibro-driving with electromechanical vibrating units clamped to a suspended monopile, and a method that combines vibro-driving with water jets. The seawater hammer method raises a large column of seawater above the pile head and then releases it to fall on the pile resulting in a longer pulse duration reducing the pulse intensity. Vibro-driving units use rotating eccentric weights operating at low frequencies (<20–40 Hertz) to induce flexural oscillations of the monopile, whose weight is suspended by crane from a surface vessel. The vibro-driving with water jets uses both vibration and water to fluidize the soil inside the monopile. These quieter monopile installation methods can yield a 20 decibel (dB) or greater reduction in source noise levels relative to unmitigated conventional impact hammering resulting in a reduction in the radius of induced marine life behavioral response (NREL 2023). For a detailed description of impacts related to conventional impact hammering, refer to Section 3.5.2, *Benthic Resources;* Section 3.5.5, *Finfish, Invertebrates, and Essential Fish Habitat;* Section 3.5.6, *Marine Mammals;* and Section 3.5.7, *Sea Turtles*.

This technology could reduce noise source levels, thereby reducing potential noise impacts on marine mammals, sea turtles, finfish, and invertebrates, producing fewer behavioral changes in these species and reducing the risk of injury. However, the seawater hammer and the combined vibro-driving with water jets method could also result in additional impacts associated with the discharge/intakes IPF for the following resources: benthic resources; finfish, invertebrates, and EFH; marine mammals; and sea turtles as each method requires intake of seawater for operation resulting in impingement and entrainment of organisms. The impacts relative to the discharge/intake IPF will have to be evaluated on a project-by-project basis since the water system flow requirements are governed by the pile dimensions and the seabed soil.

Cable-in-pipe array cable installation: The Representative Project Design Envelope (RPDE) analyzed under Alternative B for the NY Bight projects considers the following interarray cable installation methods: mechanical or jet plowing options including trencher, precision installation (using a remotely operated vehicle/diver), mechanical cutter, controlled flow excavator, jet plowing, and vertical injection. A new and emerging technology allows for the remote installation of unarmored cables from offshore electric service platforms by pressurized water flow in thermoplastic conduit pipe that has been pre-laid and buried in the seabed. This method allows for seamless transitions from the conduit pipe turbine to turbine along an array cable string. The array cable-in-pipe system uses pressurized water injected into pre-laid thermoplastic pipe, and the water flow pushes one or more pigs attached to the front end of the cable (and along the cable, as needed) enabling the cable to be carried through the pipe by the pressurized water flow (NREL 2023).

Cable-in-pipe installation enables the use of standard onshore cables on standard drums, which have a wider range of cable suppliers, and which could reduce cable supply costs compared with armored submarine cable. Moreover, unarmored cable has 10–15 percent less power loss than armored cable, due to induced current in the armor wires. In addition, repair and replacement of damaged cable can be done within the conduit pipe without disturbing the seabed. Implementation of this technology could reduce the impacts associated with periodic repair and maintenance needed for interarray cables associated with the cable emplacement and maintenance IPF for the following resources: benthic resources; finfish, invertebrates, and EFH; marine mammals; and sea turtles.

Self-installing frond mats: The RPDE analyzed under Alternative B for the NY Bight projects considers the following potential scour protection methods for WTG and OSS foundations: rock, mattress protection, sandbags, and stone bags. A new and emerging technology that lessees could install in place of these conventional scour protection methods is self-installing frond mattresses. Self-installing frond mats involve pre-attaching frond mat panels around a monopile or suction bucket. Once the foundation is at the target embedment depth, the panels would be released, much like an unfolding, inverted umbrella (NREL 2023). Test results have shown that self-installing frond mats can provide effective scour protection around both monopiles and suction bucket jackets, capable of limiting the depth of localized scour. Use of self-installing frond mats to replace conventional riprap scour protection would have the environmental benefit of substantially reducing the demand for subsea rock installation vessels, potentially eliminating hundreds of vessel trips and associated impacts, including reduced air emissions, underwater noise levels, accidental releases, and vessel strike. Frond mats can also result in the buildup of naturally contoured sandbank around the fronded area, avoiding potential edge scour that can occur with stone riprap layers. Conversely, using frond mats instead of rock or concrete scour protection could reduce benefits from an increase in hard surfaces for benthic species dependent on hardbottom habitat.

This technology could minimize resource impacts associated with the accidental releases, air emissions, noise, and vessel traffic IPFs for the following resources: air quality; water quality; marine mammals;

finfish, invertebrates, and EFH; and sea turtles. This technology could reduce beneficial impacts associated with the presence of structure IPF for the following resources: benthic resources.

B.10 Transmission Infrastructure Development Efforts – New Jersey

In November 2023, the New Jersey Board of Public Utilities (NJBPU) initiated issuance of a solicitation for construction of the Prebuild Infrastructure (PBI), which is the infrastructure between the identified landing point at Sea Girt National Guard Training Center (NGTC) in New Jersey and the point of interconnection at the Larrabee Collection Station, a distance of approximately 12 miles.[5] The PBI will consist of duct banks and cable vaults to accommodate transmission circuits for multiple future offshore wind projects along with the transition vaults at the NGTC and horizontal directional drilling (HDD) bores under the shoreline interface from the transition vaults to the offshore termination area, thereby enabling these future projects to access the wholesale transmission system. The PBI will include only the necessary infrastructure to house the transmission cables and not the cables themselves. The PBI is envisioned as a single construction effort, thereby minimizing environmental impacts and disruption to local communities. At a later date, when each offshore wind generation project is under construction, each project will be responsible for pulling its own export cables through the existing duct banks and interconnecting at the Larrabee Collection Station.

By design, the PBI is being procured, developed, owned, and operated through mechanisms that are entirely independent of the offshore wind generation projects that will ultimately use the PBI. PBI will be funded through the Federal Energy Regulatory Commission's transmission rates and will be developed, owned, and operated by a transmission system developer. Offshore wind generation projects anticipated to use the PBI include Attentive Energy Two[6] and Leading Light Wind[7].

B.10.1 Description of Onshore/Upland Activities

The onshore portion of the PBI extends from the cable vaults beside the Larrabee Collection Station to the transition vaults to be built and installed at Sea Girt. It will include duct banks and related facilities to accommodate up to four separate offshore wind circuits. Cable vaults will be constructed at intervals along the duct banks to access the duct banks and enable the offshore wind developers to pull cables through the completed PBI facilities. The PBI may consist of a single right-of-way (ROW) that can accommodate all four circuits for multiple separate offshore wind projects. Alternatively, the PBI may consist of two separate ROWs, each with two circuits, depending on the width of the routes selected. Example PBI layouts are illustrated in Figure B.10-1.

---

[5] See *In the Matter of the Opening of a Solicitation for a Transmission Infrastructure Project to Support New Jersey's Offshore Wind Public Policy*, BPU Docket No. QO23100719, Order dated November 17, 2023 (initiating a prebuild infrastructure solicitation through the release of a Prebuild Solicitation Guidance Document).

[7] https://www.nj.gov/bpu/pdf/boardorders/2024/20240124/8A%20ORDER%20Solicitation%203%20Invenergy.pdf

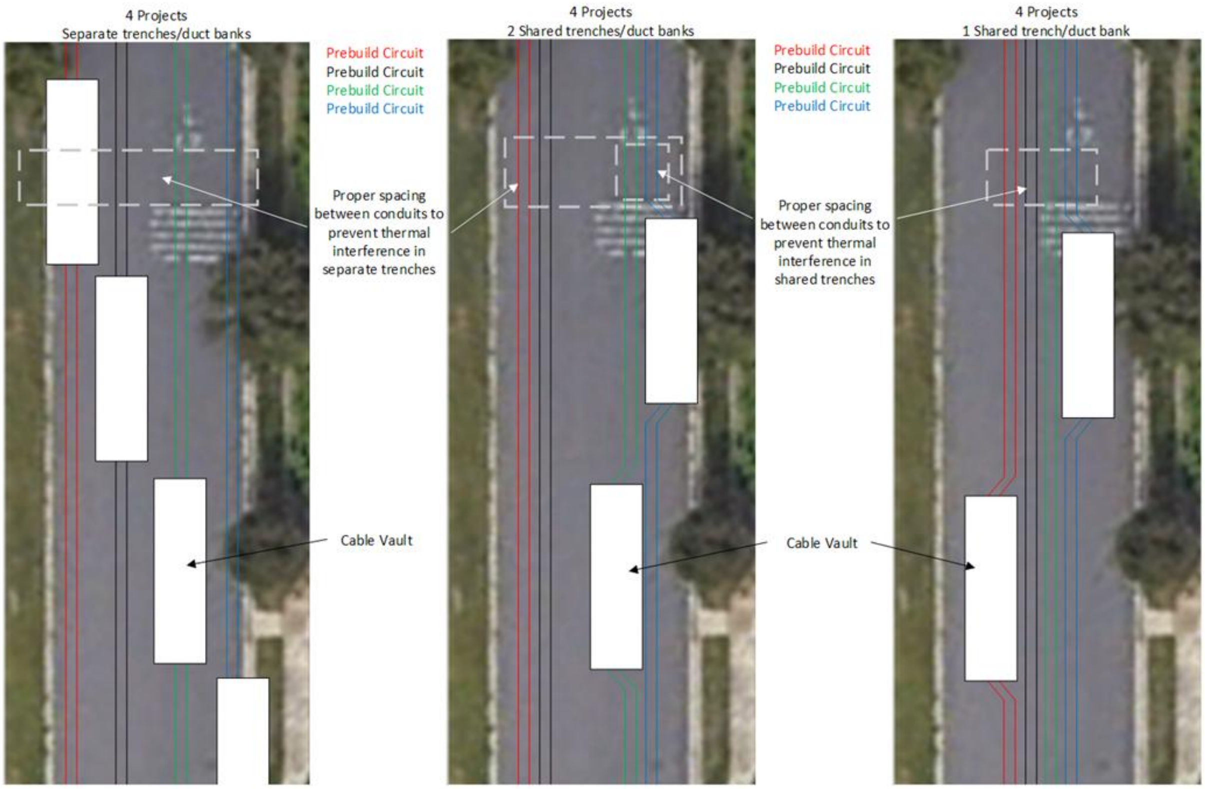

Figure B.10-1. Illustrative example of duct bank and cable vault layout

The PBI ROW is anticipated to occupy existing public roadways to a large extent. Based on the types of properties between Sea Girt and the Larrabee Collection Station and likely routes, the ROWs are expected to occupy the land uses summarized in Table B.10-1. Some categories overlap.

Table B.10-1. Affected land use categories along potential PBI routes

Land Use Category*	Single- Route Option (Miles)	Dual-Route Option (Miles)
Length	11	23
Public roads (municipal, county, state)	10	12
Bike path	2	3
Residential/private ownership	1	1.5
Forest	1.3	2.5
Wetland, including forested wetland	1.0	1.2
Parks and other open space	0.8	2
Water bodies	0.05	0.2

* All values are approximate and based on initial desktop assessments that must still be validated.

B.10.2 Description of In-water Activities

As noted in Table B.10-1, the onshore portion of the PBI could cross wetlands and waterbodies. It is expected that the majority of these features will be under the jurisdiction of the New Jersey Department of Environmental Protection (NJDEP). However, specific crossings of waters of the United States are also anticipated, including the crossing of the Manasquan River, and the landfall from the Atlantic Ocean to the Sea Girt NGTC.

The construction methodology used to cross the Manasquan River will depend on the selected PBI developer's construction plans and analysis of technical feasibility and environmental considerations. Proposed technical solutions to cross the Manasquan River under evaluation include HDD, direct bore, and use of a utility bridge.

The PBI continues seaward from the transition vaults at Sea Girt, through HDD boreholes, reaching offshore to the location of offshore cofferdams. Four transition vaults will be constructed at the onshore landfall location to accommodate the four future offshore wind circuits, as illustrated in Figure B.10-2. (Note: Figure B.10-2 presents a generalized image and does not reflect the total number of conduits expected to extend from the onshore transition vault to the offshore HDD exit pits). From the onshore transition vaults, a series of HDD bores (up to 10) will extend seaward to enable the placement of up to 10 conduits, which will ultimately house the offshore export cables for selected qualified offshore wind projects.

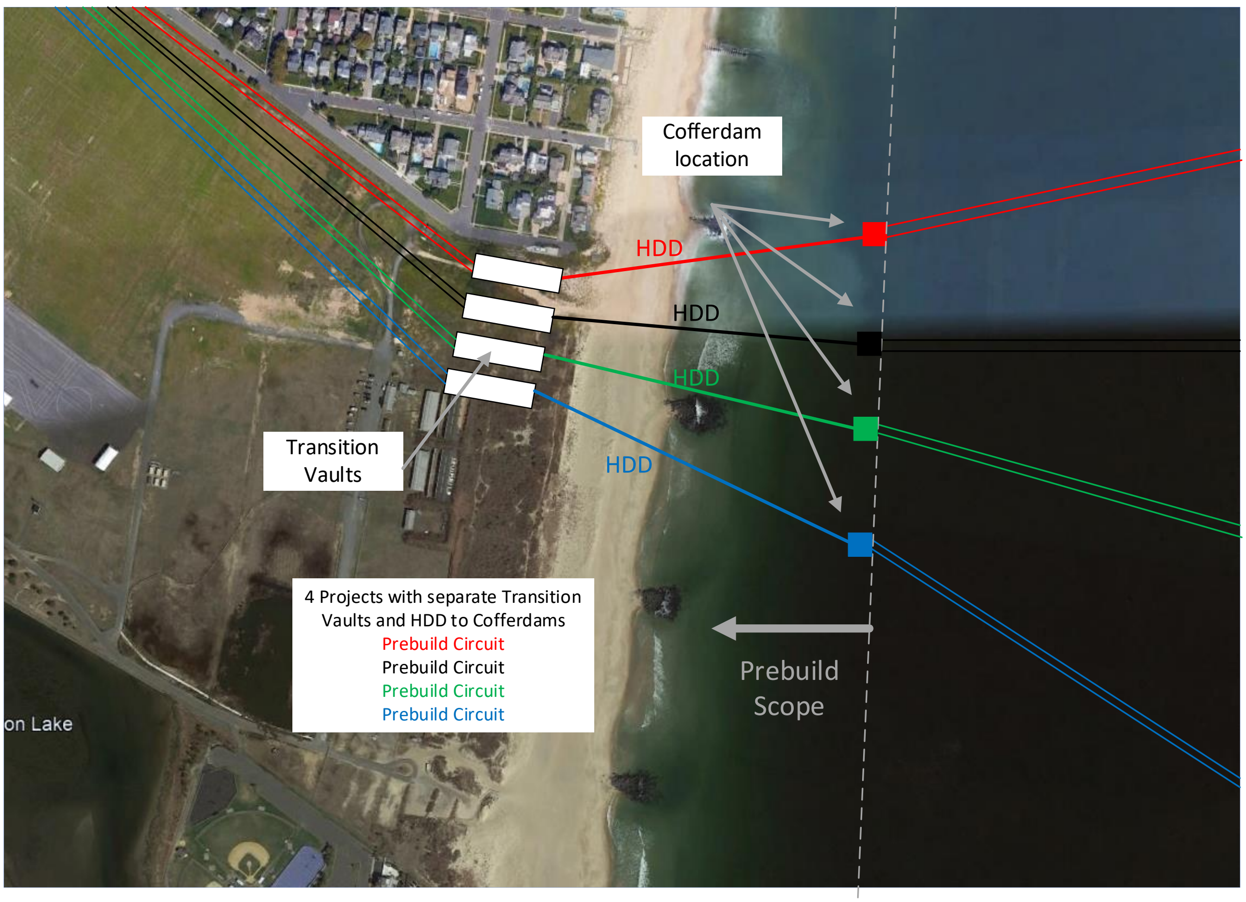

Figure B.10-2. Illustrative example of circuit arrangement at landfall

B.11 Transmission Infrastructure Development Efforts – New York

The New York City Public Policy Transmission Need process led by the New York Public Service Commission and the New York Independent System Operator (NYISO) issued a solicitation on April 4, 2024[8] for the submission of a proposed Public Policy Transmission Project or Other Public Policy Project that would 1) accommodate at least 4,770 MW of incremental offshore wind generation injected into New York City; 2) consist of complete end-to-end proposals composed of both offshore and onshore components; 3) include plans for how offshore wind generation would interconnect to the end-to-end transmission proposal at the offshore interconnection points, and 4) include demonstration plans to complete all permitting and construction activities necessary to achieve an in-service date no later than January 1, 2033.

The NYISO will conduct a multi-stage review of the project submissions and make a recommendation to the New York City Public Policy Transmission Need for consideration by the NYISO Board of Directors in 2025.

Appendix C: Tiering Guidance

The Bureau of Ocean Energy Management (BOEM) has prepared this Final Programmatic Environmental Impact Statement (PEIS) to evaluate the impacts that could result from wind energy development activities in the six New York Bight (NY Bight) lease areas, as well as the change in those impacts with avoidance, minimization, mitigation, and monitoring (AMMM) measures. The Proposed Action for the PEIS is the identification of AMMM measures at the programmatic stage that could avoid, minimize, mitigate, and monitor impacts. BOEM may require some or all of these measures as conditions of approval for activities proposed by lessees in Construction and Operations Plans (COPs) submitted for the six NY Bight lease areas. BOEM may require additional or different measures based on future, site-specific NEPA analysis or the parameters of specific COPs. BOEM may also modify the measures at the COP-specific NEPA stage to tailor them to the characteristics of the proposed project and the site(s) of proposed activities, and to ensure conformity with project-specific consultations and authorizations. Project-specific National Environmental Policy Act (NEPA) analyses for individual COPs in the NY Bight lease areas could tier from or incorporate by reference this PEIS, in accordance with 40 Code of Federal Regulations (CFR) 1501.11-12. The project-specific NEPA analyses and consultations for each NY Bight lease area will focus on the impacts of approving a particular COP, including identification of additional AMMM measures that are best suited for consideration in the COP-specific NEPA analysis.

This appendix provides clarification on how BOEM anticipates using this PEIS to provide for greater efficiency and reduce duplication of analyses in complying with NEPA requirements for future, COP-specific NEPA analyses. The information in this appendix is organized by resource topic in a tabular format. For each resource topic, an overview of the affected environment, impact analysis, and AMMM measures in the PEIS is provided. For each of these components of the analysis, this appendix also provides recommendations for information from the PEIS that could be incorporated by reference into the future COP-specific NEPA analyses and identifies general information about additional analysis that BOEM anticipates would need to be performed as part of the COP-specific NEPA analysis once detailed and site-specific project information is available. BOEM may determine additional analysis is needed during the COP-specific NEPA process.

Table C-1. PEIS and COP-specific NEPA tiering guidance

PEIS Section	Overview of Programmatic EIS Content	Additional Analysis for COP-Specific NEPA Analysis
Section 3.4.1, Air Quality and Greenhouse Gas Emissions	**Affected Environment.** Provides a discussion of the geographic analysis area, National Ambient Air Quality Standards (NAAQS), and attainment status of the area. PEIS Appendix B, *Supplemental Information and Additional Figures and Tables*, provides metocean and climate information and trends.	**Affected Environment.** The COP-specific NEPA analysis can incorporate by reference the relevant affected environment characterization in the PEIS. While it is anticipated that the geographic analysis area of a specific NY Bight lease area would be a subset of the geographic analysis area in the PEIS, additional characterization may be necessary if this is not the case. Additional characterizations of air quality in localized areas around onshore facilities will be warranted in the COP-specific NEPA analysis to the extent community-level air quality data are available.
	Impact Analysis. Provides quantitative analysis of project emissions, avoided health effects, social cost of greenhouse gases (GHGs), and a qualitative assessment of expected air quality/GHG impacts, based on generic or representative assumptions, for a highest-emissions scenario in accordance with the representative project design envelope (RPDE).	**Impact Analysis.** The COP-specific NEPA analysis can incorporate by reference the impact analysis in the PEIS. The COP-specific NEPA analysis should focus on what is unique about the project and how emissions and the locations of air quality impacts would differ from the PEIS. In addition, the COP-specific NEPA analysis should include quantitative modeling (dispersion and photochemical as applicable) to estimate ambient concentrations of criteria pollutants for comparison to the NAAQS and to assess impacts on Air Quality-Related Values. This modeling may be coordinated with the modeling required for the U.S. Environmental Protection Agency (USEPA) Outer Continental Shelf (OCS) air quality permit but should include all project emissions sources (not just those required for the permit). Air quality assessment for communities with environmental justice concerns affected by the project may also be appropriate.
	AMMM Measures. BOEM has not identified any AMMM measures for air quality**.**	**AMMM Measures.** The COP-specific NEPA analysis may include other project-specific measures to reduce impacts on air quality and greenhouse gas emissions, including a technical feasibility analysis of air quality Recommended Practices.
Section 3.4.2, Water Quality	**Affected Environment.** Provides a regional overview of the current water quality conditions within the geographic analysis area. Data are gathered from publicly available information such as the USEPA Coastal Condition Assessments and World Ocean Database, BOEM NEPA documents and environmental studies, scientific papers, and other COPs (e.g., sediment transport modeling from Empire Wind (OCS-A 0512)).	**Affected Environment.** The COP-specific NEPA analysis can incorporate by reference the water quality affected environment characterization in the PEIS for the offshore project area only. For the onshore project area, the COP-specific NEPA analysis will need to characterize water quality specifically in all areas where onshore components could be sited, including the cable landfall(s), onshore export cable routes, points of interconnection (POI), substations, operations and maintenance (O&M) facilities, ports, above ground transmission lines, or any other infrastructure proposed in the onshore environment that will support the project. The information should include a description of the water quality conditions in the onshore project area. At a minimum, the data from the state Section 305(b) Water Quality Reports and Section 303(d) List of Impaired/Total Maximum Daily Load (TMDL) Waters should be included.
	Impact Analysis. Provides qualitative analysis of impacts on overall water quality by impact producing factor (IPF) (e.g.,	**Impact Analysis.** The COP-specific NEPA analysis can incorporate by reference the qualitative impact analysis in the PEIS for the offshore project area; however

PEIS Section	Overview of Programmatic EIS Content	Additional Analysis for COP-Specific NEPA Analysis
	accidental releases, cable emplacement and presence of structures and discharges) based on the RPDE.	additional analysis such as sediment transport modeling associated with cable emplacement would be required to fully characterize the water quality impacts along the offshore export cable routes. In the onshore project area, the COP-specific NEPA analysis can incorporate by reference the general impacts on water quality associated with the IPFs. However, quantitative information is needed to address potential impacts associated with crossings of wetlands and waterbodies. This information would allow BOEM to provide a more accurate impact conclusion than that in the PEIS.
	AMMM Measures. Includes reducing potential for release of metal contaminants; submittal of oil spill response plan; submittal and approval of an anchoring plan to reduce or avoid impacts from turbidity and anchor placement; and training, recovery, prevention, and reporting to reduce and eliminate trash and debris.	**AMMM Measures.** The COP-specific NEPA analysis would include the recommended water quality AMMM measures specific to the IPFs. It would be expected that issuance of the Section 401 Water Quality Certificate from the state would include permit conditions including specific measures to avoid and minimize potential water quality impacts.
Section 3.5.1, Bats	**Affected Environment.** In the offshore environment, existing literature, and acoustic studies are used to describe bat species in the geographic analysis area. Bat information specific to the NY Bight lease areas is based on two New York State Energy Research and Development Authority (NYSERDA) meteorological buoys deployed in two of the NY Bight lease areas, as well as bat surveys conducted at nearby lease areas (e.g., Ocean Wind 1 (OCS-A 0498), Atlantic Shores South (OCS-A 0499), Empire Wind (OCS-A 0512)). Bat presence in the coastal onshore environment is primarily based on bat ranges that overlap with the coastal areas of New Jersey and New York.	**Affected Environment.** The COP-specific NEPA analysis can incorporate by reference the bats affected environment characterization in the PEIS for the offshore environment only. For the onshore environment, the COP-specific NEPA analysis will need to characterize habitats specifically in all areas where onshore components could be sited, including the offshore export cable landing(s), onshore export cable routes, POIs, substations, O&M facilities, ports, above ground transmission lines, or any other infrastructure proposed in the onshore environment that will support the project. The information should include a description of the forest habitat and acreage in the onshore project study area. At a minimum, an on-the-ground reconnaissance level field survey is recommended in order to map forest habitat at the onshore project components, including along all onshore export cable routes.
	Impact Analysis. In the offshore environment, the impact analysis is qualitative for the IPFs assessed. However, because current information on bat abundance/presence in the offshore environment indicates that bat presence is low, BOEM anticipates the exposure to any of the IPFs in the offshore environment to also be low, and, therefore, impacts on bats in the offshore environment are not anticipated to have any notable effect on bat populations. In the onshore environment, the impact assessment is qualitative and largely focuses on the land disturbance IPF. Because the types and locations of onshore project components are not known, there could be a range of impacts that are dependent upon the type and amount of habitat that could be	**Impact Analysis.** The COP-specific NEPA analysis can incorporate by reference the qualitative impact analysis in the PEIS for the offshore environment. Because current information indicates low bat presence in the offshore environment, offshore development for the NY Bight lease areas would not be likely to have different impacts than those described in the PEIS. In the onshore environment, the COP-specific NEPA analysis can incorporate by reference the noise and presence of structures IPFs. However, quantitative information is needed to address potential impacts on bat habitat (forest areas). Ideally, the habitat areas mapped for the Affected Environment (see above) along with the potential locations of all onshore project components, would allow for a quantitative assessment of forest impacts. Forest impacts should also differentiate between permanent (complete removal or conversion) and temporary impacts, as well as potential tree trimming. This information would

PEIS Section	Overview of Programmatic EIS Content	Additional Analysis for COP-Specific NEPA Analysis
	removed (forest habitat is of primary concern for bats). While BOEM anticipates that bat habitat impacts in the onshore environment would be minimal due to likely siting of project components in already disturbed areas (based on recent wind projects BOEM is reviewing), it is still possible that areas of forested habitat would be altered or removed. Therefore, BOEM cannot rule out more substantial bat habitat impacts without project-specific information.	allow BOEM to provide a more accurate impact conclusion than that in the PEIS, which currently states a range due to the fact that this forest impact is unknown.
	AMMM Measures. Includes post-construction monitoring and injured or dead bat reporting.	**AMMM Measures.** The COP-specific NEPA analysis would include the recommended bats AMMM measures specific to the IPFs.
Section 3.5.2, Benthic Resources	**Affected Environment.** Provides a regional overview of the benthic resources present within the geographic analysis area. Data are gathered from publicly available information such as the Northeast Ocean Data Portal, the U.S. Geological Survey's (USGS's) SEABED database, seabed topography, habitat mapping, BOEM NEPA documents and environmental studies, scientific papers, and other COPs.	**Affected Environment.** The COP-specific NEPA analysis can incorporate by reference the benthic resources affected environment characterization in the PEIS. However, the COP-specific NEPA will need to characterize the specific benthic resources and habitats within the lease area (including along interarray cable routes) and along the offshore export cable routes, including acquiring benthic grab sampling and seafloor imagery consistent with BOEM's Benthic Habitat Survey Information Guidelines. This benthic information combined with multibeam and side scan sonar data would allow for accurate mapping and characterization of sediment types, benthic communities, and habitat types within the project area. These surveys could also include characterization and delineation of any submerged aquatic vegetation suspected to occur within nearshore and inshore project areas within export cable routes.
	Impact Analysis. Provides qualitative discussion of the typical types of impacts on benthic habitat from offshore wind developed based on the RPDE.	**Impact Analysis.** The COP-specific NEPA analysis can incorporate by reference the qualitative impact analysis in the PEIS. The COP-specific NEPA analysis would need to include a quantitative impact analysis that includes the calculation of benthic habitats (acres) disturbed by each of the offshore activities associated by relevant IPFs (e.g., anchoring, cable emplacement, and presence of structures) associated with the offshore project area as well as any other project-specific analysis and modeling done (e.g., sediment transport modeling, electromagnetic fields emissions).
	AMMM Measures. Includes avoidance of boulders and minimization of boulder relocation distance to reduce alteration of the seabed; development and implementation of a Fisheries and Benthic Habitat Monitoring Plan; reduction and elimination of marine debris; submittal and approval of an anchoring plan to reduce or avoid impacts from turbidity and anchor placement; berm restoration to match natural contours; use of specific cable protection measures within complex hardbottom habitat	**AMMM Measures.** The COP-specific NEPA analysis would include the recommended benthic resource AMMM measures specific to the project location.

PEIS Section	Overview of Programmatic EIS Content	Additional Analysis for COP-Specific NEPA Analysis
	to reduce impacts from cable emplacement on benthic resources; vessel anchoring and benthic sampling restrictions; cable and scour protection monitoring; soft start techniques during impact pile driving; and post-storm event monitoring.	
Section 3.5.3, Birds	**Affected Environment.** In the offshore environment, existing literature, modeling, and tracking information is used to describe bird species, abundance, and populations in the geographic analysis area. Bird information specific to the NY Bight lease areas is based on NYSERDA aerial digital surveys conducted between 2018 and 2019, and two NYSERDA meteorological buoys deployed in two of the NY Bight lease areas. Bird descriptions in the coastal onshore environment are very high level with little information on specific species or abundance due to unknown location of onshore project elements.	**Affected Environment.** The COP-specific NEPA analysis can incorporate by reference the bird affected environment characterization in the PEIS for the offshore environment only. For the onshore environment, the COP-specific NEPA analysis will need to characterize habitats specifically in all areas where onshore components could be sited, including the offshore export cable landing(s), onshore export cable routes, POIs, substations, O&M facilities, ports, above ground transmission lines, or any other infrastructure proposed in the onshore environment that will support the project. The information should include a description of the habitat types and amounts (e.g., acreages) in the onshore project study area, as well as identifying and describing any special habitat areas that are important to birds (e.g., sandy/dune beaches). At a minimum, an on-the-ground reconnaissance level field survey is recommended in order to map habitat types at the onshore project components, including along all onshore export cable routes.
	Impact Analysis. In the offshore environment, the impact analysis is largely qualitative for the IPFs assessed. The presence of structures IPF analysis does provide a conservative estimate of bird strike mortalities based on onshore wind farm data (where bird numbers are much higher). However, because current information shows bird abundance in the offshore environment to be low, BOEM anticipates the exposure to any of the IPFs in the offshore environment to also be low, and, therefore, impacts on birds in the offshore environment are not anticipated to have any notable effect on bird populations. In the onshore environment, the impact assessment is qualitative and largely focuses on the land disturbance IPF. Because the types and locations of onshore project components are not known, there could be a range of impacts that are dependent upon the type and amount of habitat that could be altered or removed. While BOEM anticipates that bird habitat impacts in the onshore environment would be minimal due to likely siting of project components in already disturbed areas (based on recent wind projects BOEM is reviewing), it is still possible that areas of higher quality habitat (e.g., forest) would be altered or removed. Therefore, BOEM cannot rule out more	**Impact Analysis.** The COP-specific NEPA analysis can incorporate by reference the qualitative impact analysis in the PEIS for the offshore environment. Because current information indicates low bird presence in the offshore environment, offshore development for the NY Bight lease areas would not be likely to have different impacts than those described in the PEIS. For the presence of structures IPF, an estimate of bird mortality can be calculated with the number of wind turbine generators (WTGs) that are proposed for a specific lease area, but it will likely not change the ultimate impact assessment. In the onshore environment, the COP-specific NEPA analysis can incorporate by reference some of the qualitative impact analyses (e.g., noise, traffic [aircraft]). However, quantitative information is needed to address potential impacts to bird habitat (e.g., forest areas, sand/dune beach). Ideally, the habitat areas mapped for the Affected Environment (see above) along with the potential locations of all onshore project components, would allow for a quantitative assessment of habitat impacts. Habitat impacts should also differentiate between permanent (complete removal or conversion) and temporary impacts (e.g., cable placed in herbaceous areas that would regrow). This information would allow BOEM to provide a more accurate impact conclusion than that in the PEIS, which currently states a range due to the fact that this impact is unknown.

PEIS Section	Overview of Programmatic EIS Content	Additional Analysis for COP-Specific NEPA Analysis
	substantial bird habitat impacts without project-specific information.	
	AMMM Measures. Includes post-construction monitoring, dead or injured bird reporting, bird perching deterrents, measures to minimize light, and compensatory mitigation for Endangered Species Act (ESA) listed birds.	**AMMM Measures.** The COP-specific NEPA analysis would include the recommended bird AMMM measures specific to the project location. For example, the lessees could provide specific information on what equipment and technology would be used to limit and reduce light impacts.
Section 3.5.4, Coastal Habitat and Fauna	**Affected Environment.** Provides a regional overview of the coastal habitat and fauna present within the geographic analysis area. Data are gathered from publicly available information such as BOEM NEPA documents and environmental studies, scientific papers, and other COPs.	**Affected Environment.** Because the description of coastal habitat and fauna in the PEIS is regional, the COP-specific NEPA analysis will need to characterize specific coastal habitat and fauna within the onshore project areas based upon the location of onshore components. This characterization could include reconnaissance-level habitat and species surveys at the cable landfalls, onshore export cable routes, onshore substations, and POIs. Targeted habitat and species surveys would allow for accurate identification of beach nesting birds and sea turtles as well as ESA flowering plants within coastal habitats.
	Impact Analysis. Provides qualitative analysis of impacts on overall coastal habitat and fauna by IPF (e.g., accidental releases, noise, land disturbance, and traffic) based on the RPDE.	**Impact Analysis.** The COP-specific NEPA analysis can incorporate by reference some of the qualitative impact analysis about the typical impacts from offshore wind development, and discuss any differences based upon project-specific details. However, because the analysis in the PEIS is regional, a more focused project-specific analysis will be needed based on the specific habitat types and flora and fauna present in the project area. The COP-specific NEPA analysis would need to include a quantitative impact analysis that includes the calculation of coastal areas (acres) disturbed by each of the onshore activities associated by relevant IPFs (e.g., cable emplacement and land disturbance). Ideally, the habitat areas mapped for the Affected Environment (see above) along with the potential locations of all onshore project components, would allow for a quantitative assessment of habitat impacts.
	AMMM Measures. BOEM has not identified any AMMM measures for coastal habitat and fauna**.**	**AMMM Measures.** The COP-specific NEPA analysis may include other project-specific measures to reduce impacts on coastal habitat and fauna.
Section 3.5.5, Finfish, Invertebrates, and Essential Fish Habitat	**Affected Environment.** Provides a regional overview of the finfish, invertebrates, and essential fish habitat (EFH) present within the geographic analysis area. Data are gathered from publicly available information such as the Marine Cadastre, Northeast Ocean Data Portal, National Oceanic and Atmospheric Administration (NOAA) Essential Fish Habitat Mapper, BOEM NEPA documents and environmental studies, scientific papers, and other COPs.	**Affected Environment.** The COP-specific NEPA analysis can incorporate by reference the finfish, invertebrates, and EFH affected environment characterization in the PEIS. However, the COP-specific NEPA analysis will need to characterize finfish, invertebrates, and EFH within the project lease area (including along interarray cable routes) and along the offshore export cable routes, including acquiring benthic grab sampling and seafloor imagery consistent with BOEM's Benthic Habitat Survey Information Guidelines. This benthic information combined with multibeam, and side scan sonar data would allow for accurate mapping and characterization of fish habitat types within the project area. In addition, any information on finfish from otter trawl surveys, gillnet or trammel net surveys, beam trawl surveys, fixed gear surveys with

PEIS Section	Overview of Programmatic EIS Content	Additional Analysis for COP-Specific NEPA Analysis
		ventless traps, and shellfish surveys can inform this resource within the project area.
	Impact Analysis. Provides qualitative analysis of impacts on finfish, invertebrates, and EFH by IPF (e.g., cable emplacement, EMF, noise, and presence of structures) based on the RPDE.	**Impact Analysis.** The COP-specific NEPA analysis can incorporate by reference the qualitative impact analysis in the PEIS and discuss any differences based upon project-specific details. The COP-specific NEPA analysis would need to include a quantitative impact analysis that includes the calculation of finfish, invertebrates, and EFH (acres) disturbed by each of the offshore activities associated by relevant IPFs (e.g., anchoring, cable emplacement, and presence of structures).
	AMMM Measures. Includes avoidance of boulders and minimization of boulder relocation distance to reduce alteration of the seabed; implementation of measures to minimize noise impacts; submittal and approval of an anchoring plan to reduce or avoid impacts from turbidity and anchor placement; restoring berms to match natural contours; incorporation of ecological design elements where practicable; monitoring of cables after installation; and implementation of post-storm event monitoring.	**AMMM Measures.** The COP-specific NEPA analysis would include the recommended finfish, invertebrates, and EFH AMMM measures specific to the project.
Section 3.5.6, Marine Mammals	**Affected Environment.** Provides a regional overview of the marine mammals present within the geographic analysis area. Data are gathered from publicly available information such as the Marine Cadastre, Northeast Ocean Data Portal, NMFS stock assessment reports, Atlantic Marine Assessment Program for Protected Species (AMAPPS), habitat-based density models, regional digital aerial baseline marine wildlife surveys, BOEM NEPA documents and environmental studies, scientific papers, and other COPs.	**Affected Environment.** The COP-specific NEPA analysis can incorporate by reference the regional marine mammal affected environment characterization in the PEIS. However, the COP-specific NEPA analysis will need to characterize the occurrence of marine mammals within the lease area and along the offshore export cable routes, including implementing surveys consistent with BOEM's Marine Mammals and Sea Turtles Information Guidelines. These surveys could include seasonal vessel-based and aerial surveys for determining spatial temporal distribution and abundance of marine mammal species and Passive Acoustic Monitoring (PAM) to gather ambient sound and presence of vocalizing marine mammals.
	Impact Analysis. Provides qualitative analysis of impacts on marine mammals by IPF (e.g., noise, presence of structures, and traffic) based on the RPDE.	**Impact Analysis.** The COP-specific NEPA analysis would need to include a qualitative and quantitative impact analysis that includes the specific characterization of the intensity, geographic extent, frequency, and likelihood of impacts on marine mammals associated with each of the offshore activities associated by relevant IPFs (e.g., noise, presence of structures, and traffic). This impact analysis for marine mammals would include results from underwater acoustic modeling from proposed activities (e.g., pile-driving, unexploded ordnance [UXO], surveys) and from using BOEM's Risk Assessment to Model Encounter Rates Between Large Whales and Sea Turtles and Vessel Traffic from Offshore Wind Energy on the Atlantic OCS.
	AMMM Measures. Includes implementation of a long-term PAM monitoring system to reduce the risk of vessel strike and	**AMMM Measures.** The COP-specific NEPA analysis would include the recommended marine mammal AMMM measures specific to the IPFs. It would

PEIS Section	Overview of Programmatic EIS Content	Additional Analysis for COP-Specific NEPA Analysis
	impacts from project activities (e.g., pile-driving); submittal and approval of Reduced Visibility Monitoring Plan (RVMP)/ Nighttime Pile Driving Monitoring Plan; protected species observer (PSO) requirements; measures to limit temporal and spatial extent of noise exposure; real-time and near-real-time monitoring to inform adaptive mitigation measures; trainings; collection of baseline information used to better anticipate potential impacts and further mitigate effects on marine mammals in the future; seasonal vessel speed requirements; measures to reduce marine debris and impacts from entanglement, ingestion, and pollutants; post-storm event monitoring; and reporting of potential takes of protected species.	be expected that issuance of the Incidental Harassment Authorizations or Letter of Authorizations for construction activities from NMFS would include permit conditions, including specific measures to avoid and minimize potential marine mammal impacts.
Section 3.5.7, Sea Turtles	**Affected Environment.** Provides a regional overview of the sea turtles present within the geographic analysis area. Data are gathered from publicly available information such as the Marine Cadastre, Northeast Ocean Data Portal, NMFS stock assessment reports, AMAPPS, habitat-based density models, regional digital aerial baseline marine wildlife surveys, BOEM NEPA documents and environmental studies, scientific papers, and other COPs.	**Affected Environment.** The COP-specific NEPA analysis can incorporate by reference the regional sea turtle affected environment characterization in the PEIS. However, the COP-specific NEPA analysis will need to characterize the occurrence of sea turtles within the lease area and along the offshore export cable routes, including implementing surveys consistent with BOEM's Marine Mammals and Sea Turtles Information Guidelines. These surveys could include seasonal vessel-based and aerial surveys for determining spatial temporal distribution and abundance of sea turtle species. Targeted habitat and species surveys would allow for accurate identification of nesting sea turtles, if any, suspected to occur along the offshore export cable routes and at landfall sites.
	Impact Analysis. Provides qualitative analysis of impacts on sea turtles by IPF (e.g., noise, presence of structures, and traffic) based on the RPDE.	**Impact Analysis.** The COP-specific NEPA analysis would need to include a quantitative and qualitative impact analysis that includes the specific characterization of the intensity, geographic extent, frequency, and likelihood of impacts on sea turtles associated with each of the offshore activities associated by relevant IPFs (e.g., noise, presence of structures, and traffic). This impact analysis for sea turtles would include results from underwater acoustic modeling from proposed activities (e.g., pile-driving, UXO, surveys) and from using BOEM's Risk Assessment to Model Encounter Rates Between Large Whales and Sea Turtles and Vessel Traffic from Offshore Wind Energy on the Atlantic OCS.
	AMMM Measures. Includes submittal and approval of pile-driving monitoring plans; PSO requirements; measures to minimize vessel noise; measures to limit temporal and spatial extent of noise exposure; real-time and near–real-time monitoring to inform adaptive mitigation measures; trainings; collection of baseline information used to better anticipate potential impacts and further mitigate effects on sea turtles in	**AMMM Measures.** The COP-specific NEPA analysis would include the recommended sea turtle AMMM measures specific to the IPFs.

PEIS Section	Overview of Programmatic EIS Content	Additional Analysis for COP-Specific NEPA Analysis
	the future; seasonal vessel speed requirements; measures to reduce marine debris and impacts from entanglement, ingestion, and pollutants; post-storm event monitoring; and reporting of potential takes of protected species.	
Section 3.5.8, Wetlands	**Affected Environment.** Wetlands in the geographic analysis area (which is limited to the onshore environment) are described using publicly available New Jersey and New York state wetland geographic information system (GIS) layers, as well as the National Wetlands Inventory (NWI). The geographic analysis area in the PEIS is much larger than the geographic analysis area of a specific NY Bight lease area.	**Affected Environment.** The COP-specific NEPA analysis will need to characterize wetlands specifically in all areas where onshore components could be sited, including the offshore export cable landing(s), onshore export cable routes, POIs, substations, O&M facilities, ports, or any other infrastructure proposed in the onshore environment that will support the project. The information should include a description of the wetland types and acreages in the onshore project study area, as well as information on the functions the wetlands may provide. At a minimum, an on-the-ground reconnaissance level field survey should be conducted in order to map all wetlands at the onshore project components, including along all onshore export cable routes. A wetland delineation would need to be conducted per the U.S. Army Corps of Engineers' wetland delineation manual where access can be obtained.
	Impact Analysis. The wetland impact assessment is qualitative and largely focuses on the land disturbance IPF. Because the types and locations of onshore project components are not known, there could be a range of wetland impacts that are dependent upon the type and amount of wetland that could be affected. While BOEM anticipates that wetland impacts would be minimal due to likely siting of project components in already disturbed areas (based on recent wind projects BOEM is reviewing), it is still possible that wetlands would be temporarily or permanently altered, or permanently filled. Therefore, BOEM cannot rule out more substantial wetland impacts without project-specific information.	**Impact Analysis.** The COP-specific NEPA analysis can incorporate by reference the accidental releases IPF and the applicable qualitative analysis in the land disturbance IPF. However, quantitative information is needed to address potential impacts on wetlands. Ideally, the wetlands mapped for the Affected Environment (see above) along with the potential locations of all onshore project components would allow for a quantitative assessment of wetland impacts. The quantitative wetland impact analysis should also differentiate between permanent (wetland filling or conversion) and temporary impacts. This information would allow BOEM to provide a more accurate impact conclusion than that in the PEIS, which currently states a range due to the unknown locations of onshore project components and wetlands.
	AMMM Measures. No AMMM measures specific to wetlands are included in the PEIS.	**AMMM Measures.** The COP-specific NEPA analysis may include other project-specific measures to reduce impacts on wetlands.
Section 3.6.1, Commercial Fisheries and For-Hire Recreational Fishing	**Affected Environment.** Provides a regional overview of the commercial fisheries and for-hire recreational fishing within the geographic analysis area. Data are gathered from publicly available information such as the Marine Cadastre, Northeast Ocean Data Portal, NMFS Commercial Fisheries Landings Statistics, NMFS Descriptions of Selected Fishery Landings and Estimates of Vessel Revenue from Areas, NMFS Landing and Revenue Data for Wind Energy Areas, NMFS Recreational	**Affected Environment.** The COP-specific NEPA analysis can incorporate by reference the commercial fisheries and for-hire recreational fishing affected environment characterization in the PEIS. However, the COP-specific NEPA analysis will need to characterize commercial fisheries and for-hire recreational fishing within each lease area (including along interarray cable routes) and along the offshore export cable routes, including acquiring fishery information consistent with BOEM's Fishery Information Guidelines. This could include data from otter trawl surveys, gillnet or trammel net surveys, beam trawl surveys, fixed gear surveys with ventless traps, and shellfish surveys.

PEIS Section	Overview of Programmatic EIS Content	Additional Analysis for COP-Specific NEPA Analysis
	Fisheries Statistics Queries, BOEM NEPA documents and environmental studies, scientific papers, and other COPs.	
	Impact Analysis. Provides qualitative analysis of resource and socioeconomic impacts on commercial fisheries and for-hire recreational fishing by IPF (e.g., cable emplacement, EMF, noise, and presence of structures) based on the RPDE.	**Impact Analysis.** The COP-specific NEPA analysis would need to include a qualitative impact analysis that incorporates the characterization of impacts on commercial fisheries and for-hire recreational fishing associated with each of the offshore activities by relevant IPFs (e.g., cable emplacement, EMF, noise, and presence of structures). This impact analysis for commercial fisheries and for-hire recreational fishing would include the socioeconomic effects on fishing vessel maneuverability, reduction in fishing activities and fishing revenue, entanglement and damage or loss of commercial and recreational fishing gear, and an estimate of the amount of commercial fishing revenue that would be "exposed."
	AMMM Measures. Includes avoidance of boulders and minimization of boulder relocation distance to reduce alteration of the seabed; implementation of a Scour and Cable Protection Plan; execution of a Fisheries and Benthic Habitat Monitoring Plan that includes shellfish, such as surfclam and scallop; compensation to commercial and for-hire recreational fishermen for gear loss and loss of income due to unrecovered economic activity; compensation to shoreside businesses for losses indirectly related to the expected development; and post-storm event monitoring.	**AMMM Measures.** The COP-specific NEPA analysis would include the recommended commercial fisheries and for-hire recreational fishing AMMM measures specific to the IPFs.
Section 3.6.2, Cultural Resources	**Affected Environment.** Provides a regional overview of the cultural context and resource types in the geographic analysis area and any knowable, individual historic properties identified in a Programmatic Area of Potential Effects (APE) developed for National Historic Preservation Act (NHPA) reviews of the six NY Bight lease areas. Data are gathered from the 2021 NY Bight Environmental Assessment and NY Bight *NHPA Section 106 Summary* (Appendix I).	**Affected Environment.** The COP-specific NEPA and NHPA analysis will need to identify and characterize cultural contexts, cultural resource types, and specific historic properties in a project-specific geographic analysis area and APE. This includes completion of associated cultural resource and historic property identification efforts per BOEM guidelines. Identification of cultural resources and historic properties would allow for accurate impact analysis and development and implementation of AMMM measures.
	Impact Analysis. Provides qualitative analysis of impacts on cultural resources overall by IPF (i.e., accidental releases, anchoring, cable emplacement and maintenance, survey gear utilization, land disturbance, lighting, and presence of structures) based on the RPDE. Qualitative analysis is supported by limited quantitative data derived from BOEM's background research on the affected environment.	**Impact Analysis.** The COP-specific NEPA and NHPA analysis would need to include both a qualitative and quantitative analysis of impacts on the specific cultural resources and historic properties identified in the project-specific geographic analysis area and APE. Impact analysis would involve NHPA consultations with State Historic Preservation Officers (SHPOs), federally recognized Tribes, lessees, and other identified consulting parties to sufficiently assess effects on historic properties identified in a COP-specific APE. Identification of and assessments of effects on historic properties are required to develop and implement AMMM measures.

PEIS Section	Overview of Programmatic EIS Content	Additional Analysis for COP-Specific NEPA Analysis
	AMMM Measures. Includes requirements to establish and comply with marine cultural resource avoidance buffers, implement monitoring and post-review discovery plans for marine and terrestrial resources, and avoid terrestrial archaeological resources.	**AMMM Measures.** The COP-specific NEPA and NHPA analysis would include AMMM measures to avoid, reduce, or resolve adverse effects on historic properties as agreed upon by federally recognized Tribes, Advisory Council on Historic Preservation (ACHP), SHPOs, lessees, and other consulting parties. The AMMM measures may include those identified in the PEIS and additional measures identified during the COP-specific NEPA and NHPA process.
Section 3.6.3, Demographics, Employment, and Economics	**Affected Environment.** Provides a county-level overview of population, housing and employment data from the U.S. Census Bureau and NOAA.	**Affected Environment.** The COP-specific NEPA analysis can incorporate by reference the relevant affected environment characterization in the PEIS. While it is anticipated that the geographic analysis area of a specific NY Bight lease area would be a subset of the geographic analysis area in the PEIS, additional county-level characterization may be necessary if this is not the case. Additionally, depending on the timing of the COP-specific NEPA document, it may be warranted to provide more recent data than what is provided in the PEIS. More detailed community-level characterizations of populations with the potential to be affected by specific landings or cable routes, POIs, O&M facilities, or port utilization will be warranted in the COP-specific NEPA analysis.
	Impact Analysis. Provides qualitative analysis of impacts and benefits of development of offshore wind projects on populations, employment, and the economy based on the RPDE.	**Impact Analysis.** The COP-specific NEPA analysis can incorporate by reference the qualitative impact analysis in the PEIS. This analysis should focus on what is unique about the project and how it is different from what is discussed in the PEIS. Additionally, an economic analysis using quantitative modeling is warranted to support the COP-specific NEPA analysis. This analysis would provide: • Estimates of direct, indirect, induced jobs by project phase during construction and operations. • Estimates of economic benefits (Gross Domestic Product) generated by project phase during construction and operations. • Estimate of local expenditures during construction and operations. • Estimates of economic benefits associated with tax revenue (local, state, and federal) during construction.
	AMMM Measures. No AMMM measures specific to demographics, employment, and economics are included in the PEIS.	**AMMM Measures.** The COP-specific NEPA analysis may include other project-specific measures to reduce impacts on demographics, employment, and economics. If applicable, the analysis should provide descriptions of any local commitments or investments in workforce training and development to support the offshore wind industry.
Section 3.6.4, Environmental Justice	**Affected Environment.** Provides a county-level overview of low-income and minority populations in the geographic analysis area based on data from the U.S. Census Bureau. Provides county-level mapping of the commercial and recreational fishing engagement or reliance of coastal communities based on	**Affected Environment.** The COP-specific NEPA analysis can incorporate by reference the relevant affected environment characterization in the PEIS. While it is anticipated that the geographic analysis area of a specific NY Bight lease area would be a subset of the geographic analysis area in the PEIS, additional county-level characterization may be necessary if this is not the case. Additionally,

PEIS Section	Overview of Programmatic EIS Content	Additional Analysis for COP-Specific NEPA Analysis
	NOAA's social indicator tool and provides a description of the social stressors experienced by low-income or minority populations in coastal communities. Identifies tribal communities within the geographic analysis area.	depending on the timing of the COP-specific NEPA document, it may be warranted to provide more recent data than what is provided in the PEIS. More detailed community-level characterizations of low-income and minority populations with the potential to be affected by specific landings or cable routes, POIs, O&M facilities, or port utilization will be necessary for the COP-specific NEPA analysis.
	Impact Analysis. Provides qualitative analysis of impacts and benefits of development of offshore wind projects on populations with environmental justice concerns based on the RPDE.	**Impact Analysis.** The COP-specific NEPA analysis can incorporate by reference the qualitative impact analysis in the PEIS. The analysis should focus on what is unique about the project and how it is different from what is discussed in the PEIS. Site-specific analysis of the project impacts on populations with environmental justice concerns in areas surrounding ports, cable landings, substations, onshore construction, O&M facilities, or any other infrastructure proposed in the onshore environment that will support the project will be necessary for the COP-specific NEPA analysis. For example, potential changes in vehicle traffic near selected ports will need to be analyzed in the COP-specific NEPA analysis. The analysis will incorporate more detailed impact analyses by resource topic (e.g., project-level air quality assessments for populations with environmental justice concerns affected by the project). The COP-specific NEPA analysis will analyze and provide a determination as to whether the project has disproportionately high and adverse human health or environmental effects on low-income and minority populations when compared to the project's effect on the overall population.
	AMMM Measures. Includes the creation and reporting of an environmental justice communications plan for lessees to communicate with communities with environmental justice concerns during activities described in the COP, including construction, operations, and decommissioning	**AMMM Measures.** The COP-specific NEPA analysis may include other project-specific measures to reduce impacts on communities with environmental justice concerns.
Section 3.6.5, Land Use and Coastal Infrastructure	**Affected Environment.** Provides a regional overview of the potentially affected onshore areas, the areas where representative ports are located, and the areas closest to the NY Bight lease areas that may be affected by construction and O&M.	**Affected Environment.** Site-specific level characterizations of land use and coastal infrastructure (e.g., zoning, county/municipal-level plans) in areas surrounding ports, cable landings, substations, onshore construction, O&M facilities, or any other infrastructure proposed in the onshore environment that will support the project will be warranted with COP-specific NEPA analysis.
	Impact Analysis. Provides a qualitative analysis of the typical impacts and benefits associated with onshore development of offshore wind projects on land use and coastal infrastructure such as port improvement and expansion, vehicle traffic, and visibility of offshore structures. Because the location of onshore infrastructure is not yet known, the analysis is general and not location specific.	**Impact Analysis.** Site-specific analysis of project impacts on land use and coastal infrastructure in areas surrounding ports, cable landings, substations, onshore construction, O&M facilities or any other infrastructure proposed in the onshore environment that will support the project will be necessary for the COP-specific NEPA analysis. For example, the analysis will need to describe the specific locations that would be affected, the acreage of disturbance, and consistency with local zoning and other ordinances (e.g., noise requirements).

PEIS Section	Overview of Programmatic EIS Content	Additional Analysis for COP-Specific NEPA Analysis
	AMMM Measures. Includes the creation and reporting of an environmental justice communications plan for lessees to communicate with communities with environmental justice concerns during activities described in the COP, including construction, operations, and decommissioning.	**AMMM Measures.** The COP-specific NEPA analysis may include other project-specific measures to reduce impacts on land use and coastal infrastructure.
3.6.6, Navigation and Vessel Traffic	**Affected Environment.** Provides an overview of the current navigational setting for shipping and other maritime users in the geographic analysis area, including shipping channels, traffic schemes and fairways, and historical vessel traffic volumes within each NY Bight lease area based on 3 years of Automatic Identification System data.	**Affected Environment.** The COP-specific NEPA analysis can incorporate by reference the relevant affected environment characterization in the PEIS. While the geographic analysis area of a specific NY Bight lease would be a subset of the geographic analysis area in the PEIS, additional characterization may be necessary depending on the location of export cable routes and the location of ports to be used by the projects. Information from the COP-specific Navigation Safety Risk Assessment (NSRA) would be used to supplement the information in the PEIS related to vessel traffic and safety (e.g., search and rescue incident data, accident frequency data). The NSRA should include Automatic Identification System data and collision/allision risk.
	Impact Analysis. Provides a qualitative analysis of the impacts associated with the development of the NY Bight projects based on the location of the lease areas, including impacts from structures, increased vessel traffic, and cable placement. Analysis uses information from COPs of nearby projects to quantitatively estimate project vessel traffic and projected increases in accident frequencies.	**Impact Analysis.** The COP-specific NEPA analysis can incorporate by reference the qualitative impact analysis in the PEIS. The additional analysis should focus on what is unique about the project and how it is different from what is discussed in the PEIS based on the site-specific location, project details, and the assessment provided in the NSRA in accordance with NVIC 02-2023. The analysis should provide additional discussion regarding the following project-specific details: • Anchoring plans. • NSRA analysis results of the potential increases in accident frequencies. • Cable route locations and construction methods and timing. • Port utilization. • Number of WTG/OSS, spacing/layout, and construction methods and timing. • Project vessel traffic. Additional analysis of cable routes and their proximity to Federal Aids to Navigation would occur at the project-specific level.
	AMMM Measures. Includes boulder relocation reporting and seeking to avoid unfavorable cable placement in Federal Aids to Navigation (ATONs), Private Aids to Navigation (PATONs), anchorage areas, Traffic Separation Schemes (TSSs), and fairways.	**AMMM Measures.** The COP-specific NEPA analysis would include the recommended navigation and vessel traffic AMMM measures specific to the project location. For example, the lessees could provide details regarding avoiding cable placement in unfavorable areas.
3.6.7, Other Uses (Marine Minerals,	**Affected Environment.** Provides an overview of the current marine minerals extraction, national security and military use, aviation and air traffic, cables and pipelines, radar systems, and	**Affected Environment.** The COP-specific NEPA analysis can incorporate by reference the relevant affected environment characterization in the PEIS. While it is anticipated that the geographic analysis area of a specific NY Bight lease area

PEIS Section	Overview of Programmatic EIS Content	Additional Analysis for COP-Specific NEPA Analysis
Military Use, Aviation, Scientific Research and Surveys)	scientific research and surveys in the geographic analysis area. Data are gathered from publicly available information from the Marine Minerals Information System, Mid-Atlantic Regional Council on the Ocean, and Northeast Regional Ocean Council.	would be a subset of the geographic analysis area in the PEIS, additional site-specific characterization may be necessary, especially regarding proposed offshore export cable routes and landfall locations. Site-specific characterization of other uses potentially affected by existing cables, national security and military uses, radar systems, and scientific research and surveys in the vicinity of the geographic analysis area will be warranted with COP-specific NEPA analysis.
	Impact Analysis. Provides an analysis of the impacts associated with the development of offshore wind projects on other uses, including accessibility of marine mineral borrow areas, navigational traffic, and radar interference.	**Impact Analysis.** The COP-specific NEPA analysis can incorporate by reference the impact analysis in the other uses section of the PEIS. This analysis should focus on what is unique about the project and how it is different from what is discussed in the PEIS. For example, the analysis should include a discussion of impacts from cable routes and a quantitative assessment of the potential interference of WTGs with radar systems, national security and military uses, and scientific research and surveys.
	AMMM Measures. Includes mitigation agreements for radar systems, infrastructure removal at decommissioning in marine minerals resource areas, and a survey mitigation agreement between NMFS and the lessee.	**AMMM Measures.** The COP-specific NEPA analysis would include the recommended other uses AMMM measures specific to the project location. If applicable, the lessees should provide descriptions of any planned mitigation to decrease radar interference as a result of coordination with radar operators and avoid or minimize impacts on marine mineral resources.
3.6.8, Recreation and Tourism	**Affected Environment.** Provides a county-level description of recreation and tourism and recreational fishing activities in the geographic analysis area based on data from NOAA and other state and local sources.	**Affected Environment.** The COP-specific NEPA analysis can incorporate by reference the recreation and tourism affected environment characterization in the PEIS. However, the COP-specific NEPA analysis will need to characterize recreation and tourism and recreational fishing within the lease area (including along interarray cable routes), along the offshore export cable routes, and in areas surrounding cable landings, substations, onshore construction, O&M facilities, or any other infrastructure proposed in the onshore environment.
	Impact Analysis. Provides qualitative analysis of impacts and benefits of development of offshore wind projects on recreation and tourism and recreational fishing based on the RPDE.	**Impact Analysis.** The COP-specific NEPA analysis can incorporate by reference the qualitative impact analysis in the PEIS. The analysis should focus on what is unique about the project and how it is different from what is discussed in the PEIS. Site-specific analysis of the project impacts on recreation and tourism and recreational fishing activities in the lease area, along the offshore export cable routes, and in areas surrounding cable landings, substations, onshore construction, O&M facilities, or any other infrastructure proposed in the onshore environment that will support the project will be necessary for the COP-specific NEPA analysis.
	AMMM Measures. Includes a measure to minimize nighttime lighting associated with aviation obstruction lights.	**AMMM Measures.** The COP-specific NEPA analysis would include the recommended recreation and tourism AMMM measures specific to the project location. For example, the lessees could provide specific information on what construction windows, equipment, or technology would be used to limit and reduce light and other impacts.

PEIS Section	Overview of Programmatic EIS Content	Additional Analysis for COP-Specific NEPA Analysis
3.6.9, Scenic and Visual Resources	**Affected Environment.** Provides mapping and descriptions of seascape character area, open ocean character area, and landscape character area and key observation points.	**Affected Environment.** The COP-specific NEPA analysis can incorporate by reference the relevant affected environment characterization in the PEIS for the offshore environment. The COP-specific NEPA analysis would incorporate additional mapping and descriptions of seascape character area, open ocean character area, and landscape character area and key observation points developed specifically for the COP. The COP-specific NEPA analysis would need to provide location-specific characterization of the onshore environment based upon where the proposed landfalls, onshore cable routes, substations, and O&M facilities would be sited.
	Impact Analysis. Provides mapping and descriptions of project viewsheds for each of the six lease areas and for the six lease areas combined and presents impacts on seascape character area, open ocean character area, and landscape character area and key observation points from offshore structures. Impacts from onshore infrastructure are discussed qualitatively and are not location specific.	**Impact Analysis.** The COP-specific NEPA analysis can incorporate by reference the analysis of impacts on seascape character area, open ocean character area, and landscape character area and key observation points by lease area from offshore structures. The analysis should describe how the impacts would differ from those in the PEIS based on different turbine heights and layout and may include project-specific visual simulations. For the onshore environment, the COP-specific NEPA analysis would need to assess impacts on landscape character area and key observation points from onshore facilities, such as substations.
	AMMM Measures. Includes measures to minimize nighttime lighting associated with aviation obstruction lights and a monitoring plan to compare the visual effects of a wind farm to the findings in the COP Visual Impact Assessment.	**AMMM Measures.** The COP-specific NEPA analysis would include the recommended scenic and visual resources AMMM measures specific to the project location.

Appendix D: Planned Activities Scenario

Contents

List of Tables

This page was intentionally left blank.

D.1 Ongoing and Planned Activities Scenario

This appendix describes the other ongoing and planned activities that could occur within the geographic analysis area for each resource and potentially contribute to baseline conditions and trends for resources considered in the Final Programmatic Environmental Impact Statement (PEIS). The baseline conditions and trends described here serve as the basis for analysis of the No Action Alternative and cumulative impacts. The analysis of the action alternatives includes the potential biological, socioeconomic, physical, and cultural impacts that could result from wind energy development activities in the six New York Bight (NY Bight) lease areas, as well as the change in those impacts that could result from implementing avoidance, minimization, mitigation, and monitoring (AMMM) measures for the NY Bight lease areas.

The geographic analysis area varies for each resource as described in the individual resource sections of Chapter 3, *Affected Environment and Environmental Consequences*. Impacts could occur from the start of construction of the NY Bight projects through decommissioning. The Bureau of Ocean Energy Management (BOEM) anticipates that construction of the NY Bight projects would begin between 2026 and 2030. The decommissioning phase is anticipated to be around 35 years after construction is completed. The geographic analysis area is defined by the anticipated geographic extent of impacts for each resource. For the mobile resources—bats, birds, finfish and invertebrates, marine mammals, and sea turtles—the species potentially affected are those that occur within the area of impact of the NY Bight projects. The geographic analysis area for these mobile resources is the general range of the species. The purpose is to capture the cumulative impacts on each of those resources that would be affected by the six NY Bight projects as well as the impacts that would still occur under the No Action Alternative.

In this appendix, distances in miles are in statute miles (miles used in the traditional sense) or nautical miles (miles used specifically for marine navigation). This appendix uses statute miles more commonly and refers to them simply as *miles*, whereas nautical miles (nm) are referred to by name.

D.2 Ongoing and Planned Activities

This section includes a list and description of ongoing and planned activities that could contribute to baseline conditions and trends within the geographic analysis area for each resource topic analyzed in the Final PEIS. Projects or actions that are considered speculative per the definition provided in 43 Code of Federal Regulations (CFR) 46.30[1] are noted in subsequent tables but excluded from the cumulative impact analysis in Chapter 3.

Ongoing and planned activities and environmental stressors described in this section consist of: (1) other offshore wind energy development activities; (2) undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); (3) tidal energy projects; (4) dredging and port improvement projects; (5) marine minerals use and ocean-dredged material disposal; (6) military use; (7) marine transportation; (8) fisheries use, management, and monitoring surveys; (9) global climate change; (10) oil and gas activities; and (11) onshore development activities.

BOEM analyzed the possible extent of other planned offshore wind energy development activities on the Atlantic Outer Continental Shelf (OCS) to determine reasonably foreseeable cumulative effects measured by installed power capacity. Table D2-1 in Attachment D2 represents the status of projects as of August 2024. The methodology for developing the planned activities scenario is the same as for the Vineyard Wind 1 (OCS-A 0501) project and details of the scenario development are described in the Vineyard Wind 1 Final Environmental Impact Statement (EIS) (BOEM 2021a).

D.2.1 Offshore Wind Energy Development Activities

D.2.1.1 Site Characterization Studies

A lessee is required to provide the results of site characterization activities with its site assessment plan (SAP)[2] and Construction and Operations Plan (COP). For the purposes of the cumulative impact analysis, BOEM makes the following assumptions, which represent the maximum-case scenario for survey and sampling activities:

- Site characterization would occur on all existing leases and potential export cable routes.
- Site characterization would likely take place in the first 3 years following execution of a lease, based on the fact that a lessee would likely want to generate data for its COP at the earliest possible opportunity.
- Lessees would likely survey most or all of their lease areas during the 5-year site assessment term to collect required geophysical information for siting of a meteorological tower, two buoys, and

---

[1] 43 CFR 46.30 – Reasonably foreseeable planned actions include those federal and non-federal activities not yet undertaken, but sufficiently likely to occur, that a responsible official of ordinary prudence would take such activities into account in reaching a decision. The federal and non-federal activities that BOEM must take into account in the analysis of cumulative impacts include, but are not limited to, activities for which there are existing decisions, funding, or proposals identified by BOEM. Reasonably foreseeable planned actions do not include those actions that are highly speculative or indefinite.

[2] On May 15, 2024, BOEM issued the final Renewable Energy Modernization Rule (89 *Federal Register* 42602), which among other things eliminated the site assessment plan requirement for met buoys, which are most commonly used for site assessment activities. However, met buoys would continue to require U.S. Army Corps of Engineers (USACE) permits given the USACE's jurisdiction over obstructions deployed in U.S. navigable waters under Section 10 of the Rivers and Harbors Act.

commercial facilities (wind turbines). The surveys may be completed in phases, with the meteorological tower and buoy areas likely to be surveyed first.

- Lessees would not use air guns, which are typically used for deep-penetration, two-dimensional or three-dimensional exploratory seismic surveys to determine the location, extent, and properties of oil and gas resources (BOEM 2016).

Table D-1 describes the typical site characterization surveys, the types of equipment and method used, and which resources the survey information would inform.

Table D-1. Site characterization survey assumptions[1]

Survey Type	Survey Equipment and Method	Resource Surveyed or Information Used to Inform
HRG surveys	Side-scan sonar, sub-bottom profiler, magnetometer, multi-beam echosounder	Shallow hazards, archaeological, bathymetric charting, benthic habitat
Geotechnical/sub-bottom sampling	Vibracores, deep borings, cone penetration tests	Geological, marine archaeology
Biological	Grab sampling, benthic sled, underwater imagery/sediment profile imaging	Benthic habitat
	Aerial digital imaging; visual observation from boat or airplane	Birds, marine mammals, sea turtles
	Ultrasonic detectors installed on survey vessels used for other surveys	Bats
	Visual observation from boat or airplane	Marine fauna (marine mammals and sea turtles)
	Direct sampling of fish and invertebrates	Fish and invertebrates

Source: BOEM 2016.

[1] The May 15, 2024 Renewable Energy Modernization Rule defers and extends the required time periods for meeting certain geotechnical survey requirements, such as engineering site-specific surveys (e.g., boreholes, vibracores, grab samplers, cone penetrometer tests, and other penetrative methods), until after COP approval but before construction.

D.2.1.2 Site Assessment Activities

After SAP approval, a lessee can evaluate the meteorological conditions, such as wind resources, with the approved installation of meteorological towers and buoys. Meteorological buoys have become the preferred meteorological and oceanographic (metocean) data collection platform for developers, and BOEM expects that most future site assessments will use buoys instead of towers (BOEM 2021d). The installation and operation of meteorological buoys involves substantially less activity and a much smaller footprint than the construction and operation of a meteorological tower. Site assessment activities have been approved or are in the process of being approved for multiple lease areas on the OCS consisting of one to three meteorological buoys per SAP (Table D2-1 in Attachment D2). Site assessment would likely take place starting within 1 to 2 years of lease execution, because preparation of a SAP (and subsequent BOEM review) takes time. The No Action Alternative and cumulative analyses consider these site assessment activities.

D.2.1.3 Construction and Operation of Offshore Wind Facilities

Table D-2 depicts construction of offshore wind projects from Maine to South Carolina.[3] Also included are all the projects currently in various stages of planning within BOEM's offshore leases from Massachusetts to South Carolina. Projected construction dates for each offshore wind project are listed in Table D2-1 in Attachment D2, and each project will require a National Environmental Policy Act (NEPA) process with an EIS or environmental assessment prior to approval.

Table D-2 summarizes (1) the incremental number of construction locations that are projected to be active in each region during each year between 2023 and 2030; (2) the number of operational turbines in each region at the beginning of each year between 2021 and 2030; and (3) the total number of active construction locations and operational turbines across the Atlantic OCS by year.

BOEM assumes planned offshore wind projects will include the same or similar components as the NY Bight projects: wind turbine generators (WTGs), offshore and onshore cable systems, offshore substations (OSSs), onshore operations and maintenance (O&M) facilities, and onshore interconnection facilities. BOEM further assumes that other planned offshore wind projects will employ the same or similar construction and installation, O&M, and conceptual decommissioning activities as the NY Bight projects. However, offshore wind projects would be subject to evolving economic, environmental, and regulatory conditions. Lease areas may be split into multiple projects, expanded, or removed, and development within a particular lease area may occur in phases over long periods of time. Research currently being conducted in combination with data gathered regarding physical, biological, socioeconomic, and cultural resources during development of initial offshore wind projects in the United States could affect the design and implementation of future projects, as could advancements in technology. For the analysis of ongoing and planned activities, the ongoing and planned projects included in Table D2-1 in Attachment D2 are analyzed in Chapter 3 of the Final PEIS.

---

[3] Within this Draft PEIS, BOEM analyzes Ocean Wind 1 (OCS-A 0498) as an ongoing offshore wind project and Ocean Wind 2 (OCS-A 0532) as a planned offshore wind project. On October 31, 2023, Orsted publicly announced their decision to cease development of Ocean Wind 1 and Ocean Wind 2. However, Ocean Wind LLC (the lessee for Ocean Wind 1) has not withdrawn their COP for lease OCS-A 0498, and so BOEM has analyzed the project as described in the approved COP. On February 29, 2024, pursuant to 30 CFR § 585.418, BOEM approved a 2-year suspension of the operations term of Ocean Wind LLC's commercial lease (Renewable Energy Lease Number OCS-A 0498), lasting until February 28, 2026. This suspension was approved in response to the lessee's January 19, 2024, request for a suspension of the operations term for the lease, submitted pursuant to Section 8(p)(5) of the Outer Continental Shelf Lands Act, 43 U.S Code § 1337(p)(5) and BOEM's implementing regulations at 30 CFR § 585.416. Orsted North America Inc. (the lessee for Ocean Wind 2) has not relinquished or reassigned lease OCS-A 0532; therefore, BOEM has analyzed development of the lease area consistent with the assumptions identified in this appendix.

In January 2024, Empire Offshore Wind, LLC (the lessee for Empire Wind 1 and 2) announced it was terminating the Offshore Wind Renewable Energy Certificate (OREC) Agreement for the Empire Wind 2 project. Empire Offshore Wind, LLC has not informed BOEM of any material changes to the activities approved in its COP. Therefore, BOEM has analyzed development of the lease area in this Final PEIS consistent with the assumptions identified in Appendix D.

[1] BOEM recognizes that the estimates presented within this cumulative analysis are likely high, conservative estimates; however, BOEM believes that this analysis appropriately captures the potential cumulative impacts and errs on the side of maximum impacts.
[2] New England Wind Phase I and Phase 2 would collectively have no more than 130 foundations, and the maximum number of foundations for Phase I would be 64.
[3] Beacon Wind 1 and Beacon Wind 2 would collectively have no more than 157 foundations. BOEM made the assumption to split the foundation numbers evenly across both projects.
CVOW = Coastal Virginia Offshore Wind; GSOE = Garden State Offshore Energy; NE = Northeast

D.2.2 Incorporation by Reference of Cumulative Impacts Study and the Analyses Therein

BOEM has completed a study of Impact-Producing Factors (IPFs) on the North Atlantic OCS to consider in an offshore wind development cumulative impacts scenario (BOEM 2019). The study is incorporated in this document by reference. The study identifies cause-and-effect relationships between renewable energy projects and resources potentially affected by such projects. It further classifies those relationships into a manageable number of IPFs through which renewable energy projects could affect resources, and identifies the types of actions and activities to be considered in a cumulative impacts scenario. These IPFs and their relationships were used in the Final PEIS analysis of cumulative impacts, and BOEM decided which IPF applied to which resource. The study identifies actions and activities that may affect the same physical, biological, economic, or cultural resources as renewable energy projects and states that such actions and activities may have the same IPFs as offshore wind projects.

As discussed in the BOEM (2019) study, reasonably foreseeable activities other than offshore wind projects may also affect the same resources as the six NY Bight projects or other offshore wind projects, possibly via the same IPFs or via IPFs through which offshore wind projects do not contribute. This appendix lists reasonably foreseeable non-offshore-wind activities that may contribute to the cumulative impacts of the NY Bight projects.

D.2.3 Undersea Transmission Lines, Gas Pipelines, and Other Submarine Cables

There are 27 submarine telecommunication cables (18 active and 9 out of service) within the vicinity of the NY Bight lease areas. National Oceanic and Atmospheric Administration (NOAA) nautical charts identify multiple sewer pipelines, stormwater outfalls, and intake structures along the coast of New Jersey and New York that begin onshore and extend offshore.

There are six in-service pipelines within the vicinity of the NY Bight lease areas. The Williams Transco pipeline, which supplies a significant amount of natural gas to New York, is located in the nearshore waters between New Jersey and New York (NYSERDA 2017). A gas pipeline is buried in the northern New York Harbor utility corridor, two gas pipelines and one petroleum product pipeline are buried in the southern New York Harbor utility corridor, and the deeply tunneled replacement Brooklyn-Staten Island water siphon in the New Jersey Harbor.

The New Jersey Board of Public Utilities (NJBPU) and the New York State Public Service Commission (NYSPSC) have proposed transmission systems to which offshore wind lessees could connect. In November 2020, NJBPU asked PJM Interconnection, L.L.C. (PJM) to incorporate New Jersey's offshore wind goals into the Regional Transmission Planning Process, the state agreement approach (SAA) regulatory pathway. Through a competitive procurement, NJBPU awarded a transmission solution to Mid-Atlantic Offshore Development, LLC's and Jersey Central Power & Light Company's jointly submitted Larrabee Tri-Collector Solution to create a single onshore point of interconnection to the PJM high-voltage transmission system at the Larrabee Collector Station. The Larrabee Collector Station will enable interconnection of 3,742 megawatts (MW) of offshore wind generation.[4] As an extension of the SAA and PJM's Regional Transmission Planning Process and separate from its procurement of new offshore wind generation, NJBPU issued a solicitation for construction of the Prebuild Infrastructure (PBI), which is the infrastructure between the identified landing point at Sea Girt National Guard Training Center in New Jersey and the point of interconnection at the Larrabee Collection Station, a distance of approximately 12 miles. PBI will be funded through the Federal Energy Regulatory Commission's (FERC) transmission rates and will be developed, owned, and operated by a transmission system developer.

The New York State Energy Research and Development Authority (NYSERDA) has identified 21 potential onshore points of interconnection for planned offshore wind cables to interconnect to the existing New York State transmission grid (NYSERDA 2017). NYSERDA has more recently advanced efforts for the development and future use of coordinated transmission infrastructure. In June 2023, the New York State Public Service Commission initiated a competitive process[5] for the submission of proposals to build at least 4,700 MW, and up to 8,000 MW of transmission capacity to serve the State's 9,000-MW target (referred to as the New York City Public Policy Transmission Need) in an effort to develop offshore transmission infrastructure capable of collecting energy generated at multiple offshore platforms and delivering it to onshore interconnection points. Awards are anticipated to be issued in 2025.

The offshore wind projects listed in Table D2-1 in Attachment D2 that have a COP under review are presumed to include at least one identified cable route. Proposed cable routes have not yet been announced for the remainder of the projects.

D.2.4 Tidal Energy Projects

BOEM is not aware of any ongoing or planned tidal energy projects in the NY Bight. See the South Fork Wind Farm (OCS-A 0517) and South Fork Export Cable Project Final EIS (BOEM 2021b) for descriptions of other tidal projects that are more distant from the NY Bight projects in Maine and Massachusetts.

D.2.5 Dredging and Port Improvement Projects

The representative ports identified for potential use by the NY Bight projects in New York and New Jersey are: Port of Albany, Port of Coeymans, Brooklyn Navy Yard, South Brooklyn Marine Terminal, Howland Hook/Port Ivory, Arthur Kill Terminal, Paulsboro Marine Terminal, and New Jersey Wind Port. Some dredging projects have also been proposed or studied at ports that may be used by the NY Bight projects in New York and New Jersey, and are either in operation or are considered reasonably foreseeable:

---

[4] In March 2023, the State of New Jersey issued an offshore wind solicitation with a requirement for projects to interconnect at the Larrabee site. In January 2024, NJBPU awarded a combined 3,742 MW of offshore wind capacity to Invenergy and energyRE's Leading Light Wind Project and Attentive Energy LLC's Attentive Energy Two Project.

[5] Order Addressing Public Policy Requirements for Transmission Planning Purposes, Case 22-E-0633 (June 22, 2023), https://www.nyiso.com/documents/20142/1406395/PSC-Order-NYC-PPTN.pdf.

- Port Ivory is undeveloped, and all new infrastructure is necessary in order to prepare the site for use as a staging and installation facility. The following improvements are discussed in NYSERDA’s 2018 Ports Assessment: Port Ivory Pre-front End Engineering Design Report (NYSERDA 2019d):
    - Demolish and dispose of existing asphalt and concrete pavement and structures on site.
    - Clear and grub the site of unmaintained vegetation (e.g., trees, bushes).
    - Install marine structures along the waterfront edges of the site, to provide at least two heavy load wharves to load and unload components.
    - Improve the ground-bearing capacity and grade areas within the site.
    - Install surface treatment (i.e., crushed stone) within laydown areas of the site.
    - Dredge the berthing area to provide sufficient depth for design vessels to safely access the site.
- The Port of Albany is to be used as a manufacturing or fabrication facility. The following improvements are discussed in NYSDERA’s 2018 Ports Assessment: Port of Albany-Rensselaer Pre-front End Engineering Design Report (NYSERDA 2019a):
    - Clear and grub the site of unmaintained vegetation (e.g., trees, bushes, etc.).
    - Install marine structures along the waterfront edge of the site, to provide at least two heavy load wharves to load and unload components.
    - Improve the ground-bearing capacity and grade areas within the site.
    - Stabilize the shoreline in order to allow live loads to be applied closer to the crest of the existing shoreline slopes.
    - Install surface treatment (i.e., crushed stone) within laydown areas of the site.
    - Dredge the berthing area to provide sufficient depth for design vessels to safely access the site.
- The Port of Coeymans is currently primarily developed and is anticipating offshore wind projects. The following improvements are discussed in NYSDERA’s 2018 Ports Assessment: Port of Coeymans Pre-front End Engineering Design Report (NYSERDA 2019b):
    - Clear and grub unmaintained areas.
    - Install one heavy load quay along the northeastern shoreline.
    - Grade existing site's waterfront area and upland area, as well as the portion of land in between these zones.
    - Install a retaining wall between the westerly and northerly extents that will tie into the site’s existing slopes to remain.

    - Improve the ground-bearing capacity across the waterfront portion of the site by placing crushed rock above existing grade.
    - Dredge berth area to allow safe vessel access to the site.

- The South Brooklyn Marine Terminal is an operational marine terminal. The following improvements are discussed in NYSDERA's 2018 Ports Assessment: South Brooklyn Marine Terminal Pre-front End Engineering Design Report (NYSERDA 2019c) (groundbreaking occurred in June 2024, and the improvements are currently under construction):
    - Demolish existing buildings and the rail spur on the 39th Street Pier to increase available laydown area and facilitate ground-bearing capacity improvements.
    - Install two heavy load quays, including along the northwest end of the 39th Street Pier and along the southwest end of the 39th Street Pier.
    - Stabilize the 35th Street Pier Revetment to increase the load capacity.
    - Grade existing site.
    - Improve the ground-bearing capacity across the site by placing crushed stone fill above the existing grade.
    - Dredge berth areas to allow safe vessel access to the site.
- The Brooklyn Navy Yard is anticipating major improvements and developments with approximately 5.1 million square feet (.47 million square meters) of vertical manufacturing space, and development of a series of open space and connectivity improvements aimed at integrating the Yard with the surrounding neighborhoods (Brooklyn Navy Yard 2023).
- Arthur Kill Terminal has received $48 million in federal grants to construct Arthur Kill Terminal as an offshore wind staging and assembly coastal seaport on Staten Island (Empire State Development 2022). The New York City Department of Planning released the Final EIS for the project on May 31, 2024.
- General Electric has proposed plans to build a new factory for offshore wind turbine components at its Port of Coeymans site (ESG Review 2023).
- The Paulsboro Marine Terminal is currently receiving improvements, which will aim to support the offshore wind industry as it is being developed as a facility to manufacture and ship monopile foundations for construction of wind turbines off the coast of New Jersey (Jacobs 2022). Some of the improvements are construction of mooring dolphins, dredging, and upland placement of dredged material, and two fabrication buildings in which steel plate welding, roll bending, and circumferential welding will take place (Jacobs 2022).

- The State of New Jersey is planning to build an offshore wind port on the eastern shore of the Delaware River in Lower Alloways Creek, Salem County, approximately 7.5 miles (12 kilometers) southwest of the city of Salem. The New Jersey Economic Development Authority is leading the development of the project on behalf of the state, working alongside key departments and agencies such as the Governor's Office, the Department of the Treasury, and NJBPU. The development plan includes dredging the Delaware River Channel, and construction commenced in September 2021 with a targeted completion date of late 2023 (New Jersey Wind Port 2021; Salem County 2021). The Delaware River Channel dredging project provides deepening of the existing Delaware River Federal Navigation Channel, bend widening, partial deepening of the Marcus Hook anchorage, and relocation and addition of aids to navigation. The deeper channel will allow for more efficient transportation of containerized, dry and liquid bulk, break bulk, roll-on/roll-off, and project cargoes to and from Delaware River ports (USACE 2022b).
- In 2018, two New Jersey Department of Transportation projects, High Bar Harbor channel and Barnegat Light Stake channel, both near Barnegat Inlet in Ocean and Long Beach Townships, New Jersey, underwent dredging of approximately 39,150 cubic yards and 3,230 cubic yards (29,932 cubic meters and 2,470 cubic meters), respectively, to maintain the depths of these channels. Maintenance dredging for both projects is authorized until December 2025 and is expected to occur before the permits expire (USACE 2015a, 2015b). Barnegat Light is the primary commercial seaport on Long Beach Island and is the homeport to approximately 36 commercial vessels. Barnegat Light's two commercial docks are home to several scallop vessels, longliners, and a fleet of smaller inshore gillnetters.
- The U.S. Army Corps of Engineers (USACE) has received numerous permit applications for private dock, boat lift, and bulkhead repairs in Barnegat Bay, New Jersey (USACE 2022a).

D.2.6 Marine Minerals Use and Ocean Dredged Material Disposal

There are no active OCS lease areas for marine minerals within the other uses geographic analysis area (refer to Section 3.6.7, *Other Uses (Marine Minerals, Military Use, Aviation, Scientific Research and Surveys)*) (BOEM 2018). New York has multiple potential sand resource areas, in state and federal waters, along the coast of Long Island for beach renourishment projects. Within federal waters, there are an additional four potential federal sand resource areas. In New York, there are four identified dredge areas (Marine Cadastre 2023).

In New Jersey, the closest previous lease in BOEM's Marine Minerals Program for sand borrow areas for beach replenishment is known as the D2 borrow area, offshore near Harvey Cedars, Surf City, Long Beach Township, Ship Bottom, and Beach Haven (Lease Number OCS-A-050; executed July 1, 2014). The lessee (USACE and the New Jersey Department of Environmental Protection [NJDEP]) was approved through September 20, 2018, for the use of up to 10,000,000 cubic yards (7,645,550 cubic meters) of material to be used for the Long Beach Island Coastal Storm Risk Management Project, Barnegat Inlet to Little Egg Inlet. At present, there are 15 USACE beach renourishment projects in the USACE North Atlantic Division, which includes the New York and Philadelphia Districts, that may target OCS sand

resources (NJDEP pers. comm. 2023). The New York District projects include Sandy Hook to Barnegat Inlet in addition to the Raritan Bay Flood Control Projects of Keansburg, Port Monmouth, Union Beach and Highlands. The Philadelphia District projects include Manasquan Inlet to Barnegat Inlet, Barnegat Inlet to Little Egg Inlet, Brigantine Inlet to Great Egg Inlet (Brigantine), Brigantine Inlet to Great Egg Inlet (Absecon Island), Great Egg Inlet to Pecks Beach, Great Egg Inlet to Townsends Inlet, Townsends Inlet to Cape May Inlet, Hereford Inlet to Cape May Inlet, Cape May Inlet to Lower Township, and Lower Township to Cape May Point. In addition to the OCS sand resource needs for these projects, USACE has additional beach renourishment projects currently targeting sand resources in state waters/inlets.
U.S. Environmental Protection Agency (USEPA) Region 2 is responsible for designating and managing ocean disposal sites for materials offshore in the region of the NY Bight projects. USACE issues permits for ocean disposal sites; all ocean sites are for the disposal of dredged material permitted or authorized under the Marine Protection, Research, and Sanctuaries Act (16 U.S. Code [USC] 1431 et seq. and 33 USC 1401 et seq.).

D.2.7 National Security and Military Use

The Offshore Narragansett Bay Range Complex primarily consists of surface sea space and subsurface space off the coasts of Massachusetts, Rhode Island, and New York. As part of the range complex, the Narragansett Bay Operating Area extends from the shoreline seaward to approximately 180 nm (333 kilometers) from land at its farthest point (Empire 2022). The complex is controlled by the Fleet Area Control and Surveillance Facility at Virginia Capes Naval Air Station Oceana. The Navy installations primarily operating in this complex are in New London, Connecticut, and Newport, Rhode Island.

The Narragansett Bay Warning Area is in the western portion of the Offshore Narragansett Bay Range Complex and is designated for operations where limitations may be imposed on aircraft not participating in operations. The Narragansett Bay Warning Area is actively used for U.S. Navy subsurface and surface training and testing activities and to prepare submarines and their crews for formal voyages. Additionally, this Warning Area is used to support special-use airspace, flight testing, surface-to-air gunnery exercises using conventional ordnance, antisubmarine warfare exercises, and air-intercept training (Empire 2022).

The Atlantic City Complex is located in waters adjacent to the coasts of New Jersey and New York. The range complex is used for training and testing exercises for the U.S. Atlantic Fleet and supports training and testing by other services, primarily the U.S. Air Force. The AEGIS Combat Systems Center, controlled by the Fleet Area Control and Surveillance Facility Virginia Capes, Naval Air Station, Oceana, also conducts operations in the Atlantic City Complex. The United States Coast Guard (USCG) Air Station Atlantic City, located at the Atlantic City International Airport in Egg Harbor, New Jersey, supports a range of USCG operations, including search and rescue, port security, and marine environmental protection services.

Four danger zones/restricted areas—defined as a “water area (or areas) used for target practice, bombing, rocket firing or other especially hazardous operations, normally for the armed forces”—are in the vicinity of the NY Bight lease areas. The danger zones/restricted areas in the area are at the mouth of the New York Harbor, at the Naval Weapons Station Earle in Sandy Hook Bay, in the New York Harbor adjacent to the Stapleton Naval Station, and at the Coast Guard Rifle Range off the coast of Cape May (NOD 2022).

There are two Weapons Training Areas operated by the USCG offshore New York and New Jersey within the geographic analysis area. These training areas are used for proficiency training in law enforcement operations (BOEM 2016) and for small caliber weapons training, generally from small vessels that transit during the day to the training area.

D.2.8 Marine Transportation

Marine transportation in the region is diverse and sourced from many ports and private harbors. Commercial vessel traffic in the region includes research, tug/barge, tankers (such as those used for liquid petroleum), cargo, cruise ships, smaller passenger vessels, and commercial fishing vessels. Recreational vessel traffic includes private motorboats and sailboats. A number of federal agencies, state agencies, educational institutions, and environmental non-governmental organizations participate in ongoing research offshore including oceanographic, biological, geophysical, and archaeological surveys. Most vessel traffic, excluding recreational vessels, tends to travel within established vessel traffic routes, and the number of trips, as well as the number of unique vessels, has remained consistent (USCG 2021). In response to offshore wind projects in the NY Bight, multiple additional fairways and a new anchorage may be established to route existing vessel traffic around wind energy projects (USCG 2021). One new regional maritime highway project received funding from the Maritime Administration. A new barge service (Davisville/Brooklyn/Newark Container-on-Barge Service) is proposed to run twice each week in state waters between Newark, New Jersey, and Brooklyn, New York.

D.2.9 National Marine Fisheries Service Activities

Research and enhancement permits may be issued for marine mammals protected by the Marine Mammal Protection Act (MMPA) and for threatened and endangered species protected under the Endangered Species Act (ESA). NMFS is anticipated to continue issuing research permits under Section 10(a)(1)(A) of the ESA to allow take of certain ESA-listed species for scientific research. Scientific research permits issued by NMFS currently authorize studies on ESA-listed species in the Atlantic Ocean. Current fisheries management and ecosystem monitoring surveys conducted by or in coordination with the Northeast Fisheries Science Center (NEFSC) could overlap with offshore wind lease areas in the New England region and south into the Mid-Atlantic region. Surveys include (1) the NEFSC Bottom Trawl Survey, a more than 50-year multispecies stock assessment tool using a bottom trawl; (2) the NEFSC Sea Scallop/Integrated Habitat Survey, a sea scallop stock assessment and habitat characterization tool, using a bottom dredge and camera tow; (3) the NEFSC Surfclam/Ocean Quahog Survey, a stock assessment tool for both species using a bottom dredge; and (4) the NEFSC Ecosystem Monitoring Program, a more than 40-year shelf ecosystem monitoring program using plankton tows and conductivity, temperature, and depth units. These surveys are anticipated to continue within the region, regardless of offshore wind development.

The regulatory process administered by NMFS, which includes stock assessments for all marine mammals and 5-year reviews for all ESA-listed species, assists in informing decisions on take authorizations and the assessment of project-specific and cumulative impacts that consider ongoing and planned activities in biological opinions. Stock assessments completed regularly under the MMPA include estimates of potential biological removal that stocks of marine mammals can sustainably absorb. MMPA take authorizations require that a proposed action have no more than a negligible impact on species or stocks, and that a proposed action impose the least practicable adverse impact on the species. MMPA authorizations are reinforced by monitoring and reporting requirements so that NMFS is kept informed of deviations from what has been approved. Biological opinions for federal and non-federal actions are similarly grounded in status reviews and conditioned to avoid jeopardy and to allow continued progress toward recovery. These processes help to ensure that, through compliance with these regulatory requirements, a proposed action would not have a measurable impact on the conservation, recovery, and management of the resource.

D.2.9.1 Directed Take Permits for Scientific Research and Enhancement

NMFS issues permits for research on protected species for scientific purposes. These scientific research permits include the authorization of directed take for activities such as capturing animals and taking measurements and biological samples to study their health, tagging animals to study their distribution and migration, photographing and counting animals to get population estimates, taking animals in poor health to an animal hospital, and filming animals. NMFS also issues permits for enhancement purposes; these permits are issued to enhance the survival or recovery of a species or stock in the wild by taking actions that increase an individual's or population's ability to recover in the wild. Scientific research and enhancement permits have been issued previously for satellite, acoustic, and multi-sensor tagging studies on large and small cetaceans; research on reproduction, mortality, health, and conservation issues for North Atlantic right whales (NARWs); and research on population dynamics of harbor and gray seals. Reasonably foreseeable future impacts from scientific research and enhancement permits include physical and behavioral stressors (e.g., restraint and capture, marking, implantable and suction tagging, biological sampling).

D.2.9.2 Fisheries Use and Management

NMFS implements regulations to manage commercial and recreational fisheries in federal waters, including those within the NY Bight lease areas; the State of New Jersey and the State of New York regulate commercial fisheries in their state waters (within 3 nm [5.6 kilometers] of the coastline). The NY Bight overlaps two of NMFS's eight regional councils to manage federal fisheries: the Mid-Atlantic Fishery Management Council (MAFMC), which includes New York, New Jersey, Pennsylvania, Delaware, Maryland, Virginia, and North Carolina; and the New England Fishery Management Council (NEFMC), which includes Maine, New Hampshire, Massachusetts, Rhode Island, and Connecticut (NEFMC 2016). The councils manage species with many Fishery Management Plans (FMPs) that are frequently updated, revised, and amended and coordinate with each other to jointly manage species across jurisdictional boundaries (MAFMC 2019). Many of the fisheries managed by the councils are fished for in state waters or outside of the Mid-Atlantic region, so the council works with the Atlantic States Marine Fisheries

Commission (ASMFC). ASMFC is composed of the 15 Atlantic coast states and coordinates the management of marine and anadromous resources found in the states' marine waters. In addition, the states and NMFS, under the framework of ASMFC's *Amendment 3 to the Interstate Fishery Management Plan for American Lobster*, cooperatively manage the American lobster resource and fishery (NOAA 1997).

The FMPs of the councils and ASMFC were established, in part, to manage fisheries to avoid overfishing. They accomplish this through an array of management measures, including annual catch quotas, minimum size limits, and closed areas. These various measures can further reduce (or increase) the size of landings of commercial fisheries in the Northeast and Mid-Atlantic regions.

NMFS also manages highly migratory species, such as tuna and sharks, that can travel long distances and cross domestic boundaries. Table D-3 summarizes other FMPs and actions in the region.

Table D-3. Other fishery management plans

Area	Plan and Projects
ASMFC	ASMFC *Five-Year Strategic Plan 2019–2023* (ASMFC 2019) ASMFC 2022 Action Plan (ASMFC 2021) *Management, Policy and Science Strategies for Adapting Fisheries Management to Changes in Species Abundance and Distribution Resulting from Climate Change* (ASMFC 2018)
New York	*New York Ocean Action Plan 2017–2027*: adaptive management plan (NYSDEC 2017) New York State filed a petition with NOAA, NMFS, and MAFMC to demand that commercial fluke allocations be revised to provide fishers with equitable access to summer flounder. NMFS announced specifications for the summer flounder, scup, and black sea fisheries. This action is intended to inform the public of the specifications for the 2023 fishing year for summer flounder, scup, and black sea bass. This rule shows the state-by-state allowable commercial fishing quotas (88 *Federal Register* 11 January 3, 2023).
Long Island Regional Development Council	East Hampton Shellfish Hatchery project will consolidate the hatchery's municipal hatchery and nursing facilities. Haskell's seafood facility in East Quogue is proposed to become a fully functioning seafood processing plant.
New Jersey	NJDEP Division of Fish and Wildlife Marine Fisheries Management Rule Amendment Proposal with amendments to rules governing crab and lobster management, commercial Atlantic menhaden fishery, marine fisheries, and fishery management in New Jersey was published in the March 1, 2021, *New Jersey Register* (New Jersey Division of Fish and Wildlife 2021).

D.2.10 Global Climate Change

Climate change results primarily from the increasing concentration of greenhouse gases (GHGs) in the atmosphere, which causes planet-wide physical, chemical, and biological changes, substantially altering the world's oceans and lands. Changes include increases in global atmospheric and oceanic temperature, shifting weather patterns, rising sea levels, and changes in atmospheric and oceanic chemistry (Blunden and Arndt 2020). Section 7.6.1.4 of the Programmatic EIS *for Alternative Energy Development and Production and Alternate Use of Activities on the Outer Continental Shelf* (Minerals Management Service 2007) describes global climate change with respect to assessing renewable energy development. Key drivers of climate change are increasing atmospheric concentrations of carbon dioxide (CO_2) and other GHGs, such as methane (CH_4) and nitrous oxide (N_2O). These GHGs reduce the ability of solar radiation to re-radiate out of Earth's atmosphere and into space. Although all three of these GHGs have natural sources, the majority of these GHGs are released from anthropogenic activity. Since the industrial revolution, the rate at which solar radiation is re-radiated back into space has slowed, resulting in a net increase of energy in the Earth's system (Solomon et al. 2007). This energy increase presents as heat, raising the planet's temperature and causing climate change.

Fluorinated gases are a type of GHG released in trace amounts but are highly efficient at preventing solar radiation from being re-radiated back into space. They have a much longer lifespan than CO_2, CH_4, and N_2O. Fluorinated gases have no natural sources, are either a product or byproduct of manufacturing, and can have 23,000 times the warming potential of an equal amount of CO_2. These gases include hydrofluorocarbons, perfluorocarbons, nitrogen trifluoride, and sulfur hexafluoride. These gases are currently being phased out; however, sulfur hexafluoride is still used in WTG switchgears and OSS high-voltage and medium-voltage gas-insulated switchgears.

The Intergovernmental Panel on Climate Change (IPCC) released a special report in October 2018 that compared risks associated with an increase of global warming of 1.5°C and an increase of 2°C. The report found that climate-related risks depend on the rate, peak, and duration of global warming, and that an increase of 2°C was associated with greater risks associated with climatic changes such as extreme weather and drought; global sea level rise; impacts on terrestrial ecosystems; impacts on marine biodiversity, fisheries, and ecosystems and their functions and services to humans; and impacts on health, livelihoods, food security, water supply, and economic growth (IPCC 2018). High global temperatures increase the amount of sea level rise by the end of the century, with a projected relative sea level rise of 2.0 to 7.2 feet (0.6 to 2.2 meters) along the contiguous United States coastline by 2100 (NOAA 2022). Expected relative sea level rise would cause tide and storm surge heights to increase, leading to a shift in the U.S. coastal flood regimes by 2050 with major and moderate high tide flood events occurring as frequently as moderate and minor high tide flood events occur today (NOAA 2022).

Global emissions of GHGs have impacts whose local effects are increasingly elucidated through research. For example, a recent study concerning the NARW provides evidence that the whale's feeding area moved north following relocation of its food source related to climate change, and whale mortality may have increased because of fewer controls on fishing activities in the new, more northerly area (Meyer-Gutbrod et al. 2021). Climate change is predicted to affect Northeast fishery species in different ways (Hare et al. 2016), and the NMFS biological opinion for *Commercial Wind Lease Issuance and Site Assessment Activities on the Atlantic Outer Continental Shelf in Massachusetts, Rhode Island, New York and New Jersey Wind Energy Areas* also discusses in detail the potential impacts of global climate change on protected species that occur within the NY Bight area (NMFS 2013).

Local emissions, such as those from maintenance of and accidental chemical leaks from wind energy projects, would contribute incrementally to global GHG emissions. However, the largest climate impact from wind energy projects is expected to be beneficial: the energy generated by wind energy projects is expected to displace energy generated by combustion of fossil fuels, which would lead to reductions in regional emissions of air pollutants and GHGs from fossil-fueled power plants.

Table D-4 summarizes regional plans and policies that are in place to address climate change, and Table D-5 summarizes resiliency plans.

Table D-4. Climate change plans and policies

Plans and Policies	Summary/Goal
New York	
Order Adopting a Clean Energy Standard (State of New York Public Service Commission 2016)	Requirement that 50% of New York's electricity come from renewable energy sources by 2030.
New York State Energy Plan 2015; 2017 Biennial Report to 2015 Plan (NYSERDA 2015, 2017a)	Requires 40% reduction in GHG from 1990 levels, 50% electricity to come from renewable energy resources, and a 600-trillion-British-thermal-unit increase in statewide energy efficiency.
Governor Cuomo State of the State Address 2017, 2018, 2021	2017: Set offshore wind energy development goal of 2,400 MW by 2030 (Governor's Office 2017). 2018: Procurement of at least 800 MW of offshore wind power between two solicitations in 2018 and 2019; new energy efficiency target for investor-owned utilities to more than double utility energy efficiency progress by 2025; energy storage initiative to achieve 1,500 MW of storage by 2025 and up to 3,000 MW by 2030 (Office of the Attorney General 2018; Windpower Engineering & Development 2018). 2021: The governor's 2021 agenda—Reimagine | Rebuild | Renew—establishes a goal of building out the renewable energy program. The agenda notes the development of two new offshore wind farms more than 20 miles offshore of Long Island, as well as the creation of dedicated offshore port facilities and additional transmission capacity development.
Governor Kathy Hochul State of the State Address (2022)	2022: Announced NYSERDA's third offshore wind procurement to be initiated in 2022; the procurement is expected to result in at least 2 gigawatts (GW) of new offshore wind projects. 2022: Announced a $500 million infrastructure investment to develop offshore wind manufacturing and supply chain infrastructure. 2022: Announced a legislative proposal to ensure all new building construction reaches zero emissions by 2027, and to develop 2 million electrified or electrification-ready homes by 2030.
New York State Offshore Wind Master Plan (2017) (NYSERDA 2017) and Master Plan 2.0 (under development)	Grants NYSERDA ability to award 25-year long-term contracts for projects ranging from approximately 200 MW to approximately 800 MW, with an ability to award larger quantities if sufficiently attractive proposals are received. Each proposer is also required to submit at least one proposal of approximately 400 MW. Initial bids were received in early 2019. The State of New York's initial Master Plan included a comprehensive suite of studies and public engagement to determine the most responsible and cost-effective pathways for developing offshore wind energy off of New York State. Master Plan 2.0 will provide a plan for the future of offshore wind development, including in deeper waters off the state's coast.
New York State Clean Water, Clean Air, and Green Jobs Environmental Bond Act (Bond Act)	The Bond Act funding will support new and expanded projects across the State to safeguard drinking water sources, reduce pollution, and protect communities and natural resources from climate change.

Plans and Policies	Summary/Goal
The Climate Leadership and Community Protection Act (CLCPA), enacted on July 18, 2019, signed into law in July 2019, and effective January 1, 2020	The act establishes economy-wide targets to reduce GHG emissions by 40% of 1990 levels by 2030 and 85% of 1990 levels by 2050. Establishes a goal of 9.0 GW of offshore wind generation by 2035. The CLCPA requires that 70 percent of New York State's electricity come from renewable sources by 2030 and 100 percent of electricity come from zero-emission sources by 2040. In addition, the CLCPA requires that New York reduce statewide greenhouse gas emissions to at least 40 percent below 1990 levels by 2030 and at least 85 percent below 1990 levels by 2050.
New Jersey	
Executive Order 28: Measures to Advance New Jersey's Clean Energy Economy (2018)	Sets target of total conversion of the state's energy production profile to 100% clean energy sources on or before January 1, 2050.
New Jersey Energy Master Plan (State of New Jersey 2019, 2020)	Updated in 2019, the plan outlines key strategies to reach the State of New Jersey's goal of 100 percent clean energy by 2050, including accelerating development of offshore wind.
Executive Order 100: Protecting Against Climate Threats (PACT); Land Use Regulations and Permitting (2020)	Establishes a GHG monitoring and reporting program, establishes criteria to govern and reduce emissions, and integrates climate change considerations, such as sea level rise, into regulatory and permitting programs.
Executive Order 307: Increase Offshore Wind Goal to 11,000 Megawatts by 2040 (2022)	Establishes a goal of 11,000 MW of offshore wind energy generation by 2040.

Table D-5. Resiliency plans and policies

Plans and Policies	Summary
New York	
Community Risk and Resiliency Act of 2014	Enacted in 2014, the Act includes five major provisions: 1) Official Sea-level Rise Projections, 2) Consideration of future physical climate risk, 3) Smart Growth Public Infrastructure Policy Act Criteria, 4) Guidance on Natural Resilience Measures, and 5) Model Local Laws Concerning Climate Risk. As of 2019, New York State Department of Environmental Conservation (NYSDEC) is in the process of developing a State Flood Risk Management Guidance document for state agencies (NYSDEC n.d.).
NY Rising Community Reconstruction Program (2018)	$20.4 million in projects on Long Island to help flood-prone communities plan and prepare for extreme weather events as they continue projects to recover from Superstorm Sandy, Hurricane Irene, and Tropical Storm Lee. Three projects were announced for Suffolk County and five for Nassau County (Governor's Office 2018).
NYS Smart Growth Program	Community planning and development program with an overall approach of development and conservation strategies that help protect the health and natural environment by making communities more attractive, economically stronger, socially diverse, and resilient to climate change. The Smart Growth policies help communities contribute to both mitigating and adapting to climate change. New York State Department of State administers a portion of the State Smart Growth grant program. More information here: https://dos.ny.gov/nys-smart-growth-program.

Plans and Policies	Summary
New York Water Resources Management	New York encourages community planning at the watershed level. Watershed planning allows communities to integrate water and land resource protection and restoration with growth management at the local and regional level, balancing environmental and economic factors to encourage a healthier, more resilient watershed. New York State provides community assistance in the development and implementation of watershed management plans. More information here: https://dos.ny.gov/water-resources-management.
Local Waterfront Revitalization Program	The Local Waterfront Revitalization Program is New York State's primary program for working in partnership with waterfront communities across New York State. Local Waterfront Revitalization Programs begin with a planning process and are approved at three levels of government (local, state, and federal). Once approved, municipalities are eligible for implementation funds. More information here: https://dos.ny.gov/local-waterfront-revitalization-program.
New York City Watershed Program	The New York City Watershed Program provides technical support for local governments and regional groups in the New York City Watershed. The program provides a regional forum to aid in the long term protection of New York City's drinking water, and the economic vitality of the Upstate Watershed communities. More information here: https://dos.ny.gov/new-york-city-watershed-program.
OneNYC 2050	OneNYC 2050 is a strategy to address challenges facing New York City's future, including addressing climate change. Examples from the strategy include committing to carbon neutrality by 2050 and undertaking comprehensive projects to mitigate climate risk.
NYC Comprehensive Waterfront Plan	Every 10 years, New York City restarts a formal process of thinking collectively about New York City's waterfront and creating a vision for the next decade and beyond. The 2021 Plan, New York City's third Comprehensive Waterfront Plan, puts forth new strategies for an equitable, resilient and healthy waterfront in the face of climate change.
NY and NJ Harbor and Tributaries Focus Area Feasibility Study (HATS)	In response to coastal storms that have had severe impacts on the North Atlantic Coast, USACE is investigating measures to manage future flood risk in ways that support the long-term resilience and sustainability of the coastal ecosystem and surrounding communities, and reduce the economic costs and risks associated with flood and storm events. In support of this goal, USACE completed the North Atlantic Coast Comprehensive Study, which identified nine high-risk, focus areas on the north Atlantic Coast for further in-depth analysis into potential coastal storm risk management measures. One of the nine areas identified was the New York–New Jersey Harbor and Tributaries study area.
New Jersey	
New Jersey Draft Climate Change Resilience Strategy (NJDEP 2021)	This is New Jersey's first statewide climate resiliency strategy and was released as a draft in April 2021. The *Draft Climate Change Resilience Strategy* develops a framework for policy, regulatory, and operational changes to support the resilience of New Jersey's communities, economy, and infrastructure. It includes 125 recommended actions across the following six priority areas: build resilient and healthy communities, strengthen the resilience of New Jersey's ecosystems, promote coordinated governance, invest in information, increase public understanding, promote climate-informed investments and innovative financing, and develop a coastal resilience plan.

D.2.11 Oil and Gas Activities

The NY Bight lease areas are in the North Atlantic Planning Area of the OCS Oil and Gas Leasing Program (National OCS Program). On September 8, 2020, the White House issued a presidential memorandum for the Secretary of the Interior on the withdrawal of certain areas of the United States OCS from leasing disposition for 10 years, including the areas currently designated by BOEM as the South Atlantic and Straits of Florida Planning Areas (The White House 2020a). The South Atlantic Planning Area includes the OCS off South Carolina, Georgia, and northern Florida. On September 25, 2020, the White House issued a similar memorandum for the Mid-Atlantic Planning Area that lies south of the northern administrative boundary of North Carolina (The White House 2020b). This withdrawal prevents consideration of these areas for any leasing for purposes of oil and gas exploration, development, or production during the 10-year period beginning July 1, 2022, and ending June 30, 2032. Existing leases in the withdrawn areas are not affected. On September 29, 2023, the U.S. Department of the Interior announced the availability of the 2024–2029 National Outer Continental Shelf Oil and Gas Leasing Proposed Final Program and corresponding Final Programmatic Environmental Impact Statement. The 2024–2029 Proposed Final Program includes three potential OCS oil and gas lease sales in the Gulf of Mexico. It does not include sales in any other BOEM OCS planning area. On December 14, 2023, the Secretary of the Interior approved the 2024–2029 National Outer Continental Shelf Oil and Gas Leasing Proposed Final Program and signed the corresponding Record of Decision (ROD).

BOEM issues geophysical and geotechnical (G&G) permits to obtain data for hydrocarbon exploration and production; locate and monitor marine mineral resources; aid in locating sites for alternative energy structures and pipelines; identify possible human-made, seafloor, or geological hazards; and locate potential archaeological and benthic resources. G&G surveys are typically classified into categories by equipment type and survey technique. There are currently no such permits under review for areas offshore New York and New Jersey (BOEM 2021c).

Several liquefied natural gas ports are on the East Coast of the United States. Table D-6 lists existing, approved, and proposed liquified natural gas ports on the East Coast that provide (or may provide in the future) services such as natural gas export, natural gas supply to the interstate pipeline system or local distribution companies, storage of liquified natural gas for periods of peak demand, or production of liquified natural gas for fuel and industrial use (FERC 2022a, 2022b).

Table D-6. Liquefied natural gas terminals in the Eastern United States

Terminal Name	Type	Company	Jurisdiction	Distance from NY Bight Lease areas (approximate)	Status
Everett, MA	Import terminal	GDF SUEZ—DOMAC	FERC	90 miles north	Existing
Offshore Boston, MA	Import terminal	Neptune LNG	MARAD/USCG	100 miles north	Existing

Terminal Name	Type	Company	Jurisdiction	Distance from NY Bight Lease areas (approximate)	Status
Offshore Boston, MA	Import terminal, authorized to re-export delivered LNG	Excelerate Energy—Northeast Gateway	MARAD/USCG	95 miles north (Buoy B)	Existing
Cove Point, MD (Chesapeake Bay)	Import terminal / Export terminal	Dominion—Cove Point LNG	FERC	340 miles southwest	Existing
Elba Island, GA (Savannah River)	Import terminal	El Paso—Southern LNG	FERC	835 miles southwest	Existing
Elba Island, GA (Savannah River)	Import terminal / Export terminal	Southern LNG Company	FERC	835 miles southwest	Existing
Jacksonville, FL	Export terminal	Eagle LNG Partners	FERC	960 miles southwest	Proposed

DOMAC = Distrigas of Massachusetts LLC; GDF = Gaz de France; FL = Florida; GA = Georgia; LNG = liquified natural gas; MA = Massachusetts; MARAD = U.S. Department of Transportation Maritime Administration; MD = Maryland

D.2.12 Onshore Development Activities

Onshore development activities that may contribute to cumulative impacts include visible infrastructure such as onshore wind turbines, buildings (such as offices, retail, and multi-use spaces) and cell towers, port development, transportation projects, onshore coastal developments near landfall locations, and other energy projects such as transmission and pipeline projects. Coastal development projects permitted through regional planning commissions, counties, and towns may also contribute to cumulative impacts. These may include residential, commercial, and industrial developments spurred by population growth in the region (Table D-7).

Table D-7. Existing, approved, and planned onshore development activities

Onshore wind projects	According to the U.S. Geological Survey, there are three onshore wind projects within 40 miles of the NY Bight lease areas. The Bayonne Wind Energy Project consists of one 1.5 MW turbine with a tip height 103.60 meters and rotor diameter of 77 meters; Jersey Atlantic Wind Farm consists of five 1.5 MW turbines with a tip height of 118.6 meters and rotor diameter of 77.0 meters (Hoen et al. 2021). Additionally, there is one unnamed onshore wind project in Sunset Park, Brooklyn that consists of one turbine. The specifications of that turbine are unknown.
Development projects	As part of New York State's $100 billion infrastructure project, $5.6 billion will go to transform the Long Island Railroad to improve system connectivity. Within Suffolk County, the following stations will receive funds for upgrades: Brentwood, Deer Park, East Hampton, Northport, Ronkonkoma, Stony Brook, Port Jefferson, and Wyandanch. The East Hampton historic Long Island Railroad Station will undergo upgrades and modernizations (Metropolitan Transit Authority 2017; Press Release Point 2017). Additional plans for transit-oriented design and highway improvements are planned in Suffolk County in state and county planning documents. The Fire Island Inlet to Montauk Point Project is a $1.2 billion project by USACE, NYSDEC, and Long Island, New York, municipalities to engage in inlet management; beach, dune, and berm construction; breach response plans; raising and retrofitting 4,400 homes; road-raising; groin modifications; and coastal process features. Within Suffolk County, portions of the Towns of Babylon, Islip, Brookhaven, Southampton, and East Hampton; 12 incorporated villages along Long Island's south shore (mainland); Fire Island National Seashore; and the Poospatuck and Shinnecock Indian Reservations will be involved in this project (USACE 2018). A $2.7 million development project has been proposed for the former site of Bader Field, Atlantic City, adjacent to the Atlantic City estuary. The 143-acre Bader Field, now vacant, was the site of the first airport in the United States. The proposed development would include a 2.44-mile (4-kilometer) auto course, about 2,000 units of housing in various price ranges, a retail promenade, and other auto-themed attractions (Associated Press 2022). As part of a comprehensive flood-control strategy, Ocean City, New Jersey, is spending $25 million through 2025 to build new pumping stations, drainage systems, berms and retention walls, and new elevated road construction to control flooding in low-lying areas (City of Ocean City 2021a, 2021b). Additionally, there are several planned federal and state hurricane and storm damage reduction, beach nourishment, coastal storm risk management, flood and coastal storm damage reduction, and ecosystem restoration projects planned along coastal New Jersey (NJDEP 2022).
Port studies/ upgrades	The State of New Jersey is planning to build an offshore wind port on the eastern shore of the Delaware River in Lower Alloways Creek, Salem County, approximately 7.5 miles southwest of the city of Salem. The port site is adjacent to Public Service Electric & Gas's (PSE&G's) Hope Creek Nuclear Generating Station. The New Jersey Economic Development

Type	Description
	Authority (NJEDA) is leading the development of the project on behalf of the state, working alongside key departments and agencies such as the Governor’s Office, the Department of the Treasury, and NJBPU. Construction commenced in 2021 with a targeted completion date of late 2023. The development plan includes construction of a heavy-lift wharf with a dedicated delivery berth and an installation berth that can accommodate jack-up vessels, a 30-acre marshalling area for component assembly and staging, a dedicated overland heavy-haul transportation corridor, and potential for additional laydown areas. NJEDA estimates the project will cost $300 to $400 million (New Jersey Wind Port 2021). Both the Atlantic Shores South (OCS-A 0499) and Ocean Wind 2 (OCS-A 0532) projects have committed to building a nacelle assembly facility at the New Jersey Wind Port. The nacelle houses the components that convert the mechanical energy of the rotating blades into electrical energy and is the highest value-added offshore wind component. Atlantic Shores plans to partner with MHI Vestas for this facility while Ocean Wind will collaborate with General Electric (NJBPU 2021). In 2020, the State of New Jersey announced a $250 million investment in a manufacturing facility to build steel components for offshore wind turbines at the Port of Paulsboro on the Delaware River in New Jersey (New Jersey State 2020). Construction on the facility began in January 2021, with production anticipated to begin in 2023 (New Jersey Business 2020). Both the Atlantic Shores South and Ocean Wind 2 projects will utilize the foundation manufacturing facility at the Port of Paulsboro (NJBPU 2021). Ports in New York may require upgrades to support the offshore wind industry developing in the northeastern United States. Upgrades may include onshore developments or underwater improvements (such as dredging). In December 2017, NYSERDA issued an offshore wind master plan that assessed 54 distinct waterfront sites along the New York Harbor and Hudson River and 11 distinct areas with multiple small sites along the Long Island coast. Twelve waterfront areas and five distinct areas were singled out for “potential to be used or developed into facilities capable of supporting OSW projects” (Table 26, NYSERDA 2017). Nearly all identified sites would require some level of infrastructure upgrade (from minimal to significant) depending on offshore wind activities intended for the site. Particular sites of interest include Red Hook-Brooklyn, South Brooklyn Marine Terminal, and the Port of Coeymans (NYSERDA 2017). For additional information regarding specific proposed improvements to these ports, see Capital Region Economic Development Council 2018, American Association of Port Authorities 2016, Rulison 2018, and NYCEDC 2018. New York State has proposed port improvements that include the governor’s 2021 agenda “Reimagine | Rebuild | Renew,” which includes upgrades to create five dedicated port facilities for offshore wind, including the following: • The nation’s first offshore wind tower manufacturing facility, to be built at the Port of Albany • An offshore wind turbine staging facility and O&M hub to be established at the South Brooklyn Marine Terminal • Increasing the use of the Port of Coeymans for cutting-edge turbine foundation manufacturing • Buttressing ongoing O&M out of Port Jefferson and Port of Montauk Harbor in Long Island

Attachment D1: Ongoing and Planned Non-Offshore-Wind Activity Analysis

BOEM developed the following tables based on its 2019 study *National Environmental Policy Act Documentation for Impact-Producing Factors in the Offshore Wind Cumulative Impacts Scenario on the North Atlantic Outer Continental Shelf* (BOEM 2019), which evaluates potential impacts associated with ongoing and planned non-offshore-wind activities.

This page intentionally left blank.

Table D1-1. Summary of non-offshore-wind activities and the associated impact-producing factors for air quality

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Accidental releases: Fuel/ fluids/hazmat	Accidental releases of air toxics or hazardous air pollutants (HAPs) are due to potential chemical spills. Ongoing releases would occur in low frequencies. These may lead to short-term periods of toxic pollutant emissions through surface evaporation. According to the U.S. Department of Energy, 31,000 barrels of petroleum are spilled into U.S. waters from vessels and pipelines in a typical year. Approximately 40.5 million barrels of oil were lost as a result of tanker incidents from 1970 to 2009, according to International Tanker Owners Pollution Federation Limited, which collects data on oil spills from tankers and other sources. From 1990 to 1999, the average annual input to the coastal Northeast was 220,000 barrels of petroleum and offshore it was up to less than 70,000 barrels.	Accidental releases of air toxics or HAPs would be due to potential chemical spills. See Table D1-23 for a quantitative analysis of these risks. Gradually increasing vessel traffic over the next 35 years would increase the risk of accidental releases. These may lead to short-term periods of toxic pollutant emissions through evaporation. Air quality impacts would be short term and limited to the local area at and around the accidental release location.
Air emissions: Construction and decommissioning	Air emissions originate from combustion engines and electric power generated by burning fuel. These activities are regulated under the Clean Air Act (CAA) to meet set standards. Air quality has generally improved over the last 35 years; however, some areas in the Northeast have experienced a decline in air quality over the last 2 years. Some areas of the Atlantic coast remain in nonattainment for ozone, with the source of this pollution from power generation. Many of these states have made commitments toward cleaner energy goals to improve this, and offshore wind is part of these goals. Primary processes and activities that can affect the air quality impacts are expansions and modifications to existing fossil fuel power plants, onshore and offshore activities involving renewable energy facilities, and various construction activities. The construction, operation, and decommissioning of offshore wind projects would produce GHG emissions (nearly all CO_2) that can contribute to climate change; however, these contributions would be minuscule compared to aggregate global emissions. CO_2 is relatively stable in the atmosphere and generally mixed uniformly throughout the troposphere and stratosphere; therefore, the impact of GHG emissions does not depend upon the source location. Increasing energy production from offshore wind projects will likely decrease GHGs emissions by replacing energy from fossil fuels.	The largest air quality impacts over the next 35 years would occur during the construction phase of any one project; however, projects will be required to comply with the CAA. During the limited construction and decommissioning phases, emissions may occur that are above *de minimis* thresholds and will require offsets and mitigation. Primary emission sources would be increased commercial vehicular traffic, air traffic, public vehicular traffic, and combustion emissions from construction equipment and fugitive emissions from construction-generated dust. As projects come online, power generation emissions overall would decline, and the industry as a whole would have a net benefit on air quality.
Air emissions: O&M		Activities associated with O&M of onshore wind projects would have a proportionally very small contribution to emissions compared to the construction and installation and decommissioning activities over the next 35 years. Emissions would largely be due to commercial vehicular traffic and operation of emergency diesel generators. Such activity would result in short-term, intermittent, and widely dispersed emissions and small air quality impacts.
Air emissions: Power generation emissions reductions		Many Atlantic states have committed to clean energy goals, with offshore wind being a large part of that. Other reductions include transitioning to onshore wind and solar. The No Action Alternative without implementation of other planned onshore wind projects would likely result in increased air quality impacts regionally due to the need to construct and operate new energy generation facilities to meet future power demands. These facilities may consist of new natural-gas-fired power plants, coal-fired, oil-fired, or clean-coal-fired plants. These types of facilities would likely have larger and continuous emissions and result in greater regional scale impacts on air quality.
Air emissions: GHGs		Development of planned onshore wind projects would produce a small overall increase in GHG emissions over the next 35 years. However, these contributions would be very small compared to the aggregate global emissions. The impact on climate change from these activities would be very small. As more projects come online, there would be some reduction in GHG emissions from modifications of existing fossil fuel facilities to reduce power generation. Overall, it is anticipated that there would be no cumulative impact on global warming as a result of onshore wind project activities.
Accidental releases: Fuel/ fluids/hazmat	Accidental releases of air toxics or hazardous air pollutants (HAPs) are due to potential chemical spills. Ongoing releases would occur in low frequencies. These may lead to short-term periods of toxic pollutant emissions through surface evaporation. According to the U.S. Department of Energy, 31,000 barrels of petroleum are spilled into U.S. waters from vessels and pipelines in a typical year. Approximately 40.5 million barrels of oil were lost as a result of tanker incidents from 1970 to 2009, according to International Tanker Owners Pollution Federation Limited, which collects data on oil spills from tankers and other sources. From 1990 to 1999, the average annual input to the coastal Northeast was 220,000 barrels of petroleum and offshore it was up to less than 70,000 barrels.	Accidental releases of air toxics or HAPs would be due to potential chemical spills. See Table D1-23 for a quantitative analysis of these risks. Gradually increasing vessel traffic over the next 35 years would increase the risk of accidental releases. These may lead to short-term periods of toxic pollutant emissions through evaporation. Air quality impacts would be short term and limited to the local area at and around the accidental release location.

hazmat = hazardous materials

Table D1-2. Summary of non-offshore-wind activities and the associated impact-producing factors for bats

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Noise: Pile-driving	Noise from pile-driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded and would result in high-intensity, low-exposure-level, long-term, but localized intermittent risk to bats in nearshore waters. Direct impacts are not expected to occur, as recent research has shown that bats may be less sensitive to temporary threshold shifts (TTS) than other terrestrial mammals (Simmons et al. 2016). Indirect impacts (i.e., displacement from potentially suitable habitats) could occur because of construction activities, which could generate noise sufficient to cause avoidance behavior (Schaub et al. 2008). Construction activity would be temporary and highly localized.	Similar to Ongoing Activities, noise associated with pile-driving activities would be limited to nearshore waters and these high-intensity, but low-exposure, risks would not be expected to result in direct impacts. Some indirect impacts (i.e., displacement from potentially suitable foraging habitats) could occur as a result of construction activities, which could generate noise sufficient to cause avoidance behavior (Schaub et al. 2008). Construction activity would be temporary and highly localized, and no population-level effects would be expected.
Noise: Construction	Onshore construction occurs regularly for generic infrastructure projects in the bats geographic analysis area. There is a potential for displacement caused by equipment if construction occurs at night (Schaub et al. 2008). Any displacement would only be temporary. No individual or population-level impacts would be expected. Some bats roosting in the vicinity of construction activities may be disturbed during construction but would be expected to move to a different roost farther from construction noise. This would not be expected to result in any impacts, as frequent roost switching is a common component of a bat's life history (Hann et al. 2017; Whitaker 1998).	Onshore construction is expected to continue at current trends. Some behavioral responses and avoidance of construction areas may occur (Schaub et al. 2008). However, no injury or mortality would be expected.
Presence of structures: Migration disturbances	There may be a few structures scattered throughout the offshore bats geographic analysis area, such as navigation and weather buoys and light towers. Migrating bats can easily fly around or over these sparsely distributed structures, and no migration disturbance would be expected. Bat use of offshore areas is very limited and generally restricted to spring and fall migration. Very few bats would be expected to encounter structures on the OCS and no population-level effects would be expected.	The infrequent installation of future new structures in the marine environment of the next 35 years is expected to continue. As described under Ongoing Activities, these structures would not be expected to cause disturbance to migrating tree bats in the marine environment.
Presence of structures: Turbine strikes	There may be a few structures in the offshore bats geographic analysis area, such as navigation and weather buoys, turbines, and light towers. Migrating tree bats can easily fly around or over these sparsely distributed structures, and no strikes would be expected.	The infrequent installation of future new structures in the marine environment of the next 35 years is expected to continue. As described under Ongoing Activities, these structures would not be expected to result in increased collision risk to migrating tree bats in the marine environment.
Land disturbance: Onshore construction	Onshore construction activities are expected to continue at current trends. Potential direct effects on individuals may occur if construction activities include tree removal when bats are potentially present. Injury or mortality may occur if trees being removed are occupied by bats at the time of removal. While there is some potential for indirect impacts associated with habitat loss, no individual or population-level effects would be expected.	Planned non-offshore-wind development would continue to occur at the current rate. This development has the potential to result in habitat loss and could result in injury or mortality of individuals.

Table D1-3. Summary of non-offshore-wind activities and the associated impact-producing factors for benthic resources

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Accidental releases: Fuel/ fluids/hazmat	See Table D1-23 for a discussion of ongoing accidental releases. Accidental releases of hazmat occur periodically, mostly consisting of fuels, lubricating oils, and other petroleum compounds. Because most of these materials tend to float in seawater, they rarely contact benthic resources. The chemicals with potential to sink or dissolve rapidly often dilute to non-toxic levels before they affect benthic resources. The corresponding impacts on benthic resources are rarely noticeable.	Gradually increasing vessel traffic over the next 35 years would increase the risk of accidental releases. See the previous cell and Table D1-23 on water quality for details.
Accidental releases: Invasive species	Invasive species are periodically released accidentally during ongoing activities, including the discharge of ballast water and bilge water from marine vessels. The impacts on benthic resources (e.g., competitive disadvantage, smothering) depend on many factors, but can be noticeable, widespread, and permanent.	No future activities were identified within the geographic analysis area other than ongoing activities.
Accidental releases: Trash and debris	Ongoing releases of trash and debris occur from onshore sources, fisheries use, dredged material ocean disposal, marine minerals extraction, marine transportation, navigation and traffic, survey activities and cables, and lines and pipeline laying. However, there does not appear to be evidence that ongoing releases have detectable impacts on benthic resources.	No future activities were identified within the geographic analysis area other than ongoing activities.
Anchoring	Regular vessel anchoring related to ongoing military, survey, commercial, and recreational activities continue to cause temporary to permanent impacts in the immediate area where anchors and chains meet the seafloor. These impacts include increased turbidity levels and the potential for direct contact to cause injury and mortality of benthic resources, as well as physical damage to their habitats. All impacts are localized, turbidity is temporary, injury and mortality are recovered in the short term, and physical damage can be permanent if it occurs in eelgrass beds or hard bottom.	No future activities were identified within the geographic analysis area other than ongoing activities.
Cable emplacement and maintenance	Cable maintenance activities infrequently disturb benthic resources and cause temporary increases in suspended sediment; these disturbances would be localized and limited to the emplacement corridor. New cables are infrequently added near shore. Cable emplacement/maintenance activities injure and kill benthic resources and result in temporary to long-term habitat alterations. The intensity of impacts depends on the time (season) and place (habitat type) where the activities occur. (See also the Sub-IPFs of Seabed profile alterations and Sediment deposition and burial.)	No future activities were identified within the geographic analysis area other than ongoing activities.
Cable emplacement and maintenance: Seabed profile alterations	Ongoing sediment dredging for navigation purposes results in localized, short-term impacts (habitat alteration, injury, and mortality) on benthic resources through this IPF. Dredging typically occurs only in sandy or silty habitats, which are abundant in the geographic analysis area and are quick to recover from disturbance. Therefore, such impacts, while locally intense, have little impact on benthic resources in the geographic analysis area.	No future activities were identified within the geographic analysis area other than ongoing activities.
Cable emplacement and maintenance: Sediment deposition and burial	Ongoing sediment dredging for navigation purposes results in fine sediment deposition. Ongoing cable maintenance activities also infrequently disturb bottom sediments; these disturbances are localized and limited to the emplacement corridor. Sediment deposition could have adverse impacts on some benthic resources, especially eggs and larvae, including smothering and loss of fitness. Impacts may vary based on season/time of year. Where dredged materials are disposed of, benthic resources are smothered. However, such areas are typically recolonized naturally in the short term. Most sediment dredging projects have time-of-year restrictions to minimize impacts on benthic resources. Most benthic resources in the geographic analysis area are adapted to the turbidity and periodic sediment deposition that occur naturally in the geographic analysis area.	USACE or private ports may undertake dredging projects periodically. Where dredged materials are disposed, benthic resources are buried. However, such areas are typically recolonized naturally in the short term. Most benthic resources in the geographic analysis area are adapted to the turbidity and periodic sediment deposition that occur naturally in the geographic analysis area.
Discharges/intakes	The gradually increasing amount of vessel traffic is increasing the cumulative permitted discharges from vessels. Many discharges are required to comply with permitting standards established to ensure potential impacts on the environment are minimized or mitigated. However, there does not appear to be evidence that the volumes and extents have any impact on benthic resources.	There is the potential for new ocean dumping/dredge disposal sites in the Northeast. Impacts (disturbance, reduction in fitness) of infrequent ocean disposal on benthic resources are short term because spoils are typically recolonized naturally. In addition, USEPA has established dredge spoil criteria and it regulates the disposal permits issued by USACE; these discharges are required to comply with permitting standards established to ensure potential impacts on the environment are minimized or mitigated.
Electric and magnetic fields and cable heat	Electromagnetic fields (EMFs) continuously emanate from existing telecommunication and electrical power transmission cables. New cables generating EMFs are infrequently installed in the geographic analysis area. Some benthic species can detect EMFs, although EMFs do not appear to present a barrier to movement. The extent of impacts (behavioral changes) is likely less than 50 feet (15.2 meters) from the cable and the intensity of impacts on benthic resources is likely undetectable.	No future activities were identified within the geographic analysis area other than ongoing activities.
Noise: Onshore/offshore construction	See Table D1-10 on finfish, invertebrates, and essential fish habitat (EFH). Detectable impacts of construction noise on benthic resources rarely, if ever, overlap from multiple sources.	See Table D1-10 on finfish, invertebrates, and EFH. Detectable impacts of construction noise on benthic resources would rarely, if ever, overlap from multiple sources.

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Noise: G&G	See Table D1-10 on finfish, invertebrates, and EFH. Detectable impacts of G&G noise on benthic resources rarely, if ever, overlap from multiple sources.	See Table D1-10 on finfish, invertebrates, and EFH. Detectable impacts of G&G noise on benthic resources would rarely, if ever, overlap from multiple sources.
Noise: O&M	See Table D1-10 on finfish, invertebrates, and EFH.	See Table D1-10 on finfish, invertebrates, and EFH.
Noise: Pile-driving	Noise from pile-driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water or through the seabed can cause injury or mortality of benthic resources in a small area around each pile and can cause short-term stress and behavioral changes to individuals over a greater area. The extent depends on pile size, hammer energy, and local acoustic conditions.	No future activities were identified within the geographic analysis area other than ongoing activities.
Noise: Cable laying/ trenching	Infrequent trenching activities for pipeline and cable laying, as well as other cable burial methods, emit noise. These disturbances are localized and temporary, and they extend only a short distance beyond the emplacement corridor. Impacts of this noise are typically less prominent than the impacts of the physical disturbance and sediment suspension.	New or expanded submarine cables and pipelines are likely to occur in the geographic analysis area. These disturbances would be infrequent over the next 35 years, they would be localized and temporary, and they would extend only a short distance beyond the emplacement corridor. Impacts of this noise are typically less prominent than the impacts of the physical disturbance and sediment suspension.
Port utilization: Expansion	See Table D1-10 on finfish, invertebrates, and EFH.	See Table D1-10 on finfish, invertebrates, and EFH.
Presence of structures: Entanglement, gear loss, gear damage	Commercial and recreational fishing gear are periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures. The lost gear, moved by currents, can disturb, injure, or kill benthic resources, creating small, short-term, localized impacts.	Future new cables would present additional risk of gear loss, resulting in small, short-term, localized impacts (disturbance, injury).
Presence of structures: Hydrodynamic disturbance	See Table D1-10 on finfish, invertebrates, and EFH.	See Table D1-10 on finfish, invertebrates, and EFH.
Presence of structures: Fish aggregation	Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables, continuously create uncommon relief in a mostly sandy seascape. Structure-oriented fishes are attracted to these locations. Increased predation upon benthic resources by structure-oriented fishes can adversely affect populations and communities of benthic resources. These impacts are localized and permanent.	New cables installed in the geographic analysis area over the next 35 years would likely require hard protection atop portions of the route (see the "Cable emplacement and maintenance" IPF). Any new towers, buoys, or piers would also create uncommon relief in a mostly flat, sandy seascape. Structure-oriented fishes could be attracted to these locations. Increased predation upon benthic resources by structure-oriented fishes could adversely affect populations and communities of benthic resources. These impacts are expected to be localized and to be permanent as long as the structures remain.
Presence of structures: Habitat conversion	Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables, continuously provide uncommon hard-bottom habitat. A large portion is homogeneous sandy seascape but there is some other hard or complex habitat. Benthic species dependent on hard-bottom habitat can benefit on a constant basis, although the new habitat can also be colonized by invasive species (e.g., certain tunicate species). Structures are periodically added, resulting in the conversion of existing soft-bottom and hard-bottom habitat to the new hard-structure habitat.	See above for quantification and timing. Any new towers, buoys, piers, or cable protection structures would create uncommon relief in a mostly sandy seascape. Benthic species dependent on hard-bottom habitat could benefit, although the new habitat could also be colonized by invasive species (e.g., certain tunicate species). Soft bottom is the dominant habitat type in the region, and species that rely on this habitat would not likely experience population-level impacts (Guida et al. 2017; Greene et al. 2010).
Presence of structures: Cable infrastructure	The presence of cable infrastructure, especially hard protection atop cables, causes impacts through entanglement/ gear loss/damage, fish aggregation, and habitat conversion.	See other sub-IPFs within Presence of structures.

hazmat = hazardous materials

Table D1-4. Summary of non-offshore-wind activities and the associated impact-producing factors for birds

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Accidental releases: Fuel/fluids/hazmat	See Table D1-23 for a quantitative analysis of these risks. Ongoing releases are frequent/chronic. Ingestion of hydrocarbons can lead to morbidity and mortality due to decreased hematological function, dehydration, drowning, hypothermia, starvation, and weight loss (Briggs et al. 1997; Haney et al. 2017; Paruk et al. 2016). Additionally, even small exposures that cause feather oiling can lead to sublethal effects that include changes in flight efficiencies and result in increased energy expenditure during daily and seasonal activities including chick provisioning, commuting, courtship, foraging, long-distance migration, predator evasion, and territory defense (Maggini et al. 2017). These impacts rarely result in population-level impacts.	See Table D1-23 for a quantitative analysis of these risks. Gradually increasing vessel traffic over the next 35 years would increase the potential risk of accidental releases and associated impacts, including mortality, decreased fitness, and health effects on individuals. Impacts are unlikely to affect populations.
Accidental releases: Trash and debris	Trash and debris are accidentally discharged through onshore sources; fisheries use; dredged material ocean disposal; marine minerals extraction; marine transportation, navigation, and traffic; survey activities; and cables, lines, and pipeline laying on an ongoing basis. In a study from 2010, students at sea collected more than 520,000 bits of plastic debris per square mile. In addition, many fragments come from consumer products blown out of landfills or tossed out as litter (Law et al. 2010). Birds may accidentally ingest trash mistaken for prey. Mortality is typically a result of blockages caused by both hard and soft plastic debris (Roman et al. 2019).	As population and vessel traffic increase gradually over the next 35 years, accidental release of trash and debris may increase. This may result in increased injury or mortality of individuals. However, there does not appear to be evidence that the volumes and extents would have any impact on bird populations.
Cable emplacement and maintenance	Cable emplacement and maintenance activities disturb bottom sediments and cause temporary increases in suspended sediment; these disturbances will be temporary and generally limited to the emplacement corridor. Infrequent cable maintenance activities disturb the seafloor and cause temporary increases in suspended sediment; these disturbances will be temporary and limited to the emplacement corridor. Suspended sediment could impair the vision of diving birds that are foraging in the water column (Cook and Burton 2010). However, given the localized nature of the potential impacts, individuals would be expected to successfully forage in nearby areas not affected by increased sedimentation and no biologically significant impacts on individuals or populations would be expected.	Future new cables would occasionally disturb the seafloor and cause temporary increases in suspended sediment, resulting in localized, short-term impacts, with no biologically significant impacts on individuals or populations.
Lighting: Vessels	Ocean vessels have an array of lights including navigational lights, deck lights, and interior lights. Such lights can attract some birds. The impact is localized and temporary. This attraction would not be expected to result in an increased risk of collision with vessels. Population-level impacts would not be expected.	Gradually increasing vessel traffic over the next 35 years would increase the potential for bird and vessel interactions. While birds may be attracted to vessel lights, this attraction would not be expected to result in increased risk of collision with vessels. No population-level impacts would be expected.
Lighting: Structures	Buoys, towers, and onshore structures with lights can attract birds. Onshore structures like houses and ports emit a great deal more light than offshore buoys and towers. This attraction has the potential to result in an increased risk of collision with lighted structures (Hüppop et al. 2006). Light from structures is widespread and permanent near the coast, but minimal offshore.	Light from onshore structures is expected to gradually increase in proportion with human population growth along the coast. This increase is expected to be widespread and permanent near the coast, but minimal offshore.
Cable emplacement and maintenance	Cable emplacement and maintenance activities disturb bottom sediments and cause temporary increases in suspended sediment; these disturbances will be temporary and generally limited to the emplacement corridor. Infrequent cable maintenance activities disturb the seafloor and cause temporary increases in suspended sediment; these disturbances will be temporary and limited to the emplacement corridor. Suspended sediment could impair the vision of diving birds that are foraging in the water column (Cook and Burton 2010). However, given the localized nature of the potential impacts, individuals would be expected to successfully forage in nearby areas not affected by increased sedimentation and no biologically significant impacts on individuals or populations would be expected.	Future new cables would occasionally disturb the seafloor and cause temporary increases in suspended sediment, resulting in localized, short-term impacts, with no biologically significant impacts on individuals or populations.
Land disturbance: Onshore construction	Onshore construction activity will continue at current trends. There is some potential for indirect impacts associated with habitat loss and fragmentation.	Future non-offshore-wind development would continue to occur at the current rate. This development has the potential to result in habitat loss but would not be expected to result in injury or mortality of individuals.
Noise: Aircraft	Aircraft routinely travel in the geographic analysis area for birds. With the possible exception of rescue operations and survey aircraft, no ongoing aircraft flights would occur at altitudes that would elicit a response from birds. If flights are at a sufficiently low altitude, birds may flush, resulting in non-biologically significant increased energy expenditure. Disturbance, if any, would be localized and temporary and impacts would be expected to dissipate once the aircraft has left the area.	Aircraft noise is likely to continue to increase as commercial air traffic increases; however, very few flights would be expected to be at a sufficiently low altitude to elicit a response from birds. If flights are at a sufficiently low altitude, birds may flush, resulting in non-biologically significant increased energy expenditure. Disturbance, if any, would be localized and temporary and impacts would be expected to dissipate once the aircraft has left the area.
Noise: G&G	Infrequent site characterization surveys and scientific surveys produce high-intensity impulsive noise around sites of investigation. These activities could result in diving birds leaving the local area. Non-diving birds would be unaffected. Any displacement would only be temporary during non-migratory periods, but impacts could be greater if displacement were to occur in preferred feeding areas during seasonal migration periods.	Same as ongoing activities, with the addition of possible future oil and gas surveys.

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Noise: Pile-driving	Noise from pile-driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water could result in intermittent, temporary, localized impacts on diving birds due to displacement from foraging areas if birds are present in the vicinity of pile-driving activity. The extent of these impacts depends on pile size, hammer energy, and local acoustic conditions. No biologically significant impacts on individuals or populations would be expected.	No future activities were identified within the geographic analysis area for birds other than ongoing activities.
Noise: Onshore construction	Onshore construction is routinely used in generic infrastructure projects. Equipment could potentially cause displacement. Any displacement would only be temporary, and no individual fitness or population-level impacts would be expected.	Onshore construction will continue at current trends. Some behavioral responses could range from escape behavior to mild annoyance, but no individual injury or mortality would be expected.
Noise: Vessels	Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. Sub-surface noise from vessels could disturb diving birds foraging for prey below the surface. The consequence to birds would be similar to that of noise from G&G but likely less because noise levels are lower.	No future activities were identified within the geographic analysis area for birds other than ongoing activities.
Presence of structures: Entanglement, gear loss, gear damage	Each year, 2,551 seabirds die annually from interactions with U.S. commercial fisheries on the Atlantic (Sigourney et al. 2019). Even more die due to abandoned commercial fishing gear (nets). In addition, recreational fishing gear (hooks and lines) is periodically lost on existing buoys, pilings, hard protection, and other structures and has the potential to entangle birds.	No future activities were identified within the geographic analysis area for birds other than ongoing activities.
Presence of structures: Fish aggregation	Structures, including tower foundations, scour protection around foundations, and various hard protections atop cables, create uncommon relief in a mostly flat seascape. Structure-oriented fishes are attracted to these objects. These impacts are localized and can be short term to permanent. Fish aggregation can provide localized, short-term to permanent, beneficial impacts on some bird species because it could increase prey species availability.	New cables, installed incrementally in the geographic analysis area for birds over the next 20 to 35 years, would likely require hard protection atop portions of the cables (see the “Cable emplacement and maintenance” IPF). Any new towers, buoys, or piers would also create uncommon relief in a mostly flat seascape. Structure-oriented fishes could be attracted to these locations. Abundance of certain fishes may increase. These fish aggregations can provide localized, short-term to permanent beneficial impacts on some bird species due to increased prey species availability.
Presence of structures: Migration disturbances	A few structures may be scattered about the offshore geographic analysis area for birds, such as navigation and weather buoys and light towers. Migrating birds can easily fly around or over these sparsely distributed structures.	The infrequent installation of future new structures in the marine or onshore environment over the next 35 years would not be expected to result in migration disturbances.
Presence of structures: Turbine strikes, displacement, and attraction	A few structures may be in the offshore geographic analysis area for birds, such as navigation and weather buoys, turbines, and light towers. Given the limited number of structures currently in the geographic analysis area, individual- and population-level impacts due to displacement from current foraging habitat would not be expected. Stationary structures in the offshore environment would not be expected to pose a collision risk to birds. Some birds like cormorants and gulls may be attracted to these structures and opportunistically roost on these structures.	The installation of future new structures in the marine or onshore environment over the next 35 years would not be expected to cause an increase in collision risk or to result in displacement. Some potential for attraction and opportunistic roosting exists but would be expected to be limited given the anticipated number of structures.
Traffic: Aircraft	General aviation accounts for approximately two bird strikes per 100,000 flights (Dolbeer et al. 2022). In addition to general aviation, aircraft are used for scientific and academic surveys in marine environments.	Bird fatalities associated with general aviation would be expected to increase with the current trend in commercial air travel. Aircraft would continue to be used to conduct scientific research studies as well as wildlife monitoring and pre-construction surveys. These flights would be well below the 100,000 flights and no bird strikes would be expected to occur.
Land disturbance: Onshore construction	Onshore construction activity will continue at current trends. There is some potential for indirect impacts associated with habitat loss and fragmentation.	Future non-offshore-wind development would continue to occur at the current rate. This development has the potential to result in habitat loss but would not be expected to result in injury or mortality of individuals.

hazmat = hazardous materials

Table D1-5. Summary of non-offshore-wind activities and the associated impact-producing factors for coastal habitat and fauna

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Accidental release and discharge	See Table D1-23 for a discussion of ongoing accidental releases. Accidental releases of hazmat occur periodically, mostly consisting of fuels, lubricating oils, and other petroleum compounds. Because most of these materials tend to float in seawater, they rarely contact benthic coastal resources. The chemicals with potential to sink or dissolve rapidly often dilute to non-toxic levels before they affect coastal resources. The corresponding impacts on coastal resources are rarely noticeable.	Gradually increasing vessel traffic over the next 35 years would increase the risk of accidental releases. See the previous cell and Table D1-23 on water quality for details.
Anchoring	Regular vessel anchoring related to ongoing military, survey, commercial, and recreational activities continue to cause temporary to permanent impacts in the immediate area where anchors and chains meet the seafloor. These impacts include increased turbidity levels and the potential for direct contact to cause injury and mortality of coastal benthic resources, as well as physical damage to their habitats. All impacts are localized; turbidity is temporary; injury and mortality is permanent for individuals but populations would recover in the short term; and physical damage can be permanent if it occurs in eelgrass beds or hard bottom.	No future activities were identified within the geographic analysis area for coastal habitat and fauna other than ongoing activities.
Cable emplacement and maintenance	Cable maintenance activities infrequently disturb coastal resources and cause temporary increases in suspended sediment; these disturbances would be localized and limited to the emplacement corridor. New cables are infrequently added near shore. Cable emplacement/maintenance activities injure and kill coastal benthic resources and result in temporary to long-term habitat alterations. The intensity of impacts depends on the time (season) and place (habitat type) where the activities occur.	No future activities were identified within the geographic analysis area for coastal habitat and fauna other than ongoing activities.
Electric and magnetic fields and cable heat	Electromagnetic fields (EMFs) continuously emanate from existing telecommunication and electrical power transmission cables. New cables generating EMFs are infrequently installed in the geographic analysis area. Some benthic species can detect EMFs, although EMFs do not appear to present a barrier to movement. The extent of impacts (behavioral changes) is likely less than 50 feet (15.2 meters) from the cable and the intensity of impacts on coastal benthic resources is likely undetectable.	No future activities were identified within the geographic analysis area for coastal habitat and fauna other than ongoing activities.
Light	Buoys, towers, and onshore structures with lights can attract coastal fauna. Onshore structures like houses and ports emit a great deal more light than offshore buoys and towers. Light from structures is widespread and permanent near the coast, but minimal offshore.	Light from onshore structures is expected to gradually increase in proportion with human population growth along the coast. This increase is expected to be widespread and permanent near the coast, but minimal offshore.
Noise: Onshore construction	Onshore construction is routinely used in generic infrastructure projects. Equipment could potentially cause displacement. Any displacement would only be temporary, and no individual fitness or population-level impacts would be expected.	Onshore construction will continue at current trends. Some behavioral responses could range from avoidance behavior to mild annoyance, but no individual injury or mortality would be expected.
Presence of structures	See Table D1-3 on benthic resources.	See Table D1-3 on benthic resources.
Land disturbance: Onshore construction	Onshore residential, commercial, and industrial development are expected to continue at current trends. Construction activities may result in loss of coastal habitat and temporary or permanent displacement and injury to or mortality of individual animals, but population-level effects would not be expected.	Future non-offshore-wind development would continue to occur at the current rate. This development has the potential to result in habitat loss but would not be expected to result in injury or mortality of individuals.
Land disturbance: Onshore land use changes	Ongoing development of onshore properties, especially shoreline parcels, periodically causes the conversion of onshore coastal habitats to become developed space. Onshore construction activity will continue at current trends. There is some potential for indirect impacts associated with habitat loss and fragmentation.	Future non-offshore-wind development would continue to occur at the current rate. This development has the potential to result in habitat loss but would not be expected to result in injury or mortality of individuals.
Traffic: Vehicle collisions	Vehicle collisions may result in injury to or mortality of individual animals, but population-level effects would not be expected.	Impacts from vehicle collisions with wildlife are expected to continue and to occur at the current rate.

Table D1-6. Summary of non-offshore-wind activities and the associated impact-producing factors for commercial fisheries and for-hire recreational fishing

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Anchoring	Impacts from anchoring occur due to ongoing military, survey, commercial, and recreational activities. The short-term, localized impact on this resource is the presence of a navigational hazard (anchored vessel) to fishing vessels.	Impacts from anchoring may occur on a semi-regular basis over the next 35 years due to offshore military operations, survey activities, commercial vessel traffic, and recreational vessel traffic. Anchoring could pose a temporary (hours to days), localized (within a few hundred meters of anchored vessel) navigational hazard to fishing vessels.
Cable emplacement and maintenance	New cable emplacement and infrequent cable maintenance activities disturb the seafloor, increase suspended sediment, and cause temporary displacement of fishing vessels. These disturbances would be localized and limited to the emplacement corridor.	Future new cables and cable maintenance would occasionally disturb the seafloor and cause temporary displacement in fishing vessels and increases in suspended sediment resulting in localized, short-term impacts. If the cable routes enter the geographic analysis area for this resource, short-term disruption of fishing activities would be expected.
Noise: Construction, trenching, O&M	Noise from construction occurs frequently in coastal habitats in populated areas in New England and the Mid-Atlantic, but infrequently offshore. The intensity and extent of noise from construction are difficult to generalize, but impacts are localized and temporary. Infrequent offshore trenching could occur in connection with cable installation. These disturbances are temporary and localized, and they extend only a short distance beyond the emplacement corridor. Low levels of elevated noise from operational WTGs are likely have low to no impacts on fish and no impacts at a fishery level. Noise is also created by O&M of marine minerals extraction, which has small, localized impacts on fish, but likely no impacts at a fishery level.	Noise from construction near shore is expected to gradually increase in line with human population growth along the coast of the geographic analysis area for this resource. Noise from dredging and sand and gravel mining could occur. New or expanded marine minerals extraction may increase noise during their O&M over the next 35 years. Impacts from construction, operations, and maintenance would likely be small and localized on fish, and not seen at a fishery level. Periodic trenching would be needed for repair or new installation of underground infrastructure. These disturbances would be temporary and localized, and they extend only a short distance beyond the emplacement corridor. Impacts of trenching noise on commercial fish species are typically less prominent than the impacts of the physical disturbance and sediment suspension. Therefore, fishery-level impacts are unlikely.
Noise: G&G	Ongoing site characterization surveys and scientific surveys produce noise around sites of investigation. These activities can disturb fish and invertebrates in the immediate vicinity of the investigation and can cause temporary behavioral changes. The extent depends on equipment used, noise levels, and local acoustic conditions.	Site characterization surveys, scientific surveys, and exploratory oil and gas surveys are anticipated to occur infrequently over the next 35 years. Seismic surveys used in oil and gas exploration create high-intensity impulsive noise to penetrate deep into the seabed, potentially resulting in injury or mortality to finfish and invertebrates in a small area around each sound source and short-term stress and behavioral changes to individuals over a greater area. Site characterization surveys typically use sub-bottom profiler technologies that generate less-intense sound waves more similar to common deep-water echosounders. The intensity and extent of the resulting impacts are difficult to generalize but are likely localized and temporary.
Noise: Pile-driving	Noise from pile-driving occurs periodically in nearshore areas when ports or marinas, piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water or through the seabed can cause injury or mortality of finfish and invertebrates in a small area around each pile and can cause short-term stress and behavioral changes to individuals over a greater area, leading to temporary, localized impacts on commercial fisheries and for-hire recreational fishing. The extent depends on pile size, hammer energy, and local acoustic conditions.	No future activities were identified within the geographic analysis area for commercial fisheries and for-hire recreational fishing, other than ongoing activities.
Noise: Vessels	Vessel noise is anticipated to continue at levels similar to current levels. While vessel noise may have some impact on behavior, it is likely limited to brief startle and temporary stress responses. Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, and scientific and academic research vessels.	Planned new barge route and dredging disposal sites would generate vessel noise when implemented.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also undergoing continual upgrades and maintenance, including dredging. Port utilization is expected to increase over the next 35 years.	Ports would need to perform maintenance and upgrades to ensure that they can still receive the projected future volume of vessels visiting their ports, and to be able to host larger deep-draft vessels as they continue to increase in size. Port utilization is expected to increase over the next 35 years, with increased activity during construction. The ability of ports to receive the increase in vessel traffic may require port modifications, such as channel deepening, leading to localized impacts on fish populations. Port expansions could also increase vessel traffic and competition for dockside services, which could affect fishing vessels.
Presence of structures: Navigation hazard and allisions	Structures within and near the cumulative lease areas that pose potential navigation hazards include buoys and shoreline developments such as docks and ports. An allision occurs when a moving vessel strikes a stationary object. The stationary object can be a buoy, a port feature, or another anchored vessel. Two types of allisions occur: drift and powered. A drift allision generally occurs when a vessel is powered down due to operator choice or power failure. A powered allision generally occurs when an operator fails to adequately control their vessel movements or is distracted.	No known reasonably foreseeable structures are proposed to be located in the geographic analysis area that could affect commercial fisheries. Vessel allisions with non-offshore-wind stationary objects should not increase meaningfully without a substantial increase in vessel congestion.
Presence of structures: Entanglement, gear loss, gear damage	Commercial and recreational fishing gear is periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures. The lost gear, moved by currents, can disturb habitats and potentially harm individuals, creating small, localized, short-term impacts on fish, but likely no impacts at a fishery level.	No future activities were identified within the geographic analysis area for commercial fisheries and for-hire recreational fishing, other than ongoing activities.

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Presence of structures: Habitat conversion and fish aggregation	Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables, create uncommon relief in a mostly sandy seascape. A large portion is homogeneous sandy seascape but there is some other hard or complex habitat. Structures are periodically added, resulting in the conversion of existing soft-bottom and hard-bottom habitat to the new hard-structure habitat. Structure-oriented fishes are attracted to these locations. These impacts are localized and can be short term to permanent. Fish aggregation may be considered adverse, beneficial, or neutral. Commercial and for-hire recreational fishing can occur near these structures. For-hire recreational fishing is more popular, as commercial mobile fishing gear risks snagging on the structures.	New cables, installed incrementally in the geographic analysis area over the next 20 to 35 years, would likely require hard protection atop portions of the route (see "Cable emplacement/ and maintenance" IPF). Any new towers, buoys, or piers would also create uncommon relief in a mostly flat seascape. Structure-oriented species could be attracted to these locations and would benefit (Claisse et al. 2014; Smith et al. 2016). This may lead to more and larger structure-oriented fish communities and larger predators opportunistically feeding on the communities, as well as increased private and for-hire recreational fishing opportunities. Soft bottom is the dominant habitat type in the region, and species that rely on this habitat would not likely experience population-level impacts (Guida et al. 2017; Greene et al. 2010). These impacts are expected to be localized and may be long term.
Presence of structures: Migration disturbances	Human structures in the marine environment (e.g., shipwrecks, artificial reefs, buoys, and oil platforms) can attract finfish and invertebrates that approach the structures during their migrations. This could slow species migrations. However, temperature is expected to be a bigger driver of habitat occupation and species movement than structure (Secor et al. 2018). There is no evidence to suggest that structures pose a barrier to migratory animals.	The infrequent installation of future new structures in the marine environment over the next 35 years may attract finfish and invertebrates that approach the structures during their migrations. This could tend to slow migrations. However, temperature is expected to be a bigger driver of habitat occupation and species movement (Secor et al. 2018). Migratory animals would likely be able to proceed from structures unimpeded. Therefore, fishery-level impacts are not anticipated.
Presence of structures: Space-use conflicts	Current structures do not result in space-use conflicts.	No future activities were identified within the geographic analysis area for commercial fisheries and for-hire recreational fishing, other than ongoing activities.
Presence of structures: Cable infrastructure	The existing offshore cable infrastructure supports the economy by transmitting electric power and communications between mainland and islands. Shoreline developments are ongoing and include docks, ports, and other commercial, industrial, and residential structures.	No future activities were identified within the geographic analysis area for commercial fisheries and for-hire recreational fishing, other than ongoing activities.
Traffic: Vessels and vessel collisions	No substantial changes are anticipated to the vessel traffic volumes. The geographic analysis area would continue to have numerous ports and the extensive marine traffic related to shipping, fishing, and recreation would continue to be important to the region's economy. The region's substantial marine traffic may result in occasional collisions. Vessels need to navigate around structures to avoid allisions. When multiple vessels need to navigate around a structure, then navigation is more complex, as the vessels need to avoid both the structure and each other. The risk for collisions is ongoing but infrequent.	New vessel traffic in the geographic analysis area would consistently be generated by proposed barge routes and dredging demolition sites. Marine commerce and related industries would continue to be important to the regional economy.

Table D1-7. Summary of non-offshore-wind activities and the associated impact-producing factors for cultural resources

Associated IPF: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Accidental releases: Fuel/fluids/ hazmat	See Table D1-23 for water quality for a quantitative analysis of these risks. Accidental releases of fuel/fluids/ hazmat occur during vessel use for recreational, fisheries, marine transportation, or military purposes, and other ongoing activities. Both released fluids and cleanup activities that require the removal of contaminated soils or seafloor sediments can cause impacts on cultural resources because resources are affected by the released chemicals as well as the ensuing cleanup activities.	Gradually increasing vessel traffic over the next 35 years would increase the risk of accidental releases within the geographic analysis area for cultural resources, increasing the frequency of small releases. Although the majority of anticipated accidental releases would be small, resulting in small-scale impacts on cultural resources, a single, large-scale accidental release such as an oil spill could have significant impacts on marine and coastal cultural resources. A large-scale release would require extensive cleanup activities to remove contaminated materials, resulting in damage to or complete removal of terrestrial and marine cultural resources. In addition, the accidentally released materials in deep-water settings could settle on seafloor cultural resources such as wreck sites, accelerating their decomposition or covering them and making them inaccessible/unrecognizable to researchers, resulting in a significant loss of historic information. As a result, although considered unlikely, a large-scale accidental release and associated cleanup could result in permanent, geographically extensive, and large-scale impacts on cultural resources.
Accidental releases: Trash and debris	Accidental releases of trash and debris occur during vessel use for recreational, fisheries, marine transportation, or military purposes and other ongoing activities. While the released trash and debris can directly affect cultural resources, the majority of impacts associated with accidental releases occur during cleanup activities, especially if soil or sediment removed during cleanup affect known and undiscovered archaeological resources. In addition, the presence of large amounts of trash on shorelines or the ocean surface can affect the cultural value of traditional cultural properties (TCPs) for stakeholders. State and federal laws prohibiting large releases of trash would limit the size of any individual release and ongoing local, state, and federal efforts to clean up trash on beaches and waterways would continue to mitigate the effects of small-scale accidental releases of trash.	Future activities with the potential to result in accidental releases include construction and operations of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications). Accidental releases would continue at current rates along the Northeast Atlantic coast.
Anchoring	The use of vessel anchoring and gear (i.e., wire ropes, cables, chain, sweep on the seafloor) that disturbs the seafloor, such as bottom trawls and anchors, by military, recreational, industrial, and commercial vessels can affect cultural resources by physically damaging maritime archaeological resources such as shipwrecks and debris fields.	Future activities with the potential to result in anchoring/gear utilization include construction and operations of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); military use; marine transportation; fisheries use and management; and oil and gas activities. These activities are likely to continue to occur at current rates along the entire coast of the eastern United States.
Cable emplacement and maintenance	Infrequent cable maintenance activities disturb the seafloor and could cause impacts on submerged archaeological resources. These disturbances would be localized and limited to emplacement corridors.	Future activities with the potential to result in seafloor disturbances similar to offshore impacts include construction and operation of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); marine minerals use and ocean-dredged material disposal; military use; and oil and gas activities. Such activities could cause impacts on submerged archaeological resources including shipwrecks and formerly subaerially exposed pre-contact Native American archaeological sites.
Gear utilization: Dredging	Activities associated with dredge operations and activities could damage marine archaeological resources. Ongoing activities identified by BOEM with the potential to result in dredging impacts include construction and operation of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); marine minerals use and ocean-dredged material disposal; military use; marine transportation; fisheries use and management; and oil and gas activities.	Dredging activities would gradually increase through time as new offshore infrastructure is built, such as gas pipelines and electrical lines, and as ports and harbors are expanded or maintained.
Land disturbance: Onshore construction	Onshore construction activities can affect archaeological resources by damaging or removing resources.	Future activities that could result in terrestrial land disturbance impacts include onshore residential, commercial, industrial, and military development activities in the central Atlantic, particularly those proximate to offshore ECCs and interconnection facilities. Onshore construction would continue at current rates.
Lighting: Vessels	Light associated with military, commercial, or construction vessel traffic can temporarily affect coastal historic structures and TCP resources when the addition of intrusive, modern lighting changes the physical environment (“setting”) of cultural resources. The impacts of construction and operational lighting would be limited to cultural resources on the shoreline for which a nighttime sky is a contributing element to historic integrity. This excludes resources that are closed at night, such as historic buildings, lighthouses, and battlefields, and resources that generate their own nighttime light, such as historic districts. Offshore construction activities that require increased vessel traffic, construction vessels stationed offshore, and construction area lighting for prolonged periods can cause more sustained and significant visual impacts on coastal historic structure and TCP resources.	Future activities with the potential to result in vessel lighting impacts include construction and operation of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); marine minerals use and ocean-dredged material disposal; military use; marine transportation; fisheries use and management; and oil and gas activities. Light pollution from vessel traffic would continue at the current intensity along the Northeast coast, with a slight increase due to population increase and development over time.

Associated IPF: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Lighting: Structures	The construction of new structures that introduce new light sources into the setting of historic architectural properties or TCPs can result in impacts, particularly if the historic or cultural significance of the resource is associated with uninterrupted nighttime skies or periods of darkness. Any tall structure (e.g., commercial building, radio antenna, large satellite dishes) requiring nighttime hazard lighting to prevent aircraft collision can cause these types of impacts.	Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast, but minimal offshore.
Presence of structures	The only existing offshore structures within the viewshed of the geographic analysis area are minor features such as buoys.	Non-offshore-wind structures that could be viewed would be limited to meteorological towers. Marine activity would also occur within the marine viewshed of the geographic analysis area.

hazmat = hazardous materials

Table D1-8. Summary of non-offshore-wind activities and the associated impact-producing factors for demographics, employment, and economics

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Cable emplacement and maintenance	Infrequent cable maintenance activities disturb the seafloor and cause temporary increases in suspended sediment; these disturbances would be localized and limited to emplacement corridors. There are six existing power cables in the geographic analysis area for demographics, employment, and economics.	Future new cables would disturb the seafloor and cause temporary increases in suspended sediment resulting in infrequent, localized, short-term impacts over the next 35 years.
Land disturbance: Onshore construction	Onshore development activities support local population growth, employment, and economics. Disturbances can cause temporary, localized traffic delays and restricted access to adjacent properties. The rate of onshore land disturbance is expected to continue at or near current rates.	Onshore development projects would be ongoing in accordance with local government land use plans and regulations.
Lighting: Structures	Offshore buoys and towers emit low-intensity light, while onshore structures, including houses and ports, emit substantially more light on an ongoing basis.	Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast, but minimal offshore.
Lighting: Vessels	Ocean vessels have an array of lights including navigational lights and deck lights.	Anticipated modest growth in vessel traffic would result in some growth in the nighttime traffic of vessels with lighting.
Noise: Cable laying/ trenching	Infrequent trenching for pipeline and cable-laying activities emit noise. These disturbances are temporary and localized and extend only a short distance beyond the emplacement corridor. Impacts of trenching noise are typically less prominent than the impacts of the physical disturbance and sediment suspension.	Periodic trenching would be needed over the next 35 years for repair or new installation of underground infrastructure.
Noise: Pile-driving	Noise from pile-driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. These disturbances are temporary and localized and extend only a short distance beyond the work area.	No future activities were identified within the geographic analysis area for demographics, employment, and economics other than ongoing activities.
Noise: Vessels	Vessel noise occurs offshore and more frequently near ports and docks. Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. Vessel noise is anticipated to continue at or near current levels.	Planned new barge route and dredging disposal sites would generate vessel noise when implemented. The number and location of such routes are uncertain.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also undergoing continual upgrades and maintenance. The New Jersey Wind Port is being developed and the Paulsboro Marine Terminal is being upgraded specifically to support the construction of offshore wind energy facilities.	Ports would need to perform maintenance and upgrade facilities over the next 35 years to ensure that they can still receive the projected future volume of vessels visiting their ports, and to be able to host larger deep-draft vessels as they continue to increase in size.
Port utilization: Maintenance/dredging	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. As ports expand, maintenance dredging of shipping channels is expected to increase.	Ports would need to perform maintenance and upgrades over the next 35 years to ensure that they can still receive the projected future volume of vessels visiting their ports, and to be able to host larger deep-draft vessels as they continue to increase in size.
Presence of structures: Allisions	An allision occurs when a moving vessel strikes a stationary object. The stationary object can be a buoy, a port feature, or another anchored vessel. The likelihood of allisions is expected to continue at or near current levels.	Vessel allisions with non-offshore-wind stationary objects should not increase meaningfully without a substantial increase in vessel congestion.
Presence of structures: Entanglement, gear loss, gear damage	Commercial and recreational fishing gear is periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures. Such loss and damage are direct costs for gear owners and are expected to continue at or near current levels.	Reasonably foreseeable activities (non-offshore-wind) would not result in additional offshore structures.
Presence of structures: Fish aggregation	Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables, create uncommon relief in a mostly flat seascape. Structure-oriented fishes are attracted to these locations, which may be known as Fish Aggregating Devices (FADs). Recreational and commercial fishing can occur near the FADs, although recreational fishing is more popular, because commercial mobile fishing gear is more likely to snag on FADs.	Reasonably foreseeable activities (non-offshore-wind) would not result in additional offshore structures.
Presence of structures: Habitat conversion	Structures, including foundations, scour protection around foundations, and various means of hard protection atop cables, create uncommon relief in a mostly flat seascape. Structure-oriented species thus benefit on a constant basis.	Reasonably foreseeable activities (non-offshore-wind) would not result in additional offshore structures.
Presence of structures: Navigation hazard	Vessels need to navigate around structures to avoid allisions, especially in nearshore areas. This navigation becomes more complex when multiple vessels must navigate around a structure, because vessels need to avoid both the structure and each other.	Vessel traffic, overall, is not expected to meaningfully increase over the next 35 years. The presence of navigation hazards is expected to continue at or near current levels.
Presence of structures: Space-use conflicts	Current structures do not result in space-use conflicts.	Reasonably foreseeable activities (non-offshore-wind) would not result in additional offshore structures.
Presence of structures: Viewshed	No existing offshore structures are within the viewshed of the offshore wind lease area except buoys.	Reasonably foreseeable activities (non-offshore-wind) would not result in additional offshore structures.
Presence of structures: Transmission cable infrastructure	The existing offshore cable infrastructure supports the economy by transmitting electric power and communications between mainland and islands. Additional communication cables run between the U.S. East Coast and European countries along the eastern Atlantic.	No known proposed structures not associated with offshore wind development are reasonably foreseeable.

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Traffic: Vessels	Ports and marine traffic related to shipping, fishing, and recreation are important to the region's economy. No substantial changes are anticipated to existing vessel traffic volumes.	New vessel traffic near the geographic analysis area would be generated by proposed barge routes and dredging demolition sites over the next 35 years. Marine commerce and related industries would continue to be important to the geographic analysis area economy.
Traffic: Vessel collisions	The region's substantial marine traffic may result in occasional vessel collisions, which would result in costs to the vessels involved. The likelihood of collisions is expected to continue at or near current rates.	No substantial changes are anticipated.

FAD = fish aggregating device

Table D1-9. Summary of non-offshore-wind activities and the associated impact-producing factors for environmental justice

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Air emissions: Construction/ decommissioning	Ongoing population growth and new development within the geographic analysis area is likely to increase traffic, with resulting increases in emissions from motor vehicles. Some new industrial development may result in emission-producing uses. At the same time, many industrial waterfront areas near environmental justice communities are losing industrial uses and converting to more commercial or residential uses.	New developments may include emission-producing industry and new developments that would increase emissions from motor vehicles. Some historically industrial waterfront locations will continue to lose industrial uses, with no new industrial development to replace it.
Air emissions: O&M	Ongoing population growth and new development within the geographic analysis area is likely to increase traffic, with resulting increase in emissions from motor vehicles. Some new industrial development may result in emission-producing uses. At the same time, many industrial waterfront areas near environmental justice communities are losing industrial uses and converting to more commercial or residential uses.	New developments may include emission-producing industry and new developments that would increase emissions from motor vehicles. Some historically industrial waterfront locations will continue to lose industrial uses, with no new industrial development to replace it.
Cable emplacement and maintenance	Infrequent cable maintenance activities disturb the seafloor and cause temporary increases in suspended sediment; these disturbances would be localized and limited to emplacement corridors.	Future new cables would disturb the seafloor and cause temporary increases in suspended sediment, resulting in infrequent, localized, short-term impacts over the next 35 years.
Land disturbance: Erosion and sedimentation	Potential erosion and sedimentation from development and construction are controlled by local and state development regulations.	New development activities would be subject to erosion and sedimentation regulations.
Land disturbance: Onshore construction	Onshore development supports local population growth, employment, and economics.	Onshore development would continue in accordance with local government land use plans and regulations.
Land disturbance: Onshore, land use changes	Onshore development would result in changes in land use in accordance with local government land use plans and regulations.	Development of onshore solar and wind energy would provide diversified, small-scale energy generation.
Lighting: Structures	Offshore buoys and towers emit low-intensity light, while onshore structures, including houses and ports, emit substantially more light on an ongoing basis.	Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast, but minimal offshore.
Noise: Pile-driving	Noise from pile-driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. These disturbances are temporary and localized, and they extend only a short distance beyond the work area.	No future activities were identified within the geographic analysis area other than ongoing activities.
Noise: Trenching	Infrequent trenching for pipeline and cable-laying activities emits noise. These disturbances are temporary and localized, and they extend only a short distance beyond the emplacement corridor. Impacts of trenching noise are typically less prominent than the impacts of the physical disturbance and sediment suspension.	Periodic trenching would be needed over the next 35 years for repair or new installation of underground infrastructure.
Noise: Vessels	Vessel noise occurs offshore and more frequently near ports and docks. Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, and scientific and academic research vessels.	Vessel noise is anticipated to continue at or near current levels.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also undergoing continual upgrades and maintenance. The New Jersey Wind Port is being developed and the Paulsboro Marine Terminal is being upgraded specifically to support the construction of offshore wind energy facilities.	Ports would need to perform maintenance and upgrade facilities to ensure that they can still receive the projected future volume of vessels visiting their ports, and to be able to host larger deep-draft vessels as they continue to increase in size.
Presence of structures: Entanglement, gear loss/ damage	Commercial and recreational fishing gear is periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures. Such loss and damage are direct costs for gear owners and are expected to continue at or near current levels.	Reasonably foreseeable activities (non-offshore-wind) would not result in additional offshore structures.
Presence of structures: Navigation hazard	Vessels need to navigate around structures to avoid allisions, especially in nearshore areas. This navigation becomes more complex when multiple vessels must navigate around a structure, because vessels need to avoid both the structure and each other.	Vessel traffic is generally not expected to meaningfully increase over the next 35 years. The presence of navigation hazards is expected to continue at or near current levels.
Presence of structures: Space-use conflicts	Current structures do not result in space-use conflicts.	Reasonably foreseeable activities (non-offshore-wind) would not result in additional offshore structures.
Presence of structures: Viewshed	There are no existing offshore structures within the viewshed of the offshore wind lease area except buoys.	Reasonably foreseeable activities (non-offshore-wind) would not result in additional offshore structures.
Presence of structures: Cable infrastructure	Existing submarine cables cross cumulative lease areas.	Existing cable O&M activities would continue within the geographic analysis area.

Table D1-10. Summary of non-offshore-wind activities and the associated impact-producing factors for finfish, invertebrates, and essential fish habitat

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Accidental releases: Fuel/ fluids/hazmat	See Table D1-23 for a quantitative analysis of these risks. Ongoing releases are frequent/chronic. Impacts, including mortality, decreased fitness, and contamination of habitat, are localized and temporary, and rarely affect populations.	See Table D1-23 for a quantitative analysis of these risks. Gradually increasing vessel traffic over the next 35 years would increase the risk of accidental releases. Impacts are unlikely to affect populations.
Accidental releases: Invasive species	Invasive species are periodically released accidentally during ongoing activities, including the discharge of ballast water and bilge water from marine vessels. The resulting impacts on invertebrates and finfish depend on many factors but can be widespread and permanent, especially if the invasive species becomes established and outcompetes native species. The impacts on finfish, invertebrates, and EFH depend on many factors, but can be widespread and permanent.	No future activities were identified within the geographic analysis area for finfish, invertebrates, and essential fish habitat, other than ongoing activities.
Anchoring	Vessel anchoring related to ongoing military use and survey, commercial, and recreational activities continue to cause temporary to permanent impacts in the immediate area where anchors and chains meet the seafloor. Impacts on finfish, invertebrates, and EFH are greatest for sensitive EFH (e.g., eelgrass, hard bottom) and sessile or slow-moving species (e.g., corals, sponges, and sedentary shellfish).	Impacts from anchoring may occur on a semi-regular basis over the next 35 years due to offshore military operations, survey activities, commercial vessel traffic, and recreational vessel traffic. These impacts would include increased turbidity levels and potential for direct contact causing mortality of benthic species and, possibly, degradation of sensitive habitats. All impacts would be localized, turbidity would be temporary, and impacts from direct contact would be recovered in the short term. Degradation of sensitive habitats such as certain types of hard bottom (e.g., boulder piles), if it occurs, could be long term.
Cable emplacement and maintenance	Infrequent cable maintenance activities disturb the seafloor and cause temporary increases in suspended sediment; these disturbances are localized and limited to the cable corridor. New cables are infrequently added near shore. Cable emplacement/maintenance activities disturb, displace, and injure finfish and invertebrates and result in temporary to long-term habitat alterations. The intensity of impacts depends on the time (season) and place (habitat type) where the activities occur. (See also the IPF of Sediment deposition and burial.)	Future new cables would occasionally disturb the seafloor and cause temporary increases in suspended sediment, resulting in localized short-term impacts. If the cable routes enter the geographic analysis area for this resource, short-term disturbance would be expected. The intensity of impacts would depend on the time (season) and place (habitat type) where the activities would occur.
Cable emplacement/ maintenance: Seabed profile alterations	Ongoing sediment dredging for navigation purposes results in localized, short-term impacts (habitat alteration, change in complexity) on finfish, invertebrates, and EFH through this IPF. Dredging is most likely in sand wave areas where typical jet plowing is insufficient to meet target cable burial depth. Sand waves that are dredged would likely be redeposited in like-sediment areas. Any particular sand wave may not recover to the same height and width as pre-disturbance; however, the habitat function would largely recover post-disturbance. Therefore, seabed profile alterations, while locally intense, have little impact on finfish, invertebrates, and EFH on a regional (Cape Hatteras to Gulf of Maine) scale.	No future activities were identified within the geographic analysis area for finfish, invertebrates, and essential fish habitat, other than ongoing activities.
Cable emplacement and maintenance: Sediment deposition and burial	Ongoing sediment dredging for navigation purposes results in fine sediment deposition. Ongoing cable maintenance activities also infrequently disturb bottom sediments; these disturbances are localized and limited to the emplacement corridor. Sediment deposition could have negative impacts on eggs and larvae, particularly demersal eggs such as longfin squid, which are known to have high rates of egg mortality if egg masses are exposed to abrasion or burial. Impacts may vary based on season/time of year.	No future activities were identified within the geographic analysis area for finfish, invertebrates, and essential fish habitat, other than ongoing activities.
Discharge/intakes	Water quality impacts from ongoing onshore and offshore activities affect nearshore habitats, and accidental spills can occur from pipeline or marine shipping. Invasive species can be accidentally released in the discharge of ballast water and bilge water from marine vessels.	No future activities were identified within the geographic analysis area for finfish, invertebrates, and essential fish habitat, other than ongoing activities.
Electric and magnetic fields and cable heat	EMF emanates continuously from installed telecommunication and electrical power transmission cables. Biologically significant impacts on finfish, invertebrates, and EFH have not been documented for AC cables (CSA Ocean Sciences, Inc. and Exponent 2019; Thomsen et al. 2015), but behavioral impacts have been documented for benthic species (skates and lobster) near operating DC cables (Hutchison et al. 2018). The impacts are localized and affect the animals only while they are within the EMF. There is no evidence to indicate that EMF from undersea AC power cables negatively affects commercially and recreationally important fish species (CSA Ocean Sciences, Inc. and Exponent 2019).	During operation, future new cables would produce EMF. Submarine power cables in the geographic analysis area are assumed to be installed with appropriate shielding and burial depth to reduce potential EMF to low levels. Although the EMF would exist as long as a cable was in operation, impacts on finfish, invertebrates, and EFH would likely be difficult to detect.
Gear utilization	Abandoned or lost fishing gear remains in the aquatic environment for extended time periods, often entangling or trapping mobile invertebrate and fish species. Based on data from NOAA, bycatch affects many species throughout the geographic analysis area—most notably, windowpane flounder, blueback herring, shark species, and hake species. The majority of bycatch is a result of open area scallop trawls, large-mesh otter trawls, conch pots, and fish traps (NOAA 2019).	Future pre-construction, construction, and post-construction fisheries monitoring surveys for ongoing and planned non-offshore-wind projects would continue to harvest finfish and macroinvertebrates. These surveys could include trawl surveys (affecting finfish and squid) and clam dredge surveys (ocean quahog and surfclam). Trawl and gillnet surveys for fisheries monitoring would likely result in direct on fish, invertebrates, and essential fish habitat and has the potential to result in injury and mortality, reduced fecundity, and delayed or aborted spawning migrations.

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Lighting: Vessels	Marine vessels have an array of lights including navigational lights and deck lights. There is little downward-focused lighting, and therefore only a small fraction of the emitted light enters the water. Light can attract finfish and invertebrates, potentially affecting distributions in a highly localized area. Light may also disrupt natural cycles, e.g., spawning, possibly leading to short-term impacts.	Vessels would continue to be a light source within the geographic analysis area.
Lighting: Structures	Offshore buoys and towers emit light, and onshore structures, including buildings and ports, emit a great deal more on an ongoing basis. Light can attract finfish and invertebrates, potentially affecting distributions in a highly localized area. Light may also disrupt natural cycles, e.g., spawning, possibly leading to short-term impacts. Light from structures is widespread and permanent near the coast, but minimal offshore.	Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast, but minimal offshore.
Noise: Aircraft	Noise from aircraft reaches the sea surface on a regular basis. However, there is not likely to be any impact of aircraft noise on finfish, invertebrates, and EFH, as very little of the aircraft noise propagates through the water.	Aircraft noise is likely to continue to increase as commercial air traffic increases. However, there is not likely to be any impact of aircraft noise on finfish, invertebrates, and EFH.
Noise: Onshore/offshore construction	Noise from construction occurs frequently in near shores of populated areas in New England and the Mid-Atlantic but infrequently offshore. The intensity and extent of noise from construction is difficult to generalize, but impacts are localized and temporary. See also sub-IPF for Noise: Pile-driving.	Noise from construction nearshore is expected to gradually increase in line with human population growth along the coast of the geographic analysis area for this resource.
Noise: G&G	Ongoing site characterization surveys and scientific surveys produce noise around sites of investigation. These activities can disturb finfish and invertebrates in the immediate vicinity of the investigation and can cause temporary behavioral changes. The extent depends on equipment used, noise levels, and local acoustic conditions.	Site characterization surveys, scientific surveys, and exploratory oil and gas surveys are anticipated to occur infrequently over the next 35 years. Seismic surveys used in oil and gas exploration create high-intensity, impulsive noise to penetrate deep into the seabed, potentially resulting in injury or mortality of finfish and invertebrates in a small area around each sound source and short-term stress and behavioral changes to individuals over a greater area. Site characterization surveys typically use sub-bottom profiler technologies that generate less-intense sound waves more similar to common deep-water echosounders. The intensity and extent of the resulting impacts are difficult to generalize but are likely localized and temporary.
Noise: O&M	Some finfish and invertebrates may be able to hear the continuous underwater noise of operational WTGs. As measured at the Block Island Wind Farm, this low-frequency noise barely exceeds ambient levels at 164 feet (50 meters) from the WTG base. Based on the results of Thomsen et al. (Thomsen et al. 2015), sound pressure levels (SPLs) would be expected to be at or below ambient levels at relatively short distances (approximately 164 feet [50 meters]) from WTG foundations. These low levels of elevated noise likely have little to no impact. Noise is also created by O&M of marine minerals extraction and commercial fisheries, each of which has small, localized impacts.	New or expanded marine minerals extraction and commercial fisheries may intermittently increase noise during their O&M over the next 35 years. Impacts would likely be small and localized.
Noise: Pile-driving	Noise from pile-driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water or through the seabed can cause injury or mortality of finfish and invertebrates in a small area around each pile and can cause short-term stress and behavioral changes to individuals over a greater area. Eggs, embryos, and larvae of finfish and invertebrates could also experience developmental abnormalities or mortality resulting from this noise, although thresholds of exposure are not known (Weilgart 2018; Hawkins and Popper 2017). Potentially injurious noise could also be considered as rendering EFH temporarily unavailable or unsuitable for the duration of the noise. The extent depends on pile size, hammer energy, and local acoustic conditions.	No future activities were identified within the geographic analysis area for finfish, invertebrates, and essential fish habitat, other than ongoing activities.
Noise: Cable laying/ trenching	Infrequent trenching activities for pipeline and cable laying, as well as other cable burial methods, emit noise. These disturbances are temporary and localized and extend only a short distance beyond the emplacement corridor. Impacts of this noise are typically less prominent than the impacts of the physical disturbance and sediment suspension.	New or expanded submarine cables and pipelines are likely to occur in the geographic analysis area for this resource. These disturbances would be infrequent over the next 35 years, temporary, and localized, and would extend only a short distance beyond the emplacement corridor. Impacts of this noise are typically less prominent than the impacts of the physical disturbance and sediment suspension.
Noise: Vessels	While ongoing vessel noise may have some effect on behavior, it is likely limited to brief startle and temporary stress responses. Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, and scientific and academic research vessels.	Vessels would continue to be a noise source within the geographic analysis area.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also undergoing continual upgrades and maintenance, including dredging. Port utilization is expected to increase over the next 35 years.	Between 1992 and 2012, global shipping traffic increased fourfold (Tournadre 2014). The U.S. OCS is no exception to this trend, and growth is expected to continue as human population increases. Certain types of vessel traffic have increased recently (e.g., ferry use, cruise industry) and may continue to increase in the foreseeable future. In addition, the general trend along the coast from Virginia to Maine is that port activity will increase modestly. The ability of ports to receive the increase may require port modifications, leading to localized impacts. Future channel-deepening activities will likely be undertaken. Existing ports have already affected finfish, invertebrates, and EFH, and future port projects would implement BMPs to minimize impacts. Although the degree of impacts on EFH would likely be undetectable outside the immediate vicinity of the ports, adverse

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
		impacts on EFH for certain species or life stages may lead to impacts on finfish and invertebrates beyond the vicinity of the port.
Presence of structures: Entanglement, gear loss, gear damage	Commercial and recreational fishing gear is periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures. The lost gear, moved by currents, can disturb habitats and potentially harm individuals, creating small, localized, short-term impacts.	No future activities were identified within the geographic analysis area for finfish, invertebrates, and essential fish habitat, other than ongoing activities.
Presence of structures: Hydrodynamic disturbance	Human-made structures, especially tall vertical structures such as foundations for towers of various purposes, continuously alter local water flow at a fine scale. Water flow typically returns to background levels within a relatively short distance from the structure. Therefore, impacts on finfish, invertebrates, and EFH are typically undetectable. Indirect impacts of structures influencing primary productivity and higher trophic levels are possible but are not well understood. New structures are periodically added.	Tall vertical structures can increase seabed scour and sediment suspension. Impacts would likely be highly localized and difficult to detect. Indirect impacts of structures influencing primary productivity and higher trophic levels are possible but are not well understood.
Presence of structures: Fish aggregation	Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables, create uncommon relief in a mostly sandy seascape. Structure-oriented fishes are attracted to these locations. These impacts are localized and often permanent. Fish aggregation may be considered adverse, beneficial, or neutral.	New cables, installed incrementally in the geographic analysis area for this resource over the next 20 to 35 years, would likely require hard protection atop portions of the route (see the Cable emplacement/maintenance IPF). Any new towers, buoys, or piers would also create uncommon relief in a mostly sandy seascape. Structure-oriented fishes could be attracted to these locations. Abundance of certain fishes may increase. These impacts are localized and may be permanent.
Presence of structures: Habitat conversion	Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables, create uncommon relief in a mostly sandy seascape. A large portion is homogeneous sandy seascape but there is some other hard or complex habitat. Structure-oriented species thus benefit on a constant basis; however, the diversity may decline over time as early colonizers are replaced by successional communities dominated by blue mussels and anemones (Degraer et al. 2019 [Chapter 7]). Structures are periodically added, resulting in the conversion of existing soft-bottom and hard-bottom habitat to the new hard-structure habitat.	New cable, installed incrementally in the geographic analysis area over the next 20 to 35 years, would likely require hard protection atop portions of the route (see Cable emplacement/maintenance). Any new towers, buoys, or piers would also create uncommon relief in a mostly sandy seascape. Structure-oriented species would benefit (Claisse et al. 2014; Smith et al. 2016); however, the diversity may decline over time as early colonizers are replaced by successional communities dominated by blue mussels and anemones (Degraer et al. 2019 [Chapter 7]). Soft bottom is the dominant habitat type from Cape Hatteras to the Gulf of Maine (over 60 million acres) and species that rely on this habitat would not likely experience population-level impacts (Guida et al. 2017; Greene et al. 2010).
Presence of structures: Migration disturbances	Human structures in the marine environment (e.g., shipwrecks, artificial reefs, and oil platforms) can attract finfish and invertebrates that approach the structures during their migrations. This could slow migrations. However, temperature is expected to be a bigger driver of habitat occupation and species movement than structure is (Moser and Shepherd 2009; Fabrizio et al. 2014; Secor et al. 2018). There is no evidence to suggest that structures pose a barrier to migratory animals.	The infrequent installation of future new structures in the marine environment over the next 35 years may attract finfish and invertebrates that approach the structures during their migrations. This could tend to slow migrations. However, temperature is expected to be a bigger driver of habitat occupation and species movement (Moser and Shepherd 2009; Fabrizio et al. 2014; Secor et al. 2018). Migratory animals would likely be able to proceed from structures unimpeded.
Presence of structures: Cable infrastructure	See other sub-IPFs within the Presence of structures IPF. See Table D1-5 on coastal habitats.	See other sub-IPFs within the Presence of structures IPF. See Table D1-5 on coastal habitats.

AC = alternating current; DC = direct current; hazmat = hazardous materials

Table D1-11. Summary of non-offshore-wind activities and the associated impact-producing factors for land use and coastal infrastructure

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Accidental releases: Fuel/ fluids/hazmat	Various ongoing onshore and coastal construction projects include the use of vehicles and equipment that contain fuel, fluids, and hazmat that could be released.	Ongoing onshore construction projects involve vehicles and equipment that use fuel, fluids, or hazmat could result in an accidental release. Intensity and extent would vary depending on the size, location, and materials involved in the release.
Lighting: Structures	Various ongoing onshore and coastal construction projects have nighttime activities, as well as existing structures, facilities, and vehicles that would use nighttime lighting.	Ongoing onshore construction projects involving nighttime activity could generate nighttime lighting. Intensity and extent would vary depending on the location, type, direction, and duration of nighttime lighting.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also undergoing continual upgrades and maintenance. The New Jersey Wind Port is being developed and the Paulsboro Marine Terminal is being upgraded specifically to support the construction of offshore wind energy facilities.	Ports would need to perform maintenance and upgrade facilities to ensure that they can still receive the projected future volume of vessels visiting their ports, and to be able to host larger deep-draft vessels as they continue to increase in size.
Presence of structures: Viewshed	The only existing offshore structures within the offshore viewshed are minor features such as buoys.	Non-offshore-wind structures that could be viewed in conjunction with the offshore components would be limited to meteorological towers. Marine activity would also occur within the marine viewshed.
Presence of structures: Cable infrastructure	Onshore buried cables would only occur where permitted by local land use authorities, which would avoid long-term land use conflicts.	No known proposed structures are reasonably foreseeable and proposed to be located in the geographic analysis area for land use and coastal infrastructure.
Land disturbance: Onshore construction	Onshore construction supports local population growth, employment, and economics.	Onshore development would continue in accordance with local government land use plans and regulations.
Land disturbance: Onshore, land use changes	New development or redevelopment would result in changes in land use in accordance with local government land use plans and regulations.	Ongoing and future development and redevelopment is anticipated to reinforce existing land use patterns, based on local government planning documents.
Traffic	Onshore construction is not anticipated to noticeably add to the traffic of the local roadway system.	Onshore ongoing and planned development would likely disrupt road traffic for a short period of time depending on the type of development.

hazmat = hazardous materials

Table D1-12. Summary of non-offshore-wind activities and the associated impact-producing factors for marine mammals

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Accidental releases: Fuel/fluids/hazmat	See Table D1-23 for a quantitative analysis of these risks. Ongoing releases are frequent/chronic. Marine mammal exposure to aquatic contaminants and inhalation of fumes from oil spills can result in mortality or sublethal effects on individual fitness, including adrenal effects, hematological effects, liver effects, lung disease, poor body condition, skin lesions, and several other health effects attributed to oil exposure (Kellar et al. 2017; Mazet et al. 2001; Mohr et al. 2008; Smith et al. 2017; Sullivan et al. 2019; Takeshita et al. 2017). Additionally, accidental releases may result in impacts on marine mammals due to effects on prey species (Table D1-10).	See Table D1-23 for a quantitative analysis of these risks. Gradually increasing vessel traffic over the next 35 years would increase the risk of accidental releases. Marine mammal exposure to aquatic contaminants and inhalation of fumes from oil spills can result in mortality or sublethal effects on individual fitness, including adrenal effects, hematological effects, liver effects, lung disease, poor body condition, skin lesions, and several other health effects attributed to oil exposure (Kellar et al. 2017; Mazet et al. 2001; Mohr et al. 2008; Smith et al. 2017; Sullivan et al. 2019; Takeshita et al. 2017). Additionally, accidental releases may result in impacts on marine mammals due to effects on prey species (Table D1-10).
Accidental releases: Trash and debris	Trash and debris may be accidentally discharged through fisheries use, dredged material ocean disposal, marine minerals extraction, marine transportation, navigation and traffic, survey activities and cables, lines and pipeline laying, and debris carried in river outflows or windblown from onshore. Accidental releases of trash and debris are expected to be low-quantity, localized, and low-impact events. Worldwide 62 of 123 (50.4%) marine mammal species have been documented ingesting marine litter (Werner et al. 2016). Stranding data indicate potential debris-induced mortality rates of 0 to 22%. Mortality has been documented in cases of debris interactions, as well as blockage of the digestive tract, disease, injury, and malnutrition (Baulch and Perry 2014). However, it is difficult to link physiological effects on individuals to population-level impacts (Browne et al. 2015).	As population and vessel traffic increase gradually over the next 35 years, accidental release of trash and debris may increase. Trash and debris may continue to be accidentally released through fisheries use and other offshore and onshore activities. There may also be a long-term risk from exposure to plastics and other debris in the ocean. Worldwide 62 of 123 (50.4%) of marine mammal species have been documented ingesting marine litter (Werner et al. 2016). Mortality has been documented in cases of debris interactions, as well as blockage of the digestive tract, disease, injury, and malnutrition (Baulch and Perry 2014).
Cable emplacement and maintenance	Cable maintenance activities disturb bottom sediments and cause temporary increases in suspended sediment; these disturbances will be localized and generally limited to the emplacement corridor. Data are not available regarding marine mammal avoidance of localized turbidity plumes; however, Todd et al. (2015) suggest that because some marine mammals often live in turbid waters and some species of mysticetes and sirenians employ feeding methods that create sediment plumes, some species of marine mammals have a tolerance for increased turbidity. Similarly, McConnell et al. (1999) documented movements and foraging of gray seals in the North Sea. One tracked individual was blind in both eyes, but otherwise healthy. Despite the individual's blindness, observed movements were typical of the other study individuals, indicating that visual cues are not essential for gray seal foraging and movement (McConnell et al. 1999). If elevated turbidity caused any behavioral responses such as avoidance of the turbidity zone or changes in foraging behavior, such behaviors would be temporary, and any impacts would be temporary and short term. Turbidity associated with increased sedimentation may result in temporary, short-term impacts on marine mammal prey species (Table D1-10).	The impact on water quality from accidental sediment suspension during cable emplacement is temporary and short term. If elevated turbidity caused any behavioral responses such as avoidance of the turbidity zone or changes in foraging behavior, such behaviors would be temporary, and any negative impacts would be temporary and short term. Turbidity associated with increased sedimentation may result in temporary, short-term impacts on some marine mammal prey species (Table D1-10).
Electric and magnetic fields and cable heat	EMFs emanate constantly from installed telecommunication and electrical power transmission cables. Marine mammals appear to have a detection threshold for magnetic intensity gradients (i.e., changes in magnetic field levels with distance) of 0.1% of the Earth's magnetic field or about 0.05 μT (Kirschvink 1990) and are thus likely to be very sensitive to minor changes in magnetic fields (Walker et al. 2003). There is a potential for animals to react to local variations of the geomagnetic field caused by power cable EMFs. Depending on the magnitude and persistence of the confounding magnetic field, such an effect could cause a trivial temporary change in swim direction or a longer detour during the animal's migration (Gill et al. 2005). Such an effect on marine mammals is more likely to occur with direct current cables than with AC cables (Normandeau et al. 2011). However, there are numerous transmission cables installed across the seafloor and no impacts on marine mammals have been demonstrated from this source of EMF.	During operation, future new cables would produce EMF. Submarine power cables in the marine mammal geographic analysis area are assumed to be installed with appropriate shielding and burial depth to reduce potential EMF to low levels. EMF of any two sources would not overlap. Although the EMF would exist as long as a cable was in operation, impacts, if any, would likely be difficult to detect, if they occur at all. Marine mammals have the potential to react to submarine cable EMF; however, no effects from the numerous submarine cables have been observed. Furthermore, this IPF would be limited to extremely small portions of the areas used by migrating marine mammals. As such, exposure to this IPF would be low and impacts on marine mammals would not be expected.
Noise: Pile-driving	Noise from pile-driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water or through the seabed can result in high-intensity, low-exposure-level, long-term, but localized intermittent risk to marine mammals. Impacts would be localized in nearshore waters. Pile-driving activities may negatively affect marine mammals during foraging, orientation, migration, predator detection, social interactions, or other activities (Southall et al. 2007). Noise exposure associated with pile-driving activities can interfere with these functions and has the potential to cause a range of responses, including insignificant behavioral changes, avoidance of the ensonified area, PTS, harassment, and ear injury, depending on the intensity and duration of the exposure. BOEM assumes that all ongoing and potential future activities will be conducted in accordance with a project-specific Incidental Harassment Authorization to minimize impacts on marine mammals.	No future activities were identified within the marine mammal geographic analysis area for marine mammals, other than ongoing activities.

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Noise: G&G	Infrequent site characterization surveys and scientific surveys produce high-intensity, impulsive noise around sites of investigation. These activities have the potential to result in high-intensity, high-consequence impacts, including auditory injuries, stress, disturbance, and behavioral responses, if marine mammals are present within the ensonified area (NOAA 2018). Survey protocols and underwater noise mitigation procedures are typically implemented to decrease the potential for any marine mammal to be within the area where sound levels are above relevant harassment thresholds associated with an operating sound source to reduce the potential for behavioral responses and injury (permanent threshold shifts [PTS]/temporary threshold shifts [TTS]) close to the sound source. The magnitude of effects, if any, is intrinsically related to many factors, including acoustic signal characteristics, behavioral state (e.g., migrating), biological condition, distance from the source, duration and level of the sound exposure, and environmental and physical conditions that affect acoustic propagation (NOAA 2018).	Same as ongoing activities, with the addition of possible future oil and gas exploration surveys.
Noise: Vessels	Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, scientific and academic research vessels, and other construction vessels. The frequency range for vessel noise falls within marine mammals' known range of hearing and would be audible. Noise from vessels presents a long-term and widespread impact on marine mammals across most oceanic regions. While vessel noise may have some effect on marine mammal behavior, it would be expected to be limited to brief startle and temporary stress response. Results from studies on acoustic impacts from vessel noise on odontocetes indicate that small vessels at a speed of 5 knots in shallow coastal water can reduce the communication range for bottlenose dolphins within 164 feet (50 meters) of the vessel by 26% (Jensen et al. 2009). Pilot whales in a quieter, deep-water habitat could experience a 50% reduction in communication range from a similar size boat and speed (Jensen et al. 2009). Because lower frequencies propagate farther away from the sound source compared to higher frequencies, low frequency cetaceans (LFC) are at a greater risk of experiencing Level B Harassment produced by vessel traffic.	Any offshore projects that require the use of ocean vessels could potentially result in long-term but infrequent impacts on marine mammals, including temporary startle responses, masking of biologically relevant sounds, physiological stress, and behavioral changes. However, BOEM expects that these brief responses of individuals to passing vessels would be unlikely given the patchy distribution of marine mammals. No stock or population-level effects would be expected.
Noise: Aircraft	Aircraft routinely travel in the marine mammal geographic analysis area. With the possible exception of rescue operations, no ongoing aircraft flights would occur at altitudes that would elicit a response from marine mammals. If flights are at a sufficiently low altitude, marine mammals may respond with behavioral changes, including short surface durations, abrupt dives, and percussive behaviors (i.e., breaching and tail slapping) (Patenaude et al. 2002). Similarly, aircraft have the potential to disturb hauled-out seals if aircraft overflights occur within 2,000 feet (610 meters) of a haul-out area (Efroymson et al. 2000). However, this disturbance would be temporary and short term, and result in minimal energy expenditure. These brief responses would be expected to dissipate once the aircraft has left the area.	Future low-altitude aircraft activities such as survey activities and navy training operations could result in short-term responses of marine mammals to aircraft noise. If flights are at a sufficiently low altitude, marine mammals may respond with behavioral changes, including short surface durations, abrupt dives, and percussive behaviors (i.e., breaching and tail slapping) (Patenaude et al. 2002). These brief responses would be expected to dissipate once the aircraft has left the area.
Noise: Cable laying/trenching	Noise from cable laying could periodically occur in the geographic analysis area.	No future activities were identified within the marine mammal geographic analysis area for marine mammals, other than ongoing activities.
Noise: Turbines	Marine mammals would be able to hear the continuous underwater noise of operational WTGs. As measured at the Block Island Wind Farm, this low-frequency noise barely exceeds ambient levels at 164 feet (50 meters) from the WTG base. Based on the results of Thomsen et al. (2015) and Kraus et al. (2016), SPLs would be expected to be at or below ambient levels at relatively short distances from the WTG foundations.	This sub-IPF does not apply to future non-offshore-wind development.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also undergoing continual upgrades and maintenance. Port expansion activities are localized to nearshore habitats and are expected to result in temporary, short-term impacts, if any, on marine mammals. Vessel noise may affect marine mammals, but response would be expected to be temporary and short term (see Vessels: Noise sub-IPF above). The impacts on water quality from sediment suspension during port expansion activities is temporary and short term and would be similar to those described under the Cable emplacement/maintenance IPF above.	Between 1992 and 2012, global shipping traffic increased fourfold (Tournadre 2014). The U.S. OCS is no exception to this trend, and growth is expected to continue as human population increases. In addition, the general trend along the coastal region from Virginia to Maine is that port activity will increase modestly. The ability of ports to receive the increase in larger ships will require port modifications. Future channel-deepening activities are being undertaken to accommodate deeper-draft vessels for the Panama Canal Locks. The additional traffic and larger vessels could have impacts on water quality through increases in suspended sediments and the potential for accidental discharges. The increased sediment suspension could be long-term depending on the vessel traffic increase. Certain types of vessel traffic have increased recently (e.g., ferry use, cruise industry) and may continue to increase in the foreseeable future. Additional impacts associated with the increased risk of vessel strike could also occur (see the Traffic: Vessel collisions sub-IPF below).
Presence of structures: Entanglement or ingestion of lost fishing gear	There are more than 130 artificial reefs in the Mid-Atlantic region. This sub-IPF may result in long-term, high-intensity impacts, but with low exposure due to localized and geographic spacing of artificial reefs. Currently bridge foundations and the Block Island Wind Farm may be considered artificial reefs and may have higher	No future activities were identified within the marine mammal geographic analysis area for marine mammals, other than ongoing activities.

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
	levels of recreational fishing, which increases the chances of marine mammals encountering lost fishing gear, resulting in possible ingestions, entanglement, injury, or death of individuals (Moore and van der Hoop 2012) if present nearshore where these structures are located. There are very few, if any, areas within the OCS geographic analysis area for marine mammals that would serve to concentrate recreational fishing and increase the likelihood that marine mammals would encounter lost fishing gear.	
Presence of structures: Habitat conversion and prey aggregation	There are more than 130 artificial reefs in the Mid-Atlantic region. Hard bottom (scour control and rock mattresses) and vertical structures (bridge foundations and Block Island Wind Farm WTGs) in a soft-bottom habitat can create artificial reefs, thus inducing the “reef effect” (Taormina et al. 2018; NMFS 2015). The reef effect is usually considered a beneficial impact associated with higher densities and biomass of fish and decapod crustaceans (Taormina et al. 2018), providing a potential increase in available forage items and shelter for seals and small odontocetes compared to the surrounding soft bottoms.	The presence of structures associated with non-offshore-wind development in nearshore coastal waters has the potential to provide habitat for seals and small odontocetes as well as preferred prey species. This “reef effect” has the potential to result in long-term, low-intensity benefits. Bridge foundations will continue to provide foraging opportunities for seals and small odontocetes with measurable benefits to some individuals. Hard bottom (scour control and rock mattresses used to bury the offshore export cables) and vertical structures (i.e., WTG and OSS foundations) in a soft-bottom habitat can create artificial reefs, thus inducing the reef effect (Taormina et al. 2018; Causon and Gill 2018). The reef effect is usually considered a beneficial impact associated with higher densities and biomass of fish and decapod crustaceans (Taormina et al. 2018), providing a potential increase in available forage items and shelter for marine mammals compared to the surrounding soft bottoms.
Presence of structures: Avoidance/ displacement	No ongoing activities in the marine mammal geographic analysis area beyond offshore wind facilities are measurably contributing to this sub-IPF. There may be some impacts resulting from the existing Block Island Wind Farm, but given that there are only five WTGs, no measurable impacts are occurring.	Not contemplated for non-offshore-wind facility sources.
Presence of structures: Behavioral disruption — breeding and migration	No ongoing activities in the marine mammal geographic analysis area beyond offshore wind facilities are measurably contributing to this sub-IPF.	Not contemplated for non-offshore-wind facility sources.
Presence of structures: Displacement into higher risk areas (vessels and fishing)	No ongoing activities in the marine mammal geographic analysis area beyond offshore wind facilities are measurably contributing to this sub-IPF.	Not contemplated for non-offshore-wind facility sources.
Traffic: Vessel collisions.	Current activities that are contributing to this sub-IPF include port traffic levels, fairways, TSS, commercial vessel traffic, recreational and fishing activity, and scientific and academic vessel traffic. Vessel strike is relatively common with cetaceans (Kraus et al. 2005) and one of the primary causes of death to NARWs, with as many as 75% of known anthropogenic mortalities of NARWs likely resulting from collisions with large ships along the U.S. and Canadian eastern seaboard (Kite-Powell et al. 2007). Marine mammals are more vulnerable to vessel strike when they are within the draft of the vessel and when they are beneath the surface and not detectable by visual observers. Some conditions that make marine mammals less detectable include weather conditions with poor visibility (e.g., fog, rain, wave height) or nighttime operations. Vessels operating at speeds exceeding 10 knots have been associated with the highest risk for vessel strikes of NARWs (Vanderlaan and Taggart 2007). Reported vessel collisions with whales show that serious injury rarely occurs at speeds below 10 knots (Laist et al. 2001). Data show that the probability of a vessel strike increases with the velocity of a vessel (Pace and Silber 2005; Vanderlaan and Taggart 2007).	Vessel traffic associated with non-offshore-wind development has the potential to result in an increased collision risk. While these impacts would be of high consequence, the patchy distribution of marine mammals makes stock or population-level effects unlikely (Navy 2018).

µT = microtesla; AC = alternating current; hazmat = hazardous materials

Table D1-13. Summary of non-offshore-wind activities and the associated impact-producing factors for navigation and vessel traffic

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Anchoring	Larger commercial vessels (specifically tankers) sometimes anchor outside of major ports to transfer their cargo to smaller vessels for transport into port, an operation known as lightering. These anchors have deeper ground penetration and are under higher stresses. Smaller vessels (commercial fishing or recreational vessels) would anchor for fishing and other recreational activities. These activities cause temporary to short-term impacts on navigation in the immediate anchorage area. All vessels may anchor in an emergency scenario (such as power loss) if they lose power to prevent them from drifting and creating navigational hazards for other vessels or drifting into structures.	Lightering and anchoring operations are expected to continue at or near current levels, with the expectation of moderate increases commensurate with any increase in tankers visiting ports. Deep-draft visits to major ports are expected to increase as well, increasing the potential for an emergency need to anchor and creating navigational hazards for other vessels. Recreational and commercial fishing activity would likely stay largely the same related to this IPF.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also undergoing continual upgrades and maintenance. Impacts from these activities would be short term and could include congestion in ports, delays, and changes in port usage by some fishing or recreational vessel operators.	Ports would need to perform maintenance and perform upgrades to ensure that they can still receive the projected future volume of vessels visiting their ports, and to be able to host larger deep-draft vessels as they continue to increase in size. Impacts would be short term and could include congestion in ports, delays, and changes in port usage by some fishing or recreational vessel operators.
Presence of structures: Allisions	An allision occurs when a moving vessel strikes a stationary object. The stationary object can be a buoy, a port feature, or another anchored vessel. There are two types of allisions that occur: drift and powered. A drift allision generally occurs when a vessel is powered down due to operator choice or power failure. A powered allision generally occurs when an operator fails to adequately control their vessel movements or is distracted.	Although there are some exceptions (ferry traffic and cruise ships), BOEM expects vessel traffic to remain relatively steady into the reasonably foreseeable future (BOEM 2019:57). Vessel allisions with non-offshore-wind stationary objects should not increase meaningfully without a substantial increase in vessel congestion.
Presence of structures: Fish aggregation	Items in the water, such as ghost fishing gear, buoys, and energy platform foundations, can create an artificial reef effect, aggregating fish. Recreational and commercial fishing can occur near the artificial reefs. Recreational fishing is more popular than commercial near artificial reefs, as commercial mobile fishing gear can risk snagging on the artificial reef structure.	Fishing near artificial reefs is not expected to change meaningfully over the next 35 years.
Presence of structures: Habitat conversion	Equipment in the ocean can create a substrate for mollusks to attach to and fish eggs to settle near. This can create a reef-like habitat and benefit structure-oriented species on a constant basis.	Reasonably foreseeable activities (non-offshore-wind) would not result in additional offshore structures.
Presence of structures: Migration disturbances	Noise-producing activities, such as pile-driving and vessel traffic, may interfere with and adversely affect marine mammals during foraging, orientation, migration, response to predators, social interactions, or other activities. Marine mammals may also be sensitive to changes in magnetic field levels. The presence of structures and operational noise could cause mammals to avoid areas.	Reasonably foreseeable activities (non-offshore-wind) would not result in additional offshore structures.
Presence of structures: Navigation hazard	Vessels need to navigate around structures to avoid allisions. When multiple vessels need to navigate around a structure, then navigation is made more complex, as the vessels need to avoid both the structure and each other.	Although there are some exceptions (ferry traffic and cruise ships), BOEM expects vessel traffic to remain relatively steady into the reasonably foreseeable future (BOEM 2019:57). Even with increased port visits by deep-draft vessels, this is still a relatively small effect when considering the whole of Atlantic Coast vessel traffic. The presence of navigational hazards is expected to continue at or near current levels.
Presence of structures: Space-use conflicts	Currently, the offshore area is occupied by marine trade, stationary and mobile fishing, and survey activities.	Reasonably foreseeable activities (non-offshore-wind) would not result in additional offshore structures.
Presence of structures: Cable infrastructure	See “Anchoring” IPF.	See “Anchoring” IPF.
Cable emplacement/maintenance	Within the geographic analysis area for navigation and vessel traffic, existing cables may require access for maintenance activities. Infrequent cable maintenance activities may cause temporary increases in vessel traffic and navigational complexity.	Future new cables would cause temporary increases in vessel traffic during installation or maintenance, resulting in infrequent, localized, short-term impacts over the next 35 years. Care would need to be taken by vessels that are crossing the cable routes during these activities.
Traffic: Aircraft	USCG Search and Rescue (SAR) helicopters are the main aircraft that may be flying at low enough heights to risk interaction with WTGs. USCG SAR aircraft need to fly low enough that they can spot objects in the water.	SAR operations could be expected to increase with any increase in vessel traffic. However, as vessel traffic volume is not expected to increase appreciably, neither should SAR operations. Final PEIS Section 3.6.6 provides a discussion of navigation impacts on fishing vessel traffic.
Traffic: Vessels	See “Presence of structures: Navigation hazard” sub-IPF.	See “Presence of structures: Navigation hazard” sub-IPF.
Traffic: Vessels, collisions	See “Presence of structures: Navigation hazard” sub-IPF.	See “Presence of structures: Navigation hazard” sub-IPF.

Table D1-14. Summary of non-offshore-wind activities and the associated impact-producing factors for other uses: national security and military use

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Presence of structures: Allisions	Existing stationary facilities that present allision risks include buoys used to mark inlet approaches, channels, shoals (NOAA 2021), dock facilities, meteorological buoys associated with offshore wind lease areas, and other offshore or shoreline-based structures.	No additional non-offshore-wind stationary structures were identified within the geographic analysis area. Stationary structures such as private or commercial docks may be added close to the shoreline.
Presence of structures: Fish aggregation	No existing stationary structures that would act as FADs were identified within the geographic analysis area.	No future non-offshore-wind additional stationary structures that would act as FADs were identified within the geographic analysis area.
Presence of structures: Navigation hazard	Existing stationary facilities within the geographic analysis area that present navigational hazards include buoys used to mark inlet approaches, channels, shoals (NOAA 2021), dock facilities, meteorological buoys associated with offshore wind lease areas, and other offshore or shoreline-based structures.	No future non-offshore-wind stationary structures were identified within the offshore geographic analysis area. Onshore development activities are anticipated to continue with additional proposed communication towers and onshore commercial, industrial, and residential developments.
Presence of structures: Space-use conflicts	Existing stationary facilities within the geographic analysis area that could present a space-use conflict include onshore wind turbines, communication towers, and other onshore commercial, industrial, and residential structures.	No future non-offshore-wind stationary structures were identified within the offshore geographic analysis area. Onshore development activities are anticipated to continue with additional proposed communication towers and onshore commercial, industrial, and residential developments.
Presence of structures: Cable infrastructure	Existing submarine cables cross cumulative lease areas.	Submarine cables would remain in current locations with infrequent maintenance continuing along those cable routes for the foreseeable future.
Traffic: Vessels	Current vessel traffic in the region is described in Final PEIS Section 3.6.6. Vessel activities associated with offshore wind in the cumulative lease areas are currently limited to site assessment surveys.	Continued vessel traffic in the region, as described in Final PEIS Section 3.6.6.
Traffic: Vessels, collisions	Current vessel traffic in the region is described in Final PEIS Section 3.6.6. Vessel activities associated with offshore wind in the cumulative lease areas are currently limited to site assessment surveys.	Continued vessel traffic in the region is described in Final PEIS Section 3.6.6.

FAD = fish aggregating device

Table D1-15. Summary of non-offshore-wind activities and the associated impact-producing factors for other uses: aviation and air traffic

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Presence of structures: Towers	Existing aboveground stationary facilities within the geographic analysis area that present aviation hazards include onshore wind turbines, communication towers, dock facilities, and other onshore structures exceeding 200 feet (61 meters) in height.	No future non-offshore-wind stationary structures were identified within the offshore geographic analysis area. Onshore development activities are anticipated to continue with additional proposed communication towers.
Presence of structures: Space-use conflicts	Existing aboveground stationary facilities within the geographic analysis area that could cause space-use conflicts for aircraft include onshore wind turbines, communication towers, and other onshore structures exceeding 200 feet (61 meters) in height.	No future non-offshore-wind stationary structures were identified within the offshore geographic analysis area. Onshore development activities are anticipated to continue with additional proposed communication towers.

Table D1-16. Summary of non-offshore-wind activities and the associated impact-producing factors for other uses: cables and pipelines

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Presence of structures: Allisions and navigation hazards	Structures within and near the geographic analysis area that pose potential allision hazards include buoys used to mark inlet approaches, channels, shoals, meteorological buoys associated with offshore wind lease areas, and shoreline developments such as docks, ports, and other commercial, industrial, and residential structures.	Reasonably foreseeable non-offshore-wind structures that could affect submarine cables have not been identified in the geographic analysis area.
Presence of structures: Space-use conflicts	Existing submarine cables cross cumulative lease areas and create potential space-use conflicts with marine mineral and sand borrow areas.	Reasonably foreseeable non-offshore-wind structures that could create space-use conflicts with submarine cables have not been identified in the geographic analysis area.
Presence of structures: Cable infrastructure	Existing submarine cables cross cumulative lease areas.	Reasonably foreseeable non-offshore-wind structures have not been identified in the geographic analysis area.

Table D1-17. Summary of non-offshore-wind activities and the associated impact-producing factors for other uses: marine minerals

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Presence of structures: Space-use conflicts	Existing structures within the cumulative lease areas create potential space-use conflicts with marine mineral and sand borrow areas.	Reasonably foreseeable non-offshore-wind structures could have a small, long-term effect on marine mineral extraction.
Presence of structures: Cable infrastructure	Marine mineral extraction typically occurs within 8 miles of the shoreline, limiting adverse impacts on the offshore export cable routes.	Future cable installation would require consultation with the BOEM Marine Minerals Program.

Table D1-18. Summary of non-offshore-wind activities and the associated impact-producing factors for other uses: radar systems

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Presence of structures: Towers	Wind developments in the direct line of sight with, or extremely close to, radar systems can cause clutter and interference. Existing wind developments in the area include the Jersey-Atlantic Wind Farm in Atlantic City, New Jersey.	Reasonably foreseeable non-offshore-wind structures proposed for construction in the offshore wind lease areas that could affect radar systems have not been identified.

Table D1-19. Summary of non-offshore-wind activities and the associated impact-producing factors for other uses: scientific research and surveys

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Presence of structures: Navigation hazards	Stationary structures are limited in the open ocean environment of the geographic analysis area and include meteorological buoys associated with site assessment activities, the five Block Island Wind Farm WTGs, and the two Coastal Virginia Offshore Wind WTGs.	Reasonably foreseeable non-offshore-wind activities would not implement stationary structures within the open ocean environment that would pose navigational hazards and raise the risk of allisions for survey vessels and collisions for survey aircraft.

Table D1-20. Summary of non-offshore-wind activities and the associated impact-producing factors for recreation and tourism

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Anchoring	Anchoring occurs due to ongoing military, survey, commercial, and recreational activities.	Impacts from anchoring would continue and may increase due to offshore military operations, survey activities, commercial vessel traffic, and recreational vessel traffic. Modest growth in vessel traffic could increase the temporary, localized impacts of navigational hazards, increased turbidity levels, and potential for direct contact causing mortality of benthic resources.
Cable emplacement and maintenance	Infrequent cable maintenance activities disturb the seafloor and cause temporary increases in suspended sediment; these disturbances would be localized and limited to emplacement corridors.	Cable maintenance or replacement of existing cables in the geographic analysis area would occur infrequently and would generate short-term disturbances.
Lighting: Vessels	Ocean vessels have an array of lights including navigational lights and deck lights.	Anticipated modest growth in vessel traffic would result in some growth in the nighttime traffic of vessels with lighting.
Lighting: Structures	Offshore buoys and towers emit low-intensity light. Onshore structures, including houses and ports, emit substantially more light on an ongoing basis.	Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast, but minimal offshore.
Cable emplacement/ maintenance	Existing cables may require access for maintenance activities. Infrequent cable maintenance activities may cause temporary increases in vessel traffic and navigational complexity for recreational vessels.	Future new cables would cause temporary increases in vessel traffic during installation or maintenance, resulting in infrequent, localized, short-term impacts over the next 35 years. Care would need to be taken by vessels that are crossing the cable routes during these activities.
Noise: Pile-driving	Noise from pile-driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. These disturbances are temporary and localized and extend only a short distance beyond the work area.	No future activities were identified within the recreation and tourism geographic analysis area other than ongoing activities.
Noise: Cable laying/ trenching	Offshore trenching occurs periodically in connection with cable installation or sand and gravel mining.	No future activities were identified within the recreation and tourism geographic analysis area other than ongoing activities.
Noise: Vessels	Vessel noise occurs offshore and more frequently near ports and docks. Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. Vessel noise is anticipated to continue at or near current levels.	Planned new barge routes and dredging disposal sites would generate vessel noise when implemented. The number and location of such routes are uncertain.
Presence of structures: Allisions	An allision occurs when a moving vessel strikes a stationary object. The stationary object can be a buoy, a port feature, or another anchored vessel. The likelihood of allisions is expected to continue at or near current levels.	Vessel allisions with non-offshore-wind stationary objects should not increase meaningfully without a substantial increase in vessel congestion.
Presence of structures: Entanglement, gear loss, gear damage	Commercial and recreational fishing gear is periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures.	No future activities were identified within the recreation and tourism geographic analysis area other than ongoing activities.
Presence of structures: Fish aggregation	Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables, create uncommon relief in a mostly flat seascape. Structure-oriented fishes are attracted to these locations. Recreational and commercial fishing can occur near these aggregation locations, although recreational fishing is more popular because commercial mobile fishing gear is more likely to snag on structures.	Reasonably foreseeable activities (non-offshore-wind) would not result in additional offshore structures.
Presence of structures: Habitat conversion	Structures, including foundations, scour protection around foundations, and various means of hard protection atop cables, create uncommon relief in a mostly flat seascape. Structure-oriented species thus benefit on a constant basis.	Reasonably foreseeable activities (non-offshore-wind) would not result in additional offshore structures.

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Presence of structures: Navigation hazard	Vessels need to navigate around structures to avoid allisions, especially in nearshore areas. This navigation becomes more complex when multiple vessels must navigate around a structure, because vessels need to avoid both the structure and each other.	Vessel traffic, overall, is not expected to meaningfully increase over the next 35 years. The presence of navigational hazards is expected to continue at or near current levels.
Presence of structures: Space-use conflicts	Current structures do not result in space-use conflicts.	Reasonably foreseeable activities (non-offshore-wind) would not result in additional offshore structures.
Presence of structures: Viewshed	The only existing offshore structures within the viewshed of the projects are minor features such as buoys.	Non-offshore-wind structures that could be viewed in conjunction with the offshore components of the projects would be limited to meteorological towers. Marine activity would also occur within the marine viewshed.
Traffic: Vessels	Geographic analysis area ports and marine traffic related to shipping, fishing, and recreation are important to the region's economy. No substantial changes are anticipated to existing vessel traffic volumes.	New vessel traffic near the geographic analysis area would be generated by proposed barge routes and dredging demolition sites over the next 35 years. Marine commerce and related industries would continue to be important to the geographic analysis area economy.
Traffic: Vessel collisions	The region's substantial marine traffic may result in occasional vessel collisions, which would result in costs to the vessels involved. The likelihood of collisions is expected to continue at or near current rates.	An increased risk of collisions is not anticipated from future activities.

Table D1-21. Summary of non-offshore-wind activities and the associated impact-producing factors for sea turtles

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Accidental releases: Fuel/fluids/hazmat	See Table D1-23 for a quantitative analysis of these risks. Ongoing releases are frequent and chronic. Sea turtle exposure to aquatic contaminants and inhalation of fumes from oil spills can result in mortality (Shigenaka et al. 2021) or sublethal effects on individual fitness, including adrenal effects, dehydration, hematological effects, increased disease incidence, liver effects, poor body condition, skin effects, skeletomuscular effects, and several other health effects that can be attributed to oil exposure (Camacho et al. 2013; Bembenek-Bailey et al. 2019; Mitchelmore et al. 2017; Shigenaka et al. 2021; Vargo et al. 1986). Additionally, accidental releases may result in impacts on sea turtles due to effects on prey species (Table D1-10).	See Table D1-23 for a quantitative analysis of these risks. Gradually increasing vessel traffic over the next 35 years would increase the risk of accidental releases. Sea turtle exposure to aquatic contaminants and inhalation of fumes from oil spills can result in mortality (Shigenaka et al. 2021; Wallace et al. 2010) or sublethal effects on individual fitness, including adrenal effects, dehydration, hematological effects, increased disease incidence, liver effects, poor body condition, skin effects, skeletomuscular effects, and several other health effects that can be attributed to oil exposure (Camacho et al. 2013; Bembenek-Bailey et al. 2019; Mitchelmore et al. 2017; Shigenaka et al. 2021; Vargo et al. 1986). Additionally, accidental releases may result in impacts on sea turtles due to effects on prey species (Table D1-10).
Accidental releases: Trash and debris	Trash and debris may be accidentally discharged through fisheries use, dredged material ocean disposal, marine minerals extraction, marine transportation, navigation and traffic, survey activities, cables, lines, and pipeline laying, as well as debris carried in river outflows or windblown from onshore. Accidental releases of trash and debris are expected to be low-quantity, localized, and low-impact events. Direct ingestion of plastic fragments is well documented and has been observed in all species of sea turtles (Bugoni et al. 2001; Hoarau et al. 2014; Nelms et al. 2016; Schuyler et al. 2014). In addition to plastic debris, ingestion of tar, paper, Styrofoam™, wood, reed, feathers, hooks, lines, and net fragments has also been documented (Thomás et al. 2002). Ingestion can also occur when individuals mistake debris for potential prey items (Gregory 2009; Hoarau et al. 2014; Thomás et al. 2002). Potential ingestion of marine debris varies among species and life history stages due to differing feeding strategies (Nelms et al. 2016). Ingestion of plastics and other marine debris can result in both lethal and sublethal impacts on sea turtles, with sublethal effects more difficult to detect (Gall and Thompson 2015; Hoarau et al. 2014; Nelms et al. 2016; Schuyler et al. 2014). Long-term sublethal effects may include dietary dilution, chemical contamination, depressed immune system function, poor body condition, and reduced growth rates, fecundity, and reproductive success. However, these effects are cryptic and clear causal links are difficult to identify (Nelms et al. 2016).	Trash and debris may be accidentally discharged through fisheries use, dredged material ocean disposal, marine minerals extraction, marine transportation, navigation and traffic, survey activities and cables, lines and pipeline laying, and debris carried in river outflows or windblown from onshore. Accidental releases of trash and debris are expected to be low-quantity, localized, and low-impact events. Direct and indirect ingestion of plastic fragments and other marine debris is well documented and has been observed in all species of sea turtles (Bugoni et al. 2001; Gregory 2009; Hoarau et al. 2014; Nelms et al. 2016; Schuyler et al. 2014; Thomás et al. 2002). Ingestion can result in both lethal and sublethal impacts on sea turtles, with sublethal effects more difficult to detect (Gall and Thompson 2015; Hoarau et al. 2014; Nelms et al. 2016; Schuyler et al. 2014). However, these effects are cryptic and clear causal links are difficult to identify (Nelms et al. 2016).
Cable emplacement and maintenance	Cable maintenance activities disturb bottom sediments and cause temporary increases in suspended sediment; these disturbances will be localized and generally limited to the emplacement corridor. Data are not available regarding effects of suspended sediments on adult and juvenile sea turtles, although elevated suspended sediments may cause individuals to alter normal movements and behaviors. However, these changes are expected to be too small to be detected (NOAA 2020). Sea turtles would be expected to swim away from the sediment plume. Elevated turbidity is most likely to affect sea turtles if a plume causes a barrier to normal behaviors, but no impacts would be expected due to swimming through the plume (NOAA 2020). Turbidity associated with increased sedimentation may result in short-term, temporary impacts on sea turtle prey species (Table D1-10).	The impact on water quality from accidental sediment suspension during cable emplacement is short term and temporary. If elevated turbidity caused any behavioral responses such as avoidance of the turbidity zone or changes in foraging behavior, such behaviors would be temporary, and any impacts would be short term and temporary. Turbidity associated with increased sedimentation may result in short-term, temporary impacts on some sea turtle prey species (Table D1-10).
Electric and magnetic fields and cable heat	EMFs emanate constantly from installed telecommunication and electrical power transmission cables. Sea turtles appear to have a detection threshold of magnetosensitivity and behavioral responses to field intensities ranging from 0.0047 to 4000 µT for loggerhead turtles, and 29.3 to 200 µT for green turtles, with other species likely similar due to anatomical, behavioral, and life history similarities (Normandeau et al. 2011). Juvenile or adult sea	During operations, future new cables would produce EMF. Submarine power cables in the geographic analysis area for sea turtles are assumed to be installed with appropriate shielding and burial depth to reduce potential EMF to low levels (MMS 2007: Section 5.2.7). EMF of any two sources would not overlap. Although the EMF would exist as long as a cable was in operation, impacts, if any, would likely be difficult to detect, if they occur at all.

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
	turtles foraging on benthic organisms may be able to detect magnetic fields while they are foraging on the bottom near the cables and up to potentially 82 feet (25 meters) in the water column above the cable. Juvenile and adult sea turtles may detect the EMF over relatively small areas near cables (e.g., when resting on the bottom or foraging on benthic organisms near cables or concrete mattresses). There are no data on impacts on sea turtles from EMFs generated by underwater cables, although anthropogenic magnetic fields can influence migratory deviations (Luschi et al. 2007; Snoek et al. 2016; 2020). However, any potential impacts from AC cables on turtle navigation or orientation would likely be undetectable under natural conditions, and thus would be insignificant (Normandeau et al. 2011).	Furthermore, this IPF would be limited to extremely small portions of the areas used by resident or migrating sea turtles. As such, exposure to this IPF would be low and impacts on sea turtles would not be expected.
Lighting: Vessels	Ocean vessels such as ongoing commercial vessel traffic, recreational and fishing activity, and scientific and academic research traffic have an array of lights including navigational, deck lights, and interior lights. Such lights have some limited potential to attract sea turtles although the impacts, if any, are expected to be localized and temporary.	Construction, operations, and decommissioning vessels associated with non-offshore-wind activities produce temporary and localized light sources that could result in attraction or avoidance behavior of sea turtles. These short-term impacts are expected to be of low intensity and occur infrequently.
Lighting: Structures	Artificial lighting on nesting beaches or in nearshore habitats has the potential to result in disorientation to nesting females and hatchling turtles. Artificial lighting on the OCS does not appear to have the same potential for effects. Decades of oil and gas platform operation in the Gulf of Mexico, which can have considerably more lighting than offshore WTGs, has not resulted in any known impacts on sea turtles (BOEM 2019).	Non-offshore-wind activities would not be expected to appreciably contribute to this sub-IPF. As such, no impact on sea turtles would be expected.
Noise: G&G	Infrequent site characterization surveys and scientific surveys produce high-intensity, impulsive noise around sites of investigation. These activities have the potential to result in some impacts including potential auditory injuries, short-term disturbance, behavioral responses, and short-term displacement of feeding or migrating sea turtles if present within the ensonified area (NSF and USGS 2011). The potential for PTS and TTS is considered possible in proximity to G&G surveys utilizing air guns, but impacts are unlikely, as turtles would be expected to avoid such exposure and survey vessels would pass quickly (NSF and USGS 2011). No significant impacts would be expected at the population level.	Same as ongoing activities, with the addition of possible future oil and gas exploration surveys.
Noise: Impact and vibratory pile-driving	Noise from pile-driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water or through the seabed can result in high-intensity, low-exposure-level, and long-term but localized intermittent risk to sea turtles. Impacts, potentially including behavioral responses, masking, TTS, and PTS, would be localized in nearshore waters. Data regarding threshold levels for impacts on sea turtles from sound exposure during pile-driving are very limited, and no regulatory threshold criteria have been established for sea turtles. Based on current literature, the following thresholds are used to assess impacts on turtles: • Potential mortal injury: SEL_{24h} 210 dB re 1 μPa^2 s or greater than Lpk 207 dB re 1 μPa (Popper et al. 2014) • PTS: SEL_{24h} 204 dB re 1 μPa^2 s, Lpk 232 dB re 1 μPa (Finneran et al. 2017) • TTS: SEL_{24h} 189 dB re 1 μPa^2 s, Lpk 226 dB re 1 μPa (Finneran et al. 2017) • Behavioral harassment: SPL 175 dB re 1 μPa (Finneran et al. 2017)	No future activities were identified within the geographic analysis area for sea turtles other than ongoing activities.
Noise: Vessels	The frequency range for vessel noise (10 to 1000 Hz) (MMS 2007) overlaps with sea turtles' known hearing range (less than 1,000 Hz with maximum sensitivity between 200 to 700 Hz) (Bartol 1994) and would therefore be audible. However, Hazel et al. (2007) suggest that sea turtles' ability to detect approaching vessels is primarily vision-dependent, not acoustic. Sea turtles may respond to vessel approach or noise with a startle response (diving or swimming away) and a temporary stress response (NSF and USGS 2011). Samuel et al. (2005) indicated that vessel noise could have an effect on sea turtle behavior, especially their submergence patterns.	Any offshore projects that require the use of ocean vessels could potentially result in long-term but infrequent impacts on sea turtles, including temporary startle responses, masking of biologically relevant sounds, physiological stress, and behavioral changes, especially their submergence patterns (NSF and USGS 2011; Samuel et al. 2005). However, BOEM expects that these brief responses of individuals to passing vessels would be unlikely given the patchy distribution of sea turtles, and no stock or population-level effects would be expected.
Noise: Drilling	Noise from drilling prior to pile-driving could occur in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Drilling activities used prior to pile-driving activities to remove soil or boulders from inside the piles in cases of pile refusal may produce SPL of 140 dB re μPa at 3,280 ft (Austin et al. 2018). This would exceed the continuous noise threshold of 120 dB re 1 μPa (Table 3.7-3) beyond 3,000 ft, but these events are expected to be short term, which limits the sea turtles potentially present during construction. While behavioral responses may occur from drilling, they are not expected to be long lasting or biologically significant to sea turtle populations.	No future activities were identified within the geographic analysis area for sea turtles other than ongoing activities.
Noise: Aircraft	Aircraft routinely travel in the geographic analysis area for sea turtles. With the possible exception of rescue operations, no ongoing aircraft flights would occur at altitudes that would elicit a response from sea turtles. If flights are at a sufficiently low altitude, sea turtles may respond with a startle response (diving or swimming	Future low-altitude aircraft activities such as survey activities and navy training operations could result in short-term responses of sea turtles to aircraft noise. If flights are at a sufficiently low altitude, sea turtles may respond with a startle response (diving or swimming away), altered submergence patterns, and a temporary stress

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
	away), altered submergence patterns, and a temporary stress response (NSF and USGS 2011; Samuel et al. 2005). These brief responses would be expected to dissipate once the aircraft has left the area.	response (NSF and USGS 2011; Samuel et al. 2005). These brief responses would be expected to dissipate once the aircraft has left the area.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also undergoing continual upgrades and maintenance. Port expansion activities are localized to nearshore habitats and are expected to result in short-term, temporary impacts, if any, on sea turtles. Vessel noise may affect sea turtles, but response would be expected to be short term and temporary (see the Vessels: Noise sub-IPF above). The impacts on water quality from sediment suspension during port expansion activities are short term and temporary, and would be similar to those described under the Cable emplacement/maintenance IPF above.	Between 1992 and 2012, global shipping traffic increased fourfold (Tournadre 2014). The U.S. OCS is no exception to this trend, and growth is expected to continue as human population increases. In addition, the general trend along the coastal region from Virginia to Maine is that port activity will increase modestly. The ability of ports to receive the increase in larger ships will require port modifications. Future channel-deepening activities are being undertaken to accommodate deeper-draft vessels for the Panama Canal Locks. The additional traffic and larger vessels could have impacts on water quality through increases in suspended sediments and the potential for accidental discharges. The increased sediment suspension could be long term depending on the vessel traffic increase. Certain types of vessel traffic have increased recently (e.g., ferry use and cruise industry) and may continue to increase in the foreseeable future. Additional impacts associated with the increased risk of vessel strikes could also occur (see the Traffic: Vessel collisions sub-IPF below).
Presence of structures: Entanglement or ingestion of lost fishing gear	The Mid-Atlantic region has more than 130 artificial reefs. Currently, bridge foundations and the Block Island Wind Farm may be considered artificial reefs and may have higher levels of recreational fishing, which increases the chances of sea turtles encountering lost fishing gear, resulting in possible ingestions, entanglement, injury, or death of individuals (Berreiros and Raykov 2014; Gregory 2009; Vegter et al. 2014) if present where these structures are located. At the scale of the OCS geographic analysis area for sea turtles, there are very few areas that would serve to concentrate recreational fishing and increase the likelihood that sea turtles would encounter lost fishing gear.	No future activities were identified within the geographic analysis area for sea turtles other than ongoing activities.
Presence of structures: Habitat conversion and prey aggregation	The Mid-Atlantic region has more than 130 artificial reefs. Hard-bottom (scour control and rock mattresses) and vertical structures (bridge foundations, Block Island Wind Farm WTGs, and two WTGs with the Coastal Virginia Offshore Wind pilot project) in a soft-bottom habitat can create artificial reefs, thus inducing the reef effect (Taormina et al. 2018; NMFS 2015). The reef effect is usually considered a beneficial impact associated with higher densities and biomass of fish and decapod crustaceans (Taormina et al. 2018), providing a potential increase in available forage items and shelter for sea turtles compared to the surrounding soft bottoms.	The presence of structures associated with non-offshore-wind development in nearshore coastal waters has the potential to provide habitat for sea turtles as well as preferred prey species. This reef effect has the potential to result in long-term, low-intensity, beneficial impacts. Bridge foundations will continue to provide foraging opportunities for sea turtles with measurable benefits to some individuals.
Presence of structures: Avoidance/displacement	No ongoing activities in the geographic analysis area for sea turtles beyond offshore wind facilities are measurably contributing to this sub-IPF. There may be some impacts resulting from the existing Block Island Wind Farm (five WTGs) and Coastal Virginia Offshore Wind pilot project (two WTGs) but, given the limited number of WTGs, no measurable impacts are occurring.	Not contemplated for non-offshore-wind facility sources.
Presence of structures: Behavioral disruption — breeding and migration	No ongoing activities in the geographic analysis area for sea turtles beyond offshore wind facilities are measurably contributing to this sub-IPF.	Not contemplated for non-offshore-wind facility sources.
Presence of structures: Displacement into higher risk areas (vessels and fishing)	No ongoing activities in the geographic analysis area for sea turtles beyond offshore wind facilities are measurably contributing to this sub-IPF.	Not contemplated for non-offshore-wind facility sources.
Traffic: Vessel collisions	Current activities contributing to this sub-IPF include port traffic levels, fairways, TSS, commercial vessel traffic, recreational and fishing activity, and scientific and academic vessel traffic. Propeller and collision injuries from boats and ships are common in sea turtles. Vessel strike is an increasing concern for sea turtles, especially in the southeastern United States where development along the coasts is likely to result in increased recreational boat traffic. In the United States, the percentage of strandings of loggerhead sea turtles attributed to vessel strikes increased from approximately 10% in the 1980s to a record high of 20.5% in 2004 (NMFS and USFWS 2007). Sea turtles are most susceptible to vessel collisions in coastal waters, where they forage from May through November. Vessel speed may exceed 10 knots in such waters, and evidence suggests that they cannot reliably avoid being struck by vessels exceeding 2 knots (Hazel et al. 2007).	Vessel traffic associated with non-offshore-wind development has the potential to result in an increased collision risk. While these impacts would be of high consequence, the patchy distribution of sea turtles makes stock or population-level effects unlikely (Navy 2018).
Gear utilization	A primary threat to sea turtles is their unintended capture in fishing gear, which can result in drowning or cause injuries that lead to mortality (e.g., swallowing hooks). For example, trawl fishing is among the greatest continuing primary threats to the loggerhead turtle (NMFS and USFWS 2019), and sea turtles are also caught as bycatch in other fishing gear, including longlines, gillnets, hook and line, pound nets, pot/traps, and dredge fisheries. A	No future activities were identified within the geographic analysis area for sea turtles other than ongoing activities.

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
	substantial impact of commercial fishing on sea turtles is the entrapment or entanglement that occurs with a variety of fishing gear.	

µPa = micropascal; µT = microtesla; AC = alternating current; L_{pk} = peak sound pressure level in units of decibels referenced to 1 micropascal; SEL_{24h} = sound exposure level over 24 hours (in units of decibels referenced to 1 micropascal squared second).

Table D1-22. Summary of non-offshore-wind activities and the associated impact-producing factors for scenic and visual resources

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Accidental releases	Ongoing offshore and onshore construction projects involve the use of vehicles, vessels, and equipment that contain fuel, fluids, and hazmat that have the potential for accidental release. Offshore and onshore construction can also result in sedimentation from land and seabed disturbance and accidental releases of trash and debris with associated visual impacts.	Planned offshore and onshore construction projects have the potential to result in accidental releases from vehicles, vessels, and equipment that contain fuel, fluids, and hazmat. Future offshore and onshore construction could also result in sedimentation from land and seabed disturbance and accidental releases of trash and debris with associated visual impacts.
Land disturbance	Onshore human-caused and naturally occurring erosion and sedimentation results from construction, maintenance, and weather events.	Ongoing onshore construction projects could generate noticeable disturbance in the landscape. Intensity and extent would vary depending on the location, type, and duration of activities.
Lighting	Offshore vessels have an array of lights including navigational lights, deck lights, and interior lights. Various ongoing onshore and coastal construction projects have nighttime activities, as well as existing structures, facilities, and vehicles that would require nighttime lighting.	Ongoing onshore construction projects involving nighttime activity could generate nighttime lighting. Intensity and extent would vary depending on the location, type, direction, and duration of nighttime lighting.
Presence of structures	Buoys are the only existing stationary structures within the offshore viewshed of the projects. Typically, buoys are visible only in the immediate foreground (less than 1 mile). Stationary and moving barges, boats, and ships also are visible in the daytime and nighttime viewsheds.	Onshore wind-related structures that could be viewed in conjunction with the offshore project components would be limited to meteorological towers, substations, and electrical transmission towers and conductors.
Traffic	Ongoing activities contribute air, marine, and onshore traffic and visible congestion.	Planned onshore and offshore construction projects involving vessel, vehicle, and helicopter traffic could generate noticeable changes in the characteristic seascape and landscape and viewer experience. Intensity and extent of the changes would vary depending on the location, type, direction, and duration of the traffic.

Table D1-23. Summary of non-offshore-wind activities and the associated impact-producing factors for water quality

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Accidental releases: Fuel/ fluids/hazmat	Accidental releases of fuels and fluids occur during vessel usage for dredge material ocean disposal, fisheries use, marine transportation, military use, survey activities, and submarine cable lines and pipeline-laying activities. According to the U.S. Department of Energy, 31,000 barrels of petroleum are spilled into U.S. waters from vessels and pipelines in a typical year. Approximately 40.5 million barrels of oil were lost as a result of tanker incidents from 1970 to 2009, according to International Tanker Owners Pollution Federation Limited, which collects data on oil spills from tankers and other sources. From 1990 to 1999, the average annual input to the coastal Northeast was 220,000 barrels of petroleum and into the offshore was fewer than 70,000 barrels. Impacts on water quality would be expected to brief and localized from accidental releases.	Future accidental releases from offshore vessel usage, spills, and consumption will likely continue on a similar trend. Impacts are unlikely to affect water quality.
Accidental releases: Trash and debris	Trash and debris may be accidentally discharged through fisheries use, dredged material ocean disposal, marine minerals extraction, marine transportation, navigation and traffic, survey activities, and cables, lines, and pipeline laying. Accidental releases of trash and debris are expected to be low-probability events. BOEM assumes operator compliance with federal and international requirements for management of shipboard trash; such events also have a relatively limited spatial impact.	As population and vessel traffic increase gradually over the next 35 years, accidental release of trash and debris may increase. However, there does not appear to be evidence that the volumes and extents anticipated would have any effect on water quality.
Anchoring	Impacts from anchoring occur due to ongoing military use and survey, commercial, and recreational activities.	Impacts from anchoring may occur semi-regularly over the next 35 years due to offshore military operations or survey activities. These impacts would include increased seabed disturbance, resulting in increased turbidity levels. All impacts would be localized, short term, and temporary.
Cable emplacement and maintenance	Elevated suspended sediment concentrations can occur under natural tidal conditions and increase during storms, trawling, and vessel propulsion. Survey activities and new cable- and pipeline-laying activities disturb bottom sediments and cause temporary increases in suspended sediment; these disturbances would be short term and either limited to the emplacement corridor or localized.	Suspension of sediments may continue to occur infrequently over the next 35 years due to survey activities and submarine cable, lines, and pipeline-laying activities. Future new cables would occasionally disturb the seafloor and cause short-term increases in turbidity and minor alterations in localized currents, resulting in localized, short-term impacts. If the cable routes enter the water quality geographic analysis area, short-term disturbance in the form of increased suspended sediment and turbidity would be expected.

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Port utilization: Expansion	Between 1992 and 2012, global shipping traffic increased fourfold (Tournadre 2014). The U.S. OCS is no exception to this trend, and growth is expected to continue as human population increases. In addition, the general trend along the coastal region from Virginia to Maine is that port activity will increase modestly. The ability of ports to receive the increase in larger ships will require port modifications, which, along with additional vessel traffic, could have impacts on water quality through increases in suspended sediments and the potential for accidental discharges. The increased sediment suspension could be long-term depending on the vessel traffic increase. Certain types of vessel traffic have increased recently (e.g., ferry use and cruise industry) and may continue to increase in the foreseeable future.	The general trend along the coastal region from Virginia to Maine is that port activity will increase modestly over the next 35 years. Port modifications and channel-deepening activities are being undertaken to accommodate the increase in vessel traffic and deeper-draft vessels that transit the Panama Canal Locks. The additional traffic and larger vessels could have impacts on water quality through increases in suspended sediments and the potential for accidental discharges. Certain types of vessel traffic have increased recently (e.g., ferry use and cruise industry) and may continue to increase in the foreseeable future.
Presence of structures	The installation of onshore and offshore structures leads to alteration of local water currents. These disturbances would be localized but, depending on the hydrologic conditions, have the potential to affect water quality through the formation of sediment plumes.	Impacts associated with the presence of structures include temporary sediment disturbance during maintenance. This sediment suspension would lead to interim and localized impacts.
Discharges/intakes	Discharges affect water quality by introducing nutrients, chemicals, and sediments to the water. There are regulatory requirements related to prevention and control of discharges, accidental spills, and nonindigenous species.	Increased coastal development is causing increased nutrient pollution in communities. In addition, ocean disposal activity in the North and Mid-Atlantic is expected to gradually decrease or remain stable. Impacts of ocean disposal on water quality are minimized because USEPA has established dredge spoil criteria and regulates the disposal permits issued by USACE. The impact on water quality from sediment suspension during these future activities would be short term and localized.
Land disturbance: Erosion and sedimentation	Ground-disturbing activities may lead to unvegetated or otherwise unstable soils. Precipitation events could potentially mobilize the soils into nearby surface waters, leading to potential erosion and sedimentation effects and subsequent increased turbidity.	Ground disturbance associated with construction and installation of onshore components could lead to unvegetated or unstable soils. Precipitation events could mobilize these soils, leading to erosion and sedimentation effects and turbidity. The impacts would be short term and localized with an increased likelihood of impacts limited to onshore construction periods.
Land disturbance: Onshore construction	Onshore construction activities may lead to unvegetated or otherwise unstable soils as well as soil contamination due to leaks or spills from construction equipment. Precipitation events could potentially mobilize the soils into nearby surface waters, leading to increased turbidity and alteration of water quality.	The general trend along coastal regions is that port activity will increase modestly in the future. This increase in activity includes expansion needed to meet commercial, industrial, and recreational demand. Modifications to cargo-handling equipment and conversion of some undeveloped land to meet port demand would be required to receive the increase in larger ships.

hazmat = hazardous materials

Table D1-24. Summary of non-offshore-wind activities and the associated impact-producing factors for wetlands

Associated IPFs: Sub-IPFs	Ongoing Activities	Planned Activities Intensity/Extent
Accidental releases: Fuel/oil	Onshore construction activities are a potential source of wetland water contamination from heavy equipment oil leaks or accidental spills. Precipitation events could potentially mobilize the soils into nearby wetlands, leading to alteration of water quality.	Onshore construction activities would require heavy equipment use and HDD activities, and potential spills could occur because of an inadvertent release from the machinery or during refueling activities. Applicants would develop and implement a Spill Prevention, Control, and Countermeasure Plan to minimize impacts on water quality (prepared in accordance with applicable NJDEP and NYSDEC regulations). Minor and short-term impacts are unlikely to affect wetland water quality.
Land disturbance: Erosion and sedimentation	Ground disturbance activities may lead to unvegetated or otherwise unstable soils. Precipitation events could potentially mobilize the soils into nearby wetlands, leading to potential erosion and sedimentation effects and subsequent increased turbidity.	Ground disturbance associated with construction and installation of onshore components could lead to unvegetated or unstable soils. Precipitation events could mobilize these soils, leading to erosion and sedimentation effects and turbidity. The impacts would be short term and localized, with an increased likelihood of impacts limited to onshore construction periods.
Land disturbance: Onshore construction	Onshore construction activities may lead to unvegetated or otherwise unstable soils as well as soil contamination due to leaks or spills from construction equipment. Precipitation events could potentially mobilize the soils into nearby wetlands, leading to increased turbidity and alteration of water quality.	The general trend along coastal regions are that port activity and land development will increase modestly in the future. This increase in activity includes expansion needed to meet commercial, industrial, and recreational demand. Modifications to cargo-handling equipment and conversion of some undeveloped land to meet port demand would be required to receive the increase in larger ships.

Attachment D2: Maximum-Case Scenario Estimates for Offshore Wind Projects

The following tables provide maximum-case scenario estimates of potential offshore wind project impacts assuming maximum buildout within the NY Bight PEIS geographic analysis areas. BOEM developed these estimates based on offshore wind demand, as discussed in its 2019 study *National Environmental Policy Act Documentation for Impact-Producing Factors in the Offshore Wind Cumulative Impacts Scenario on the North Atlantic Outer Continental Shelf* (BOEM 2019). Estimates disclosed in the Final PEIS's Chapter 3, No Action Alternative analyses were developed by summing acreage or number calculations across all lease areas noted as occurring within, or overlapping, a given geographic analysis area. This likely overestimates some impacts in cases where lease areas only partially overlap analysis areas. However, this approach was used to provide the most conservative estimate of planned offshore wind development.

This page was intentionally left blank.

[1] The spacing/layout for projects are as follows: NE State water projects include a single strand of WTGs and no OSS. For projects in the RI, MA, NY, NJ, DE, and MD lease areas, a 1×1–nm grid spacing is assumed. For the CVOW Project, the spacing is 0.7 nm; and the Dominion commercial lease area off the coast of Virginia would utilize 0.5 nm average spacing, which is less than the 1×1–nm spacing due to the need to attain the state's goals.
[2] Because development could occur anywhere within the RI and MA lease areas and assumes a continuous 1x1–nm grid, the actual development for these projects is expected to be approximately 73% of the collective technical capacity. Under the scenario described in this appendix, the total area in the RI and MA lease areas is greater than the area needed to meet state demand. Therefore, if a project is not constructed, BOEM assumes that another future project would be constructed to fulfill the unmet demand.
[3] This column identifies lease areas that are applicable to each resource based on the geographic analysis areas.
[4] The estimated construction schedule is based on information known at the time of this analysis and could be different when an applicant submits a COP.
[5] The number of turbines for those lease areas without an announced number of turbines has been calculated based on lease size, a 1×1-nm grid spacing, or the generating capacity.
[6] BOEM assumes that each offshore wind development would have its own cable (both onshore and offshore) and that future projects would not utilize a regional transmission line. The length of offshore export cable for those lease areas without a known project size is assumed to include two offshore cables totaling 120 miles (193 kilometers). The offshore export cable would be buried a minimum of 4 feet (1.8 meters) but not more than 10 feet (3.1 meters).
[7] If information for a future project could not be obtained from a COP, the length of interarray cabling is assumed to be the average amount per foundation based on the COPs submitted to date, which is 1.48 miles (2.4 kilometers). In addition, for those lease areas that require more than one OSS, it is assumed that an additional 6.2 miles (9.9 kilometers) of interlink cable would be required to link the two OSSs. Interarray cable is assumed to be buried between 4 and 6 feet (1.2 and 1.8 meters).
[8] The hub height, rotor diameter, and turbine height for lease areas is based on worst-case scenario for the resource area. Presentation of heights vary by COP and may be presented relative to MLLW, mean sea level, or height above highest astronomical tide.
[9] BOEM recognizes that the estimates presented within this analysis are likely high, conservative estimates; however, BOEM believes that this analysis is appropriately capturing the potential cumulative impacts and errs on the side of maximum impacts. Totals by lease area and by OCS may not fully sum due to rounding errors.
[10] Atlantic Shores South consists of two energy facilities (Project 1 and Project 2). Project 1 would have a capacity of 1,510 MW; Project 2's capacity is not yet determined, but Atlantic Shores has a goal of 1,327 MW.
[11] Total turbines across all six NY Bight lease areas provided by the lessees. These are estimates used for analysis purposes only and do not reflect the actual number of turbines that may be constructed in each NY Bight lease area.
[12] Total export cable length is the anticipated total across all six NY Bight lease areas as calculated by BOEM based upon information provided by the lessees.
[13] Cable disturbance width based on max value of the RPDE.
[14] Total interarray cable length is the anticipated total across all six NY Bight lease areas provided by the lessees.
[15] Rotor diameter based on max value of the RPDE.
[16] Height of turbine based on max value of the RPDE.

[1] BOEM recognizes that the estimates presented within this cumulative analysis are likely high, conservative estimates; however, BOEM believes that this analysis is appropriately capturing the potential cumulative impacts and errs on the side of maximum impacts.
[2] This column identifies lease areas that are applicable to each resource based on the geographic analysis areas.
[3] The estimated number of foundations is the total number of turbines plus OSSs and met towers. If information for a future project could not be obtained from a publicly available COP, it is assumed that for every 50 turbines there would be one OSS installed.
[3] BOEM used the estimated foundation footprint acreage provided in the COP (if available). If not available, BOEM used this formula: foundation footprint = 0.26 acre * foundation number.
[4] The WTG seabed disturbance with the addition of scour protection was calculated based on scour protection expected in submitted COPs. If not available, BOEM used this formula: (1 acre * foundation #) + foundation footprint.
[5] BOEM used the estimated offshore export cable seabed disturbance provided in the COP (if available). If not available, BOEM used this formula: ([COP export cable length OR estimated export cable length)] * 5,280 feet/mile * installation tool disturbance width)/(43,560 square feet/acre)
[6] BOEM used the estimated offshore export cable footprint provided in the COP (if available). If not available, BOEM used this formula: ([COP export cable length OR estimated export cable length] * 5,280 feet/mile * 1 foot)/(43,560 square feet/acre).
[7] BOEM used the estimated offshore export cable hard protection area provided in the COP (if available). If not available, BOEM used this formula: ([COP export cable length OR estimated export cable length] * 5,280 feet/mile * 0.10 * 9.8 feet) / (43,560 square feet/acre).
[8] BOEM used the estimated anchoring disturbance area provided in the COP (if available). If not available, BOEM used this formula: (COP export cable length OR estimated export cable length) * (the corresponding subregion total COP anchoring disturbance per export cable length total).
[9] BOEM used the estimated interarray construction footprint/seabed disruption area provided in the COP (if available). If not available, BOEM used this formula: foundation # * (the corresponding subregion total COP interarray construction seabed disruption per foundation total).
[10] BOEM used the estimated interarray operating footprint/seabed disruption area provided in the COP (if available). If not available, BOEM used this formula: foundation # * (the corresponding subregion total COP interarray operating seabed disruption per foundation total).
[11] BOEM used the estimated interarray hard protection area provided in the COP (if available). If not available, BOEM assumed the interarray cable hard protection to be zero.
[12] Includes disturbance from offshore export cables and substation interconnector cables. Assumes an 82-foot-wide corridor would be disturbed per cable, based on the Ocean Wind 1 COP.
[13] Assumes an 82-foot-wide corridor would be disturbed, based on the Ocean Wind 1 COP.
[14] Total foundations are the anticipated number of WTG and OSS across all six NY Bight lease areas provided by the lessees. These are estimates used for analysis purposes only and do not reflect the actual number of foundations that may be constructed in each NY Bight lease area.
[15] Calculated based on maximum length of export cable of 1,772 miles and 131 maximum feet (width) of disturbance from the RPDE.
[16] Calculated based on maximum length of interarray cable of 1,582 miles and 131 maximum feet (width) of disturbance from the RPDE.
NJ = New Jersey; NA = not applicable; NY = New York; PPA = Power Purchase Agreement

[1] BOEM recognizes that the estimates presented within this cumulative analysis are likely high, conservative estimates; however, BOEM believes that this analysis is appropriately capturing the potential cumulative impacts and errs on the side of maximum impacts.
[2] This column identifies lease areas that are applicable to each resource based on the geographic analysis areas.
[3] BOEM estimated the total coolant fluids in WTGs using this formula: (sum of all coolants provided in the COP [any material used as a coolant, not including water]) * turbine #.
[4] BOEM estimated the total coolant fluids in OSSs or ESPs using this formula: (sum of all coolants provided in the COP [any material used as a coolant, not including water]) * ESP/OSS #.
[5] BOEM estimated the total oils and lubricants in WTGs using this formula: (sum of all oils & lubricants provided in the COP) * turbine #.
[6] BOEM estimated the total oils and lubricants in OSSs or ESPs using this formula: (sum of all oils & lubricants provided in the COP) * turbine #.
[7] BOEM estimated the total diesel fuel in WTGs using this formula: (sum of all diesel fuel provided in the COP) * turbine #.
[8] BOEM estimated the total diesel fuel in OSSs or ESPs using this formula: (sum of all diesel fuel provided in the COP) * ESP/OSS #.
[9] Atlantic Shores South may include up to 10 small OSSs, up to 5 medium OSSs, or up to 4 large OSSs. The total values for diesel fuel, coolants, and oils/lubricants for Atlantic Shores OSS in Table D.A-3 are based on 4 large OSSs; 4 large OSSs would result in larger volumes of diesel fuel, coolants, and oils/lubricants than would 10 small OSSs or 5 medium OSSs. The total values for 10 small OSSs for Atlantic Shores South would be 75,000 gallons diesel fuel, 381,600 gallons oils/lubricants, and 15,060 coolants. The total values for 5 medium OSSs would be 60,000 gallons diesel fuel, 563,825 gallons oils/lubricants, and 15,010 gallons coolants.
[10] Quantities of coolant, oil and lubricants, and diesel fuel are scaled to Ocean Wind 1 based on number of turbines and OSSs.
ESP = electrical service platform; NA = not applicable; NJ = New Jersey; NY = New York; PPA = Power Purchase Agreement

[1] This column identifies lease areas that are applicable to each resource based on the geographic analysis areas.

Note: Emissions for NY Bight were calculated based upon RPDE values using the BOEM Wind Tool model. Emissions for NY Bight Six Projects were calculated as six times the values for One Project. Based on input from the lessees, the calculated emissions for Six Projects are likely to be conservative (tending to overestimate emissions). Emissions for Ocean Wind 2 and Atlantic Shores North are scaled from Ocean Wind 1 and Atlantic Shores South, respectively, based on number of turbines and estimated construction schedule.

NJ = New Jersey; NY = New York; PPA = Power Purchase Agreement

Appendix E: Analysis of Incomplete and Unavailable Information

In accordance with Section 1502.21 of the Council on Environmental Quality (CEQ) regulations implementing the National Environmental Policy Act (NEPA), when an agency is evaluating reasonably foreseeable significant adverse effects on the human environment in an environmental impact statement (EIS) and when information is incomplete or unavailable, the agency shall make clear that such information is lacking. When incomplete or unavailable information was identified, the Bureau of Ocean Energy Management (BOEM) considered whether the information was relevant to the assessment of impacts and essential to its analysis of alternatives based upon the resource analyzed. If essential to making a reasoned choice among the alternatives, BOEM considered whether it was possible to obtain the information and if the cost of obtaining it was exorbitant. If it could not be obtained or if the cost of obtaining it was exorbitant, BOEM applied acceptable scientific methodologies to inform the analysis in light of this incomplete or unavailable information.

Because the Programmatic EIS (PEIS) is being prepared prior to the submittal of Construction and Operations Plans (COPs), the specific locations of wind turbine generators (WTGs) and offshore substations (OSSs), interarray cables, offshore and onshore export cable routes, cable landfall locations, and onshore facility locations for the New York Bight (NY Bight) projects are not known at this time. Therefore, site-specific impacts associated with the construction and installation, operations and maintenance (O&M), and conceptual decommissioning of these facilities that deviate from the broad-scale analysis presented in the PEIS will be analyzed in subsequent COP-specific NEPA documents. Because the analysis in the Final PEIS is intended to be programmatic in nature and because future site-specific NEPA analysis will be required for each COP, BOEM does not believe site-specific information on facility locations is essential to the reasoned choice among alternatives. The following sections present an analysis by resource topic of incomplete or unavailable information in the PEIS.

E.1 Incomplete or Unavailable Information Analysis for Resource Areas

E.1.1 Air Quality and Greenhouse Gas Emissions

BOEM expects that any action alternative would lead to reduced emissions regionally and a net improvement in regional air quality because offshore wind energy would displace a portion of the energy generated from fossil fuel combustion. Although a quantitative emissions inventory analysis of the region, and regional modeling of pollutant concentrations over the next 30 to 35 years would more accurately assess the overall impacts of the changes in emissions from the six NY Bight projects, regional air quality conditions would apply to the programmatic alternatives and subsequent project-specific alternatives alike. When specific projects are proposed and undergo Outer Continental Shelf (OCS) air quality permitting, the required air quality modeling will provide additional insight into regional air quality conditions. Construction cannot begin on any project before an air permit is acquired. As such, the analysis provided in the Final PEIS is sufficient to support sound scientific judgments and informed decision-making related to the use of the offshore portions of the NY Bight lease areas and offshore export cable route corridors. Therefore, BOEM does not believe that there is incomplete or unavailable information on air quality that is essential to making a reasoned choice among alternatives.

E.1.2 Water Quality

At this early analysis stage, there is some inherent uncertainty regarding the impacts of the activities covered in the PEIS on water quality. However, the information that is available is appropriate for this programmatic level of analysis, and subsequent project-specific environmental analysis on water quality will be required for each individual COP before any construction activities may begin. Therefore, BOEM does not believe that there is incomplete or unavailable information that is essential to making a reasoned choice among alternatives for this PEIS.

E.1.3 Bats

Habitat use and distribution of bats vary between seasons and species; therefore, there will always be some level of incomplete information on the distribution and habitat use of bats in the offshore portions of the NY Bight lease areas. Additionally, surveying bat activity offshore provides challenges as limited methods have been developed and tested for surveying within this environment. No BOEM-issued guidance for bat surveys currently exists for renewable energy development on the OCS. However, an evaluation of scientific studies and available, relevant information was examined, including New York State Energy Research and Development Authority (NYSERDA) remote metocean data from two buoys in two of the NY Bight lease areas (see Section 3.5.1.1, *Description of the Affected Environment and Future Baseline Conditions*), to provide a baseline understanding of the presence, abundance, and seasonality of bats that may occur within the NY Bight lease areas.

Given the infancy of U.S. offshore wind development, there is some level of uncertainty regarding the potential collision risk to individual bats that may be present within the offshore portions of the NY Bight lease areas. However, sufficient information on collision risk to bats observed at land-based U.S. wind projects exists and was used to analyze and corroborate the potential for this impact as a result of WTG operations in the NY Bight lease areas. In addition, as described in Section 3.5.1, *Bats*, the likelihood of a bat encountering an operating WTG during migration is very low; therefore, the differences among alternatives with respect to bats for wind development in the NY Bight lease areas are expected to be small. As such, the analysis provided in the Final PEIS is sufficient to support sound scientific judgments and informed decision-making related to distribution and use of the offshore portions of the NY Bight lease areas as well as to the potential for collision risk of bats. Consequently, BOEM does not believe that there is incomplete or unavailable information on bat resources that is essential to making a reasoned choice among alternatives.

E.1.4 Benthic Resources

There is uncertainty regarding the spatial and temporal distribution of benthic (faunal) resources and periods during which they might be especially vulnerable to disturbance; however, project-specific COP surveys of benthic resources for other nearby projects and a broad-scale study (Guida et al. 2017) provided a suitable basis for generally predicting the species, abundances, and distributions of benthic resources within the geographic analysis area. Uncertainty also exists regarding the impact of some impact-producing factors (IPFs) on benthic resources. For example, specific stimulus-response related to acoustics and electromagnetic fields (EMFs) is not well studied, although there is some emerging information from benthic monitoring at European wind facilities and the Block Island Wind Farm in the United States that allows for a broad understanding of the impacts. Similarly, specific secondary impacts, such as changes in diets throughout the food chain resulting from habitat modification and synergistic behavioral impacts from multiple IPFs, are not fully known. Again, results of benthic monitoring at European wind facilities and the Block Island Wind Farm in the United States provide general knowledge of the overall impacts of these IPFs combined, if not individually. Therefore, the analysis provided in the Final PEIS is sufficient to support sound scientific judgments and informed decision-making related to the overall impacts. For these reasons, BOEM does not believe that there is incomplete or unavailable information on benthic resources that is essential to making a reasoned choice among alternatives.

E.1.5 Birds

Habitat use and distribution of birds vary between seasons, species, and years; therefore, there will always be some level of incomplete information on the distribution and habitat use of birds in the offshore portions of the geographic analysis area, including the NY Bight lease areas. Additionally, given the infancy of U.S. offshore wind development, there will be some level of uncertainty regarding the potential for collision risk and avoidance behaviors for some of the bird species that may be present within the offshore portions of the geographic analysis area. For the Final PEIS, publicly available avian survey data (e.g., NYSERDA remote metocean data from two buoys), marine life data and analysis team (MDAT) modeling, and NYSERDA aerial digital avian survey data that covers most of the NY Bight lease areas were used to describe bird presence and inform the analysis of potential adverse impacts on bird resources in the offshore environment.

Bird mortality data are available for onshore wind facilities and, based on several assumptions regarding their applicability to offshore environments, were used to inform the analysis of bird mortality associated with the offshore WTGs analyzed in the Final PEIS. However, uncertainties exist regarding the use of the onshore bird mortality rate to estimate the offshore bird mortality rate due to differences in species groups present and life history and behavior of species as well as differences in the offshore marine environment compared to onshore habitats.

Modeling is commonly used to predict the potential mortality rates for bird species in Europe and the United States (BOEM 2015, 2021). Due to inherent data limitations, these models often represent only a subset of species potentially present. Still, the datasets used by BOEM (e.g., MDAT) to assess the potential for exposure of birds to the NY Bight lease areas represent the best available data and provide context at both local and regional scales. Furthermore, sufficient and relevant information on collision risk and avoidance behaviors observed in related species at European offshore wind projects is available and was used to analyze and corroborate the potential for these impacts as a result of wind farm operations in the NY Bight lease areas (e.g., Skov et al. 2018). As such, the analysis provided in the Final

PEIS is sufficient to support sound scientific judgments and informed decision-making related to distribution and use of the offshore portions of the geographic analysis area as well as to the potential for collision risk and avoidance behaviors in bird resources. Furthermore, the similarity between the different alternatives does not render any of this incomplete and unavailable information essential to making a reasoned choice among alternatives. Therefore, BOEM does not believe that there is incomplete or unavailable information on birds that is essential to making a reasoned choice among alternatives.

E.1.6 Coastal Habitat and Fauna

Although the preferred habitats of terrestrial and coastal fauna are generally known, specific data on abundances and distributions within the geographic analysis area of various fauna within these habitats are likely to remain unknown without site-specific surveys. However, the species inventories and other general information about the area provide an adequate basis for evaluating the fauna likely to inhabit the onshore geographic analysis area. Additionally, the onshore activities expected to be proposed involve only common, industry-standard activities for which impacts are generally understood. Therefore, BOEM believes that the analysis provided in the Final PEIS is sufficient to make a reasoned choice among the alternatives in terms of coastal habitat and fauna.

E.1.7 Finfish, Invertebrates, and Essential Fish Habitat

There is some uncertainty regarding the spatial and temporal distribution of finfish and invertebrate resources and periods during which they might be especially vulnerable to disturbance; however, project-specific COP aquatic resource surveys for other nearby projects and a broad-scale study (Guida et al. 2017) provided a suitable basis for general predictions of finfish and invertebrate resources with respect to species, densities, and distributions within the geographic analysis area. Future project-specific Biological Assessments (BAs) and essential fish habitat (EFH) assessments will be prepared for each offshore wind project and will provide additional information about impacts on Endangered Species Act (ESA) listed species and EFH. While impacts on specific finfish and invertebrate species are not anticipated to vary from the general impacts provided in the Final PEIS, specific impact discussions for ESA-listed species and EFH will be provided in these future assessments.

Uncertainty also exists regarding the impact of some IPFs on invertebrate resources, such as the effects of EMFs and underwater noise (e.g., generated from pile-driving activities). The available information on invertebrate sensitivity to EMF is equivocal (Hutchinson et al. 2020), and sensitivity to sound pressure and particle motion effects is not well understood for many species, nor are synergistic or antagonistic impacts from multiple IPFs. Similarly, specific secondary impacts such as changes in diets throughout the food chain resulting from habitat modification are not well known for finfish and invertebrates. Where applicable, the analysis drew upon information in the available literature and an increasing number of monitoring and research studies related to wind development, other undersea development, or artificial reefs in Europe and the United States, several of which were recently drafted or published. These monitoring studies help provide a broad understanding of the overall impacts of the combined IPFs, if not individually.

For these reasons, the information provided in the Final PEIS is sufficient to support sound scientific judgments and informed decision-making related to the overall impacts. Therefore, BOEM does not believe that there is incomplete or unavailable information on finfish, invertebrate, and EFH resources that is essential to making a reasoned choice among alternatives.

E.1.8 Marine Mammals

The National Marine Fisheries Service (NMFS) has summarized the most current information about marine mammal population status, occurrence, and use of the region in its stock status reports for the Atlantic OCS and Gulf of Mexico (Waring et al. 2015; Hayes et al. 2019, 2020, 2021, 2022; Palka et al. 2021, 2017). These studies provided a suitable basis for predicting the species, abundances, and distributions of marine mammals in the geographic analysis area. However, population trend data from NMFS are unavailable for 32 species (of which only 7 are common or regular in the NY Bight area), and annual human-caused mortality is unknown for two species (see Table 3.5.6-1 in the Final PEIS). Most species lacking population trend data are offshore species, such as blue whale, fin whale, and non-porpoise odontocetes (e.g., beaked whales and dolphins). As a result, there is uncertainty regarding how the NY Bight lease area project activities and cumulative effects may affect these populations. In addition to species distribution information, effects of some IPFs on marine mammals are also uncertain or ambiguous, as described below.

Potential effects of EMF have not been scaled to consider impacts on marine mammal populations or their prey in the geographic analysis area (Taormina et al. 2018). The widespread ranges of marine mammals and difficulty obtaining permits make experimental studies challenging. As a result, few scientific studies have been conducted that examine the effects of altered EMF on marine mammals. Scientific studies summarized by Normandeau et al. (2011) demonstrate that marine mammals are sensitive to, and can detect, small changes in magnetic fields (Section 3.5.6, *Marine Mammals*), but potential impacts would likely only occur within a few feet of cable segments. Therefore, the current literature does not support a conclusion that EMF could lead to changes in behavior that would cause significant adverse effects on marine mammal populations.

The behavioral effects of anthropogenic noises on marine mammals are increasingly being studied. However, behavioral responses vary depending on a variety of factors such as life stage, previous experience, and current behavior (e.g., feeding, nursing), and they are therefore difficult to predict. In addition, the current NMFS disturbance criteria apply a single threshold for all marine mammals for impulsive noise sources and do not consider the overall duration, exposure, or frequency content of the sound to account for species-dependent hearing acuity. While elevated underwater sound could startle or displace animals, behavioral responses are not necessarily predictable from received levels alone (Southall et al. 2007).

In addition, research regarding the potential behavioral effects of pile-driving noise has generally focused on harbor porpoises and seals; studies that examine the behavioral responses of baleen whales to pile-driving activities are absent from the literature. Of the available research, most studies (e.g., Brandt et al. 2016; Dahne et al. 2013; Benhemma-Le Gall et al. 2021) conclude that, although pile-driving activities could cause avoidance behaviors or disruption of feeding activities, individual harbor porpoises and seals would likely return to normal behaviors once the activity had stopped; this is unknown for baleen whales and other marine mammals. Uncertainty remains regarding the long-term cumulative acoustic impacts associated with multiple pile-driving projects that may occur over several years. An acoustic narrative in Appendix J, *Introduction to Sound and Acoustic Assessment*, Section, J.4, *Acoustic Assessment,* drawing on the hypothetical case study of two wind farms constructed in New England, provides further insight about the relative risk of multi-project development on select marine mammal species and the factors that should be considered in reducing acoustic impacts. This also applies to other project activities (e.g., vessel traffic, high-resolution geophysical (HRG) surveys, geotechnical drilling, dredging activities) that may elicit behavioral reactions in marine mammals. As a result, it is not possible to predict with certainty the potential long-term behavioral effects on marine mammals from the project-related pile-driving or other activities, as well as ongoing concurrent and cumulative pile-driving and other activities.

The Final PEIS used the best available information when considering behavioral effects related to underwater noise to address this uncertainty. For the assessment of large baleen whales, studies on other impulsive noises (e.g., airguns) were used to inform the potential behavioral reactions to pile-driving noise (Southall et al. 2021, McCauley et al. 1998, Johnson 2002, Richardson et al. 1999). Monitoring studies would provide insight into species-specific behavioral reactions to project-generated underwater noise. Long-term monitoring of concurrent and multiple projects could inform the understanding of long-term effects and subsequent consequences from cumulative underwater noise activities on marine mammal populations.

There is a lack of research regarding the responses of large whale species to extensive networks of new structures due to the novelty of offshore wind development on the Atlantic OCS. Although new structures are anticipated from multiple offshore wind projects in the NY Bight area (see Chapter 2, *Alternatives*), it is expected that spacing would allow large whales to access areas within and between wind facilities. No physical obstruction of marine mammal migration routes or habitat areas are anticipated, but it is unknown if avoidance of offshore wind lease areas due to new structures would occur. Additionally, while there is some uncertainty regarding how hydrodynamic changes around foundations may affect prey availability, these changes are expected to have limited impacts on the local conditions around WTG foundations. The potential consequences of these impacts on marine mammals are unknown. Monitoring studies would provide insight into species-specific avoidance behaviors and other potential behavioral reactions to project structures.

At present, the Final PEIS has no basis to conclude that these IPFs (i.e., noise, EMF, presence of structures) would result in significant adverse behavioral impacts on marine mammal populations.

BOEM determined that the overall costs of obtaining the missing information for or addressing these uncertainties are exorbitant, or the means to obtain it are unknown. Therefore, to address these gaps, BOEM extrapolated or drew assumptions from known information for similar species and studies using acceptable scientific methodologies to inform the analysis considering this incomplete or unavailable information, as presented in Section 3.5.6, *Marine Mammals*. The information and methods used to predict potential impacts on marine mammals represent the best available information, and the information provided in the Final PEIS is sufficient to support sound scientific judgments and informed decision-making. Therefore, BOEM does not believe that there is incomplete or unavailable information on marine mammal resources that is essential to making a reasoned choice among alternatives.

E.1.9 Sea Turtles

There are limited data and information on the distribution and abundance of sea turtle species that occur in the Atlantic OCS and the NY Bight lease areas. Four species of sea turtles are considered in the PEIS: the leatherback sea turtle, loggerhead sea turtle, Kemp's ridley sea turtle, and green sea turtle. A digital aerial baseline survey of marine wildlife was conducted off the southern shores of New York and northern shores of New Jersey by NYSERDA. The survey boundaries overlap with the majority of the NY Bight lease areas. Sea turtle abundance increased from the coastal zones out to the shelf break. Densities of sea turtles were most abundant in the summer months (Normandeau Associates Inc. and APEM Inc. 2021a, 2021b).

Future project-specific BAs will be prepared for each offshore wind project and will provide additional information about impacts on ESA-listed species. While impacts on sea turtles are not anticipated to vary from the general impacts provided in the Final PEIS, specific impact discussions for ESA-listed species will be provided in these future BAs.

Some uncertainty exists about the effects of certain IPFs on sea turtles and their habitats. The effects of EMF on sea turtles are not completely understood. However, the available relevant information is summarized in the BOEM-sponsored report by Normandeau et al. (2011) and a more recent review by Bilinski (2021). Although the thresholds for EMF disturbing various sea turtle behaviors are not known, the evidence suggests that impacts may only occur on hatchlings over short distances, and no adverse effects on sea turtles have been documented to occur from the numerous submarine power cables around the world.

There is also uncertainty about sea turtle responses to NY Bight project construction activities, and data are not available to evaluate potential changes to movements of juvenile and adult sea turtles due to elevated suspended sediments. However, although some exposure may occur, total suspended solid impacts would be limited in magnitude and duration and would occur within the range of exposures periodically experienced by these species. On this basis, any resulting impact on sea turtle behavior due to sediment plumes would likely be too small to be biologically meaningful, and no adverse impacts would be expected (NOAA 2020). Some potential exists for sea turtle displacement, but it is unclear if this would result in adverse impacts (e.g., because of lost foraging opportunities or increased exposure to potentially fatal vessel interactions). Additionally, it is currently unclear whether concurrent construction of multiple projects, increasing the extent and intensity of impacts over a shorter duration, or spreading out project construction with lower intensity impacts over multiple years would result in the least potential harm to sea turtles.

There is also uncertainty regarding the cumulative acoustic impacts associated with pile-driving activities. Information on sea turtle hearing is limited, and there are some discrepancies between hearing range determinations. Cumulative acoustic impacts associated with pile-driving activities are unknown, including whether sea turtles affected by construction activities would resume normal feeding, migrating, or breeding behaviors once daily pile-driving activities cease, or if secondary impacts would continue. Under the planned activities scenario, individual sea turtles may be exposed to acoustic impacts from multiple offshore wind projects in a single day or from one or more projects over the course of multiple days. Although the consequences of these exposure scenarios have been analyzed with the best available information, some level of uncertainty remains due to the lack of observational data on species' responses to pile-driving activities.

Some uncertainty exists regarding the potential for sea turtle responses to Federal Aviation Administration (FAA) hazard lights and navigation lighting associated with offshore wind development. Specific projects would limit lighting on WTGs and OSSs to minimum levels required by regulation for worker safety, navigation, and aviation. Although sea turtles' sensitivity to these minimal light levels is unknown, sea turtles do not appear to be adversely affected by oil and gas platform operations, which produce far more artificial light than offshore wind structures (BOEM 2019). The placement of new structures would be far from known nesting beaches, so no impacts on nesting female or hatchling sea turtles are anticipated.

Considerable uncertainty exists about how sea turtles would interact with the long-term changes in biological productivity and community structure resulting from the reef effect of offshore wind farms across the geographic analysis area. Artificial reef and hydrodynamic impacts could influence predator-prey interactions and foraging opportunities in ways that influence sea turtle behavior and distribution. Also, the extent of sea turtle entanglement on artificial reefs and shipwrecks is not captured in sea turtle stranding records, and the significance and potential scale of sea turtle entanglement in lost fishing gear are not quantified. These impacts are expected to interact with the ongoing influence of climate change on sea turtle distribution and behavior over broad spatial scales, but the nature and significance of these interactions are not predictable. BOEM anticipates that ongoing monitoring of offshore energy structures will provide some useful insights into these synergistic effects.

BOEM considered the level of effort required to address the uncertainties for sea turtles and determined that the methods necessary to do so are lacking or the associated costs would be exorbitant. Therefore, where appropriate, BOEM inferred conclusions about the likelihood of potential biologically significant impacts from available information for similar species and situations to inform the analysis considering this incomplete or unavailable information. These methods are described in greater detail in Section 3.5.7, *Sea Turtles*. Therefore, the analysis provided is sufficient to support sound scientific judgments and informed decision-making about the NY Bight projects with respect to impacts on sea turtles. For these reasons, BOEM does not believe that there is incomplete or unavailable information on sea turtles that is essential to making a reasoned choice among alternatives.

E.1.10 Wetlands

At this early analysis stage, there is some inherent uncertainty regarding the impacts of the activities covered in the PEIS on wetlands. However, the information that is available is appropriate for this programmatic level of analysis, and subsequent project-specific environmental analysis on wetlands will be required for each individual COP before any construction activities may begin. Therefore, BOEM does not believe that there is incomplete or unavailable information that is essential to making a reasoned choice among alternatives for this PEIS.

E.1.11 Commercial Fisheries and For-Hire Recreational Fishing

Fisheries are managed in the context of an incomplete understanding of fish stock dynamics and effects of environmental factors on fish populations. The commercial fisheries information used in this assessment has limitations. For example, vessel trip report data are only an approximation because this information is self-reported and may not account for all trips. The vessel trip report data also do not include all commercial fishing operations that may be affected by offshore wind development in the NY Bight lease areas and only represent vessel logbook data for species managed by the Greater Atlantic Regional Fisheries Office. While these data include incidental catch of Atlantic menhaden, highly migratory species, or species managed by the NMFS Southeast Regional Office (e.g., wahoo and mahi mahi), when targeting other species, they are not specifically identified as a subset of total catch of these species within the NY Bight lease areas. Additionally, available historical data lack consistency, making comparisons challenging.

Vessel monitoring system (VMS) data are also limited, with a number of factors contributing to their limitations.

- VMS coverage is not universal for all fisheries, with some fisheries (summer flounder, scup, black sea bass, bluefish, American lobster, spiny dogfish, skate, whiting, and tilefish) not covered at all by VMS.
- There is limited historical coverage for most fisheries (e.g., monkfish is optional and elective on a yearly basis, 2005 or earlier for herring, 2006 for groundfish and scallops, 2008 for surfclams/ocean quahogs, 2014 for mackerel, and 2016 for longfin squid/butterfish).
- Trip declaration does not necessarily correspond to actual operation.
- Hourly position pings limit area resolution based on speed.
- Fishing time/location can be mis-estimated by operational assumptions (speed and direction) that are affected by externalities (weather, sea state, mechanical issues).
- Catch data are limited for where there is no information on catch rates, retained catch composition is limited to target species and some bycatch species, and the data are not universal.
- Catch information is for the full trip, not sub-trips.
- Not all information is collected from all fisheries (gear type).

However, these data represent the best available data, and sufficient information exists to support the findings presented in the Final PEIS.

A second limitation is that recent annual revenue for for-hire recreational fishing in the NY Bight lease areas is not available. NMFS completed planning-level assessments of revenues from recreational party and charter vessels for each of the six lease areas (NMFS 2022a–f), but the assessments do not include detailed information on revenues from for-hire recreational fishing charters. However, BOEM does not believe that there is incomplete or unavailable information on commercial fisheries and for-hire recreational fishing resources that is essential to making a reasoned choice among alternatives.

E.1.12 Cultural Resources

At this stage of analysis, BOEM does not have enough information available from the lessees and their COPs or Project Design Envelopes (PDEs) to delineate either a cultural resources geographic analysis area or Programmatic Area of Potential Effects (APE) that would fully encompass all areas that may be subject to potential effects from NY Bight offshore wind project development. Specific areas associated with anticipated NY Bight offshore wind project development but excluded from delineation of the NY Bight Final PEIS cultural resources geographic analysis area and Programmatic APE are:

- Any other offshore areas, aside from the six NY Bight lease areas, potentially physically affected by seabed-disturbing activities (i.e., other marine areas in which temporary or permanent construction or staging areas are proposed to occur, such as offshore export cable route corridors and horizontal directional drilling [HDD] locations, which may have physical impacts on cultural resources).
- All onshore areas potentially physically affected by ground-disturbing activities (i.e., terrestrial areas in which temporary or permanent construction or staging areas are proposed to occur, such as onshore export cable route corridors, substations, or HDD locations, which may have physical impacts on cultural resources).
- Any other areas within the viewshed of offshore renewable energy structures measuring greater than 1,312 feet in height.
- Any other onshore areas potentially visually affected by the presence of onshore renewable energy structures (e.g., the viewshed from which onshore structures would be visible, such as onshore export cable routes, substations, or switching stations, and which may have visual impacts on cultural resources).

As discussed in Section 3.6.2, *Cultural Resources*, and Appendix I, *NHPA Section 106 Summary*, BOEM conducted background research to identify cultural resource types in the Programmatic APE. However, other cultural resources and cultural resource types subject to potential impacts and not identified in BOEM's background research are possible.

As part of compliance with federal and state requirements, offshore wind project applicants are required to conduct requisite cultural resource and historic property identification studies and commit to measures for avoiding, minimizing, or mitigating identified resources. BOEM will require each lessee to complete the requisite cultural resource technical studies per BOEM (2020) historic property identification guidelines including, but not limited to, the delineation of a preliminary APE (PAPE) per the COP PDE, completion of associated cultural resource and historic property identification efforts, assessment of potential effects, and development of potential avoidance, minimization, mitigation, and monitoring (AMMM) measures for identified historic properties. BOEM will then delineate the COP APE and assess the specific impacts on historic properties in the APE in COP-specific NEPA and National Historic Preservation Act (NHPA) documents.

BOEM considered the level of effort required to address the incomplete data described above for historic properties and determined that there is insufficient project definition to establish a comprehensive and sufficient cultural resources geographic analysis area that would account for all areas where project activities have the potential to result in impacts on marine cultural, terrestrial archaeological, or historic aboveground resources. Therefore, where appropriate, BOEM inferred conclusions about the likelihood of potential impacts from available information on cultural resource types likely to be present in the Programmatic APE to inform the analysis in light of this incomplete or unavailable information. These methods are described in greater detail in Section 3.6.2 and Appendix I. Therefore, the analysis provided is sufficient to support sound judgments and informed decision-making about the alternatives with respect to their impacts on cultural resources. For these reasons, BOEM does not believe that there is incomplete or unavailable information on cultural resources that is essential to making a reasoned choice among alternatives at this stage.

E.1.13 Demographics, Employment, and Economics

At this early analysis stage, there is some inherent uncertainty regarding the impacts of the activities covered in the PEIS on demographics, employment, and economics. However, no specific incomplete or unavailable information related to the analysis of impacts on demographics, employment, and economics was identified.

E.1.14 Environmental Justice

Evaluations of impacts on communities with environmental justice concerns rely on the assessment of impacts on other resources. As a result, incomplete or unavailable information related to other resources, as described in this appendix, also affects the completeness of the analysis of impacts on communities with environmental justice concerns.

As discussed in other sections, BOEM has determined that incomplete and unavailable resource information for environmental justice or for other resources on which communities with environmental justice concerns rely was either not relevant to assess reasonably foreseeable significant adverse impacts, was not essential to making a reasoned choice among alternatives, alternative data or methods could be used to predict potential impacts and provided the best available information, or the overall costs of obtaining the information were exorbitant or the means to do so were unknown. Therefore, the information provided in the Final PEIS is sufficient to support sound scientific judgments and informed decision-making related to the proposed uses of the onshore and offshore portions of the geographic analysis area.

Meaningful engagement with communities with environmental justice concerns is an essential element of assessing environmental justice impacts. For the PEIS, BOEM held a series of quarterly environmental justice forums with federal and state partners and community-based organizations that serve environmental justice and underserved communities (https://www.boem.gov/renewable-energy/state-activities/new-york-new-jersey-offshore-wind-environmental-justice-forums). As BOEM receives COPs for NY Bight projects, additional engagement opportunities, which provide information on locations for offshore and onshore infrastructure, will support COP-specific reviews.

E.1.15 Land Use and Coastal Infrastructure

At this early analysis stage, there is some inherent uncertainty regarding the impacts of the activities covered in the PEIS on land use and coastal infrastructure. However, the information that is available is appropriate for this programmatic level of analysis, and subsequent project-specific environmental analysis on land use and coastal infrastructure will be required for each individual COP before any construction activities may begin. Therefore, BOEM does not believe that there is incomplete or unavailable information that is essential to making a reasoned choice among alternatives for this PEIS.

E.1.16 Navigation and Vessel Traffic

At this early analysis stage, there is some inherent uncertainty regarding the impacts of the activities covered in the PEIS on navigation and vessel traffic. However, the information that is available is appropriate for this programmatic level of analysis, and subsequent project-specific environmental analysis on navigation and vessel traffic will be required for each individual COP before any construction activities may begin. Therefore, BOEM does not believe that there is incomplete or unavailable information that is essential to making a reasoned choice among alternatives for this PEIS.

E.1.17 Other Uses

At this early analysis stage, there is some inherent uncertainty regarding the impacts of the activities covered in the PEIS on other uses, including marine minerals, national security and military use, aviation and air traffic, cables and pipelines, radar systems, and scientific research and surveys. However, the information that is available is appropriate for this programmatic level of analysis, and subsequent project-specific environmental analysis on other uses will be required for each individual COP before any construction activities may begin. Therefore, BOEM does not believe that there is incomplete or unavailable information that is essential to making a reasoned choice among alternatives for this PEIS.

E.1.18 Recreation and Tourism

At this early analysis stage, there is some inherent uncertainty regarding the impacts of the activities covered in the PEIS on recreation and tourism. However, the information that is available is appropriate for this programmatic level of analysis, and subsequent project-specific environmental analysis on recreation and tourism will be required for each individual COP before any construction activities may begin. Therefore, BOEM does not believe that there is incomplete or unavailable information that is essential to making a reasoned choice among alternatives for this PEIS.

E.1.19 Scenic and Visual Resources

At this early analysis stage, there is some inherent uncertainty regarding the impacts of the activities covered in the PEIS on scenic and visual resources. However, the information that is available is appropriate for this programmatic level of analysis, and subsequent project-specific environmental analysis on scenic and visual resources will be required for each individual COP before any construction activities may begin. Therefore, BOEM does not believe that there is incomplete or unavailable information that is essential to making a reasoned choice among alternatives for this PEIS.

Appendix F: Assessment of Resources with Moderate (or Lower) Impacts

Contents

List of Tables

List of Figures

F.1 Introduction

To focus on the impacts of most concern in the main body of this Final PEIS, BOEM has included the analysis of resources with no greater than **moderate** adverse impacts below. These include:

- Air quality and greenhouse gas emissions
- Water quality
- Bats
- Birds
- Coastal habitat and fauna
- Sea turtles
- Wetlands
- Demographics, employment, and economics
- Land use and coastal infrastructure
- Recreation and tourism

This page was intentionally left blank.

3.4 Physical Resources

3.4.1 Air Quality and Greenhouse Gas Emissions

This section discusses potential impacts on air quality from the Proposed Action, alternatives, and ongoing and planned activities in the air quality and GHG emissions geographic analysis area. The air quality and GHG emissions geographic analysis area, as shown on Figure 3.4.1-1, includes the airshed within 25 miles (40 kilometers) of the NY Bight lease areas and the airshed within 15.5 miles (25 kilometers) of potential onshore construction areas and activities at representative ports supporting offshore construction for the NY Bight projects. In accordance with BOEM practice, the geographic analysis area for activities on the leases encompasses the geographic region that BOEM anticipates would be subject to USEPA review as part of OCS air permitting under the Clean Air Act (CAA) (42 USC 7409) for the NY Bight projects. The geographic analysis area also considers potential air quality impacts associated with the onshore construction areas and the mustering port(s) outside of the OCS permit area. Given the dispersion characteristics of emissions from marine vessels, equipment, vehicles, and other similar emission sources that would be used during proposed construction activities, the maximum potential air quality impacts would likely occur within a few miles of the emissions sources. For onshore areas, BOEM selected the 15.5-mile (25-kilometer) distance to assure that the locations of maximum potential air quality impact would be considered.

The air quality impact analysis in this PEIS is intended to be incorporated by reference into the project-specific environmental analyses for individual COPs expected for each of the NY Bight lease areas. Refer to Appendix C, *Tiering Guidance,* which identifies additional analyses anticipated to be required for the project-specific environmental analysis of individual COPs.

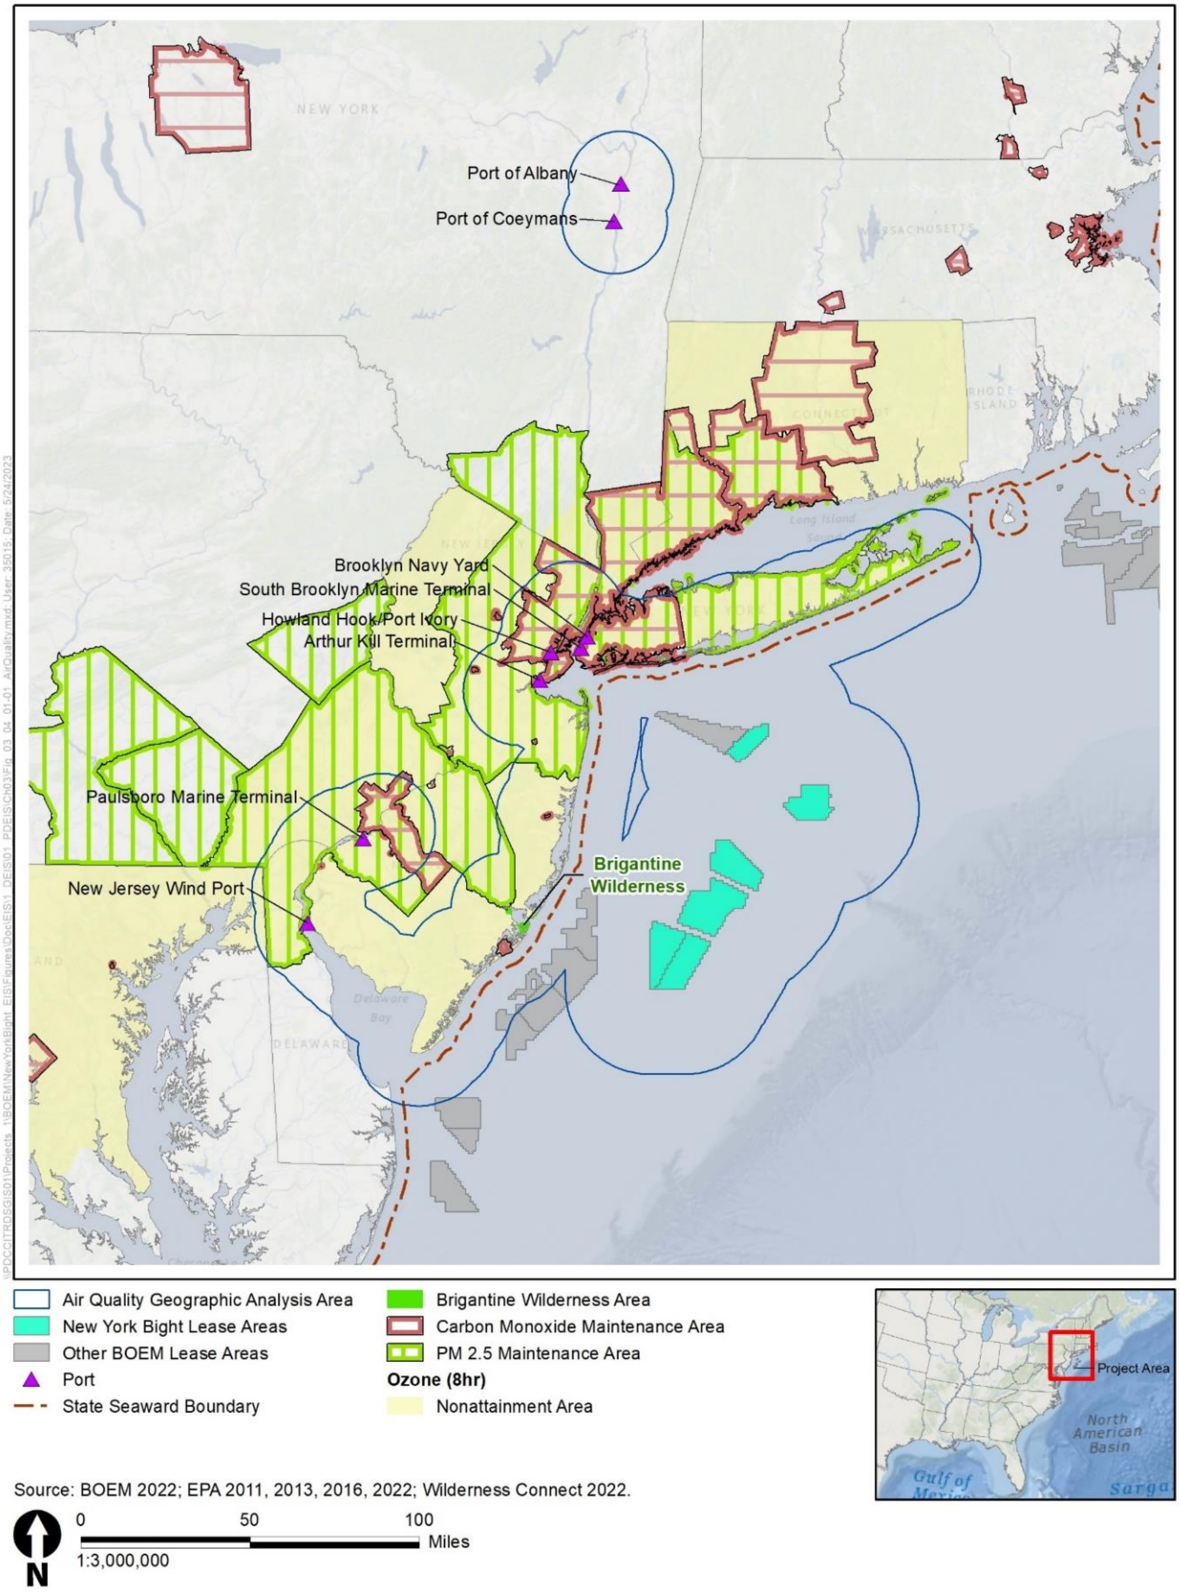

Figure 3.4.1-1. Air quality and GHG emissions geographic analysis area and attainment status

3.4.1.1 Description of the Affected Environment and Future Baseline Conditions

The overall geographic analysis area for air quality covers portions of northern and central Delaware, northeastern New Jersey, New York City, and Long Island; the area around the Port of Albany, New York; and over the ocean southeast of New York Harbor, as well as much of southern New Jersey and the adjacent portions of Delaware Bay and the Atlantic Ocean. This includes the air above the NY Bight projects and adjacent OCS area, potential offshore and onshore export cable routes, onshore substations and converter stations, construction staging areas, onshore construction and proposed project-related sites, and ports used to support construction and O&M activities. Appendix B, *Supplemental Information and Additional Figures and Tables,* provides information on climate and meteorological conditions in the NY Bight region.

Air quality within a region is measured in comparison to the National Ambient Air Quality Standards (NAAQS), which are established by USEPA pursuant to the CAA (42 USC 7409) for several common pollutants, known as criteria pollutants, to protect human health and welfare. The criteria pollutants are carbon monoxide (CO), lead (Pb), nitrogen dioxide (NO_2), ozone (O_3), particulate matter (PM) with diameter of 10 microns and smaller (PM_{10}), particulate matter with diameter of 2.5 microns and smaller ($PM_{2.5}$), and sulfur dioxide (SO_2). Table B.1-11 in Appendix B shows the NAAQS. New York and New Jersey have established ambient air quality standards (AAQS) that are similar to the NAAQS. Emissions of lead from offshore wind projects would be negligible because lead is not a component of liquid or gaseous fuels; accordingly, lead is not analyzed in this PEIS. Ozone is not emitted directly but is formed in the atmosphere from precursor chemicals, primarily nitrogen oxides (NO_X) and VOCs, in the presence of sunlight. Potential impacts of a project on O_3 levels are evaluated in terms of NO_X and VOC emissions.

USEPA designates all areas of the country as attainment, nonattainment, or unclassified for each criteria pollutant. An attainment area is an area where all criteria pollutant concentrations are within all NAAQS. A nonattainment area does not meet the NAAQS for one or more pollutants. Unclassified areas are those where attainment status cannot be determined based on available information and are regulated as attainment areas; this includes all of the OCS. An area can be in attainment for some pollutants and nonattainment for others. If an area was nonattainment at any point in the last 20 years but currently meets the NAAQS, then the area is designated a maintenance area. Nonattainment and maintenance areas are required to prepare a State Implementation Plan (SIP), which describes the region's program to attain and maintain compliance with the NAAQS. The attainment status of an area can be found at 40 CFR part 81 and in the USEPA Green Book (USEPA 2022). Attainment status for criteria pollutants is determined through evaluation of air quality data from a network of monitors.

The nearest onshore designated areas to the NY Bight lease areas are the New York City boroughs of Brooklyn, Queens, and Staten Island; the southern portion of Nassau County and the southwestern portion of Suffolk County, New York; and the northeastern portion of Monmouth County, New Jersey, as well as Ocean, Atlantic, and Cape May Counties in New Jersey. Parts or all of these counties are in designated nonattainment or maintenance areas for CO, $PM_{2.5}$, or O_3. The nonattainment areas include facilities that the NY Bight projects could use at the Port of Albany, Port of Coeymans, Brooklyn Navy Yard, South Brooklyn Marine Terminal, Howland Hook/Port Ivory, Arthur Kill Terminal, Paulsboro Marine

Terminal, and the New Jersey Wind Port. Figure 3.4.1-1 displays the nonattainment and maintenance areas[1] that intersect the geographic analysis area.

The CAA prohibits federal agencies from approving any activity that does not conform to a SIP. This prohibition applies only with respect to nonattainment or maintenance areas. Conformity to a SIP means conformity to a SIP's purpose of reducing the severity and number of violations of the NAAQS to achieve attainment of such standards. The activities for which BOEM has authority are outside of any nonattainment or maintenance area and therefore not subject to the requirement to show conformity. However, agencies issuing future approvals related to offshore wind projects in the NY Bight are responsible for evaluating the applicability of the CAA General Conformity requirements to their actions.

The CAA defines Class I areas as certain national parks and wilderness areas where very little degradation of air quality is allowed. Class I areas consist of national parks larger than 6,000 acres and wilderness areas larger than 5,000 acres that were in existence before August 1977. Projects subject to federal permits are required to notify the federal land manager responsible for designated Class I areas within 62 miles (100 kilometers) of a project.[2] The federal land manager identifies appropriate air quality–related values for the Class I area and evaluates the impact of a project on air quality–related values. The Brigantine Wilderness Area, approximately 35 miles (56 kilometers) southwest of the nearest edge of the NY Bight lease areas, is the only Class I area within 62 miles (100 kilometers) of the NY Bight projects. Air quality–related values identified by the U.S. Fish and Wildlife Service (USFWS) for Brigantine Wilderness include aquatic resources, fauna/wildlife, soils, vegetation, visibility, and acidic deposition (CSU 2022). Because there is the potential to affect a Class I area, these impacts will need to be evaluated for each NY Bight project within 62 miles (100 kilometers) of the Brigantine Wilderness Area.

The CAA amendments (42 USC 7401 et seq., Section 328) directed USEPA to establish requirements to control air pollution from the Atlantic OCS. The OCS Air Regulations (40 CFR 55) establish the applicable air pollution control requirements, including provisions related to permitting, monitoring, reporting, fees, compliance, and enforcement for facilities subject to the CAA. These regulations apply to OCS sources that are beyond state seaward boundaries. Projects within 25 nautical miles (46 kilometers) of a state seaward boundary are required to comply with the air quality requirements of the nearest or corresponding onshore area, including applicable permitting requirements.

3.4.1.2 Impact Level Definitions for Air Quality and Greenhouse Gas Emissions

Definitions of adverse impact levels are provided in Table 3.4.1-1. Beneficial impacts on air quality are described using the definitions described in Section 3.3.2 (Table 3.3-1). Impact levels for air quality are

---

[1] Figure 3.4.1-1 also indicates the nonattainment area for the 1979 1-hour ozone NAAQS, which USEPA has revoked; however, this area still must meet the provisions of the former State Implementation Plan for the 1-hour ozone standard.

[2] The 100-kilometer distance applies to notification and is not a threshold for use in evaluating impacts. Impacts at Class I areas at distances greater than 100 kilometers may need to be considered for larger emission sources if there is reason to believe that such sources could affect the air quality in the Class I area (USEPA 1992).

intended to serve NEPA purposes only, and are not intended to establish thresholds or other requirements with respect to permitting under the CAA.

Table 3.4.1-1. Adverse impact level definitions for air quality and GHG emissions

Impact Level	Definition
Negligible	Increases in ambient pollutant concentrations due to project emissions would be so small that they would be extremely difficult or impossible to discern or measure.
Minor to Moderate	Increases in ambient pollutant concentrations due to project emissions would be detectable but would not lead to exceedance of the NAAQS.
Major	Increases in ambient pollutant concentrations due to project emissions potentially would lead to exceedance of the NAAQS.

Accidental releases and air emissions are contributing IPFs to impacts on air quality. However, these IPFs may not necessarily contribute to each individual issue outlined in Table 3.4.1-2.

Table 3.4.1-2. Issues and indicators to assess impacts on air quality and GHG emissions

Issue	Impact Indicator
Compliance with NAAQS	Emissions (U.S. tons per year) during construction, operation, and conceptual decommissioning from marine vessels, vehicles, and equipment activity within 25 miles of the outer edge of the NY Bight lease areas. The significance thresholds for criteria pollutants are the NAAQS.
GHG emissions	GHG emissions (metric tons per year) during construction, operation, and conceptual decommissioning; operational GHG emissions reductions due to displacement of fossil-fuel power plants by wind energy. There are currently no significance thresholds for GHG emissions.

3.4.1.3 Impacts of Alternative A – No Action – Air Quality and Greenhouse Gas Emissions

When analyzing the impacts of the No Action Alternative on air quality, BOEM considered the impacts of past and ongoing trends and activities, including ongoing non-offshore-wind and ongoing offshore wind activities on the baseline conditions for air quality. The cumulative impacts of the No Action Alternative considered the impacts of the No Action Alternative in combination with other planned non-offshore-wind and offshore wind activities, which are described in Appendix D, *Planned Activities Scenario*.

3.4.1.3.1 Impacts of the No Action Alternative

Under the No Action Alternative, baseline conditions for air quality described in Section 3.4.1.1, *Description of the Affected Environment and Future Baseline Conditions*, would continue to follow current regional trends, and respond to IPFs introduced by other ongoing non-offshore-wind and offshore wind activities. Ongoing non-offshore-wind activities within the geographic analysis area that contribute to impacts on air quality are generally associated with existing onshore land uses, including residential, commercial, industrial, and transportation activities as well as onshore construction activities. Ongoing offshore wind activities within the geographic analysis area that contribute to impacts on air quality include ongoing construction of Ocean Wind 1 (OCS-A 0498) and Empire Wind (OCS-A 0512). Ongoing construction of Ocean Wind 1 and Empire Wind would have the same types of impacts on air quality that are described in Section 3.4.1.3.2, *Cumulative Impacts of the No Action Alternative,* for all ongoing and planned offshore wind activities in the geographic analysis area.

In March 2023, DOE announced the release of its Offshore Wind Energy Strategy, a comprehensive summary of DOE's efforts to meet President Biden's goal[3] to deploy 30 GW of offshore wind energy by 2030 and set the nation on a pathway to 110 GW or more by 2050. In addition, states in the region have developed policies and plans to encourage and develop renewable energy sources in the region, as summarized below.

New York

Power sector trends in New York State indicate that without recent GHG reduction initiatives, the largest shares of total electricity generation would remain natural gas, nuclear, and imported power. With the last coal-fired plants in New York having closed in 2020, future emissions would decrease slightly due to improvements in efficiency (New York State Climate Action Council 2022). Under the No Action Alternative, without implementation of other offshore wind projects, the electricity that would have been generated by offshore wind would likely be provided by a similar mix of generation sources (the "grid mix"), with an increased reliance on solar power and other renewable energy sources to meet New York State's renewable energy goals, as discussed further below (New York State Climate Action Council 2022).

In 2014, Governor Andrew Cuomo launched an energy policy, Reforming the Energy Vision, to build an integrated energy network able to harness the combined benefits of the central grid with clean, locally generated power. The State Energy Plan (New York State 2015) set a roadmap for the Reforming the Energy Vision policy, combining agency coordination, regulatory reform, and measures to encourage private capital investment. The initiatives outlined in the State Energy Plan, along with private sector innovation and investment fueled by Reforming the Energy Vision, were intended to put New York State on a path to achieving the following GHG emissions limits and clean energy goals:

- 40 percent reduction in GHG emissions from 1990 levels.
- 50 percent of energy generation from renewable energy sources.
- 600 trillion British thermal unit–increase in statewide energy efficiency (reduction in energy use through efficiency improvements).

In 2019, the New York State Climate Leadership and Community Protection Act (CLCPA) set an expanded Clean Energy Standard and provided statutory requirements that supersede the Reforming the Energy Vision policy and State Energy Plan goals. The CLCPA requires that 70 percent of New York's electricity come from renewable sources by 2030 and 100 percent of electricity come from zero-emission sources

[3] Executive Order on Tackling the Climate Crisis at Home and Abroad, January 27, 2021.

by 2040. In addition, the CLCPA requires that New York reduce statewide GHG emissions to at least 40 percent below 1990 levels by 2030 and at least 85 percent below 1990 levels by 2050.

Lastly, NYSERDA led the development of the New York State Offshore Wind Master Plan and is leading the coordination of offshore wind opportunities in New York State and supporting the development of 9,000 MW of offshore wind energy by 2035.

New Jersey

The New Jersey Department of Environmental Protection (NJDEP) has projected that under a scenario of continuation of current regulations and policies, emissions from electricity generation would decline slowly through 2050 due to improvements in efficiency and switching to cleaner fuels (NJDEP 2019). Under the No Action Alternative, without implementation of other offshore wind projects, the electricity that would have been generated by offshore wind would likely be provided by fossil fuel-fired facilities.[4] As a result, a continuation of ongoing activities under the No Action Alternative could lead to less decline in emissions than would occur with offshore wind development. An overall mix of natural gas, solar, wind, and energy storage would likely occur in the future due to market forces and state energy policies. New Jersey Executive Order 307 (September 21, 2022) sets a goal of developing 11,000 MW of offshore wind energy off the coast of New Jersey by 2040. The New Jersey Energy Master Plan (New Jersey Board of Public Utilities 2019) sets a goal of transitioning New Jersey to 100 percent renewable electricity by 2050. In addition to electricity generation, emissions from other ongoing activities including vessel and vehicle emissions and accidental releases of fuel or other hazardous material would continue to contribute to ongoing regional air quality impacts.

3.4.1.3.2 Cumulative Impacts of the No Action Alternative

The cumulative impact analysis for the No Action Alternative considers the impacts of the No Action Alternative in combination with other planned non-offshore-wind activities and planned offshore wind activities (without the six NY Bight projects).

Planned non-offshore-wind activities that could contribute to air quality impacts include construction of undersea transmission lines and transmission systems, gas pipelines, and other submarine cables; marine minerals use and ocean-dredged material disposal; military use; marine transportation; oil and gas activities; and onshore development activities (Appendix D). These planned non-offshore-wind activities have the potential to affect air quality through their emissions. Impacts associated with climate change could affect ambient air quality through increased formation of ozone and PM associated with increasing air temperatures.

Ongoing and planned offshore wind activities within the geographic analysis area that contribute to impacts on air quality and greenhouse gas emissions are listed in Table 3.4.1-3.

---

[4] In 2020, the generation mix of the PJM Interconnection, the regional grid that serves New Jersey, was approximately 40 percent natural gas, 34 percent nuclear, 19 percent coal, 3 percent wind, 2 percent hydroelectric, and 2 percent other sources, on an annual average basis (Monitoring Analytics 2021).

Table 3.4.1-3. Ongoing and planned offshore wind in the geographic analysis area for air quality and GHG emissions

Ongoing/Planned	Projects by Region
Ongoing – 3 projects[1] 	**NY/NJ** • Ocean Wind 1 (OCS-A 0498) • Empire Wind 1 (OCS-A 0512) • Empire Wind 2 (OCS-A 0512)
Planned – 3 projects[2] 	**NY/NJ** • Ocean Wind 2 (OCS-A 0532) • Atlantic Shores North (OCS-A 0549) • Atlantic Shores South (OCS-A 0499)

NJ = New Jersey; NY = New York

Note: The 15.5-mile onshore buffer of the air quality geographic analysis area overlaps with a very small portion of the Garden State Offshore Energy (GSOE) I (OCS-A 0482) lease area. BOEM has not included the GSOE I project in the air quality analysis because the overlap is small and it is unlikely any onshore component of the NY Bight projects would be located in the southern part of New Jersey within 15.5 miles of the GSOE I lease area. Additionally, BOEM is including estimated emissions for the complete buildout of the Ocean Wind 1, Ocean Wind 2, and Atlantic Shores South lease areas in the analysis even though only a portion of those lease areas fall within the geographic analysis area (see Figure 3.4.1-1). Therefore, even by excluding the GSOE I project, BOEM's analysis likely overestimates the emissions for the No Action Alternative and the cumulative analysis of air quality impacts.

[1] Refer to footnotes 9 and 10 in PEIS Chapter 1 for additional information on the status of Ocean Wind 1, Empire Wind 1, and Empire Wind 2.

[2] Status as of September 20, 2024.

BOEM expects ongoing and planned offshore wind activities to affect air quality through the following primary IPFs.

Air emissions: Most air pollutant emissions and air quality impacts from ongoing and planned offshore wind projects would occur during construction, potentially from multiple projects occurring simultaneously. All projects would be required to obtain an OCS air quality permit from USEPA and to comply with any other applicable requirements of the CAA. Primary emission sources would include increased public and commercial vehicular traffic, air traffic, combustion emissions from construction equipment, and fugitive particle emissions from construction-generated dust. As wind energy projects come online, power generation emissions overall could decrease, and the region as a whole could realize a net benefit to air quality.

The ongoing and planned offshore wind projects that may result in air pollutant emissions and air quality impacts within the air quality geographic analysis area would produce an estimated 9,561 MW of renewable power from the installation of 697 WTGs (Appendix D, Table D2-1). Based on the assumed offshore construction schedule in Appendix D, Table D2-1, those projects within the geographic analysis area would have overlapping construction periods beginning in 2024 and continuing through 2030.

During the construction phase, the total emissions of criteria pollutants and O_3 precursors from offshore wind projects other than the NY Bight projects proposed within the air quality geographic analysis area, summed over all construction years, are estimated to be 11,582 tons of CO, 47,127 tons of NO_X, 1,501 tons of PM_{10}, 1,361 tons of $PM_{2.5}$, 635 tons of SO_2, 1,811 tons of VOCs, and 3,043,329 tons of carbon dioxide (CO_2) (Appendix D, Table D2-4). Most emissions would occur from diesel-fueled construction equipment, vessels, and commercial vehicles. The magnitude of the emissions and the resulting air quality impacts would vary spatially and temporally during the construction phases. Construction activity would occur at different locations and could overlap temporally with activities at other locations, including operational activities at previously constructed projects. As a result, air quality impacts would be minor to moderate, shifting spatially and temporally across the air quality geographic analysis area. Conceptual decommissioning would involve vessels and equipment similar to those used for construction, and impacts of conceptual decommissioning are expected to be similar to the impacts of construction.

During operations, emissions from offshore wind projects within the air quality geographic analysis area would overlap temporally, but operations would contribute few criteria pollutant emissions compared to construction and conceptual decommissioning. Operational emissions would come largely from commercial vessel traffic and emergency diesel generators. The aggregate operational emissions for all projects within the air quality analysis area would vary by year as successive projects begin operation. Estimated operational emissions would be 228–694 tons per year of CO, 479–1,963 tons per year of NO_X, 13–60 tons per year of PM_{10}, 12–55 tons per year of $PM_{2.5}$, 7–17 tons per year of SO_2, 21–59 tons per year of VOCs, and 45,918–159,045 tons per year of CO_2 (Appendix D, Table D2-4)[5]. Cumulatively, operational emissions would result in negligible air quality impacts because emissions would be intermittent, localized, and dispersed throughout the lease areas and vessel routes from the onshore O&M facilities.

Offshore wind energy development could help reduce emissions from onshore energy sources, potentially improving regional air quality and reducing GHGs. Millstein et al. (2018) estimated that between 2007 and 2015, wind power in the U.S. avoided as much as 127,698,000 metric tons (MT) of CO_2 per year, 147,000 MT of SO_2 per year, 93,000 MT of NO_X per year, and 9,000 MT of $PM_{2.5}$ per year. A study by DOE estimated emissions for a future scenario with wind energy supplying 10 percent of total U.S. electricity demand by 2020, 20 percent by 2030, and 35 percent by 2050. The study estimated cumulative emissions reductions from 2013 to 2050 of 2.6 million MT of SO_2, 4.7 million MT of NO_X, and 0.5 million MT of $PM_{2.5}$ (DOE 2015). Similarly, the study scenario was estimated to reduce GHG emissions in the electric sector by 130 million MT of CO_2 equivalent (CO_2e) in 2020, 380 million MT CO_2e in 2030, and 510 million MT CO_2e in 2050 (DOE 2015).

An analysis by Barthelmie and Pryor (2021) calculated that, depending on global trends in GHG emissions and the amount of wind energy expansion, development of wind energy could reduce

[5] Aggregate operational emissions do not include operational emissions from Atlantic Shores North, as such emissions are not available in Appendix D, Table D2-4.

predicted increases in global surface temperature by 0.5–1.4 degrees Fahrenheit (°F) (0.3–0.8 degrees Celsius [°C]) by 2100.

Estimations and evaluations of potential health and climate benefits from offshore wind activities for specific regions and project sizes rely on information about the air pollutant emission contributions of the existing and projected mixes of power generation sources, and generally estimate the annual health benefits of an individual commercial scale offshore wind project to be valued in the hundreds of millions of dollars (Kempton et al. 2005; Buonocoure et al. 2016).

The potential health benefits of avoided emissions can be evaluated using USEPA's CO-Benefits Risk Assessment (COBRA) health impacts screening and mapping tool (USEPA 2020a). COBRA is a tool that estimates the health and economic benefits of clean energy policies. For example, COBRA was used to analyze the avoided emissions that were calculated for development of 8.6 GW of reasonably foreseeable wind power on the OCS. Table 3.4.1-4 presents the estimated monetized health benefits and avoided mortality for this example scenario.

Table 3.4.1-4. COBRA estimate of annual avoided health effects with 8.6 GW reasonably foreseeable offshore wind power

Discount Rate[1] (2023)	Monetized Total Health Benefits (million U.S. dollars/year)		Avoided Mortality (cases/year)	
	Low Estimate[2]	High Estimate[2]	Low Estimate[2]	High Estimate[2]
3%	$288	$649	25.868	58.534
7%	$252	$571	25.868	58.534

[1] The discount rate is used to express future economic values in present terms. Not all health effects and associated economic values occur in the year of analysis. Therefore, COBRA accounts for the "time value of money" preference (i.e., a general preference for receiving economic benefits now rather than later) by discounting benefits received later (USEPA 2020b).
[2] The low and high estimates are derived using two sets of assumptions about the sensitivity of adult mortality and non-fatal heart attacks to changes in ambient $PM_{2.5}$ levels. Specifically, the high estimates are based on studies that estimated a larger effect of changes in ambient $PM_{2.5}$ levels on the incidence of these health effects (USEPA 2020b).

BOEM anticipates that the air quality impacts associated with ongoing and planned offshore wind activities in the geographic analysis area would result in minor to moderate adverse impacts due to emissions of criteria pollutants, VOCs, HAPs, and GHGs, mostly released during construction and conceptual decommissioning. Impacts would be minor to moderate because these emissions would increase ambient pollutant concentrations, though not by enough to cause a violation of the NAAQS, New Jersey AAQS, or New York AAQS. Offshore wind projects likely would lead to reduced emissions from fossil-fuel power plants and consequently minor to moderate beneficial impacts on air quality (see Table 3.3-1 for definitions of beneficial impacts).

Construction and operation of ongoing and planned offshore wind projects would produce GHG emissions that would contribute to climate change. CO_2 is relatively stable in the atmosphere and, for the most part, mixed uniformly throughout the troposphere and stratosphere. As such, the impact of GHG emissions does not depend upon the source location. Increasing energy production from offshore wind projects could reduce regional GHG emissions by displacing energy from fossil fuels. The amount of emissions reduction from displaced generation is uncertain because the future grid mix is not known. This reduction would likely more than offset the relatively small GHG emissions from offshore wind projects. This reduction in regional GHG emissions would be noticeable in the regional context and contribute to addressing climate change, and would represent a minor to moderate beneficial impact in the regional context but a negligible beneficial impact in the global context (see Table 3.3-1 for definitions of beneficial impacts).

Accidental releases: Ongoing and planned offshore wind activities could release air toxics or HAPs because of accidental chemical spills within the air quality geographic analysis area. Section 3.4.2, *Water Quality*, includes a discussion of the nature of releases anticipated. Based on Appendix D, Table D2-3, up to about 2,022,116 gallons (7.7 million liters) of coolants, 4,583,097 gallons (17.3 million liters) of oils and lubricants, and 743,373 (2.8 million liters) of diesel fuel would be contained in the 738 wind turbine and substation structures for the wind energy projects within the air quality geographic analysis area. If accidental releases occur, they would be most likely during construction but could occur during operations and conceptual decommissioning of offshore wind facilities. These may lead to short-term periods (hours to days)[6] of HAPs emissions through surface evaporation. HAPs emissions would consist of VOCs, which are important for O_3 formation. By comparison, the smallest tanker vessel operating in these waters (a general-purpose tanker) has a capacity of between 3.2 and 8 million gallons (12.1 million and 30.3 million liters). Tankers are relatively common in these waters, and the total WTG chemical storage capacity within the geographic analysis area for air quality is much less than the volume of hazardous liquids transported by ongoing activities (U.S. Energy Information Administration 2014). BOEM expects air quality impacts from accidental releases would be negligible because impacts would be short term and limited to the area near the accidental release location. Accidental spills would occur infrequently over a 35-year period with a higher probability of spills during future project construction, but they would not be expected to contribute appreciably to cumulative impacts on air quality.

3.4.1.3.3 Conclusions

Impacts of the No Action Alternative. Under the No Action Alternative, air quality would continue to be affected by existing environmental trends and ongoing activities. More, higher-emitting, fossil-fuel power plants would be kept in service to meet future power demand under the No Action Alternative compared to the action alternatives. These impacts would be partially mitigated once the approved Ocean Wind 1 offshore wind project is operational. BOEM expects ongoing offshore wind and non-offshore-wind activities would continue to have regional air quality impacts primarily through air pollutant emissions, accidental releases, and climate change. BOEM anticipates that ongoing activities would likely result in **moderate** impacts on air quality because of air pollutant emissions and GHGs.

Cumulative Impacts of the No Action Alternative. Under the No Action Alternative, air quality would continue to be affected by natural and human-caused IPFs. Planned non-offshore-wind activities may also contribute to impacts on air quality because air pollutant and GHG emissions would increase through construction and operation of new energy generation facilities to meet future power demands. Continuation of current regional trends in energy development could include new power plants that

---

[6] For example, small diesel fuel spills (500–5,000 gallons) usually will evaporate and disperse within a day or less (NOAA 2006).

could contribute to air quality and GHG impacts in New York, New Jersey, and the neighboring states. BOEM expects the combination of ongoing and planned activities other than offshore wind to result in **moderate** impacts on air quality, primarily driven by recent market and permitting trends indicating future fossil-fueled electric generating units would most likely include natural-gas-fired facilities (BOEM 2017a; BOEM 2021).

Offshore wind activities in the geographic analysis area would contribute to the emissions of criteria pollutants, VOCs, HAPs, and GHGs, mostly released during construction and conceptual decommissioning. Impacts would be minor to moderate because these emissions would increase ambient pollutant concentrations, though not by enough to cause a violation of the NAAQS, New Jersey AAQS, or New York AAQS or contribute substantially to an existing violation. Pollutant emissions during operations would be generally lower and more transient. Most air pollutant emissions and air quality impacts would occur during multiple overlapping project construction phases from 2024 through 2030 (Appendix D, Table D2-4). Overall, adverse air quality impacts from offshore wind projects are expected to be relatively small and transient. Offshore wind projects likely would lead to reduced emissions from fossil-fuel power plants and consequently **minor** to **moderate beneficial** impacts on regional air quality after offshore wind projects are operational.

BOEM anticipates that the cumulative impacts of the No Action Alternative would likely result in **moderate** impacts due to emissions of criteria pollutants, VOCs, and HAPs, mostly released during construction and conceptual decommissioning. Impacts would be **moderate** because these emissions would increase ambient pollutant concentrations (more than would activities without offshore wind or offshore wind alone), though not by enough to cause a violation of the NAAQS, New Jersey AAQS, or New York AAQS or contribute substantially to an existing violation.

3.4.1.4 Impacts of Alternative B – No Identification of AMMM Measures at the Programmatic Stage – Air Quality and Greenhouse Gas Emissions

Alternative B considers the potential impacts of future offshore wind development for the NY Bight area without the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts.

3.4.1.4.1 Impacts of One Project

A single NY Bight project may generate emissions and affect air quality in the New York-New Jersey region and nearby coastal waters during construction and installation, O&M, and conceptual decommissioning activities. Onshore emissions would occur in the onshore export cable corridors and at POIs. Offshore emissions would be released over the OCS and state waters. Offshore emissions would occur in any one of the six NY Bight lease areas and the offshore export cable corridors.

The emissions estimates in this section do not include emissions from raw material extraction, materials processing, and manufacturing of components, i.e., full life-cycle analysis. However, recently published studies have analyzed the life-cycle impacts of offshore wind (Ferraz de Paula and Carmo 2022; Rueda-Bayona et al. 2022; Shoaib 2022). These studies concluded that the materials that have the greatest impact on life-cycle emissions generally are steel and concrete, and that materials recycling rates have a large influence on life-cycle emissions. The National Renewable Energy Laboratory (NREL) harmonized approximately 3,000 life cycle assessment studies with around 240 published life-cycle analyses of land-based and offshore wind technologies (NREL 2021). Though wind has higher upstream emissions than many other generation methods, its life-cycle GHG emissions are orders of magnitude lower. NREL (2021) estimated that the central 50 percent of GHG estimates reviewed were in the range of 9.4–14 grams of CO_2e per kilowatt-hour (g CO_2-eq/kWh) while life-cycle GHG estimates for coal and natural gas are on the scale of 1,000 grams CO_2-eq/kWh (Dolan and Heath 2012) and 480 grams CO_2-eq/kWh (O'Donoughue et al. 2014), respectively.

One NY Bight project would provide beneficial impacts on the air quality near the proposed location and the surrounding region to the extent that energy produced by that one project would displace energy produced by fossil-fuel power plants.

Air emissions – construction: Fuel combustion and solvent use would cause construction-related emissions. The air pollutants would include criteria pollutants, VOCs, and HAPs, as well as GHGs. During the construction phase, the activities of additional workers, increased traffic congestion, additional commuting miles for construction personnel, and increased air-polluting activities of supporting businesses also could have impacts on air quality. BOEM used its Wind Tool model (BOEM 2017b) to estimate the construction emissions for a single NY Bight project based on a maximum-case scenario (280 WTGs and 5 OSSs) of the RPDE. The total estimated construction emissions of each pollutant are summarized in Table 3.4.1-5. BOEM assumes that construction of a NY Bight project would start in 2026 at the earliest. The duration of construction for a single NY Bight project is anticipated to occur during the period of 2026–2030, and possibly beyond.

Table 3.4.1-5. Total construction emissions (U.S. tons, except GHGs in metric tons) for a single NY Bight project

Period	CO	NO_X	PM_{10}	$PM_{2.5}$	SO_2	VOC	CO_2	CH_4	N_2O	CO_2e
Total	5,555	26,104	527	504	1,014	755	1,533,965	10	75	1,556,503

CH_4 = methane; CO_2e = carbon dioxide equivalent; N_2O = nitrous oxide
CO_2e values were calculated using the 100-year Global Warming Potential (GWP) values from the Intergovernmental Panel on Climate Change's (IPCC) Fourth Assessment Report (Forster et al. 2007).

Offshore Construction

Emissions from potential sources or construction activities would vary throughout the construction and installation of offshore components. Emissions from offshore activities would occur during pile and scour protection installation, offshore cable laying, turbine installation, and substation/converter station installation. Offshore construction-related emissions also would come from diesel-fueled generators used to temporarily supply power to the WTGs and substation/converter stations so that workers could operate lights, controls, and other equipment before cabling is in place. There also would be emissions from engines used to power pile-driving hammers and air compressors used to supply compressed air to noise-mitigation devices during pile-driving (if used). Emissions from vessels and helicopters used to transport workers, supplies, and equipment to and from the construction areas would result in additional air quality impacts. A NY Bight project may need to use emergency generators at times, potentially resulting in increased emissions for limited periods.

Air quality impacts due to a single NY Bight project within the air quality geographic analysis area are anticipated to be small relative to larger emission sources such as fossil-fuel power plants.[7] The largest air quality impacts are anticipated during construction, with smaller and more infrequent impacts anticipated during conceptual decommissioning.

The majority of air pollutant and GHG emissions from a single NY Bight project alone would come from the main engines, auxiliary engines, and auxiliary equipment on marine vessels used during offshore construction activities. Emissions from the OCS source, as defined in the CAA, would be allowed as part of the OCS permit for which each project must apply. A NY Bight project must demonstrate compliance with the NAAQS and must demonstrate no adverse impact on air quality–related values. The OCS air permitting process includes air dispersion modeling of emissions to demonstrate compliance with the NAAQS. As part of the air quality–related values analysis, a NY Bight project must demonstrate that significant visibility degradation at a Class I area would not occur as a result of increased haze or plumes.

Onshore Construction

Onshore activities of a NY Bight project would consist primarily of tunneling/drilling/excavation for cable installation, duct bank construction, cable-pulling operations, and substation or converter station construction. Emissions would be primarily from operation of diesel-powered equipment and vehicle activity such as bulldozers, excavators, and diesel trucks, and fugitive particulate emissions from excavation and hauling of soil.

These emissions would be highly variable and limited in spatial extent at any given period and would result in minor to moderate impacts (less than the NAAQS), as they would be temporary in nature. Fugitive particulate emissions would vary depending on the spatial extent of the excavated areas, soil type, soil moisture content, and magnitude and direction of ground-level winds.

Air emissions – O&M: During O&M, air quality impacts are anticipated to be smaller in magnitude compared to construction and conceptual decommissioning. Offshore O&M activities would consist of WTG operations, planned maintenance, and unplanned emergency maintenance and repairs. The WTGs operating would have no pollutant emissions. The WTGs are not anticipated to include permanently installed emergency generators; however, a temporary backup diesel generator may be installed at a turbine during the commissioning phase until the grid connection is made. Emergency generators on the substations/converter stations would operate only during emergencies or testing, so emissions from these sources would be small and transient. Pollutant emissions from O&M would be mostly the result of operations of ocean vessels and helicopters used for maintenance activities. Crew transfer vessels and helicopters would transport crews to the NY Bight offshore project area for inspections, routine

---

[7] For example, the annual operational emissions from a single NY Bight project would represent the following percentages of the emissions from fossil-fuel power plants in New Jersey, based on the USEPA 2020 National Emissions Inventory (USEPA 2023): CO 2%; NO_X 7%; PM_{10}, $PM_{2.5}$, and SO_2 less than 1% each; and VOC less than 2%.

maintenance, and repairs. Jack-up vessels, multipurpose offshore support vessels, and rock-dumping vessels would travel infrequently to the NY Bight offshore project area for significant maintenance and repairs. The annual estimated emissions for O&M of one NY Bight project are summarized in Table 3.4.1-6.

Table 3.4.1-6. Operations and maintenance (O&M) emissions (U.S. tons, except GHGs in metric tons) from a single NY Bight project

Period	CO	NO_X	PM_{10}	$PM_{2.5}$	SO_2	VOC	CO_2	CH_4	N_2O	CO_2e
Annual	52	227	5	4	9	5	12,505	0.1	0.6	13,971
Operating Lifetime (35 years)	1,810	7,928	159	154	308	186	437,688	4	21	488,998

CH_4 = methane; CO_2e = carbon dioxide equivalent; N_2O = nitrous oxide
CO_2e values were calculated using the 100-year GWP values from the IPCC's Fourth Assessment Report (Forster et al. 2007).

If one NY Bight project were to use switchgear containing the GHG SF_6, then additional GHG emissions could occur from leakage of SF_6 from switchgear. SF_6 is a synthetic gas that has been used as an anti-arcing insulator in electrical systems for approximately 70 years. It is a dense gas and a potent GHG, with an environmental lifespan of thousands of years. There are international efforts to minimize and eventually phase out the production and use of this gas. Potential emissions of SF_6 are not shown in Table 3.4.1-6 because it is unknown whether SF_6 would be used. Based on other projects, if SF_6 were used in all project switchgear then the total quantity of SF_6 contained in project switchgear could be about 66,400 pounds (30,100 kilograms). At an assumed leakage rate of 0.5 percent per year, the GHG emissions from this quantity of SF_6 would be 3,431 metric tons of CO_2e per year. However, this is a conservative assumption because SF_6 may not be used.

Depending on the wind conditions at the time of emissions, it is likely that not all emissions generated offshore would reach land. BOEM anticipates that air quality impacts from O&M of one NY Bight project would be minor (less than the NAAQS), occurring for short periods of time several times per year during the estimated 35 years of activity.

Emissions from onshore O&M activities would be limited to periodic use of construction vehicles and equipment. Onshore O&M activities would include occasional inspections and repairs to onshore substations/converter stations and splice vaults, which would require minimal use of worker vehicles and construction equipment. BOEM anticipates that air quality impacts due to onshore O&M from one NY Bight project would be minor, intermittent, and occurring for short periods.

Increases in renewable energy could lead to reductions in emissions from fossil-fuel power plants. BOEM used its Wind Tool (BOEM 2017b) to estimate the emissions avoided as a result of a NY Bight project. Once operational, the 280 WTGs from a single NY Bight project would result in annual avoided emissions of 1,818 tons of NO_X, 268 tons of $PM_{2.5}$, 999 tons of SO_2, and 5,414,326 metric tons of CO_2. The avoided CO_2 emissions are equivalent to the emissions generated by about 1,200,000 passenger vehicles in a year (USEPA 2020c). Accounting for construction emissions and assuming conceptual decommissioning emissions would be the same, and including emissions from future operations, a single NY Bight project would offset emissions related to its construction and conceptual decommissioning within different time periods of operation depending on the pollutant: NO_X would be offset in approximately 28 years of operation, $PM_{2.5}$ in 4 years, SO_2 in 2 years, and CO_2 in 7 months. If emissions from future operations and conceptual decommissioning were not included, the times required for emissions to "break even" would be shorter. From that point, one NY Bight project would have lower emissions that otherwise might be generated from another fossil fuel source.

The potential health benefits of avoided emissions can be evaluated using USEPA's COBRA health impacts screening and mapping tool as discussed in Section 3.4.1.3.2, *Cumulative Impacts of the No Action Alternative*. COBRA was used to analyze the avoided emissions that were calculated for a NY Bight project. Table 3.4.1-7 presents the results.

Table 3.4.1-7. COBRA estimate of annual avoided health effects with a single NY Bight project

Discount Rate[1] (2023)	Monetized Total Health Benefits (million U.S. dollars/year)		Avoided Mortality (cases/year)	
	Low Estimate[2]	High Estimate[2]	Low Estimate[2]	High Estimate[2]
3%	$149	$337	13.416	30.358
7%	$131	$296	13.416	30.358

[1] The discount rate is used to express future economic values in present terms. Not all health effects and associated economic values occur in the year of analysis. Therefore, COBRA accounts for the "time value of money" preference (i.e., a general preference for receiving economic benefits now rather than later) by discounting benefits received later (USEPA 2020b).
[2] The low and high estimates are derived using two sets of assumptions about the sensitivity of adult mortality and non-fatal heart attacks to changes in ambient $PM_{2.5}$ levels. Specifically, the high estimates are based on studies that estimated a larger effect of changes in ambient $PM_{2.5}$ levels on the incidence of these health effects (USEPA 2020b).

The overall impacts of GHG emissions can be assessed using "social costs." The "social cost of carbon," "social cost of nitrous oxide," and "social cost of methane"—together, the "social cost of greenhouse gases" (SC-GHG)—are estimates of the monetized damages associated with incremental increases in GHG emissions in a given year. NEPA does not require monetizing costs and benefits but allows the use of the social cost of carbon, SC-GHG, or other monetized costs and benefits of GHGs in weighing the merits and drawbacks of alternative actions. In January 2023, CEQ issued interim guidance (CEQ 2023) that updated and reinstated its 2016 guidance document (CEQ 2016) on consideration of GHGs and climate change under NEPA. The interim guidance recommends that agencies provide context for GHG emissions, including through the use of SC-GHG estimates, to translate climate impacts into the more accessible metric of dollars.

For federal agencies, the best currently available estimates of SC-GHG are the interim estimates of the social costs of CO_2, methane (CH_4), and nitrous oxide (N_2O) developed by the Interagency Working Group (IWG) on SC-GHG and published in its Technical Support Document (IWG 2021). IWG's SC-GHG estimates are based on complex models describing how GHG emissions affect global temperatures, sea level rise, and other biophysical processes; how these changes affect society through, for example, agricultural, health, or other effects; and monetary estimates of the market and nonmarket values of these effects. One key parameter in the models is the discount rate, which is used to estimate the present value of the stream of future damages associated with emissions in a particular year. The discount rate accounts for the "time value of money," i.e., a general preference for receiving economic benefits now rather than later, by discounting benefits received later. A higher discount rate assumes that future benefits or costs are more heavily discounted than benefits or costs occurring in the present (i.e., future benefits or costs are less valuable or are a less significant factor in present-day decisions). IWG developed the current set of interim estimates of SC-GHG using three different annual discount rates: 2.5 percent, 3 percent, and 5 percent (IWG 2021).

There are multiple sources of uncertainty inherent in the SC-GHG estimates. Some sources of uncertainty relate to physical effects of GHG emissions, human behavior, future population growth and economic changes, and potential adaptation (IWG 2021). To better understand and communicate the quantifiable uncertainty, the IWG method generates several thousand estimates of the social cost for a specific gas, emitted in a specific year, with a specific discount rate. These estimates create a frequency distribution based on different values for key uncertain climate model parameters. The shape and characteristics of that frequency distribution demonstrate the magnitude of uncertainty relative to the average or expected outcome.

To further address uncertainty, IWG recommends reporting four SC-GHG estimates in any analysis. Three of the SC-GHG estimates reflect the average damages from the multiple simulations at each of the three discount rates. The fourth value represents higher-than-expected economic impacts from climate change. Specifically, it represents the 95th percentile of damages estimated, applying a 3 percent annual discount rate for future economic effects. This is a low-probability but high-damage scenario and represents an upper bound of damages within the 3 percent discount rate model. The estimates below follow the IWG recommendations.

Table 3.4.1-8 presents the SC-GHG associated with estimated emissions from a single NY Bight project. These estimates represent the present value of future market and nonmarket costs associated with CO_2, methane, and nitrous oxide emissions. In accordance with IWG's recommendation, four estimates were calculated based on IWG estimates of social cost per metric ton of emissions for a given emissions year and estimates of emissions from one NY Bight project in each year. In Table 3.4.1-8, negative values represent social benefits of avoided GHG emissions. The negative values for net SC-GHG indicate that the impact of one NY Bight project on GHG emissions and climate would be a net benefit in terms of SC-GHG.

Table 3.4.1-8. Estimated social cost of GHGs associated with a single NY Bight project

Description	Social Cost of GHGs (2020$)[1,2]			
	Average Value, 5% Discount Rate	Average Value, 3% Discount Rate	Average Value, 2.5% Discount Rate	95th Percentile Value, 3% Discount Rate
SC-CO_2				
Construction, Operation, and Conceptual Decommissioning	$34,033,000	$141,232,000	$219,195,000	$428,483,000
Avoided Emissions	-1,772,701,000	-7,652,784,000	-11,928,208,000	-23,421,568,000
Net SCC- CO_2	-1,738,668,000	-7,511,552,000	-11,709,013,000	-22,993,085,000

Description	Social Cost of GHGs (2020$)[1,2]			
	Average Value, 5% Discount Rate	Average Value, 3% Discount Rate	Average Value, 2.5% Discount Rate	95th Percentile Value, 3% Discount Rate
SC-CH_4				
Construction, Operation, and Conceptual Decommissioning	$11,000	$31,000	$43,000	$82,000
Avoided Emissions	-7,379,000	-21,843,000	-30,449,000	-58,202,000
Net SCC-CH_4	-7,368,000	-21,812,000	-30,406,000	-58,120,000
SC-N_2O				
Construction, Operation, and Conceptual Decommissioning	$668,000	$2,582,000	$3,992,000	$6,860,000
Avoided Emissions	-8,598,000	-34,635,000	-53,797,000	-92,390,000
Net SCC-N_2O	-7,930,000	-32,053,000	-49,805,000	-85,530,000
Total SC-GHG[3]				
Construction, Operation, and Conceptual Decommissioning	$34,712,000	$143,845,000	$223,230,000	$435,425,000
Avoided Emissions	-1,788,678,000	-7,709,262,000	-12,012,454,000	-23,572,160,000
Net SC-GHG	-1,753,966,000	-7,565,417,000	-11,789,224,000	-23,136,735,000

[1] The following calendar years were assumed in calculating SC-GHG: construction 2026–2028, operation (35 years) 2029–2064, and decommissioning 2065–2067.
[2] Negative cost values indicate benefits.
[3] SC-GHG is the sum of the social costs for CO_2, CH_4, and N_2O.
Estimates are over the lifetime of a single NY Bight project. Estimates are rounded to the nearest $1,000.

Table 3.4.1-9 presents the annual emissions, avoided emissions, and net emissions of CO_2 over the operational lifetime of a single NY Bight project. Net emissions are the NY Bight project emissions minus the avoided emissions. The lifetime net emissions for the No Action Alternative (which has no avoided emissions) represents the amount of emissions that would occur from the grid (as configured in 2018) to produce the same quantity of electrical energy as would have been produced by one NY Bight project. The No Action Alternative would result in no emissions during construction and O&M because no project would be built, but would also offer no avoided emissions, resulting in higher GHG emissions over the project duration due to not displacing fossil-fueled power generation via offshore wind. The emissions not avoided, 5,414,326 MT per year of CO_2 (Table 3.4.1-9), would be equivalent to about 1,200,000 additional passenger vehicles per year. These estimates are relative to the 2018 grid configuration as noted, but the actual annual quantity of avoided emissions attributable to this proposed facility is expected to diminish over time if the electric grid becomes lower-emitting due to the addition of other renewable energy facilities and retirement of high-emitting generators.

Table 3.4.1-9. Net emissions of CO_2 for a single NY Bight project

Alternative	CO_2 Emissions (metric tons)[1,2]					
	Construction	Operation				Construction + Operation
	Construction (Total)	O&M Emissions (Annual)	Avoided Emissions (Annual)	Net Emissions (Annual)	Operational Lifetime Net Emissions (Total)	Total Lifetime Net Emissions
No Action	0	0	0	0	0	189,501,413 [3]
One NY Bight Project	1,533,965	13,785	-5,414,326	-5,400,541	-189,018,942	-187,484,977

[1] Positive values are emissions increases; negative values are emissions decreases.

[2] Emissions from decommissioning are not included.

[3] Represents emissions from the grid in the absence of one NY Bight project.

One NY Bight project would produce GHG emissions that contribute to climate change; however, its contribution would be less than the emissions reductions from fossil-fueled sources during operation of the NY Bight project. Because GHG emissions disperse and mix within the troposphere, the climatic impact of GHG emissions does not depend upon the source location. Therefore, regional climate impacts are largely a function of global emissions. Nevertheless, a single NY Bight project would have an overall net beneficial impact on criteria pollutant and O_3 precursor emissions as well as GHGs, compared to a similarly sized fossil-fuel power plant or to the generation of the same amount of energy by the existing grid.

Climate change can make ecosystems, resources, and communities more susceptible as well as lessen resilience to other environmental impacts apart from climate change. In some instances, this may exacerbate the environmental effects of a project. Although one NY Bight project would produce criteria pollutant emissions, the predicted impacts would be within applicable standards and would be unlikely to contribute substantially to increasing susceptibility or decreasing resilience of ecosystems. Similarly, foreseeable climate change would be unlikely to contribute substantially to increasing the impacts of criteria pollutant emissions from a single NY Bight project.

Air emissions – decommissioning: At the end of the operational lifetime of one NY Bight project, the lessee would decommission the project's facilities. All structures above the seabed level or aboveground would be completely removed. The dismantling and removal of the turbine components (blades, nacelle, and tower) and other offshore components would largely be a "reverse installation" process subject to the same constraints as the original construction phase. Onshore conceptual decommissioning activities would include removal of facilities and equipment and restoration of the sites to pre-project conditions where warranted. Emissions from conceptual decommissioning of a single NY Bight project were not quantified but are expected to be less than for construction. One NY Bight project likely would pursue a separate OCS Air Permit for those activities because it might assume that marine vessels, equipment, and construction technology will change substantially in the next 35 years and in the future will have lower emissions than current vessels and equipment. BOEM anticipates minor and temporary air quality impacts from a single NY Bight project due to conceptual decommissioning.

Accidental releases: One NY Bight project could release VOCs or HAPs because of accidental chemical spills. Accidental releases—including spills from vessel collisions and allisions—may lead to short-term periods of VOC and HAP emissions through evaporation. VOC emissions also would be a precursor to O_3 formation. Air quality impacts would be short term and limited to the local area at and around the accidental release location. BOEM anticipates that a major spill is very unlikely due to vessel and offshore wind energy industry safety measures, as discussed in Section 3.4.2, *Water Quality*, as well as the distributed nature of the material. BOEM anticipates that these activities would have a negligible air quality impact as a result of one NY Bight project.

Similarly, a catastrophic failure of switchgear could release SF_6. Such a failure would be extremely unlikely and no such release is expected. Even if all of the SF_6 from all project switchgear were released, the contribution of GHGs to the atmosphere would be negligible relative to the avoided GHG emissions associated with project operation.

3.4.1.4.2 Impacts of Six Projects

With six NY Bight projects, the total emissions and SC-GHG described for a single NY Bight project would be multiplied by as much as six.[8] BOEM anticipates that air quality impacts from construction, operation, and conceptual decommissioning of six NY Bight projects would be minor to moderate (i.e., would not cause an exceedance of the NAAQS). However, to the extent that project activities overlap, impacts at any particular time or place could be greater than for one NY Bight project. If projects do not overlap, then impacts may not be greater in degree than for one NY Bight project but would occur over a longer time or larger area.

Air emissions – construction: As with one NY Bight project, BOEM assumes that construction of six NY Bight projects would start in 2026 at the earliest. The offshore and onshore construction activities for six NY Bight projects would be of the same types as described for one NY Bight project. However, the estimated construction emissions given in Table 3.4.1-5 for a single NY Bight project would be multiplied by as much as six with six NY Bight projects. Construction and operation of six NY Bight projects could overlap in time, and potentially in space if common port facilities or cable corridors are used. Several factors could influence the amount of overlap, such as availability of vessels and port facilities and the rate of progress of baseline surveys. As with one NY Bight project, most emissions with six NY Bight projects would occur from diesel-fueled construction equipment, vessels, and commercial vehicles. The magnitude of the emissions and the resulting air quality impacts would vary spatially and temporally during the construction phases.

Air emissions – O&M: The types of O&M activities, vessels, and equipment with six NY Bight projects would be the same as those for one NY Bight project. However, with six NY Bight projects, the O&M emissions and SC-GHG described for one NY Bight project would be multiplied by as much as six. As with

[8] As indicated in Section 2.1.2.2, the number of WTGs in the six NY Bight lease areas is expected to be less than 1,680 (280 WTGs multiplied by 6 projects). However, in the interest of capturing the highest amount of potential emissions, this section describes emission estimates as being as much as six times greater than a single NY Bight project. Therefore, this analysis likely overstates total emissions and impacts for six NY Bight projects.

a single NY Bight project, the air quality impacts during O&M are anticipated to be smaller in magnitude compared to construction and conceptual decommissioning.

Increases in renewable energy could lead to reductions in emissions from fossil-fuel power plants. Emissions avoided with six NY Bight projects would be greater than with a single NY Bight project. The amount of energy contributed to the grid with six NY Bight projects could be large enough to affect electricity pricing, which could influence decisions by power plant operators to reduce output or take plants offline in response, to a greater degree than with a single NY Bight project.

The potential health benefits of avoided emissions with six NY Bight projects would be greater than with one NY Bight project. As well, the SC-GHG with six NY Bight projects would indicate greater social benefits than with one NY Bight project. Six NY Bight projects would have negligible impacts on climate change and an overall net beneficial impact on criteria pollutant and O_3 precursor emissions as well as GHGs, compared to the generation of the same amount of energy by the existing grid. Based on the avoided GHG emissions described for a single NY Bight project, operation of six NY Bight projects would result in annual avoided emissions of 10,908 tons of NO_X, 1,608 tons of $PM_{2.5}$, 5,994 tons of SO_2, and 32,485,956 metric tons of CO_2 per year.

Air emissions – decommissioning: As with one NY Bight project, BOEM anticipates that each of the six NY Bight projects would pursue a separate OCS Air Permit for decommissioning activities because it is assumed that marine vessels, equipment, and construction technology will change substantially in the next 35 years and in the future will have lower emissions than current vessels and equipment. BOEM anticipates minor and temporary air quality impacts from six NY Bight projects due to conceptual decommissioning.

Accidental releases: Six NY Bight projects could release VOCs or HAPs because of accidental chemical spills, although the potential volume and number of spills would be greater. As with a single NY Bight project, air quality impacts would be short term and limited to the local area at and around the accidental release location. BOEM anticipates that these activities would have a negligible air quality impact as a result of six NY Bight projects.

3.4.1.4.3 Cumulative Impacts of Alternative B

The analysis of cumulative impacts of six NY Bight projects considered the impacts of six NY Bight projects in combination with other ongoing and planned activities. The OCS permit application for each of the six NY Bight projects, which BOEM anticipates the lessees will file after the COPs are submitted and this PEIS is finalized, will give some indication of impacts, but the analysis in those applications would be focused on each individual project. To accurately assess cumulative impacts, a more comprehensive modeling study would be required. BOEM is considering conducting or participating in a regional modeling study that would assess development impacts of six NY Bight projects along with other planned and reasonably foreseeable projects.

Air emissions – construction: Six NY Bight projects would contribute a noticeable addition to the cumulative impacts on air quality associated with offshore construction, which would be moderate during construction. Impacts would be greatest during overlapping construction activities, but these effects would be short term in nature because supply chain demand and vessel availability are limiting factors of the construction of six NY Bight projects in the geographic analysis area. Six NY Bight projects would contribute a noticeable addition to cumulative air quality impacts associated with onshore construction, which would be minor to moderate.

Air emissions – O&M: O&M of six NY Bight projects would contribute a noticeable addition to cumulative impacts, which would be moderate. O&M emissions from ongoing and planned activities, including six NY Bight projects, could begin between 2026 and 2030. Some emissions associated with O&M activities of six NY Bight projects could overlap with offshore and non-offshore-wind construction-related emissions. Six NY Bight projects would also contribute a noticeable addition to the cumulative GHG impacts on air quality, which would be beneficial from the net decrease in GHG emissions to the extent that fossil-fuel power plants would reduce operations as a result of increased energy generation from offshore wind projects. The GHG emissions benefits would diminish over time as the grid becomes cleaner and the emissions displaced by wind energy become less (on a per-megawatt-hour basis) than at the time six NY Bight projects would begin operation.

A known impact of offshore wind facilities on meteorological conditions is the wake effect. A WTG extracts energy from the free flow of wind, creating turbulence downstream of the WTG. Under certain conditions, offshore wind farms can also affect temperature and moisture downwind of the facilities. Section B.1.4, *Potential General Impacts of Offshore Wind Facilities on Meteorological Conditions*, in Appendix B provides further information on these effects. For large numbers of WTGs in a single region, these effects can be large enough to have potential local climate impacts. Akhtar et al. (2022) used a high-resolution regional climate model to investigate the impact on the sea surface climate of large-scale offshore wind farms that are proposed for the North Sea. Their results showed local decreases in wind speed, local increases in precipitation, a significant reduction in the air-sea heat fluxes and a local, annual mean net cooling of the lower atmosphere in the wind farm areas. The atmosphere below the hub height showed an increase in temperature, which is on the order of up to 10 percent of the climate change signal at the end of the century, but it is much smaller than the interannual climate variability. In contrast, wind speed changes with wind farms were larger than projected mean wind speed changes due to climate change. Based on the modeling results the authors suggest that the impacts of large clustered offshore wind farms should be considered in climate change impact studies.

Air emissions – decommissioning: Conceptual decommissioning of six NY Bight projects would contribute a noticeable addition to the cumulative air quality impacts, which would represent a moderate impact. Because the emissions related to conceptual decommissioning activities would be widely dispersed and transient, BOEM expects all air quality impacts to occur close to the emitting sources.

Accidental releases: Six NY Bight projects would contribute an undetectable addition to the cumulative accidental release impacts on air quality, which would be negligible due to the short-term nature and localized potential effects. Accidental spills would occur infrequently over the 35-year period with a higher probability of spills during construction of projects.

3.4.1.4.4 Conclusions

Impacts of Alternative B. A single NY Bight project and six NY Bight projects under Alternative B would result in a net decrease in overall emissions (larger decrease for six NY Bight projects than for one NY Bight project) over the region compared to the emissions from conventional fossil-fuel power plants. Although there could be some short-term air quality impacts due to various activities associated with construction and installation, O&M, and conceptual decommissioning, emissions would be relatively small and limited in duration. Alternative B would result in air quality–related health effects avoided in the region due to the reduction in emissions associated with fossil-fuel energy generation. As described above, the impact from air pollutant emissions is anticipated to be minor, and the impact from accidental releases would be negligible. Considering all IPFs together, **minor** to **moderate** air quality impacts would likely be anticipated for a limited time during construction and installation, O&M, and conceptual decommissioning. Six NY Bight projects would have a greater impact than one NY Bight project, but the impact level would remain the same. There would be a **minor beneficial** impact on air quality near the NY Bight area and the surrounding region overall to the extent that the wind energy produced would displace energy produced by fossil-fuel power plants. Six NY Bight projects would have a greater beneficial impact than one NY Bight project, but the impact level would remain the same. Because of the amount of emissions, the fact that emissions would be spread out in time, and the large geographic area over which they would be dispersed (throughout the lease areas and the vessel routes from the onshore facilities), air pollutant concentrations associated with the NY Bight projects are not expected to exceed the NAAQS, New Jersey AAQS, and New York AAQS.

Cumulative Impacts of Alternative B. The impacts contributed by six NY Bight projects to the cumulative impacts on air quality would range from undetectable to noticeable, with noticeable beneficial impacts. BOEM anticipates that the cumulative impacts associated with six NY Bight projects would likely result in **moderate** impacts and **moderate beneficial** impacts. The main driver for this adverse impact rating is emissions related to construction activities increasing commercial vessel traffic, air traffic, and truck and worker vehicle traffic. Combustion emissions from construction equipment, and fugitive emissions, would be higher during overlapping construction activities but short term in nature, as the overlap would be limited in time to the construction period. Therefore, the adverse impact on air quality would likely be **moderate** because, while emissions would increase ambient pollutant concentrations, the concentrations are not expected to exceed the NAAQS, New Jersey AAQS, and New York AAQS.

Six NY Bight projects and other offshore wind projects would benefit air quality in the region surrounding the six NY Bight projects to the extent that energy produced by offshore wind projects would displace energy produced by fossil-fuel power plants. Though the benefit is regional, BOEM anticipates a **moderate beneficial** impact because the magnitude of the potential reduction in emissions from displacing fossil-fuel generated power would be small relative to total energy generation emissions in the area.

At present, there is limited data available on which to base an assessment of six NY Bight projects' cumulative impacts. The cumulative impact rating of **moderate** adverse and **moderate beneficial** is based on the projected emissions levels, the geographic dispersal of the emission sources, existing pollutant concentrations as measured by NJDEP and New York State Department of Environmental Conservation (NYSDEC), regional meteorology, and expected levels of avoided emissions. The available data on offshore wind projects consist primarily of previous EISs for such projects and the modeling studies performed for OCS permit applications to date, which are all for single projects. As noted above, to accurately assess cumulative impacts of six NY Bight projects along with other planned and reasonably foreseeable projects a more comprehensive, regional-scale modeling study would be required. BOEM expects that, over time, air quality modeling studies performed for OCS permits or by review agencies will provide further insight into cumulative air quality impacts.

3.4.1.5 Impacts of Alternative C (Proposed Action) – Identification of AMMM Measures at the Programmatic Stage – Air Quality and Greenhouse Gas Emissions

Alternative C, the Proposed Action, considers the potential impacts of future offshore wind development in the NY Bight area with the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts. Alternative C consists of two sub-alternatives – Sub-alternative C1: Previously Applied AMMM Measures, and Sub-alternative C2: Previously Applied and Not Previously Applied AMMM Measures. The analysis for Sub-alternative C1 is presented as the change in impacts from those impacts discussed under Alternative B, and the analysis for Sub-alternative C2 is presented as the change from those impacts discussed in Sub-alternative C1. Refer to Table G-1 in Appendix G, *Mitigation and Monitoring*, for a complete description of AMMM measures that make up the Proposed Action.

3.4.1.5.1 Sub-alternative C1 (Preferred Alternative): Previously Applied AMMM Measures

Sub-alternative C1 analyzes the AMMM measures that BOEM has required as conditions of approval for previous activities proposed by lessees in COPs submitted for the Atlantic OCS or through related consultations. However, BOEM has not identified any previously applied AMMM measures for air quality, and therefore, the impacts on air quality under Sub-alternative C1 are the same as for Alternative B.

3.4.1.5.2 Sub-alternative C2: Previously Applied and Not Previously Applied AMMM Measures

Sub-alternative C2 analyzes the AMMM measures under Sub-alternative C1 plus the AMMM measures that have not been previously applied. However, BOEM has not identified any previously applied AMMM measures for air quality under Alternative C1, and has not identified any AMMM measures under Sub-alternative C2 that were not previously applied. Therefore, the impacts on air quality under Sub-alternative C2 are the same as Sub-alternative C1.

3.4.1.5.3 Conclusions

Impacts of Alternative C. Under Sub-alternative C1, BOEM has not identified any previously applied AMMM measures for air quality. Therefore, impacts under Sub-alternative C1 would be the same as under Alternative B. Under Sub-alternative C2, BOEM has not identified any AMMM measures for air quality that were not previously proposed. Therefore, impacts under Sub-alternative C2 would be the same as under Alternative B and Sub-alternative C1. Under Sub-alternative C1 and Sub-alternative C2, for one NY Bight project and six NY Bight projects, **minor to moderate** air quality impacts would likely be anticipated for a limited time during construction and installation, O&M, and conceptual decommissioning, with **minor beneficial** impacts.

Cumulative Impacts of Alternative C. As with Alternative B, the impacts contributed by six NY Bight projects to the cumulative impacts on air quality with Sub-alternative C1 and Sub-alternative C2 would range from undetectable to noticeable, with noticeable beneficial impacts. BOEM anticipates that under Sub-alternatives C1 and C2 the cumulative impacts associated with six NY Bight projects would likely be **moderate** adverse and **moderate beneficial**. These impact ratings are the same as expected with Alternative B.

3.4.1.6 Recommended Practices for Consideration at the Project-Specific Stage

BOEM is recommending that lessees consider analyzing the RPs in Table 3.4.1-10 to further reduce potential air quality and greenhouse gas emissions impacts. Refer to Table G-2 in Appendix G for a complete description of the RPs.

Table 3.4.1-10. Recommended Practices for air quality and greenhouse gas emissions impacts and related benefits

Recommended Practice	Potential Benefit
AQ-1: Use a substitute insulator gas rather than SF_6 in the switchgear and transmission systems, if feasible.	Using a substitute insulator gas rather than SF_6 in the switchgear and transmission systems would reduce potential SF_6 emissions during construction, operations, and decommissioning.
AQ-2: Replace diesel fuel and marine fuel oil with alternative fuels such as natural gas, propane, or hydrogen, to the extent feasible.	Replacing diesel fuel and marine fuel oil with alternative fuels such as natural gas, propane, or hydrogen would reduce criteria air pollutant and GHG emissions during construction, operations, and decommissioning.
AQ-3: Replace combustion engines with zero-emissions technology (e.g., fuel cell-electric or battery-electric), if feasible.	Replacing combustion engines with zero-emissions technology (e.g., fuel cell-electric or battery-electric) would reduce criteria air pollutant and GHG emissions during construction, operations, and decommissioning.
AQ-4: Implement exhaust aftertreatment, such as scrubbers for SO_2 and selective catalytic reduction for NO_X, on a vessel-specific basis, if feasible.	Using exhaust aftertreatment, such as scrubbers for SO_2 and selective catalytic reduction for NO_X, for example, would reduce SO_2 and NO_X emissions, respectively.
AQ-5: Use diesel particulate filters and diesel oxidation catalysts to retrofit older (USEPA Tiers 1–3) diesel engines, if feasible.	Using diesel particulate filters and diesel oxidation catalysts to retrofit older (USEPA Tiers 1–3) diesel engines would reduce diesel particulate matter emissions and associated health risks.
AQ-6: Require their contractors to use ports equipped with shore power and zero-emissions material-handling equipment and construction firms that offer	Using ports equipped with shore power and zero-emissions material-handling equipment, in addition to alternative-fueled or zero-emissions equipment and

Recommended Practice	Potential Benefit
alternative-fueled or zero-emissions equipment and vehicles, if feasible.	vehicles, would reduce criteria air pollutant and GHG emissions during construction.
AQ-7: Require their contractors to use a combination of combustion and post-combustion controls to meet or exceed applicable marine engine standards.	Using a combination of combustion and post-combustion controls to meet or exceed applicable marine engine standards would reduce criteria air pollutant and GHG emissions during construction, operations, and decommissioning.
AQ-8: Perform and present a technical feasibility analysis for air quality RPs 1 through 5 (AQ-1 – AQ-5), ensuring a comprehensive review of each measure's effectiveness, and readiness for implementation. The technical feasibility analysis should be submitted as part of a brief memo following finalization of the Facility Design Report and Fabrication and Installation Report, totaling no more than 10 pages.	Performance of technical feasibility analysis would ensure a comprehensive review of each measure's effectiveness and readiness for implementation, which potentially could lead to more reduction of criteria air pollutant and GHG emissions than would otherwise occur.
MUL-12: Incorporate ecological design elements where practicable. For example, nature inclusive design products are an alternative to conventional concrete that could result in reduced GHG emissions.	Using ecological design elements, such as alternatives to conventional concrete, could reduce criteria air pollutant and GHG emissions during construction.

3.4 Physical Resources

3.4.2 Water Quality

This section discusses potential impacts on water quality from the Proposed Action, alternatives, and ongoing and planned activities in the water quality geographic analysis area. The water quality geographic analysis area, as shown on Figure 3.4.2-1, includes a 10-mile (16.1-kilometer) radius around the NY Bight lease areas along with inshore waterways around representative ports that may be used for the NY Bight projects. The offshore geographic analysis area accounts for some transport of water masses due to ocean currents. The inshore geographic analysis area was chosen to capture the extent of the natural network of waterbodies that could be affected by port utilization for construction and operation activities of the NY Bight projects.

The water quality impact analysis in this PEIS is intended to be incorporated by reference into the project-specific environmental analyses for individual COPs expected for each of the NY Bight lease areas. Refer to Appendix C, *Tiering Guidance*, which identifies additional analyses anticipated to be required for the project-specific environmental analysis of individual COPs. Project- and site-specific analysis of water quality impacts, including the analysis of offshore and onshore cable and landfall installation, would be required in the COP NEPA document.

3.4.2.1 Description of the Affected Environment and Future Baseline Conditions

Waters in the geographic analysis area include both offshore waters and inshore waterways. The offshore waters include the Atlantic Ocean within the NY Bight lease areas that include vessel routes to/from representative port facilities. Inshore waterways include those of the Delaware Bay, Delaware River, Raritan Bay, Sandy Hook Bay, Newark Bay, East River, Passaic River, Hackensack River, Hudson River, and New York Bay to potential transmission POIs. As the exact locations and activities for each project are not known at this programmatic stage, the project-specific NEPA analysis will include inshore areas for each NY Bight lease area if conditions or activities are different than the analyses of representative areas and projects included in this PEIS.

Table 3.4.2-1 identifies key parameters that characterize water quality, with several of these parameters being accepted proxies for ecosystem health (e.g., dissolved oxygen, nutrient levels). Temperature and salinity delineate fresh from marine surface waters. States assess a variety of other water quality parameters (bacteria, metals, total suspended solids, etc.) as part of their requirements to evaluate and list state waters as impaired under CWA Section 303(d). If a water body is classified as non-attaining per the 303(d) requirements, a designated beneficial use (e.g., recreation, fish consumption) is considered impaired by an exceedance of one or more water quality parameters.

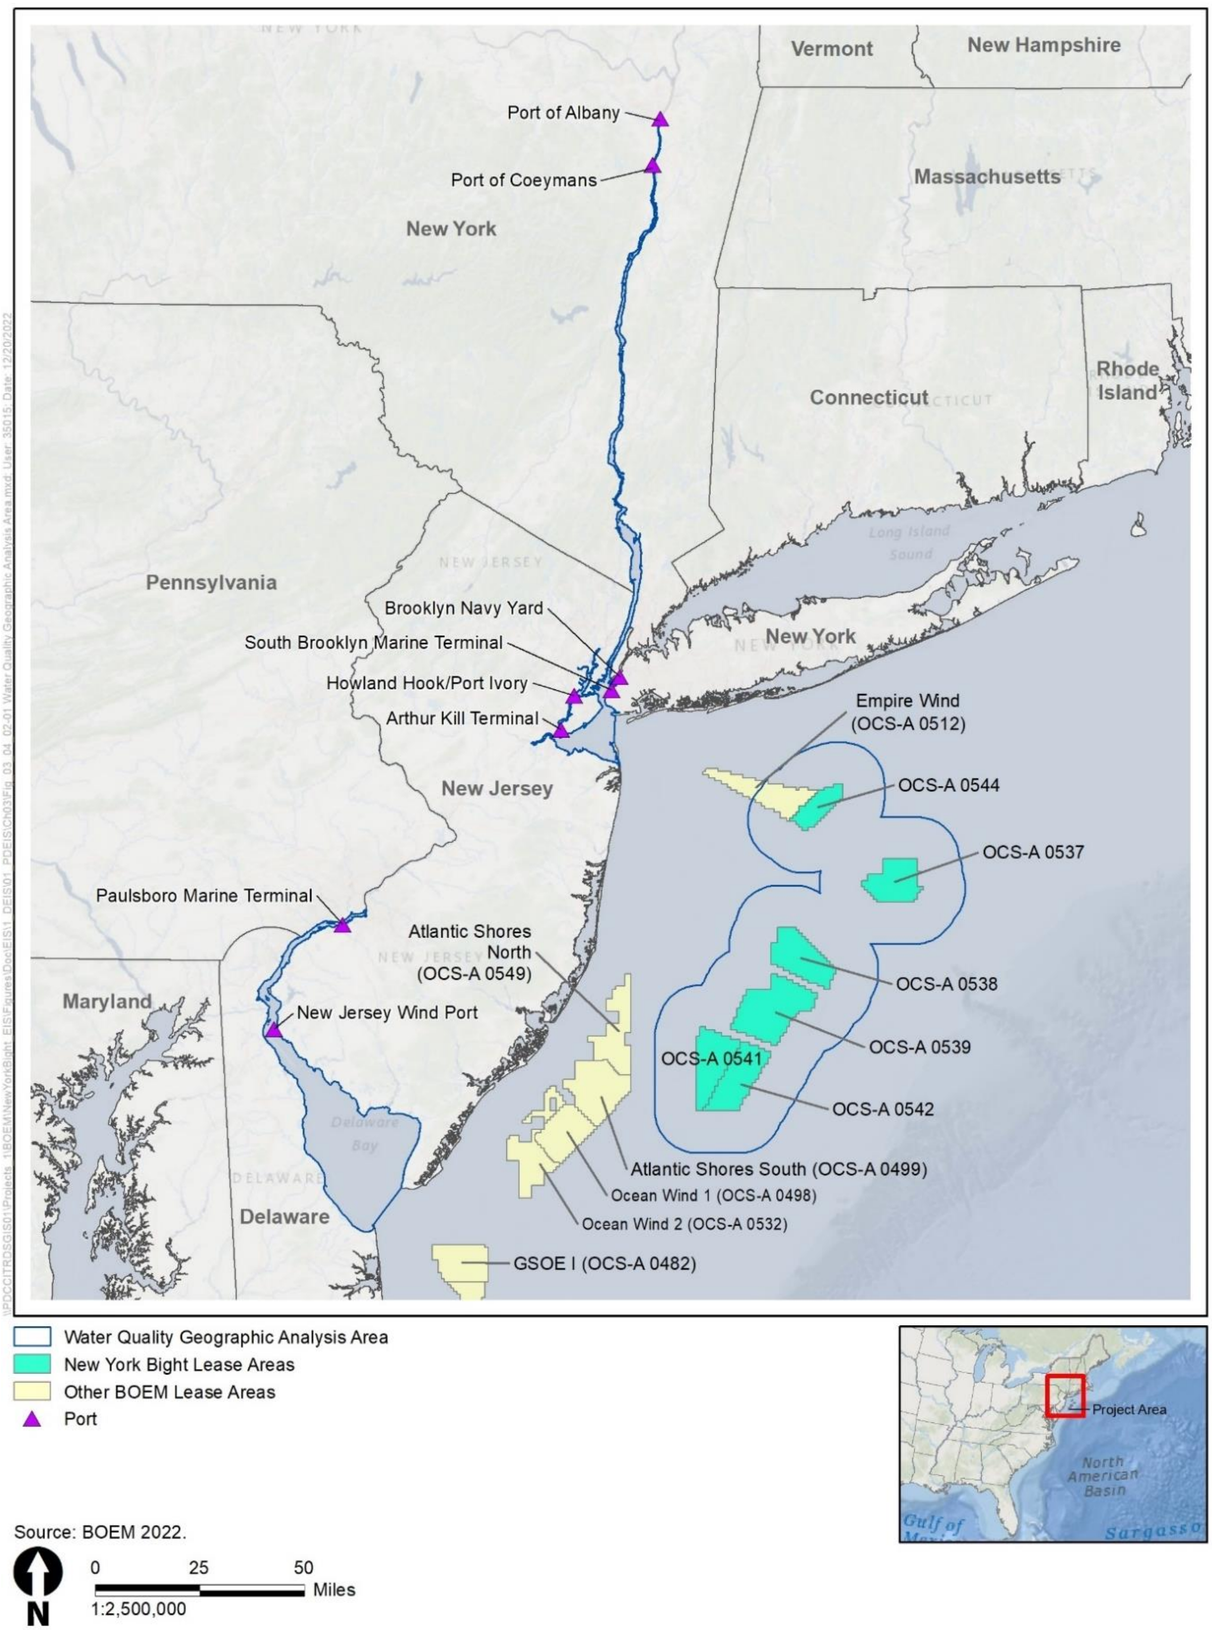

Figure 3.4.2-1. Water quality geographic analysis area

Table 3.4.2-1. Key water quality parameters with characterizing descriptions

Parameter	Characterizing Description
Temperature	Water temperature heavily affects species distribution in the ocean with large-scale changes that may impact seasonal phytoplankton blooms.
Salinity	Salinity, or salt concentration, also affects species distribution. Seasonal variation is smaller than year-to-year variation and less predictable than temperature changes (Wallace et al. 2018).
Dissolved oxygen	Dissolved oxygen concentrations should be above 5 mg/L to maintain a stable environment; lower levels may affect sensitive organisms (USEPA 2000).
Chlorophyll *a*	Chlorophyll *a* is an indicator of primary productivity. The USEPA considers estuarine and marine levels of chlorophyll <5 µg/L to be good, 5 to 20 µg/L to be fair, and >20 µg/L to be poor (USEPA 2021a).
Turbidity	Turbidity is a measure of water clarity. High turbidity reduces light penetration, reduces ecological productivity, and provides attachment places for other pollutants (USGS 2018). Marine waters generally have less turbidity than estuaries.
Nutrients	Phytoplankton are the foundation of the marine food web, and their associated growth rates depend on nutrient (e.g., nitrogen, phosphorus, and carbon, plus calcium and silicon are various micronutrients) availability in the water. Excess nutrients (i.e., from natural or human-derived sources) can cause problematic algal blooms that significantly lower dissolved oxygen concentrations in ambient waters.

mg/L = milligrams per liter; µg/L = microgram per liter.

The offshore U.S. waters of the Atlantic Ocean, including potential offshore export cable corridors and lease areas, have little variation in salinity and temperature though a vertical variation (i.e., stratification) occurs on a seasonal basis (conductivity-temperature-depth data from the World Ocean Database 2021). Stratification typically is strongest in the summer when surface waters are warmer and somewhat less saline than bottom waters; well-mixed and more uniform vertical salinity and temperature profiles are evident in the fall. In late spring and early summer, a strong thermocline develops at an approximately 20-meter depth across the entire shelf of the Mid-Atlantic Bight, isolating a continuous mid-shelf cold pool of water that extends from Nantucket to Cape Hatteras (Miles et al. 2021). The Mid-Atlantic Bight Cold Pool holds nutrients over the shelf during the spring and summer, which in turn promotes phytoplankton productivity and affects fish distributions and behavior (Lentz 2017; Miles et al. 2021; Nye et al. 2009).

The Mid-Atlantic Bight Cold Pool is highly dynamic over its annual lifespan and among years (Chen and Curchitser 2020), experiencing significant changes in stratification, with peak stratification occurring in summer and with weaker stratification occurring during its formation and breakdown in spring and fall (Miles et al 2021). Additionally, the isolated volume of cold bottom water shifts location, predominately moving southwestward along the shelf as it slowly warms through the season (Miles et al. 2021).

As of 2022, the offshore U.S. waters of the Atlantic Ocean are considered attainable (i.e., meeting water quality standards/goals) per the 303(d) requirements. With increasing distance from shore, oceanic circulation patterns play an increasingly larger role in dispersing and diluting anthropogenic contaminants and determining water quality. Waters are assessed as impaired when an applicable water quality standard is not being attained. The top causes of pollution associated with impairment in assessed bays and estuaries are mercury, most common in fish tissue; polychlorinated biphenyls (PCBs), persisting in sediments and fish tissue; and pathogens, which indicate possible fecal contamination (USEPA 2017). PCBs in sediments, among other legacy chemicals (i.e., mercury, dichlorodiphenyltrichloroethane, and dioxin), potentially exceed water quality standards and can be resuspended in the water column during major storm events or from activities such as dredging.

Waterbodies within the state of New York include 1,530 square miles (3,963 square kilometers) of estuaries. As of 2016, the most recent reporting year for 303(d), 29 percent of the impaired coastal waters for fishing in New York state was impaired because of bacteria and other microbes (USEPA 2022). Waterbodies within the state of New Jersey include 1,098 square miles (2,844 square kilometers) of estuarine/ocean waters. The top reasons for impairment of coastal waters in New Jersey are low oxygen (48 percent) for aquatic life and PCBs (39 percent) in fish tissue affecting fish consumption (USEPA 2022). Waterbodies within the state of Delaware include 902 square miles (2,336 square kilometers) of estuarine waters with 100 percent of coastal waters impaired for fish consumption due to PCBs and 33 percent impaired for fish, aquatic life, and wildlife due to low oxygen; however, Delaware is seeing reductions in nutrients and toxins through the implementation of the Watershed Approach to Toxics Assessment and Restoration Program (USEPA 2022).

Table 3.4.2-2 lists the 303(d) non-attainable waterbodies per state authority for the waterbodies (oceans, estuaries, bays, rivers, and lakes) within the geographic analysis area. The estuaries and rivers (inshore waterways) are impaired for fish consumption due to various pollutants such as mercury, PCBs and other toxins, dioxin, and chlordane in fish tissues and for shellfish restrictions due to fecal coliform.

The USEPA monitors water quality trends over time through a national coastal condition assessment. This assessment establishes a water quality index to describe the water quality of various coastal areas by assigning three condition levels (good, fair, and poor) for several water quality parameters. Table 3.4.2-3 lists the USEPA Region 2 (including New Jersey and New York) and 3 (Mid-Atlantic, including Delaware) condition levels per parameter for 2005, 2010, and 2015 (USEPA 2021b). Regions 2 and 3 include the offshore waters and inshore waterways in the geographic analysis area. Since 2005, the percentage of "good" ratings has increased for most of the parameters analyzed (i.e., water clarity ratings within the good category have increased from 72.5 percent in 2005 to 93.3 percent in 2015 for Region 2 and from 4.17 percent in 2005 to 52.5 percent in 2015 for Region 3). Exceptions to this trend are evident for dissolved phosphorus for both regions and chlorophyll *a* for Region 2. Dissolved phosphorus in Region 2 increased, resulting in a greater number of "fair" ratings from 2005 to 2015 as well as fewer "good" ratings from 2010 to 2015. For Region 3, dissolved phosphorus increased, resulting in fewer "good" ratings from 2005 to 2015. In Region 2, chlorophyll *a* decreased, resulting in a greater number of "good" ratings from 2005 to 2010; however, it increased from 2010 to 2015, resulting in fewer "good" ratings. Overall, based on the USEPA's National Coastal Condition Assessment (USEPA 2021b), water quality is in good condition for both regions.

Table 3.4.2-2. 303(d) non-attainable waterbodies per State authority found in the geographic analysis area

Waterbody	Last Year Reported	CWA 303(d) Classification	Non-attainable Use	Impairment
Under Delaware Authority				
Delaware River	2022	Impaired	1) Fish Consumption (Zones 5 and 5c) 2) Fish, Aquatic Life, and Wildlife (Zone 5c)	1) Dieldrin; dioxin; furan compounds; PCBs 2) Dissolved oxygen
Delaware Bay	2022	Impaired	1) Fish Consumption	1) Mercury; PCBs
Under New Jersey Authority				
Delaware River	2020	Impaired	1) Fish Consumption	1) Chlordane, DDT, dieldrin; mercury and PCBs in fish tissue
Delaware Bay	2020	Impaired	1) Aquatic Life 2) Fish Consumption 3) Shellfish Harvesting	1) Turbidity 2) Chlordane, DDT, dieldrin, and mercury; PCBs in fish tissue 3) Fecal coliform
Coastal Atlantic Water (Herring Island to Barnegat Inlet)	2020	Impaired	1) Aquatic Life	1) Dissolved oxygen
Upper New York Bay/ Kill Van Kull	2020	Impaired	1) Aquatic Life 2) Fish Consumption	1) Index of biological integrity[1] 2) Benzo[a]pyrene (PAHs), heptachlor epoxide, and PCBs; chlordane, dieldrin, dioxin, and hexachlorobenzene in fish tissue
Kill Van Kull West	2020	Impaired	1) Aquatic Life 2) Fish Consumption	1) Index of biological integrity 2) Benzo[a]pyrene (PAHs) and heptachlor epoxide; chlordane, dieldrin, dioxin, hexachlorobenzene, and PCBs in fish tissue
East River-Hudson River	2020	Impaired	1) Aquatic Life 2) Fish Consumption	1) Index of biological integrity; total phosphorous 2) Benzo[a]pyrene (PAHs) and heptachlor epoxide; chlordane, DDT, dieldrin, dioxin, hexachlorobenzene, and mercury and PCBs in fish tissue
Hackensack River	2020	Impaired	1) Aquatic Life 2) Fish Consumption	1) Dissolved oxygen; index of biological integrity; nickel 2) Benzo[a]pyrene (PAHs), heptachlor epoxide, and nickel; chlordane, DDT, dieldrin, dioxin, mercury, and PCBs in fish tissue

Waterbody	Last Year Reported	CWA 303(d) Classification	Non-attainable Use	Impairment
Under New York Authority				
Upper New York Bay	2018	Impaired	1) Fish consumption	1) Copper, dioxin, PCBs
Lower East River	2018	Impaired	1) Secondary contact recreation	1) Dissolved oxygen, floating debris, PCBs, trash
Hudson River	2018	Impaired	1) Fish and shellfish consumption	1) PCBs
Long Island Sound	2018	Impaired	1) Shellfish consumption	1) Fecal coliform
Manhasset Bay	2018	Impaired	1) Shellfish consumption	1) Fecal coliform
Hempstead Harbor	2018	Impaired	1) Shellfish consumption	1) Fecal coliform
Oyster Bay Harbor	2018	Impaired	1) Shellfish consumption	1) Fecal coliform
Dosoris Pond	2018	Impaired	1) Shellfish consumption	1) Fecal coliform
Mill Neck Creek	2018	Impaired	1) Shellfish consumption	1) Fecal coliform
Cold Spring Harbor	2018	Impaired	1) Shellfish consumption	1) Fecal coliform
South Oyster Bay	2018	Impaired	1) Shellfish consumption	1) Fecal coliform
East Bay	2018	Impaired	1) Shellfish consumption	1) Fecal coliform
Middle Bay	2018	Impaired	1) Shellfish consumption	1) Fecal coliform
Garret Lead/East Channel	2018	Impaired	1) Shellfish consumption	1) Fecal coliform
Reynolds Channel, East	2018	Impaired	1) Shellfish consumption	1) Fecal coliform
Freeport Cr/East Meadow Br, Lower	2018	Impaired	1) Shellfish consumption	1) Fecal coliform
Hempstead Bay, Broad Channel	2018	Impaired	1) Shellfish consumption	1) Fecal coliform
Hewlett Bay	2018	Impaired	1) Shellfish consumption	1) Fecal coliform
Brosewere Bay	2018	Impaired	1) Shellfish consumption	1) Fecal coliform
East Rockaway Inlet	2018	Impaired	1) Shellfish consumption	1) Fecal coliform
Woodmere Channel	2018	Impaired	1) Shellfish consumption	1) Fecal coliform
Bannister Creak/Bay	2018	Impaired	1) Shellfish consumption	1) Fecal coliform

CWA = Clean Water Act; DDT = dichlorodiphenyltrichloroethane; PAHs = polycyclic aromatic hydrocarbons; PCBs = polychlorinated biphenyls.

Table 3.4.2-3. Water quality conditions in estuarine coastal areas for the USEPA Regions 2 and 3 to stations based on data collected in 2005, 2010, and 2015

Parameter	2005	2010	2015
Region 2, including New Jersey, New York			
Dissolved oxygen	Fair (17.2%), good (59.6%)	Fair (22.1%), good (71.8%)	Fair (27%), good (73%)
Chlorophyll *a*	Fair (25.2%), good (36.7%)	Fair (28.9%), good (61%)	Fair (35.1%), good (52%)
Water clarity	Fair (1.2%), good (72.5%)	Fair (5.3%), good (86.2%)	Fair (5.1%), good (93.3%)
Dissolved nitrogen	Fair (9.8%), good (54.9%)	Fair (19.8%), good (74.2%)	Fair (11.9%), good (82.7%)
Dissolved phosphorous	Fair (34.2%), good (19.2%)	Fair (70.7%), good (1.3%)	Fair (79.1%), good (5.6%)
Region 3, including Delaware			
Dissolved oxygen	Fair (20%), good (62%)	Fair (10.7%), good (62.5%)	Fair (14.3%), good (65.4%)
Chlorophyll *a*	Fair (56%), good (7.3%)	Fair (88%), good (5.6%)	Fair (71.2%), good (9.4%)
Water clarity	Fair (31.3%), good (41.7%)	Fair (28.7), good (49.1%)	Fair (18.3%), good (52.5%)
Dissolved nitrogen	Fair (14.8%), good (76.2%)	Fair (11.3%), good (83.4%)	Fair (7.4%), good (89.1%)
Dissolved phosphorous	Fair (23.6%), good (64.8%)	Fair (29.4%), good (60.4%)	Fair (37.6%), good (52.5%)

The NY Bight is a storm-dominated shelf, with the general southwestward drift of water modulated by more intense storm-induced flows (Vincent et al. 1981). The northeast area of the geographic analysis area (Figure 3.4.2-1) is characterized by moderate ocean currents, with very few observations of speeds greater than 1.3 miles per hour (0.6 meter per second) (UKHO 2009). The net direction of currents south of Long Island Sound, New York is southwest along-coast (Levin et al. 2018; Lentz 2008; UKHO 2009). In the Southern New England and Mid-Atlantic Bight subregions (Clark and Brown 1977), the direction of currents on the shelf is offshore and south (Townsend et al. 2004). Across the shelf in deeper waters, the current flows in the opposite direction of the shelf current (Stevenson et al. 2004). Although ocean currents are largely stable, local-scale (i.e., meters to a few kilometers) variability in currents is observed, in part due to wind and tides and their combined effects.

Groundwater reservoirs underlie areas where onshore project activities could occur. Some of these reservoirs provide water supplies to communities, including USEPA-designated sole source aquifers, which are aquifers that supply at least 50-percent of the drinking water for an area with no other sources available if the aquifer is contaminated. Sole-source aquifers that overlap areas where onshore project activities may occur include the New Jersey Coastal Plains aquifer system, Kings/Queens Counties (Brooklyn-Queens) aquifer system, and the Nassau/Suffolk Counties Long Island aquifer system.

A series of representative ports have been identified for analysis within the PEIS. These ports include the Brooklyn Navy Yard, South Brooklyn Marine Terminal, Howland Hook/Port Ivory, Arthur Kill Terminal, Paulsboro Marine Terminal, New Jersey Wind Port, Port of Albany, and Port of Coeymans.

Ongoing activities that define current conditions and trends within the geographic analysis area that contribute to impacts on water quality resources are diverse and numerous: weather/natural events; global climate change; terrestrial runoff and point source discharges; atmospheric deposition related to urbanization; forestry practices; municipal waste discharges; agriculture; marine vessel traffic related discharges, including the potential for accidental releases and marine debris; wastewater; marine minerals use and ocean-dredged material disposal regulated by the U.S. Army Corps of Engineers (USACE); bridge and coastal road construction; fisheries use, management, and monitoring surveys; recreation and tourism; port expansions; undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); tidal energy projects; and military operations.

As one of the key drivers behind water quality change over time, climate change (including warming sea temperatures, rising sea levels, ocean acidification, etc.) can affect water quality, causing changes and variability within the ecosystem. Northeast regional ocean temperatures have warmed faster than the global ocean over the last two decades according to the National Oceanic and Atmospheric Administration (NOAA 2021). Additionally, there is some evidence indicating that the Mid-Atlantic Bight Cold Pool is both warming and shrinking due to the effects of climate change, which will likely affect species distributions and total ecosystem productivity in the Mid-Atlantic Bight (Friedland et al. 2022).

3.4.2.2 Impact Level Definitions for Water Quality

Definitions of potential impact levels are provided in Table 3.4.2-4. Beneficial impacts on water quality are described using the definitions described in Section 3.3.2 (see Table 3.3-1).

Table 3.4.2-4. Adverse impact level definitions for water quality

Impact Level	Definition
Negligible	There would be no measurable impacts, or impacts would be so small that they would be extremely difficult or impossible to discern or measure.
Minor	Changes would be measurable but would not result in degradation of water quality in exceedance of water quality standards.
Moderate	Changes would be measurable and would result in localized, short-term degradation of water quality in exceedance of water quality standards.
Major	Changes would be measurable and would result in extensive, long-term degradation of water quality in exceedance of water quality standards.

Accidental releases, anchoring, cable emplacement and maintenance, discharges/intakes, land disturbance, port utilization, and presence of structures are contributing IPFs to impacts on water quality. However, these IPFs may not necessarily contribute to each individual issue outlined in Table 3.4.2-5.

Table 3.4.2-5. Issues and indicators to assess impacts on water quality

Issue	Impact Indicator
Runoff, sedimentation, sediment movement, suspension or resuspension, changes to stratification or mixing patterns, or release of contaminants.	Changes to turbidity, nutrients, dissolved oxygen, temperature, salinity, or chlorophyll *a*. Introduction of new contaminants/oil or changes to sediments, or changes in flows.
Disturbance or seepage to groundwater resources.	Changes to turbidity, nutrients, dissolved oxygen, temperature, salinity, or chlorophyll *a*. Introduction of new contaminants/oil or changes to sediments, or changes in flows.

3.4.2.3 Impacts of Alternative A – No Action – Water Quality

When analyzing the impacts of the No Action Alternative on water quality, BOEM considered the impacts of ongoing activities, including non-offshore-wind and offshore wind activities on the baseline conditions for water quality. The cumulative impacts of the No Action Alternative considered the impacts of the No Action Alternative in combination with the other planned non-offshore and offshore wind activities, which are described in Appendix D*, Planned Activities Scenario*.

3.4.2.3.1 Impacts of the No Action Alternative

Under the No Action Alternative, water quality is likely to continue to follow current regional trends and respond to current environmental and societal activities. Ongoing activities within the geographic analysis area that contribute to impacts on water quality generally relate to or include stormwater runoff, ground disturbance (e.g., construction) and erosion, point and non-point source discharges, and atmospheric deposition (see Appendix D, Table D1-23). Empire Wind (OCS-0512) is the only ongoing offshore wind project in the offshore geographic analysis area. Impacts from ongoing construction of the Empire Wind project are described as part of the cumulative impacts of the No Action Alternative in Section 3.4.2.3.2. The accumulation of pollutants in surface waters from stormwater runoff and leaching into groundwater can result in exceedances of water quality standards that can affect the uses of the water (e.g., drinking water, aquatic life, recreation). While water quality impacts may be temporary and localized (e.g., construction), and state and federal statutes, regulations and permitting requirements (e.g., Clean Water Act Section 402) avoid or minimize these impacts, issues with water quality can still persist, resulting in minor impacts.

Additionally, global climate change is an ongoing and developing phenomenon, in the absence of offshore wind development, that causes ocean acidification, warming sea temperatures, rising sea levels, and changes in ocean circulation patterns that can affect water quality.

3.4.2.3.2 Cumulative Impacts of the No Action Alternative

The cumulative impact analysis for the No Action Alternative considers the impacts of the No Action Alternative in combination with other planned non-offshore-wind activities and planned offshore wind activities (without the NY Bight projects).

Other planned non-offshore-wind activities that affect water quality include onshore development activities (including urbanization, forestry practices, municipal waste discharges, and agriculture), marine transportation-related discharges, dredging and port improvement projects, commercial fishing, military use, and new submarine cables, transmission systems (e.g., PBI), and pipelines (see Appendix D, Section D.2 for a description of planned activities). Water quality impacts from these activities, especially from dredging and harbor, port, and terminal operations, are expected to be localized and temporary to permanent, depending on the nature of the activities and associated IPFs. Similar to ongoing activities, the discharge of contaminated runoff into surface waters and groundwater can result in exceedances of water quality standards that can affect water uses (e.g., drinking water, aquatic life, recreation). State and federal water quality protection requirements and permitting would result in avoiding and minimizing these impacts.

Ongoing and planned offshore wind activities within the geographic analysis area that contribute to impacts on water quality are listed in Table 3.4.2-6. Empire Wind (OCS-A 0512) is the only ongoing offshore wind project in the offshore geographic analysis area (Table 3.4.2-6). The inshore waterways leading to ports that may be used by the NY Bight projects may also be used by other planned offshore wind projects along the U.S. Atlantic coast. If construction of offshore export cables for the NY Bight projects overlap with other offshore wind projects, impacts from these other projects are expected to be similar to those described in the following IPFs.

Table 3.4.2-6. Ongoing and planned offshore wind in the geographic analysis area for water quality

Ongoing/Planned	Projects by Region
Ongoing – 2 projects[1] 	**NY/NJ** • Empire Wind 1 (OCS-A 0512) • Empire Wind 2 (OCS-A 0512)
Planned – 0 projects[2] 	**NY/NJ** • None within the geographic analysis area

NJ = New Jersey; NY = New York.
[1] Refer to footnote 10 in PEIS Chapter 1 for additional information on the status of Empire Wind 1 and 2.
[2] Status as of September 20, 2024.

Accidental releases: Planned non-offshore-wind and offshore wind activities could expose offshore and inshore waterways to contaminants (such as fuel; sewage; solid waste; or chemicals, solvents, oils, or grease from equipment) in the event of a spill or release during routine vessel use, collisions and allisions, or equipment failure including WTGs or OSSs. As described in Section 2.3, *Non-Routine Activities and Events*, accidental releases of chemicals, gases, or man-made debris may occur as a result of a structural failure and could result in impacts on water quality. All planned non-offshore-wind and offshore wind activities would be required to comply with regulatory requirements related to the prevention and control of accidental spills administered by the USCG and BSEE. OSRPs or Construction Spill Prevention Control and Countermeasures (SPCCs) are required for every project and would provide for rapid spill response, clean up, and other measures that would help to minimize potential impacts on affected resources from spills. BOEM assumes all projects and activities would comply with laws and regulations to minimize releases.

Vessel activity would increase during offshore wind construction and installation stages and would therefore increase the potential for vessel allisions/collisions and fuel spills. The probability of a fuel spill would be minimized by preventative measures (i.e., onboard containment measures and OSRPs/SPCCs) during routine vessel operations (i.e., fuel transfer). The extent and persistence of water quality impacts from a fuel spill would depend on the meteorological and oceanographic conditions at the time and the effectiveness of spill response measures.

Using the assumptions in Appendix D, Table D2-3, approximately 128,184 gallons (485,229 liters) of coolants and 1,053,770 gallons (3,988,953 liters) of fuels, oils, and lubricants would be involved during construction of the WTGs and OSSs for the Empire Wind 1 and 2 (OCS-A 0512) projects (the only ongoing offshore wind projects within the water quality geographic analysis area). Other chemicals, including grease, paints, and sulfur hexafluoride, would also be used at the offshore wind projects, and black and grey water may be stored in vessels and at onshore facilities. BOEM's study "Environmental Risks, Fate and Effects of Chemicals Associated with Wind Turbines on the Atlantic Outer Continental Shelf" presented extensive analysis and modeling to determine the probability and potential environmental consequences of a chemical spill at offshore wind facilities (Bejarano et al. 2013). The modeling effort revealed the most likely type of spill is a non-routine event and could occur from the WTGs at a volume of 90 to 440 gallons (341 to 1,666 liters), at a rate of one time in 1 to 5 years, or a diesel fuel spill of up to 2,000 gallons (7,571 liters) at a rate of one time in 91 years. The likelihood of a spill occurring from multiple WTGs and OSSs at the same time is very low and, therefore, the potential impacts from a spill larger than 2,000 gallons (7,571 liters) are largely discountable. BOEM anticipates that the likelihood of a non-routine catastrophic, or maximum-case scenario, release of all oils and chemicals to be very low (Bejarano et al. 2013). Small-volume spills could occur during OSS transformer maintenance or transfer of fluids (oils and chemicals), while low-probability small- or large-volume spills could occur due to vessel collisions, allisions such as a vessel striking against a WTGs/OSS, or incidents such as toppling during a storm or earthquake.

The use of heavy equipment onshore could result in potential spills during use or refueling activities. Onshore construction and installation activities and associated equipment would involve fuel and lubricating and hydraulic oils.

Trash and debris accidentally released into the marine environment can harm marine animals through entanglement and ingestion. All vessel operators are required to adhere to the International Convention for the Prevention of Pollution from Ships (MARPOL 73/78) Annex V requirements, USEPA and USCG regulations, and BSEE regulations. Therefore, it would be infrequent and negligible.

An accidental release would generally be localized and likely result in no degradation to water quality in exceedance of water quality standards. In the unlikely event a large spill occurred, impacts on water quality would be short- to long-term and negligible to moderate, depending on the type and volume of material released and the specific conditions (e.g., depth, currents, weather conditions) at the spill location, as well as the effectiveness of spill response measures. Due to the low likelihood of an accidental spill occurring and the expected size of the most likely spill, the overall impact of accidental releases is anticipated to be localized, resulting in no to little degradation to water quality in exceedance of water quality standards. As such, accidental releases from planned non-offshore and offshore wind development would not be expected to contribute appreciably to the cumulative impacts on water quality.

Anchoring: Anchoring associated with planned non-offshore and offshore wind activities could contribute to changes in water quality through resuspension of sediments during construction and installation, O&M, and conceptual decommissioning stages. Additional anchoring associated with military use and survey, commercial, and recreational activities could also contribute to changes in water quality. Disturbances to the seabed during anchoring would temporarily increase suspended sediment and turbidity levels in and immediately adjacent to the anchorage area. The intensity and extent of the additional sediment suspension effects would be less than that of cable emplacement (see *Cable emplacement and maintenance* IPF) and would therefore be unlikely to have an impact beyond the immediate vicinity.

BOEM estimates that approximately 18 acres (7.3 hectares) of seabed could be affected by anchoring for the Empire Wind (OCS-A 0512) projects within the NY Bight water quality geographic analysis area (Appendix D, Table D2-2). Due to the current ambient conditions and the localized area of disturbances around each of the individual anchors, the overall impact of increased sediment and turbidity from vessel anchoring is anticipated to be minor and localized, and it would not result in degradation of ambient water quality. Therefore, anchoring would not be expected to appreciably contribute to the cumulative impacts on water quality.

Cable emplacement and maintenance: The installation of array cables and offshore export cables would include site preparation activities (e.g., boulder removal), cable installation via jetting (primary method), plowing, trenching, and dredging, which can cause temporary increases in turbidity and sediment resuspension. A sediment transport analysis model was conducted for the only ongoing offshore wind projects within the geographic analysis area, the Empire Wind 1 and 2 projects (OCS-A 0512) (Tetra Tech 2022). The model showed the displacement of sediments would be low, and that sediments would remain suspended for a short period of time (4 hours) and typically dissipate to background levels very close to the trench.

The model simulated jet plowing, the primary installation method to be used for the Empire Wind projects (OCS-A 0512). The sediment transport model predicted that the sediment plume would typically travel between 328 feet (100 meters) and 1,640 feet (500 meters) during flood and ebb conditions but could travel more than 3,280 feet (1,000 meters) in some areas with stronger currents. Maximum plume concentrations at 3,280 feet (1,000 meters) would be below 30 milligrams per liter at all stations, with the exception of the two stations with strong currents. Project-specific NEPA analysis will provide greater details for the specific New York Bight lease areas.

Coarse particles (medium sand and larger) would not be suspended in the water column from jet plow activities. Fine sand would settle to the bed in less than 1 minute and within 3 feet (1 meter) to 16 feet (5 meters) of the trench centerline, depending on current velocities. Silts and clays would remain suspended for approximately 4 hours and would be transported farther from the trench. The maximum deposition thickness would be at the trench centerline, with an average deposition thickness of 9.52 inches (24 centimeters). Deposition thickness would decrease rapidly with distance from the jet plow; at a distance of 82 feet (25 meters), the average deposit thickness would be less than 0.37 inch (0.95 centimeter) for flood tides, and less than 0.08 inch (0.20 centimeter) for ebb tides. Within 492 feet (150 meters) of the trench, deposition thicknesses would be negligible, at less than 0.04 inch (0.1 centimeter), along most of the proposed submarine export cable routes. The mass flow excavation installation method was also modeled because there are some known locations for Empire Wind where jet plowing would not be feasible. The plume distance and distance at which sediment would settle from the trench would be similar to or less than under jet plowing.

Due to the prevailing ambient water quality conditions, localized areas of disturbances, and range of variability within the water column, the overall impacts of increased sediments and turbidity from cable emplacement and maintenance are anticipated to be minor, localized, and short-term, resulting in no degradation to ambient water quality. New cable emplacement and maintenance activities would not be expected to appreciably contribute to cumulative impacts on water quality.

Port utilization: Planned non-offshore and offshore wind activities could increase port utilization, possibly including port expansion/modification. Port expansion could include dredging, deepening, and construction of new berths, resulting in increased potential for increased turbidity, sedimentation, and accidental releases (fuel spills, trash/debris, etc.). However, any port expansions/modifications would comply with all applicable permit requirements. Vessels would adhere to all USCG and MARPOL 73/78 Annex V requirements and, as applicable, the NPDES vessel general permit. Due to construction timeframes and decreased operational traffic, the overall impact of accidental spills and sedimentation during port utilization is anticipated to be minor, localized, and short-term, resulting in little to no degradation to water quality. Port utilization is not expected to contribute to cumulative impacts on water quality.

Presence of structures: Empire Wind 1 and 2 (OCS- A 0512) (the only ongoing wind projects in the NY Bight water quality geographic analysis area) would result in 140 structures in the water, 135 acres (55 hectares) of impact from installation of foundations and scour protection, and 123 acres (49.8 hectares) of impact from hard protection (e.g., armoring) for the offshore export cables and interarray cables. These structures would result in some alteration of local water currents leading to increased movement, suspension, and deposition of sediments, but significant scour is not expected in deep water locations, where most of the structures would be located. Scouring that leads to impacts on water quality through the formation of sediment plumes generally occurs in shallow areas with tidally dominated currents (Harris et al. 2011). Structures may reduce wind-forced mixing of surface waters, whereas water flowing around the foundations may increase vertical mixing.

Offshore wind facilities could have impacts on atmospheric and oceanographic processes (including the Mid-Atlantic Bight Cold Pool) through the presence of structures and the extraction of energy from the wind. There has been extensive research into characterizing and modeling atmospheric wakes created by wind turbines to design the layout of wind facilities and hydrodynamic wake/turbulence related to predicting seabed scour. However, relatively few studies have analyzed the hydrodynamic wakes coupled with the interaction of atmospheric wakes with the sea surface. Further, even fewer studies have analyzed wakes and their impact on regional scale oceanographic processes (i.e., Mid-Atlantic Bight Cold Pool) and potential secondary changes to primary production and ecosystems. Studies on this topic have focused on ocean modeling rather than field measurement campaigns.

The general understanding of offshore wind–related impacts on hydrodynamics is derived primarily from European-based studies. A synthesis of European studies by Van Berkel et al. (2020) summarized the potential effects of wind turbines on hydrodynamics, the wind field, and fisheries. Local to a wind facility, the range of potential impacts include increased turbulence downstream, remobilization of sediments, reduced flow inside wind farms, downstream changes in stratification, redistribution of water temperature, and changes in nutrient upwelling and primary productivity. Human-made structures, especially tall vertical structures such as foundations, alter local water flow at a fine scale by potentially reducing wind-driven mixing of surface waters or increasing vertical mixing as water flows around the structure (Carpenter et al. 2016; Cazenave et al. 2016; Segtnan and Christakos 2015). When water flows around the structure, turbulence is introduced that influences local current speed and direction. Turbulent wakes have been observed and modeled at the kilometer scale (Cazenave et al. 2016; Vanhellemont and Ruddick 2014). While impacts on current speed and direction decrease rapidly around monopiles, there is a potential for hydrodynamic effects out to a kilometer from a monopile (Li et al. 2014). Direct observations of the influence of a monopile extended to at least 984 feet (300 meters); however, changes were indistinguishable from natural variability in a subsequent year (Schultze et al. 2020). The range of observed changes in current speed and direction 984 to 3,281 feet (300 to 1,000 meters) from a monopile is likely related to local conditions, wind farm scale, and sensitivity of the analysis. In strongly stratified locations such as the NY Bight, the mixing seen at monopiles is often masked by processes forcing toward stratification (Schultze et al. 2020), but the introduction of nutrients from depth into the surface mixed layer can lead to a local increase in primary production (Floeter et al. 2017; refer to Section 3.5.5, *Finfish, Invertebrates, and Essential Fish Habitat*, Section 3.5.6, *Marine Mammals*, Section 3.5.7, *Sea Turtles*, and Section 3.6.1, *Commercial Fisheries and For-Hire Recreational Fishing*, regarding hydrodynamic and atmospheric wake effects on primary production). The same factors that form and maintain the Mid-Atlantic Bight Cold Pool are likely to limit the extent of measurable hydrodynamic effects. Localized mixing will still occur, bringing nutrients to the surface.

A hydrodynamic model was run for four different WTG build-out scenarios of the offshore Rhode Island and Massachusetts lease areas that found offshore wind projects have the potential to alter local and regional physical oceanic processes (e.g., currents, temperature stratification), via their influence on currents from WTG foundations and by extracting energy from the wind (Johnson et al. 2021). The model demonstrated that introduction of the WTGs modifies the oceanic responses of current magnitude (flow speed), wave heights, and temperature in the following three ways:

- WTGs exert a drag force on flowing water, resulting in a reduction in current magnitude.

- Current magnitude and wave height are reduced as the WTGs extract energy from the wind, reducing the wind field surrounding the WTGs and therefore reducing the energy transfer from the wind to the sea.
- The presence of the WTGs initiates a downstream wake, where eddies and turbulence influence the temperature stratification through vertical mixing.

The changes in currents and mixing would fluctuate seasonally and regionally and affect water quality parameters (e.g., temperature, dissolved oxygen, salinity). Each of the three ways in which WTGs modify ocean conditions could influence ocean mixing and, in turn, stratification that is a key characteristic of the Mid-Atlantic Bight Cold Pool. However, the net impact of offshore wind farms on ocean stratification is dependent on the relative contribution of these three processes and potentially other currently unknown processes in a particular wind farm facility (Miles et al. 2021). WTGs and the OSSs would be placed in water depths ranging from 100 to 200 feet (31 to 61 meters) where current speeds are relatively low, and offshore cables would be buried where possible. Cable armoring would be used where burial is not possible, such as in hard-bottomed areas. BOEM anticipates that developers would implement BMPs to minimize seabed disturbance from foundations, scour protection, and cable installation. As a result, impacts on offshore water quality would likely be minor and localized and would not degrade water quality in exceedance of water quality standards.

The exposure of offshore wind structures, which are mainly made of steel, to the marine environment can result in corrosion without protective measures. Corrosion is a general problem for offshore infrastructures, and corrosion protection systems are necessary to maintain their structural integrity. Protective measures for corrosion (e.g., coatings, cathodic protection systems) are often in direct contact with seawater and have different potentials for emissions of metals or organic compounds into the marine environment, e.g., galvanic anodes emitting metals, such as aluminum, zinc, and indium, and organic coatings releasing organic compounds due to weathering or leaching.

Research conducted in the North Sea found that galvanic anodes result in the continuous emission of inorganic matter into the local marine environment for the life of the project. Reese et al. (2020) stated that more than 80 kilograms of aluminum-anode material per monopile foundation per year are emitted into the marine environment. Kirchgeorg et al. (2018) found that the use of aluminum anodes would reduce the total annual emissions by a factor of approximately 2.5 (5,511 pounds [118, 000 kilograms]) due to the higher current capacity than zinc anodes for an offshore wind farm with 80 WTG monopile foundations. Depending on the pH of the ambient water, Reese et al. (2020) found that, along with the main elements that compose a galvanic anode, toxicologically relevant elements such as zinc, cadmium, and lead will be emitted during the anode's lifetime. In-situ measurements of the leached elements are confounded by background levels of these elements in both sediment and seawater within the wind farms (Reese et al. 2020).

The current understanding of chemical emissions for offshore wind structures is that emissions appear to be low, suggesting a low environmental impact, especially compared to other offshore activities; however, these emissions may become more relevant for the marine environment with increased numbers of offshore wind projects and a better understanding of the potential long-term effects of corrosion protection systems (Kirchgeorg et al. 2018). Based on the current understanding of offshore wind structure corrosion effects on water quality, BOEM anticipates the potential impact to be minor. The presence of structures would not be expected to appreciably contribute to the cumulative impacts on water quality.

Discharges/intakes: While WTGs and OSSs are typically self-contained and do not generate discharges under normal operating conditions, some offshore wind projects may use HVDC converter stations that would convert AC to DC before transmission to onshore project components. The most effective way to cool these HVDC systems is by pumping in seawater through a heat exchanger to cool the deionized water within the system (Middleton and Barnhart 2022) and then discharge warmer water back into the ocean. The seawater is filtered through 500 microns to remove sand and other small particles. While the discharge is warmer than the surrounding ocean water, it is normally considered to have a minimal effect because thermal discharge will be quickly absorbed by the surrounding water mass and returned to ambient temperatures within a minimal distance from the discharge pipe. The discharge pipes are typically positioned about 30 feet (9.1 meters) above the seafloor. Chemicals such as bleach (sodium hypochlorite) in a concentration of roughly 10 to 200 parts per million would be used to prevent the growth of biofilms and encrusting organisms in the system. As a result, due to potential impacts on water quality to surrounding sea water, a USEPA NPDES permit would be required (Middleton and Barnhart 2022). Empire Wind 1 and 2 (OCS-A 0512) are the only ongoing offshore wind projects in the geographic analysis area and have not proposed the use of HVDC substations.

Planned offshore wind activities would result in a small increase in overall vessel traffic, with a short-term peak during construction. Vessel activity associated with planned offshore wind construction activities within the geographic analysis area for water quality, excluding the NY Bight lease areas, is expected to occur regularly beginning in 2023 and continuing through 2030 and then lessen to near existing condition levels during operations. Increased vessel traffic would be localized near affected ports and offshore construction areas. Planned offshore wind activities would result in an increase in regulated discharges from vessels, particularly during construction and conceptual decommissioning, but the events would be staggered over time and localized. Offshore permitted discharges would include uncontaminated bilge water and treated liquid wastes. BOEM assumes that all vessels/facilities operating in the same area will comply with federal and state regulations on effluent discharge, including the requirement for a USEPA NPDES permit and interim requirements of the Vessel Incidental Discharge Act (85 *Federal Register* 67818). All planned offshore wind projects would be required to comply with regulatory requirements related to the prevention and control of discharges and the prevention and control of nonindigenous species. All vessels would need to comply with USCG ballast water management requirements outlined in 33 CFR part 151 and 46 CFR part 162. Furthermore, all vessels would need to meet USCG bilge water regulations outlined in 33 CFR part 151, and allowable vessel discharges, such as bilge and ballast water, would be restricted to uncontaminated or properly treated liquids. Therefore, due to the minimal amounts of allowable discharges from vessels associated with planned non-offshore and offshore wind activities, BOEM expects impacts on water quality resulting from vessel discharges are likely to be minimal and not result in degradation of water quality in exceedance of water quality standards.

The overall impacts of discharges from vessels are anticipated to be negligible due to the staggered increase in vessels from various projects; the current regulatory requirements administered by the USEPA, USACE, USCG, and BSEE; and the restricted allowable discharges. Based on the above, the level of impact in the water quality geographic analysis area from planned non-offshore and offshore wind activities would be similar to existing conditions and would not be expected to appreciably contribute to the cumulative impacts on water quality.

Land disturbance: Planned non-offshore and offshore wind activities could include onshore components that could contribute to water quality impacts through sedimentation and accidental spills of fuels and lubricants. BOEM assumes that each project would avoid and minimize water quality impacts through BMPs, OSRPs/SPCCs, stormwater pollution prevention plans (SWPPPs), and compliance with applicable permit requirements. Overall, the impacts from onshore activities that occur near waterbodies could result in temporary introduction of sediments or pollutants into inshore waterways in small amounts where erosion and sediment controls fail. Land disturbance for planned offshore wind activities that are at a distance from waterbodies and that implement erosion and sediment control measures would be less likely to affect water quality. Impacts on water quality would be minor and localized with no degradation in water quality in exceedance of water quality standards and would be limited to periods of onshore construction and periodic maintenance over the life of each project. Land disturbance from planned non-offshore and offshore wind activities is not expected to appreciably contribute to the cumulative impacts on water quality.

3.4.2.3.3 Conclusions

Impacts of the No Action Alternative. Water quality would continue to follow current regional trends and respond to current environmental and societal activities, including climate change. BOEM expects ongoing non-offshore-wind activities would likely have temporary and **negligible** to **minor** impacts on water quality primarily through accidental releases and sediment suspension related to vessel traffic, port utilization, presence of structures, discharges/intakes, and land disturbance.

Cumulative Impacts of the No Action Alternative. Under the No Action Alternative, existing environmental trends and ongoing activities, including climate change, would continue to affect water quality in the geographic analysis area. Planned non-offshore-wind activities—including installation of new submarine cables and pipelines, onshore development, marine surveys, and port improvements—would contribute to cumulative impacts on water quality and would likely be undetectable. Similarly, planned offshore wind projects would also contribute to water quality impacts from sediment resuspension during construction and conceptual decommissioning, specifically from cable laying (including seabed preparations and pre-installation grapple runs), vessel discharges, sediment contamination, discharges from the WTGs and OSSs during operation, sediment plumes due to scour, and erosion and sedimentation from onshore construction. Construction and conceptual decommissioning activities associated with planned offshore wind activities would lead to increases in sediment suspension and turbidity. However, sediment suspension and turbidity increases would be temporary and localized, and BOEM anticipates the impacts to be minor. BOEM has considered the possibility of impacts resulting from accidental releases. A moderate impact could occur if there was a large-volume, catastrophic release; however, the probability of catastrophic release occurring is very low and the expected size of the most likely spill would be very small and of low frequency. Therefore, the cumulative impacts of the No Action Alternative on water quality from ongoing and planned activities would likely be **negligible** to **minor** because any potential detectable impacts are not anticipated to exceed water quality standards.

3.4.2.4 Impacts of Alternative B – No Identification of AMMM Measures at the Programmatic Stage – Water Quality

3.4.2.4.1 Impacts of One Project

Alternative B considers the potential impacts of future offshore wind development for the NY Bight area without the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts.

Accidental releases: Accidental releases during construction and installation, O&M, and conceptual decommissioning could involve fuel, oil, and lubricants. As discussed in Section 3.4.2.3, *Impacts of Alternative A – No Action – Water Quality*, the risk of a spill from an offshore structure would be low, and any effects would likely be localized. Increased vessel activity during construction, installation, and conceptual decommissioning would increase the potential for vessel allisions/collisions and fuel spills. However, collisions and allisions are anticipated to be unlikely based on the following factors that would be considered for a single NY Bight project and applied at the project-specific NEPA stage: USCG requirement for lighting on vessels, NOAA vessel speed restrictions, the lighting and marking plan that would be implemented, and the inclusion of a single NY Bight project's components on navigation charts. The single NY Bight project's SPCC and OSRP would be implemented and adhered to, which would provide for rapid spill response, cleanup, and other measures to minimize any potential impact on affected resources from spills and accidental releases, including spills resulting from catastrophic events.

In the unlikely event an allision or collision involving vessels or components associated with one single NY Bight project resulted in a large spill, impacts from a single NY Bight project alone on water quality would be short- to long-term depending on the type and volume of material released and the specific conditions (e.g., depth, currents, weather conditions) at the location of the spill. Overall, the probability of an oil or chemical spill occurring that is large enough to affect water quality is extremely low, and the degree of impact on water quality would depend on the spill volume. This risk and impact would be minor and localized with no degradation in water quality in exceedance of water quality standards, with the unlikely event of a large accidental release potentially causing a moderate and short-term impact.

Increased accidental releases of trash and debris may occur from vessels primarily during construction but also during operations and conceptual decommissioning of planned offshore wind facilities. BOEM assumes all vessels would comply with laws and regulations to properly dispose of marine debris and to minimize releases. In the event of a release, it would likely be an accidental, localized event in the vicinity of projects; therefore, project-related marine debris would only have a short-term effect on water quality.

The onshore construction site size and overall weather conditions can affect the total volume of stormwater discharge. Through the SWPPP and applicable NPDES permits for a NY Bight project, proper spill containment gear and absorption materials would be required to be maintained for immediate use in the event of any inadvertent spills or leaks. BOEM anticipates that the impacts from accidental releases on water quality would result in negligible and temporary impacts on surface and groundwater quality including sole source aquifers as a result of releases from heavy equipment during construction or conceptual decommissioning and other cable installation activities.

Anchoring: During construction, installation, and conceptual decommissioning activities, there is a potential for increased vessel anchoring. Anchoring can cause resuspension and deposition of sediments in the immediate area of disturbance. The anticipated acreage of impact from anchoring is not known for one NY Bight project; however, assuming anchoring impacts are similar to Empire Wind (OCS-A 0512), which has proposed 18 acres (7.3 hectares) of potential anchor disturbance, the impacts on water quality from a single NY Bight project due to anchoring would be localized, temporary, and minor during construction and conceptual decommissioning. Anchoring during operation would decrease due to fewer vessels required during operation, resulting in reduced impacts.

Cable emplacement and maintenance: The installation of array cables and offshore export cables would be conducted via jet plow, mechanical plow, or mechanical trenching, which can cause temporary increases in turbidity and sediment resuspension. Other projects using similar installation methods observed minor impacts on water quality due to the localized nature of the disturbance (Latham et al. 2017). Impacts from suspended contaminated sediments if present would result in detectable, localized, short-term degradation of water quality in exceedance of water quality standards along the offshore export cable corridor. A sediment transport model for Empire Wind (OCS-A 0512) (Tetra Tech 2022), which may be representative of the NY Bight lease areas, indicated that displacement of sediments would be low, would remain suspended for a short period of time (4 hours), and typically dissipate to background levels (Section 3.4.2.3.2 contains additional details on the sediment transport modeling). Based on the RPDE (Chapter 2, Section 2.1.2, *Alternative B – No Identification of AMMM Measures at Programmatic Stage*), a single NY Bight project offshore export cable emplacement would disturb an estimated maximum width of 131 feet (40 meters) of seabed, with up to 929 miles (1,495 kilometers) of export cable. Impacts on water quality from construction and conceptual decommissioning due to new cable emplacement and maintenance would be short-term and minor.

Port utilization: The Brooklyn Navy Yard, South Brooklyn Marine Terminal, Howland Hook Port Ivory, Arthur Kill Terminal, Paulsboro Marine Terminal, New Jersey Wind Port, Port of Albany, and Port of Coeymans have been identified for analysis within the PEIS, although not all ports would be used at the same time. Each port facility under consideration already has sufficient existing infrastructure or has an area where other entities intend to develop infrastructure with the capacity to support offshore wind activity, including one NY Bight project. Activities associated with the development of a single NY Bight project would add to existing baseline impacts on water quality due to routine port operations. If port expansions or modifications are necessary for a single NY Bight project, they would be completed in accordance with state and federal regulations and permits and would be completed in collaboration with multiple entities (e.g., port owners, local governmental agencies, states, other offshore wind developers). Port expansion could include dredging, deepening, and construction of new berths, resulting in impacts on water quality through accidental spills, leaks, or discharges or sedimentation during port use. Specific ports and expansions will be further discussed in project-specific COPs and COP-level NEPA analyses. Additionally, impacts on water quality would result from vessel traffic. The increase in vessel activity during the construction and installation stage of a single NY Bight project would be small. Multiple authorities regulate water quality impacts from port activities, and vessel activity would decrease during operations and conceptual decommissioning stages. Therefore, impacts of construction, operation, and conceptual decommissioning on water quality from port utilization would be negligible.

Presence of structures: A single NY Bight project would add up to 280 WTGs and would include a disturbance width of up to 131 feet (40 meters) per export cable. As described under the No Action Alternative, results from a hydrodynamic modeling study found that offshore wind projects have the potential to alter local and regional physical oceanic processes (e.g., currents, temperature stratification) via their influence on currents from WTG foundations and by extracting energy from the wind (Johnson et al. 2021). These disturbances would be localized but, depending on the hydrologic conditions, have the potential to impact water quality through altering mixing patterns and the formation of sediment plumes.

BOEM expects an analysis for potential for scouring and mobility of the seabed using information collected during the marine site investigations during COP development to identify areas within the NY Bight lease areas where significant scour could occur around foundations and other hard structures (dependent on water currents, wave action, and water depths). Low current speeds and minimal seabed mobility are good indicators that potential significant scour would not occur. The addition of scour protection would minimize the potential for scour at the base of foundations. Also, limited scour is anticipated around the cables due to the cable burial depths (3 to 9.8 feet [0.9 to 3 meters] for interarray cables and 3 to 19.6 feet (0.9 to 6 meters) for export cables).

In addition, as described under the No Action Alternative, the exposure of offshore wind structures to the marine environment can result in emissions of metals and organic compounds from corrosion protection systems. However, the current understanding of chemical emissions for offshore wind structures is that emissions appear to be low, suggesting a low environmental impact (Kirchgeorg et al. 2018).

Impacts on water quality from the presence of structures during construction and installation, O&M, and conceptual decommissioning would be reoccurring and continual but range from negligible to minor.

Discharges/intakes: Construction of a single NY Bight project would generate up to 51 vessels operating in a lease area or over the offshore export cable route at any given time (Section 3.6.6, *Navigation and Vessel Traffic*). Various vessel types (e.g., installation, cable-laying, support, transport/feeder, and crew vessels) would be deployed throughout the NY Bight project area during the construction and installation phase. Impacts from discharges from vessel traffic from one NY Bight project would be similar as described under the No Action Alternative as all vessels would need to comply with USCG ballast water discharge and other regulatory requirements, which would minimize impacts. Based on the BMPs and compliance with applicable vessel requirements, BOEM anticipates that the impacts on water quality from discharges would be minor during construction and, to a lesser degree, during O&M and conceptual decommissioning activities due to the decrease in the number of vessels needed for these activities.

Sediment resuspension during potential dredging for one NY Bight project could result in release of sediment contaminants into the water column. The dredged material would be transported for disposal at a licensed facility in accordance with applicable regulations and permit requirements. The total suspended sediments and associated contaminant concentrations generated by the in-water activities would be temporary and would result in minor short-term impacts on water quality.

One NY Bight project may use a HVDC converter OSS that would convert AC to DC before transmission to onshore project components. These HVDC systems are typically cooled by an open loop system that intakes cool sea water and discharges warmer water back into the ocean (Middleton and Barnhart 2022). Chemicals such as bleach (sodium hypochlorite) would be used to prevent growth in the system and keep pipes clean. The warm water discharged is generally considered to have a minimal effect as it will be mixed by the surrounding water and returned to ambient temperatures over time. Even though localized effects on water quality from the discharge of warmer water could take place in the area immediately surrounding the outlet pipe, the overall impacts are expected to be minimal with no degradation of water quality. CWA Section 316(b) requires NPDES permits to ensure that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available to minimize adverse environmental impacts.

Land disturbance: Onshore components of one NY Bight project are anticipated to include a specific transmission POI in New York or New Jersey and an interconnection point to a regional offshore grid substation. Proper erosion and sedimentation controls would be maintained to avoid and minimize unstable soils that could potentially be moved by wind and runoff into surface waters or groundwater resources and increase turbidity per permitting requirements or the applicable rules/regulations. This would continue protecting groundwater as drinking water resources, including sole source aquifers. BOEM assumes a SWPPP would be developed and implemented and the appropriate NPDES permit obtained to avoid and minimize water quality impacts during construction. HDD is expected to be used at landfall sites to minimize land disturbance near the shoreline. It is possible that potential, limited sediment releases could occur during the HDD, but impacts would be localized and not long lasting. As such, impacts on water quality from land disturbance is anticipated to be temporary, lasting only the duration of construction, and would be negligible.

3.4.2.4.2 Impacts of Six Projects

The same IPFs (accidental releases, anchoring, cable emplacement and maintenance, presence of structures, discharges/intakes, and land disturbance) described for a single NY Bight project apply to six NY Bight projects with more of a potential for impacts due to the greater amount of offshore and onshore development under six NY Bight projects. This includes an increase in the number of vessels for potential accidental releases and discharges/intakes that could affect water quality as well as additional anchoring and cable emplacement and maintenance causing increased sediment resuspension and deposition. Under six NY Bight projects, up to 1,125 foundation locations for WTGs and OSSs could be installed, which would increase the potential for scour and mobility of the seabed and include hydrodynamic impacts from the WTGs. However, due to the anticipated low currents and the use of scour protection, potential sediment transport would be minimized. Therefore, the impacts from presence of structures would increase for six NY Bight projects due to the increased number of WTGs and the associated hydrodynamic changes; however, impacts on water quality would be minimized due to the use of scour protection. If multiple projects are being constructed within the same timeframe, the impacts on water quality would be greater than those identified for one NY Bight project but not enough to change the overall impact ratings that range from negligible to minor, depending on the IPF, since the projects would likely not overlap each other geographically and the most impacts would be localized and short-term. As stated for one NY Bight project, multiple authorities regulate the impacts on water quality through permits and regulations that would still apply to six NY Bight projects.

Port utilization is still anticipated to be negligible (see Section 3.4.2.4.1, *Impacts on One Project*). The increase in vessel activity would be small with multiple authorities regulating water quality impacts. If any port expansions are required to accommodate six NY Bight projects, the impact on water quality is anticipated to be minor due to the port improvements complying with all applicable permit requirements to minimize, reduce, or avoid impacts.

3.4.2.4.3 Cumulative Impacts of Alternative B

The construction and installation, O&M, and conceptual decommissioning of Alternative B would contribute to the primary IPFs of accidental releases, anchoring, cable emplacement and maintenance, port utilization, presence of structures, discharges/intakes, and land disturbance and result in sediment resuspension and deposition, an increased potential for accidental releases, and changes to water mixing patterns that could affect water quality. However, impacts on water quality would range from negligible to minor, depending on the IPF, given the short-term temporary impacts of suspended sediment including contaminant resuspension, and the regulatory and permitting requirements to avoid and minimize impacts on water quality. In the unlikely event of an accidental release, the impacts would remain moderate.

In context of reasonably foreseeable environmental trends and planned actions, if multiple projects are constructed within the same timeframe, impacts of Alternative B would range from undetectable to noticeable. If construction timeframes of the six NY Bight projects were staggered, this could further minimize the potential for overlapping impacts. BOEM anticipates that the cumulative impacts associated with Alternative B when combined with past, present, and future activities would be minor and would not alter the overall character of water quality in the geographic analysis area for all IPFs except for a large accidental release, which would remain moderate.

The measurable impacts anticipated would be small, and water quality would recover completely without remedial or mitigating action. Six NY Bight projects would contribute to—but would not have an appreciable change to—the overall impact rating within the geographic area.

3.4.2.4.4 Conclusions

Impacts of Alternative B. Construction and installation, O&M, and conceptual decommissioning of Alternative B for either one NY Bight project or six NY Bight projects would likely have **negligible** to **minor** impacts on water quality, depending on the IPF, with the unlikely event of a large accidental release potentially causing a **moderate** impact.

Cumulative Impacts of Alternative B. Alternative B would contribute to the cumulative impact rating primarily through the increased turbidity, potential contaminant resuspension, and sedimentation due to anchoring and cable emplacement during construction, and alteration of water currents and increased sedimentation during O&M due to the presence of structures. Considering all the IPFs together, BOEM anticipates that the impacts of six NY Bight projects in the geographic analysis area combined with ongoing activities, planned offshore wind activities, and reasonably foreseeable environmental trends would likely result in **negligible** to **minor** cumulative impacts on water quality. BOEM has considered the possibility of impacts resulting from accidental releases. A **moderate** cumulative impact could occur if there was a large-volume, catastrophic release; however, the probability of this occurring is very low. In context of reasonably foreseeable environmental trends, the impacts contributed by Alternative B to the cumulative impacts on water quality would be undetectable.

3.4.2.5 Impacts of Alternative C (Proposed Action) – Identification of AMMM Measures at the Programmatic Stage – Water Quality

Alternative C, the Proposed Action, considers the potential impacts of future offshore wind development for the NY Bight Area with the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts. Alternative C consists of two sub-alternatives – Sub-alternative C1: Previously Applied AMMM Measures, and Sub-alternative C2: Previously Applied and Not Previously Applied AMMM Measures. The analysis for Sub-alternative C1 is presented as the change in impacts from those impacts discussed under Alterative B, and the analysis for Sub-alternative C2 is presented as the change from Sub-alternative C1. Refer to Table G-1 in Appendix G, *Mitigation and Monitoring*, for a complete description of AMMM measures that make up the Proposed Action.

3.4.2.5.1 Sub-Alternative C1 (Preferred Alternative): Previously Applied AMMM Measures

Sub-alternative C1 analyzes the AMMM measures that BOEM has required as conditions of approval for previous activities proposed by lessees in COPs submitted for the Atlantic OCS or through related consultations (Table 3.4.2-7).

Table 3.4.2-7. Summary of previously applied avoidance, minimization, mitigation, and monitoring measures for water quality

Measure ID	Measure Summary
WQ-1	This measure would require lessees avoid using zinc sacrificial anodes on external components of WTG and OSS foundations to reduce the release of metal contaminants in the water column.
WQ-2	This measure proposes lessees submit an Oil Spill Response Plan (33 U.S.C. 1321) subject to BSEE review and approval that would contain information regarding facility location, oil type, notification procedures, clean-up equipment, sensitive resources at risk, and other information.
MUL-1	This measure proposes training, recovery, prevention, and reporting to reduce and eliminate trash and debris in order to reduce impacts from entanglement, ingestion, smothering of benthic species, and pollutants in the water column.
MUL-2	This measure proposes submittal and implementation of an anchoring plan to reduce impacts from turbidity and avoid anchor placement in sensitive habitats, including hardbottom and structurally complex habitats, as well as any known or potential cultural resources.

Impacts of One Project

AMMM measures are intended to minimize marine debris emanating from project vessels and shoreline activities, turbidity resulting from anchoring, and sediment disturbance. Identification of AMMM measures under Sub-alternative C1 could minimize some impacts on accidental releases and anchoring. Impacts for other IPFs would remain the same as described under Alternative B.

Accidental releases: MUL-1 would potentially reduce water quality impacts because there would theoretically be a reduced amount of trash and debris entering the water, and therefore fewer pollutants that could have negative impacts on water quality. WQ-1 would reduce the potential for water quality impacts from the release of metal contaminants into the water column by avoiding the use of zinc sacrificial anodes on WTG and OSS foundations. WQ-2 would require lessees prepare an Oil Spill Response Plan subject to BSEE review, which would minimize the potential effects from accidental oil spills by ensuring spills are cleaned up effectively and in a timely manner.

Anchoring: MUL-2 would require an Anchoring Plan, which could minimize sediment disturbance and the related turbidity through the use of anchor chain midline buoys to prevent cable sweep as well as not side-casting materials during cable emplacement, thereby reducing turbidity impacts on water quality.

Impacts of Six Projects

Identification of the AMMM measures for six NY Bight projects would have greater benefits to the overall water quality from NY Bight project activities than measures for one NY Bight project by minimizing local water quality impacts from turbidity, debris, and discharges due to the potential larger geographic area where impacts on water quality would be reduced. The potential impacts on water quality for six NY Bight projects under Sub-alternative C1 compared to six NY Bight projects under Alternative B are not anticipated to be substantially different.

Cumulative Impacts of Sub-Alternative C1 (Preferred Alternative)

Under Sub-alternative C1, the same ongoing and planned non-offshore-wind and offshore wind activities that would occur with Alternative B would continue to contribute to the primary IPFs of accidental releases, anchoring, cable emplacement and maintenance, port utilization, presence of structures, discharges/intakes, and land disturbance. Impacts on water quality are anticipated to be the same as described under Alternative B for six NY Bight projects with reduction through AMMM measures by minimizing local water quality impacts from turbidity, debris, and discharges. In context of reasonably foreseeable environmental trends, the impacts contributed by Sub-alternative C1 to the cumulative impacts on water quality would be undetectable. Impacts would remain minor for all IPFs, except for a large accidental release, which would remain moderate.

3.4.2.5.2 Sub-Alternative C2: Previously Applied and Not Previously Applied AMMM Measures

Sub-alternative C2 analyzes the AMMM measures under Sub-alternative C1 plus the AMMM measures that have not been previously applied. However, BOEM has not identified AMMM measures that have not been previously applied for water quality, and therefore, the impacts on water quality under Sub-alternative C2 are the same as Sub-alternative C1.

3.4.2.5.3 Conclusions

Impacts of Alternative C. AMMM measures would reduce impacts from trash and debris, anchoring, and sediment disturbance under Sub-alternative C1. However, these reductions likely would not alter the impact rating from Alternative B for either one NY Bight project or six NY Bight projects (**negligible** to **minor**; **moderate** for a large spill). Because no not previously applied AMMM measures were identified under Sub-alternative C2 impacts would remain the same as Sub-alternative C1 for both one and six NY Bight projects.

Cumulative Impacts of Alternative C. BOEM anticipates that the cumulative impacts for six NY Bight projects on water quality in the geographic analysis area would likely be **negligible** to **minor**, depending on the IPF, with the unlikely event of a large accidental release potentially causing a **moderate** impact. In context of reasonably foreseeable environmental trends, the impacts contributed by Sub-alternative C1 to the cumulative impacts on water quality would be undetectable. The identification of AMMM measures that would have otherwise not been implemented under Alternative B would not alter the impact rating. Because no not previously applied AMMM measures were identified under Sub-alternative C2, impacts would remain the same as Sub-alternative C1.

3.4.2.6 Recommended Practices for Consideration at the Project-Specific Stage

In addition to the AMMM measures identified under Sub-alternatives C1 and C2, BOEM is recommending lessees consider analyzing the RPs in Table 3.4.2-8 to further reduce potential water quality impacts. Refer to Table G-2 in Appendix G for a complete description of the RPs.

Table 3.4.2-8. Recommended Practices for water quality impacts and related benefits

Recommended Practice	Potential Benefit
MUL-21: Use or upgrade/retrofit to the best available technology, including new and emerging technology, when possible, which may include using closed-loop cooling systems.	A closed-loop subsea cooler system is an emerging technology, that, if applied, would not involve the intake or discharge of seawater, potentially reducing the potential effects from this IPF.
MUL-27: Employ methods to minimize sediment disturbance.	The impacts from turbidity through the use of anchor chain midline buoys to prevent cable sweep, as well as not side-casting materials during cable emplacement, could reduce turbidity impacts on water quality.
MUL-28: Develop an *Inadvertent Returns Plan*, and details preferred drilling solutions and methods.	This RP would potentially reduce pollutant impacts on water quality, as an *Inadvertent Returns Plan* would address prevention, control, and cleanup of potential inadvertent return and would avoid discharging drilling fluids onto the seabed.

3.5 Biological Resources

3.5.1 Bats

This section discusses potential impacts on bat resources from the Proposed Action, alternatives, and ongoing and planned activities in the geographic analysis area. The bat geographic analysis area, as shown on Figure 3.5.1-1, includes the United States coastline from Maine to Florida and extends 100 miles (161 kilometers) offshore and 5 miles (8 kilometers) inland to capture the movement range for species in this group. The offshore limit was established to capture the migratory movement of most species in this group, while the onshore limits cover onshore habitats used by species that may be affected by onshore and offshore components of the NY Bight projects.

The bat impact analysis in this PEIS is intended to be incorporated by reference into the project-specific environmental analyses for individual COPs expected for each of the NY Bight lease areas. Because the locations of onshore components for the NY Bight projects are not known at this time, the analysis of onshore bat impacts is dependent on a hypothetical project analysis, and impact conclusions consider a maximum-case scenario for onshore development. Additional detailed site-specific analysis will be required for individual COPs. Refer to Appendix C, *Tiering Guidance*, which identifies additional analyses anticipated to be required for the project-specific environmental analysis of individual COPs.

3.5.1.1 Description of the Affected Environment and Future Baseline Conditions

The number of bat species in the geographic analysis area varies by state, ranging from 8 species (Rhode Island, New Hampshire, and Maine) to 17 (Virginia and North Carolina) (Rhode Island Department of Environmental Management n.d.; Maine Department of Inland Fisheries and Wildlife 2021; New Hampshire Fish and Game n.d.; Virginia Department of Wildlife Resources 2021; North Carolina Wildlife Resources Commission 2017). There are 9 bat species present in New Jersey and New York, 8 of which may be present in coastal New Jersey and New York, and 6 that are year-round residents (Table 3.5.1-1) (NYSDEC n.d.; Maslo, B., Leu, K., 2013).

Bats are terrestrial species that spend almost their entire lives on or over land. Bat species can be broken down into cave-hibernating bats and migratory tree bats based on their wintering strategy. Both groups are nocturnal insectivores that use a variety of forested and open habitats for foraging during the summer. Migratory tree bats fly to southern parts of the United States in the winter. On occasion, migratory tree bats may potentially occur offshore during spring and fall migration and under very specific conditions like low wind and high temperatures. Recent studies, combined with historical anecdotal accounts, indicate that migratory tree bats periodically travel offshore during spring and fall migration, with 80 percent of acoustic detections occurring in August and September (Dowling et al. 2017; Hatch et al. 2013; Pelletier et al. 2013; Stantec 2016). However, unlike migratory tree bats, the likelihood of detecting a *Myotis* species or other cave bat is substantially less in offshore areas, including at distances of lease areas on the OCS (Pelletier et al. 2013).

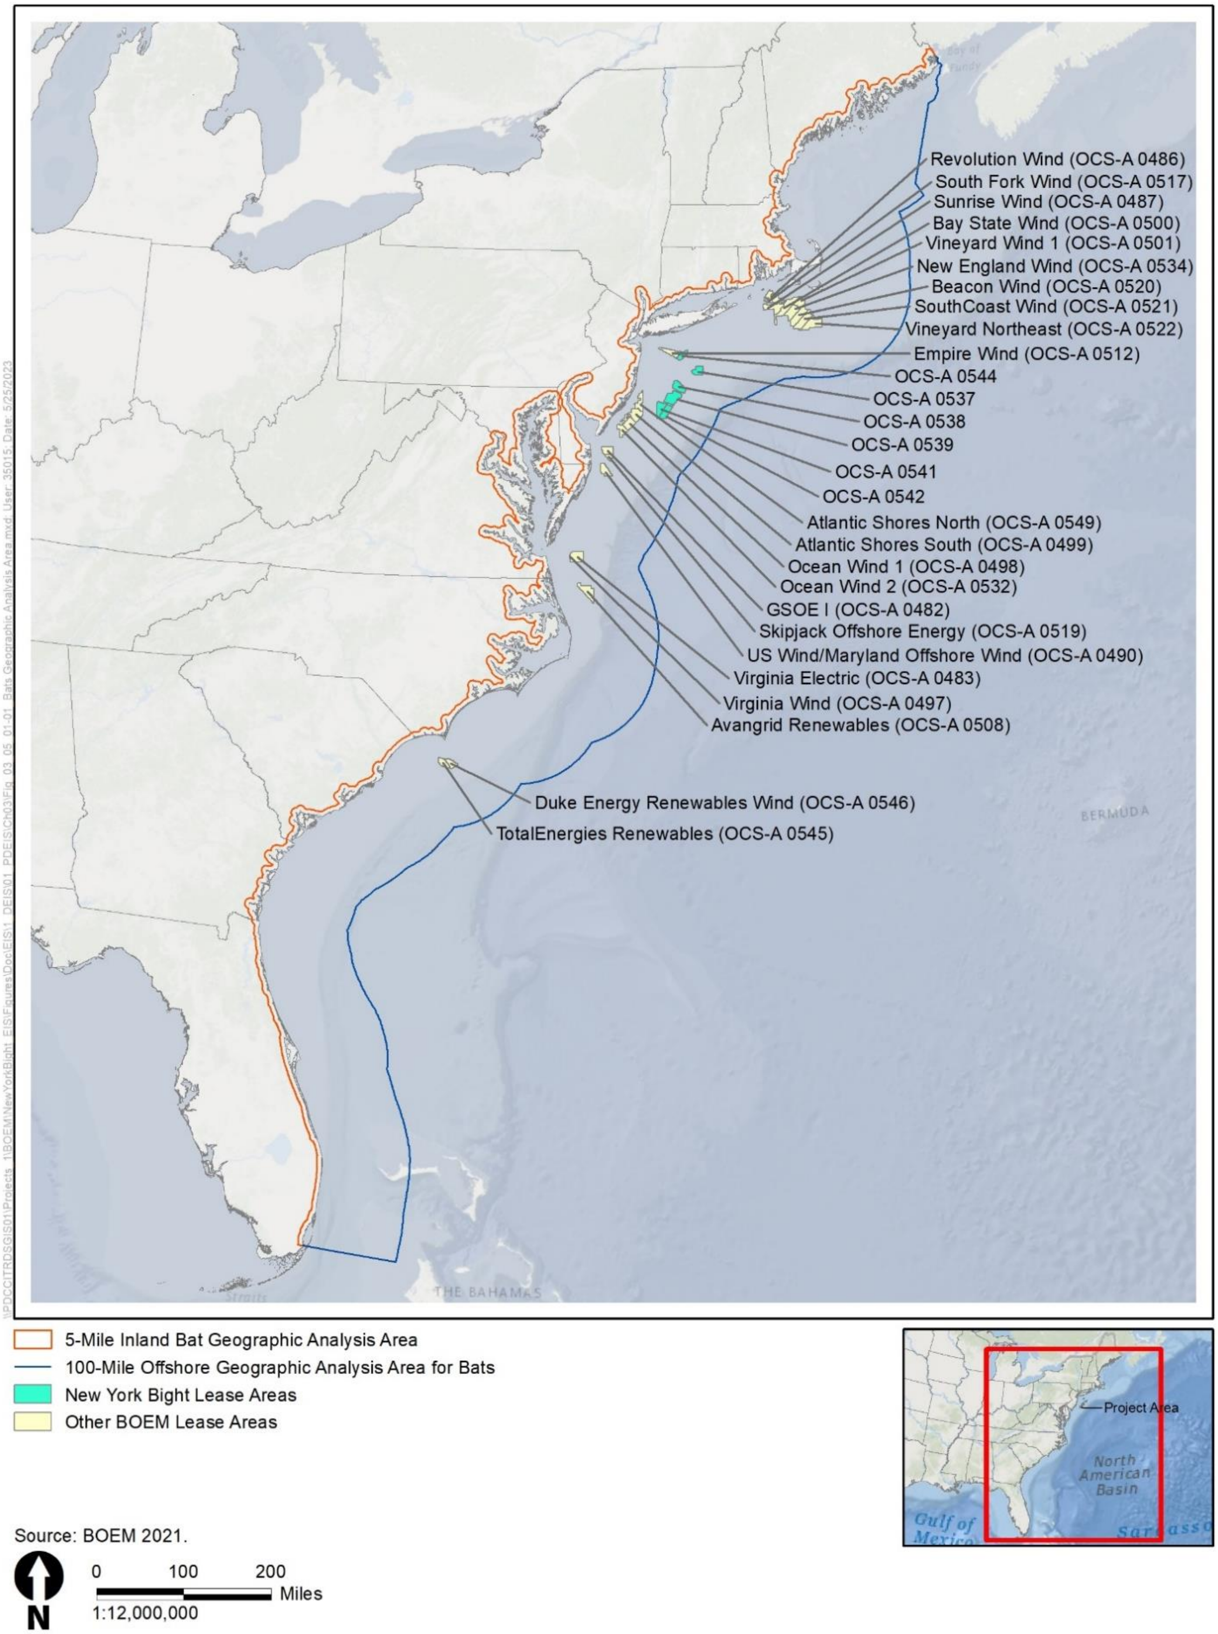

Figure 3.5.1-1. Bats geographic analysis area

Table 3.5.1-1. Bats present in New Jersey and New York and their conservation status

Common Name	Scientific Name	NY Status	NJ Status	Federal Status
Cave-Hibernating Bats				
Eastern small-footed bat[1]	*Myotis leibii*	Species of Concern	--	--
Little brown bat[1]	*Myotis lucifugus*	Species of Greatest Conservation Need	--	Under Review[3]
Northern long-eared bat[1, 2]	*Myotis septentrionalis*	Endangered	Endangered	Endangered
Indiana bat[4]	*Myotis sodalis*	Endangered	Endangered	Endangered

Hoary bat[5]	*Lasiurus cinereus*	--	--	--
Silver-haired bat[5]	*Lasionycteris noctivagans*	--	--	--

Source: USFWS 2021

[1] Currently a candidate for state listing as endangered pending rule promulgation (NJDEP 2013).

[2] On November 29, 2022, USFWS announced its intention to reclassify the northern long-eared bat as endangered. The new rule pertaining to the further conservation of the species took effect on March 31, 2023.

[3] Currently under a USFWS discretionary status review. Results of the review may be to propose listing, make a species a candidate for listing, provide notice of a not warranted candidate assessment, or other action as appropriate.

[4] Range does not indicate species presence in coastal New Jersey and New York.

[5] Currently a candidate for New Jersey state listing as special concern pending rule promulgation (NJDEP 2013).

The presence of bats has been documented in the offshore marine environment in the United States (Cryan and Brown 2007; Dowling et al. 2017; Hatch et al. 2013; Pelletier et al. 2013). Bats have been documented temporarily roosting on structures (i.e., lighthouses) on nearshore islands and there is evidence of eastern red bats migrating offshore in the Atlantic. In a Mid-Atlantic bat acoustic study conducted for a total of 86 nights during the spring and fall of 2009 and 2010, the maximum distance that bats were detected from shore was 13.6 miles (21.9 kilometers) and the mean distance was 5.2 miles (8.4 kilometers) (Sjollema et al. 2014). In Maine, bats were detected on islands up to 25.8 miles (41.6 kilometers) from the mainland (Peterson et al. 2014). In the Mid-Atlantic acoustic study, eastern red bats represented 78 percent of all bat detections offshore and bat activity decreased as wind increased (Sjollema et al. 2014). In addition, eastern red bats were detected in the Mid-Atlantic up to 27.3 miles (44 kilometers) offshore by high-definition video aerial surveys (Hatch et al. 2013).

The available data indicates that bat activity levels are generally lower offshore compared to onshore (Hein et al. 2021). A bat migration study in the North Sea off Belgium found that the number of bat detections was up to 24 times lower at offshore locations compared to the onshore locations (Brabant et al. 2021). During shipboard acoustic surveys conducted by Stantec in 2017 at the operational Block Island Wind Farm in Rhode Island, 911 bat passes were detected offshore. Bats were detected during 41 of 125 (33 percent) survey nights (Stantec 2018). The overall bat detection rate (passes/detector night) was 7.3, with up to 190 passes recorded during a single night. In addition, USDOE funded an acoustic survey of bat activity offshore and at coastal sites (onshore mainland locations on and near the shoreline) in the New England Gulf of Maine, mid-Atlantic coast, and Great Lakes regions from 2012–2014 (Stantec 2016). This was a very large survey effort across a wide area that detected a total of

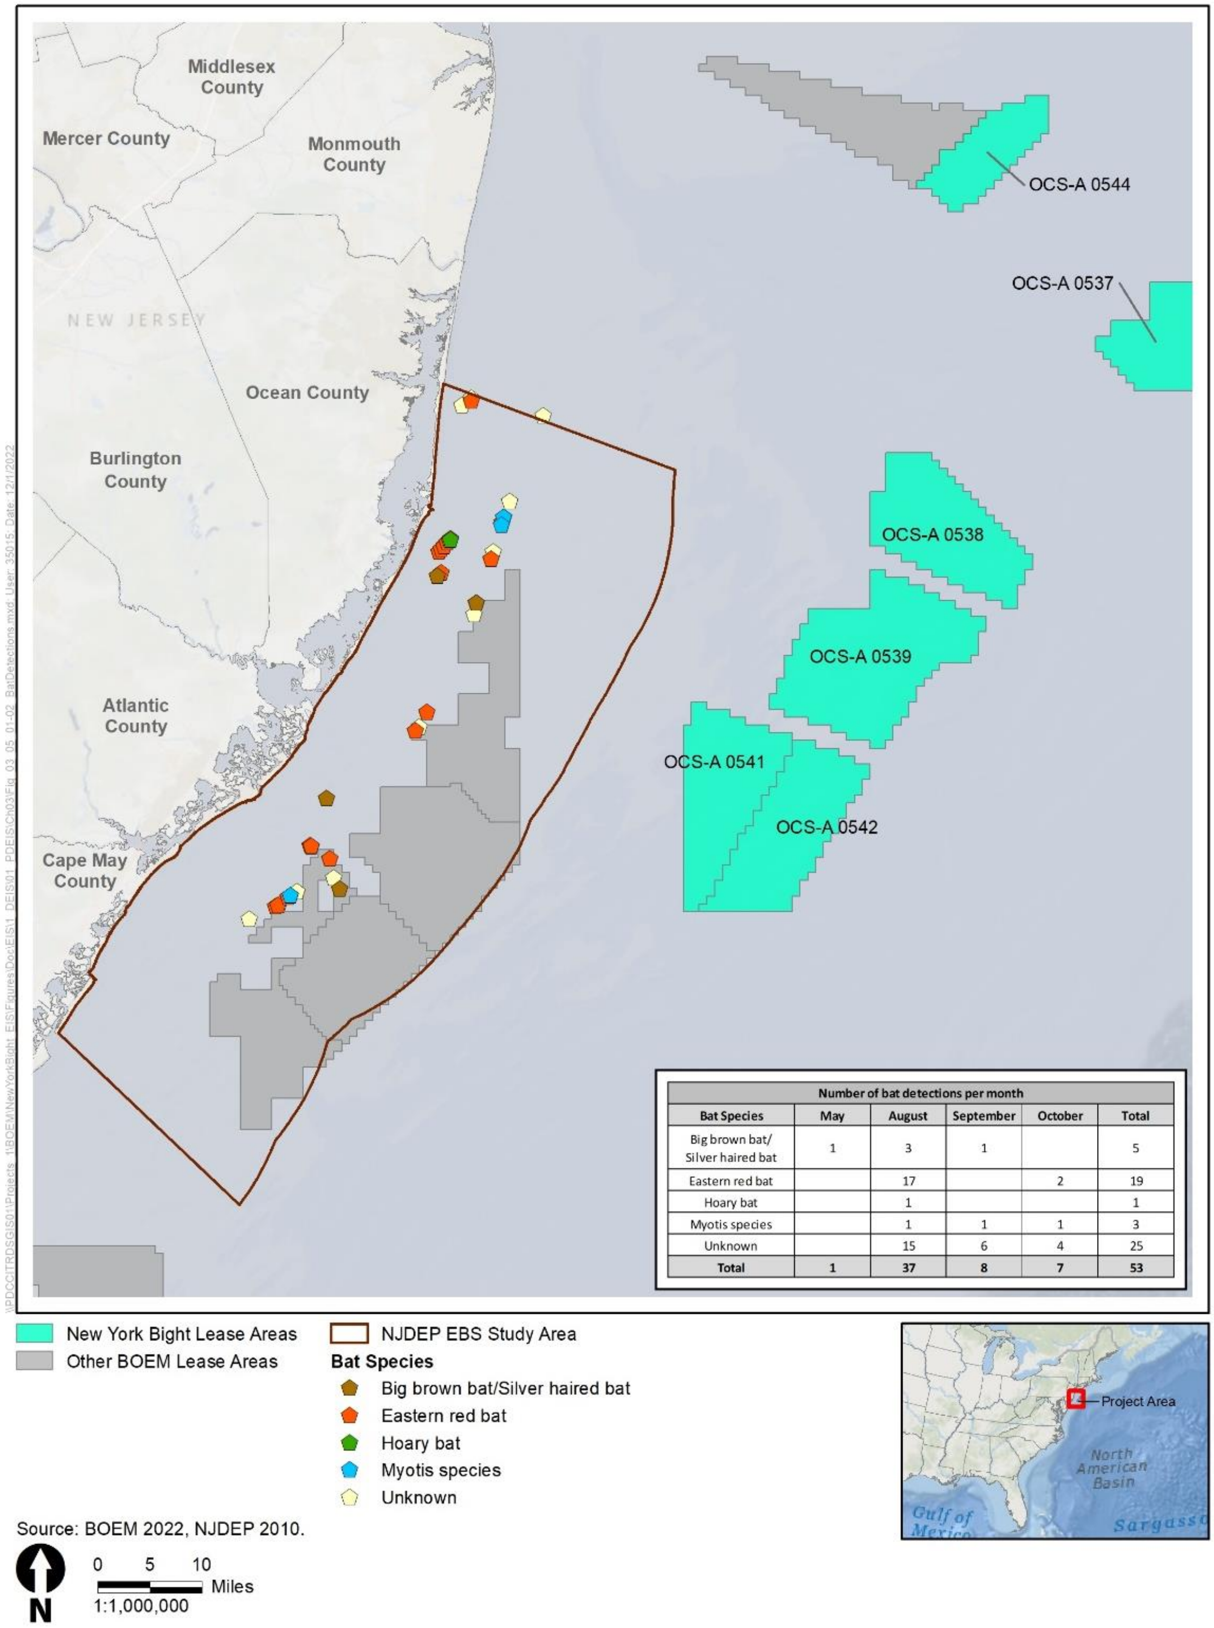
565,158 bat passes during a total of 17,730 detector nights. The mean number of bat passes per night in offshore open water was 4.96, while the number of bat passes per night for coastal onshore was significantly higher at 112.6. Surveys also found that 90 percent of bat passes occurred at times when wind speeds were below 5.0 m/s and temperatures were at or above 15.0 degrees Celsius (Stantec 2018).

Cave-hibernating bats hibernate regionally in caves, mines, and other structures and feed primarily on insects in terrestrial and freshwater habitats. These species generally exhibit lower activity in the offshore environment than the migratory tree bats (Sjollema et al. 2014), with movements primarily during the fall. In the Mid-Atlantic, the maximum distance *Myotis* bats were detected offshore was 7.2 miles (11.5 kilometers) (Sjollema et al. 2014). A recent nano-tracking study on Martha's Vineyard recorded little brown bat movements off the island in late August and early September, with one individual flying from Martha's Vineyard to Cape Cod (Dowling et al. 2017). Big brown bats were also detected migrating from the island later in the year (October–November) (Dowling et al. 2017). These findings are supported by an acoustic study conducted on islands and buoys off the Gulf of Maine that indicated the greatest percentage of activity was in July–October (Peterson et al. 2014). Given that the use of the coastline as a migratory pathway by cave-hibernating bats is likely limited to their fall migration period, that acoustic studies indicate lower use of the offshore environment by cave-hibernating bats, and that cave-hibernating bats do not regularly feed on insects over the ocean, exposure to the NY Bight lease areas is unlikely for this group.

Tree bats migrate south to overwinter and have been documented in the offshore environment (Hatch et al. 2013). Eastern red bats have been detected migrating from Martha's Vineyard late in the fall, with one bat tracked as far south as Maryland (Dowling et al. 2017). These results are supported by historical observations of eastern red bats offshore and recent acoustic and survey results (Hatch et al. 2013; Peterson et al. 2014; Sjollema et al. 2014). While little data is available throughout all six NY Bight lease areas, there is some bat data collected by NYSERDA in Lease Areas OCS-A 0537 and OCS-A 0539. NYSERDA remote metocean data from one buoy (latitude 39.9692, longitude -72.7166) in NY Bight Lease Area OCS-A 0537 and one buoy (latitude 39.54677, longitude -73.4292) in NY Bight Lease Area OCS-A 0539 detected nine silver-haired bats and one unknown low-frequency bat between September 2019 and September 2022 (NYSERDA 2022). The buoy in Lease Area OCS-A 0539 detected three bats in September/October 2019 and no bats for the remaining years. The buoy in Lease Area OCS-A 0537 detected three bats in September 2019, one bat in August 2020, and two bats in October 2020; no bats were detected in the remaining time frame.

Closer to the New Jersey coast, and outside of the NY Bight lease areas, the NJDEP Ecological Baseline Studies (EBS) surveys recorded several observations of bats flying over the ocean (NJDEP 2010), with observations of migratory tree bats in the near-shore portion of the Ocean Wind 1 and Atlantic Shores North project lease areas off of New Jersey (Figure 3.5.1-2). In addition to the NJDEP EBS survey data, offshore acoustic bat surveys were conducted in 2020 and 2021 in Lease Area OCS-A 0499 (Atlantic Shores South), which is near the southern end of the NY Bight lease areas (Atlantic Shores 2022). Eastern red bat represented the most detections (495), followed by big brown/silver-haired bat group (478), silver-haired bat (80), hoary bat (37), big brown bat (26), tri-colored bat (5), and *Myotis* spp. (3). Overall, 1,124 total bat detections were identified to species or species group across the 180 survey nights in the Lease Area OCS-A 0499. This averages to 6.2 bat detections per detector-night, which is a small fraction of bat passage rates typically found onshore during migration in eastern North America. For a nearby onshore comparison, Johnson et al. (2011) found bat activity along the coast of Maryland to average 25 passes per detector-night over the span of an entire year. During fall migration, the number of bat passes there commonly exceeded 500 per detector-night and peaked around 1,000 (Johnson et al. 2011), compared to an average of only 6.2 bat passes per night in Lease Area OCS-A 0499 during a similar time of year. Further, recent offshore acoustic surveys recorded bats within Lease Area OCS-A 0512 (Empire Wind project; adjacent to one of the NY Bight lease areas), with observations primarily composed of eastern red bats and silver-haired bats, concentrated during fall migration. Big brown bats were documented infrequently in Lease Area OCS-A 0512, and hoary bats were also detected in the offshore environment, but closer to shore and not within Lease Area OCS-A 0512. Given that tree bats have been detected in the offshore environment, they may pass through the NY Bight lease areas during the migration period, although BOEM would anticipate even lower bat use of the NY Bight lease areas because these areas are even farther offshore on the OCS than the NJDEP EBS survey area, Atlantic Shores South, and Empire Wind survey area (as shown by the NYSERDA buoy data).

Onshore coastal areas throughout the geographic analysis area provide a variety of habitats that support a diversity of bat species. The New Jersey coast, where potential onshore export cables for the NY Bight lease areas would be constructed and operated, consists of a diverse set of habitats including coastal wetlands, forested wetlands, forested uplands, forested lowlands, barrier beaches, and bay island habitats that can support a diversity of bat species. Forested habitats can provide roosting areas for both migratory and non-migratory species. All bat species present in New Jersey (migratory and non-migratory) are known to utilize forested areas (of varying types) during summer for roosting and foraging. Some of these species roost solely in the foliage of trees, while others select dead and dying trees where they roost in peeling bark or inside crevices. Some species may select forest interior sites, while others prefer edge habitats. Caves and mines provide key habitat for non-migratory bats. These locations serve as winter hibernacula, fall swarm locations (areas where mating takes place in the fall months), and summer roosting locations for some individuals. Hibernacula are documented in New Jersey, but the numbers of individuals at the sites have declined dramatically because of the fungal disease white-nose syndrome (WNS) (New Jersey Division of Fish and Wildlife 2017). Overall, while both cave-hibernating and migratory tree bats may occur along the New Jersey coast, BOEM anticipates the onshore export cables to be mostly co-located with existing disturbed areas (e.g., roads, transmission lines) and substations and other facilities to be sited in previously disturbed areas.



Number of bat detections per month					
Bat Species	May	August	September	October	Total
Big brown bat/ Silver haired bat	1	3	1		5
Eastern red bat		17		2	19
Hoary bat		1			1
Myotis species		1	1	1	3
Unknown		15	6	4	25
Total	**1**	**37**	**8**	**7**	**53**

Figure 3.5.1-2. Bat occurrences in the NJDEP EBS

The New York coast, where potential onshore export cables could be constructed and operated for the NY Bight projects, consists primarily of highly urbanized environments and existing infrastructure with few natural habitat areas. Areas of New York City (e.g., the boroughs of Brooklyn and Queens) are highly developed with commercial, industrial, and residential development and are expected to provide little, if any, bat habitat. East of Queens, Long Island is still highly developed as part of the greater New York City metropolitan area, but more natural areas are present moving eastward, with isolated areas of shrub and forest habitats with little connectivity to larger habitat areas. These habitats may support bats for foraging and roosting during summer (i.e., foliage trees, dead and dying trees with peeling bark and crevices), but these areas are not expected to be important habitat for any species because they are typically isolated by surrounding developments. Hibernacula are documented in New York, but the numbers of individuals at the sites have declined dramatically because of WNS (Ingersoll et al. 2016; New Jersey Division of Fish and Wildlife 2017). Since 2011, WNS has substantially reduced *Myotis* bat populations in New York (New Jersey Division of Fish and Wildlife 2017). Therefore, the presence of both cave-hibernating and migratory tree bats that may occur along the western Long Island coast is expected to be minimal.

One bat species protected under the ESA may occur in the area where the NY Bight lease areas' onshore wind project components would likely be sited: the northern long-eared bat (USFWS 2021). It is not expected that northern long-eared bats will be present in the NY Bight lease areas themselves. A 2016 tracking study on Martha's Vineyard (July–October 2016) did not record any offshore movements (Dowling et al. 2017). If northern long-eared bats were to migrate over water, movements would likely be close to the mainland. The related little brown bat has been documented to migrate from Martha's Vineyard to Cape Cod, and northern long-eared bat may likewise migrate to mainland hibernacula from these islands in August–September (Dowling et al. 2017). Given that there is little evidence of use of the offshore environment by northern long-eared bats, exposure to the NY Bight lease areas, if it occurs, is anticipated to be minimal. On June 20, 2024, BOEM initiated consultation with the USFWS on a Programmatic Framework ESA Section 7 consultation.

Cave bat species, including the northern long-eared bat, are experiencing drastic declines due to WNS. WNS has been confirmed present in every state in the geographic analysis area, except Florida (Whitenosesyndrome.org 2021). WNS was confirmed present in New York in 2006 and has killed large numbers of cave bats during hibernation—more than 90 percent at many sites (Whitenosesyndrome.org 2021). WNS was confirmed present in New Jersey in 2009 and, as in New York, has killed large numbers of cave bats during hibernation—more than 90 percent at many sites (Whitenosesyndrome.org 2021; New Jersey Division of Fish and Wildlife 2019). However, New Jersey's bat population appears to be stabilizing (New Jersey Division of Fish and Wildlife 2019). Development of the NY Bight lease areas, including onshore wind components (e.g., export cables) have the potential to affect cave bat populations already affected by WNS. The unprecedented mortality of more than 5.5 million bats in northeastern North America as of 2015 reduces the likelihood of many individuals being present within the onshore project area (USFWS 2015). However, given the drastic reduction in cave bat populations in the region, the biological significance of mortality resulting from offshore wind projects in the NY Bight lease areas, if any, may be increased.

3.5.1.2 Impact Level Definitions for Bats

Definitions of impact levels are provided in Table 3.5.1-2. Issues and indicators to assess impacts on bats are described using the definitions described in the Table 3.5.1-3.

Table 3.5.1-2. Impact level definitions for bats

Impact Level	Definition
Negligible	There would be no measurable impacts, or impacts would be so small that it is extremely difficult or impossible to discern or measure.
Minor	Most impacts could be avoided; if impacts occur, the loss of one or few individuals or temporary alteration of habitat could represent a minor impact, depending on the time of year and number of individuals involved.
Moderate	Impacts are unavoidable but would not result in population-level effects or threaten overall habitat function.
Major	Impacts would result in severe, long-term habitat or population-level effects on species.

Land disturbance, noise, and presence and operation and conceptual decommissioning of structures are contributing IPFs to impacts on bats. However, these IPFs may not necessarily contribute to each individual issue outlined in Table 3.5.1-3.

Table 3.5.1-3. Issues and indicators to assess impacts on bats

Issue	Impact Indicator
Collision/attraction	Qualitative estimate of collision risk
Displacement/barrier effects/disturbance	Changes to noise levels Projected traffic patterns/volume changes
Habitat loss and modification	Area of suitable habitat removed or modified

3.5.1.3 Impacts of Alternative A – No Action – Bats

When analyzing the impacts of the No Action Alternative on bats, BOEM considered the impacts of ongoing activities, including ongoing non-offshore-wind and ongoing offshore wind activities on the baseline conditions for bats. The cumulative impacts of the No Action Alternative considered the impacts of the No Action Alternative in combination with the other planned non-offshore-wind and offshore wind activities, as described in Appendix D, *Planned Activities Scenario*. Separate impact conclusions are presented for both scenarios.

3.5.1.3.1 Impacts of the No Action Alternative

Under Alternative A, baseline conditions for bats described in Section 3.5.1.1, *Description of the Affected Environment and Future Baseline Conditions*, would continue to follow current regional trends and respond to IPFs introduced by other ongoing activities. Ongoing activities within the geographic analysis area that contribute to impacts on bats are generally associated with onshore construction and climate change. Onshore construction activities and associated impacts are expected to continue at current trends and have the potential to affect bat species through temporary and permanent habitat removal and temporary noise impacts, which could cause avoidance behavior and displacement. Mortality of individual bats could occur, but population-level effects would not be anticipated. Impacts associated with climate change have the potential to reduce reproductive output and increase individual mortality and disease occurrence.

Ongoing offshore wind activities within the geographic analysis area that contribute to impacts on bats are listed in Table 3.5.1-4. The effects of approved projects have been evaluated through previous NEPA review and are incorporated by reference. Ongoing O&M of the Block Island and Coastal Virginia Offshore Wind Pilot projects and ongoing construction of the Vineyard Wind 1 (OCS-A 0501), South Fork Wind (OCS-A 0517), Ocean Wind 1 (OCS-A 0498),Revolution Wind (OCS-A 0486), Sunrise Wind (OCS-A 0487), New England Wind (OCS-A 0534) Phase 1 and 2, Empire Wind (OCS-A 0512) 1 and 2, and CVOW-Commercial (OCS-A 0483) projects would affect bats through the primary IPFs of noise, presence of structures, and land disturbance. Ongoing offshore wind activities would have the same types of impacts from noise, presence of structures, and land disturbance that are described in detail in Section 3.5.1.3.3, *Cumulative Impacts of the No Action Alternative,* for planned offshore wind activities, but the impacts would be of lower intensity.

3.5.1.3.2 Impacts of the No Action Alternative on ESA-Listed Bats

The federally endangered northern long-eared bat is the only bat species listed as threatened or endangered under the ESA that may be affected by offshore wind activities. As described below, northern long-eared bats are not expected to use the OCS in any significant numbers, if at all. The IPFs described previously for all bats would also apply to the northern long-eared bat. Any future federal activities that could affect the northern long-eared bat would need to comply with ESA Section 7 to ensure that proposed activities do not jeopardize the continued existence of the species. Future non-federal activities would be addressed under ESA Section 10 to ensure that proposed activities do not jeopardize the continued existence of the species.

3.5.1.3.3 Cumulative Impacts of the No Action Alternative

The cumulative impact analysis for the No Action Alternative considers the impact of the No Action Alternative in combination with other planned non-offshore-wind activities and planned offshore wind activities (without the NY Bight projects). Table 3.5.1-4 lists the ongoing and planned offshore wind activities in the geographic analysis area for bats.

Table 3.5.1-4. Ongoing and planned offshore wind in the geographic analysis area for bats

Ongoing/Planned	Projects by Region
Ongoing – 12 projects[1] 	**MA/RI** • Block Island (State waters) • Vineyard Wind 1 (OCS-A 0501) • Revolution Wind (O CS-A 0486) • South Fork Wind (OCS-A 0517) • Sunrise Wind (OCS-A 0487) • New England Wind (OCS-A 0534) Phase 1 • New England Wind (OCS-A 0534) Phase 2

Ongoing/Planned	Projects by Region
	NY/NJ • Ocean Wind 1 (OCS-A 0498) • Empire Wind 1 (OCS-A 0512) • Empire Wind 2 (OCS-A 0512) **VA/NC** • CVOW-Pilot (OCS-A 0497) • CVOW-Commercial (OCS-A 0483)
Planned – 18 projects[2] 	**MA/RI** • SouthCoast Wind (OCS-A 0521) • Beacon Wind 1 (OCS-A 0520) • Beacon Wind 2 (OCS-A 0520) • Bay State Wind (OCS-A 0500) • OCS-A 0500 remainder • OCS-A 0487 remainder • Vineyard Wind Northeast (OCS-A 0522) **NY/NJ** • Ocean Wind 2 (OCS-A 0532) • Atlantic Shores North (OCS-A 0549) • Atlantic Shores South (OCS-A 0499) **DE/MD** • Skipjack (OCS-A 0519) • US Wind/Maryland Offshore Wind (OCS-A 0490) • GSOE I (OCS-A 0482) • OCS-A 0519 remainder **VA/NC** • Kitty Hawk North (OCS-A 0508) • Kitty Hawk South (OCS-A 0508) **SC** • Duke Energy Renewables Wind (OCS-A 0546) • TotalEnergies Renewables (OCS-A 0545)

CVOW = Coastal Virginia Offshore Wind; DE = Delaware; GSOE = Garden State Offshore Energy; MA = Massachusetts; MD = Maryland; NC = North Carolina; NJ = New Jersey; NY = New York; RI = Rhode Island; SC = South Carolina; VA = Virginia

[1] Refer to footnotes 9 and 10 in PEIS Chapter 1 for additional information on the status of Ocean Wind 1, Empire Wind 1, and Empire Wind 2.

[2] Status as of September 20, 2024.

Other planned non-offshore-wind activities that may affect bats include new submarine cables, transmission systems (e.g., PBI) and pipelines, oil and gas activities, increasing onshore construction, marine minerals extraction, port expansions, and installation of new structures on the OCS (see Appendix D for a description of planned activities). These activities may result in temporary or permanent displacement and injury or mortality to individual bats, but population-level effects would not be expected.

The sections below summarize the potential impacts of other offshore wind activities on bats during construction and installation, O&M, and conceptual decommissioning of the projects. The federally listed northern long-eared bat is the only bat species listed under the ESA that may be affected by other offshore wind activities. Impacts on the northern long-eared bat would most likely be limited to onshore impacts, and generally during onshore facility construction.

Noise: Anthropogenic noise on the OCS associated with planned offshore wind development, including noise from pile-driving and construction activities, has the potential to affect bats on the OCS. Additionally, onshore construction noise has the potential to affect bats. BOEM anticipates that these impacts would be temporary and highly localized.

The construction of 1,682 WTGs and 48 OSSs associated with planned offshore wind projects on the Atlantic OCS would create noise and may temporarily affect some migrating tree bats, if conducted at night during spring or fall migration. The greatest impact of noise is likely to be caused by pile-driving activities during construction. Noise from pile-driving would likely occur during installation of foundations for offshore structures at a typical frequency of 4 to 6 hours at a time during construction. Construction activity would be temporary and highly localized. Auditory impacts are not expected to occur, as recent research has shown that bats may be less sensitive to temporary threshold shifts (TTS) than other terrestrial mammals (Simmons et al. 2016). Offshore habitat-related impacts (i.e., displacement from potentially suitable habitats) could occur as a result of construction activities, which could generate noise sufficient to cause avoidance behavior by individual migrating tree bats (Schaub et al. 2008). These impacts would likely be limited to behavioral avoidance of pile-driving or construction activity, and no temporary or permanent hearing loss would be expected (Simmons et al. 2016). However, these impacts are highly unlikely to occur, as use of the OCS by bats is limited, and only during spring and fall migration.

Some potential for temporary, localized habitat impacts arising from onshore construction noise exists; however, no auditory impacts on bats would be expected to occur. Recent literature suggests that bats are less susceptible to temporary or permanent hearing loss from exposure to intense sounds (Simmons et al. 2016). Nighttime work may be required on an as-needed basis. Some temporary displacement or avoidance of potentially suitable foraging habitat could occur, but these impacts would not be expected to be biologically significant. Some bats roosting in the vicinity of construction activities may be disturbed during construction but would be expected to move to a different roost farther from construction noise. This would not be expected to result in any impacts, as frequent roost switching is common among bats (Hann et al. 2017; Whitaker 1998).

Non-routine activities associated with the offshore wind facilities would generally require intense, temporary activity to address emergency conditions. The noise made by onshore construction equipment or offshore repair vessels could temporarily deter bats from approaching the site of a given non-routine event. Impacts on bats, if any, would be temporary and last only as long as repair or remediation activities were necessary to address these non-routine events.

Given the temporary and localized nature of potential impacts and the expected biologically insignificant response to those impacts, no individual fitness or population-level impacts would be expected to occur as a result of onshore or offshore noise associated with planned offshore wind development.

Presence of structures: Ongoing and planned offshore wind-related activities would account for up to 2,459 WTGs and 66 OSSs in the geographic analysis area, and the presence of these structures could result in potential long-term effects on bats. Cave bats (including the federally listed northern long-eared bat) do not tend to fly offshore (even during fall migration), and, therefore, exposure to construction vessels during construction or maintenance activities, or the rotor-swept zone (RSZ) of operating WTGs in the offshore wind lease areas, is expected to be negligible, if exposure occurs at all (BOEM 2015; Pelletier et al. 2013).

As discussed above tree bats may occur in the offshore marine environment (Cryan and Brown 2007; Dowling et al. 2017; Hatch et al. 2013; Pelletier et al. 2013) and potentially pass through the offshore wind lease areas during the fall migration; however, bat activity levels are generally lower offshore compared to onshore (Hein et al. 2021, Brabant et al. 2021). The low presence of bats in the offshore environment of the Atlantic OCS is further supported by multi-year post-construction bat monitoring at the existing Block Island Wind Farm (five wind turbines offshore Block Island, Rhode Island) and the Coastal Virginia Offshore Wind Pilot (two turbines offshore Virginia), as well as lease-area-specific bat surveys (e.g., Atlantic Shores and Empire Wind). These monitoring and survey results are summarized below.

- **Block Island Wind Farm (Stantec 2020):** Three years of post-construction bat monitoring with bat detectors deployed for 1,808 calendar nights from August 3, 2017, to February 4, 2020. Collectively, the detectors operated successfully for 1,707 detector-nights, during which time 2,294 bat passes were detected. The overall bat detection rate during the survey period (passes/detector-night) was 1.3. Detection rates were highest during August and September, with no bat passes recorded from December through April. Eastern red bats and silver-haired bats accounted for a combined 76.5 percent of the passes. Big brown and hoary bats comprised the majority of the remaining passes. Two passes identified as little brown bats were plausible, but the monitoring report notes that these could have been fragments of eastern red bat call sequences. No northern long-eared bats were detected.

- **Coastal Virginia Offshore Wind Pilot (Dominion Energy 2022):** Post-construction monitoring occurred from April 1 to June 15, 2021 (spring season); August 15 to October 31, 2021 (fall season); and January 15 to March 15, 2022 (winter season). Across all bat detection sensors during the entire three season monitoring period, there were 521 detections of bats. Only two bat detections occurred in the spring, and the remaining 519 occurred in the fall (mostly in September); no bats were detected in the winter. The detection rate for the fall season was 6.6 bats per detector-day. Slightly over half (56 percent) of detections occurred when turbine blades were spinning, and bats avoided collisions while foraging within the RSZ using microavoidance behavior. Bats detected included the silver-haired bat, hoary bat, and eastern red bat. No federally or state listed bat species were detected during the survey period.

- **Lease Area OCS-A 0499 (Atlantic Shores South [Atlantic Shores 2022]):** Offshore acoustic bat surveys were conducted in the lease area in 2020 and 2021. Overall, there were 1,124 total bat detections identified to species or species group across the 180 survey nights. This averages to

6.2 bat detections per detector-night. Detections occurred from July to October, with peak activity in August and September, and the latest detection occurring on November 1. Eastern red bat represented the most detections (495), followed by big brown/silver-haired bat group (478), silver-haired bat (80), hoary bat (37), big brown bat (26), tri-colored bat (5), and *Myotis* spp. (3).

- **Lease Area OCS-A 0512 (Empire Wind [TetraTech 2022]):** Offshore acoustic bat surveys were conducted in the lease area in 2018. Overall, there were 584 total bat detections identified to species level or frequency group across 188 survey nights. This averages to 3.1 bat detections per detector-night. There was a minimum of zero passes and a maximum of 133 passes recorded in a single night. Eastern red bat represented the most detections (229) followed by silver-haired bat (184), unidentified high frequency bat (133), unidentified low frequency bat (21), and big brown bat (17). Detection rates were highest in early August through early November.

These bat survey data indicate that bat presence in the offshore environment is a small fraction of bat passage rates typically found onshore during migration in eastern North America. For a nearby onshore comparison, Johnson et al. (2011) found bat activity along the coast of Maryland to average 25 passes per detector-night over the span of an entire year. During fall migration, the number of bat passes there commonly exceeded 500 per detector-night and peaked around 1,000 (Johnson et al. 2011), compared to an average of only 1.3 for Block Island Wind Farm, 6.6 for Coastal Virginia Offshore Wind Pilot, 6.2 in Lease Area OCS-A 0499 (Atlantic Shores South), and 3.1 in Lease Area OCS-A 0512 (Empire Wind) during a similar time of year. As another comparison, a recent study farther inland, along Lake Erie, reported an average of 155 bat passes per detector-night during the fall migration period of 2020 (Haddaway and McGuire 2022). As such, while some bats may fly offshore during migration, they appear to represent a very small percentage of their species' total population onshore. In addition to ongoing monitoring of the Block Island Wind Farm and Coastal Virginia Offshore Wind Pilot (summarized above), the Vineyard Wind 1 and South Fork Wind Farm projects have post-construction requirements to monitor bat activity, which will provide additional information to developers and agencies on bat activities near wind farms and to help minimize bat impacts.

Based on recent bat survey data on the Atlantic OCS (as described above), the limited number of tree bat species that may encounter the operating WTGs in the offshore wind lease areas would likely be composed of the eastern red bat, hoary bat, big brown bats, and silver-haired bat. Offshore O&M would present a seasonal risk factor to migratory tree bats that may utilize the offshore habitats during fall migration. While some potential exists for migrating tree bats to encounter operating WTGs during fall migration, the overall occurrence of bats on the OCS is relatively very low (as previously described). Additionally, unlike with terrestrial migration routes, there are no landscape features that would concentrate bats and thereby increase exposure to the offshore wind lease areas. There is some evidence that bats could use offshore structures to provide shelter from adverse weather or to rest after a long flight (Solick and Newman 2021), which could increase exposure and risk of collision with turbine blades. While bats have been found roosting in the nacelles of turbines close to shore (3.6 miles [5.8 kilometers]) in the Baltic Sea (Ahlén et al. 2009), given the low presence of bats offshore of New York and New Jersey and the farther distance of offshore wind projects from shore in the geographic analysis area, the potential for bats to roost on WTGs is expected to be low.

Given the expected infrequent and limited use of the OCS by migrating tree bats, very few individuals would be expected to encounter operating WTGs or other structures associated with offshore wind development. Further, with the typical spacing between many structures associated with planned offshore wind development being 0.6 to 1 nautical mile (1.1 to 1.9 kilometers) and the distribution of anticipated projects, the limited number of individual bats migrating over the OCS within the RSZ of project WTGs would likely pass through projects with only slight course corrections, if any, to avoid operating WTGs (Baerwald and Barclay 2009; Cryan and Barclay 2009; Fiedler 2004; Hamilton 2012; Smith and McWilliams 2016). As seen with some birds (Masden et al. 2012; Peschko et al. 2021), wide spacing between WTG rows is expected to reduce barrier effects by providing bats ample space to fly through wind farms while staying far away from the nearest WTG. As such, BOEM expects that adverse impacts of additional energy expenditure due to course corrections to avoid WTGs are not expected to be biologically significant. Furthermore, the potential collision risk to migrating tree bats differs with climatic conditions; for example, bat activity is associated with relatively low wind speeds and warm temperatures (Arnett et al. 2008; Cryan and Brown 2007; Fiedler 2004; Kerns et al. 2005). Post-construction acoustic and video monitoring of bats at the Coastal Virginia Offshore Wind Pilot Project from the spring of 2021 through winter of 2022 found bat activity to decline with increasing wind speed and no video evidence of collisions with the WTGs (Dominion Energy 2022). Given the relatively low numbers of tree bats in the offshore environment, the wide spacing of WTGs, and the intermittence of projects, the likelihood of collisions is expected to be low; therefore, impacts on bats would be negligible. Additionally, the likelihood of a migrating individual encountering one or more operating WTGs during adverse weather conditions is extremely low, as bats onshore and offshore have been shown to suppress activity during periods of strong winds, low temperatures, and rain (Arnett et al. 2008; Erickson et al. 2002; Sjollema et al. 2014; Dominion Energy 2022).

Land disturbance: Construction of onshore power infrastructure would be required to connect offshore wind energy projects to the electrical grid. Typically, this would require only small amounts of habitat removal, if any, and would occur in previously disturbed areas. Transmission infrastructure, such as PBI, would likely be primarily co-located with existing roads and rights-of-way. However, the conversion of habitat would likely still occur. PBI would potentially have an impact on 2 acres of wetland (including forested wetland) habitat and 4 acres of forest (deciduous, evergreen, and mixed) habitat. Habitat and/or species surveys may be conducted in accordance with federal and state requirements to support federal and state agency consultation and permitting requirements, and consultation and permitting may require that construction activities be seasonally restricted to occur when bats are inactive. Short-term and long-term impacts associated with habitat loss or avoidance during construction may occur, but no injury or mortality of individuals would be expected. As such, onshore construction activities associated with offshore wind development would not be expected to appreciably contribute to overall impacts on bats.

In addition to electrical infrastructure, some amount of habitat conversion may result from port expansion activities required to meet the demands for fabrication, construction, transportation, and installation of wind energy structures. The general trend along the coastal region from Virginia to Maine points to port activity increasing modestly, requiring some conversion of undeveloped land to meet port demand. This conversion would result in permanent habitat loss for local bat populations. However, the increase from planned offshore wind development would be a minimal contribution in the port expansion required to meet increased commercial, industrial, and recreational demand.

3.5.1.3.4 Conclusions

Impacts of the No Action Alternative. Under the No Action Alternative, bats would continue to be affected by existing environmental trends and ongoing activities. BOEM expects ongoing activities to have continuing temporary, long-term, and permanent impacts (disturbance, displacement, injury, mortality, and habitat conversion) on bats primarily through onshore construction impacts, the presence of structures, and climate change. Given the infrequent and limited anticipated use of the OCS by migrating tree bats during spring and fall migration and given that cave bats do not typically occur on the OCS, ongoing offshore wind activities would not appreciably contribute to impacts on bats. Temporary disturbance and permanent loss of habitat onshore may occur as a result of ongoing offshore wind development. However, habitat removal is anticipated to be minimal, and any impacts resulting from habitat loss or disturbance would not be expected to result in individual fitness or population-level effects within the geographic analysis area. The No Action Alternative would likely result in **negligible** impacts on bats.

Cumulative Impacts of the No Action Alternative. Under the No Action Alternative, existing environmental trends and ongoing activities would continue, and bats would continue to be affected by natural and human-caused IPFs. Planned activities would contribute to the impacts on bats due to habitat loss from increased onshore construction. In the offshore environment, impacts are anticipated to be negligible because bat presence on the OCS is anticipated to be limited. Impacts on onshore bat habitat are expected to be negligible to minor, depending on the amount and quality of forest habitat removed. Overall, BOEM anticipates cumulative impacts of the No Action Alternative would likely be **negligible** to **minor.**

3.5.1.4 Impacts of Alternative B – No Identification of AMMM Measures at the Programmatic Stage – Bats

3.5.1.4.1 Impacts of One Project

Alternative B considers the potential impacts of future offshore wind development for the NY Bight area without the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts.

Noise: Pile-driving noise and onshore and offshore construction noise associated with a single NY Bight project is expected to result in temporary and highly localized impacts. Auditory impacts are not expected to occur, as recent research has shown that bats may be less sensitive to TTS than other terrestrial mammals (Simmons et al. 2016). Impacts, if any, are expected to be limited to behavioral avoidance of pile-driving or construction activity, and no temporary or permanent hearing loss would be expected (Simmons et al. 2016).

Presence of structures: The various types of impacts on bats that could result from the presence of structures, such as migration disturbance and turbine strikes, are described in detail in *Cumulative Impacts of the No Action Alternative*. Between 50 and 280 WTGs and 1 and 5 OSSs on the OCS would result from one NY Bight project where few currently exist. The structures, and related bat impacts, associated with one NY Bight project would remain at least until conceptual decommissioning of the project is complete and could pose long-term effects on bats.

Migratory tree bats have the potential to pass through the NY Bight lease areas and be exposed to structures, but, overall, a small number of bats is expected in the lease areas given their distance from shore and low occurrence on the OCS. As detailed in Section 3.5.1.3.3, *Cumulative Impacts of the No Action Alternative* section, and Section 3.5.1.1, *Description of the Affected Environment and Future Baseline Conditions*, bat surveys (in lease areas on the OCS), buoy data on the OCS, and recent bat monitoring at existing wind turbines on the OCS, indicate that bats are generally absent on the OCS during most of the year, with very limited presence typically during the late summer/fall months (August–October). Compared to bat presence in the onshore environment, bat presence offshore represents a very small percentage of bat species' total population onshore. The NY Bight lease areas are also farther offshore on the OCS compared to most other projects (like Ocean Wind 1 [OCS-A 0498] and Atlantic Shores South [OCS-A 0499]), and BOEM anticipates that bat numbers would be even lower due to distance. Therefore, because available information and bat survey data on the OCS indicate bat presence on the OCS is limited in both numbers and time of year, BOEM anticipates the presence of structures would have a negligible impact on bat populations.

Land disturbance: Impacts associated with construction of onshore elements of a single NY Bight project could occur if construction activities take place during the active season (generally April through October), and may result in injury or mortality of individuals, particularly juveniles who are unable to flush from a roost, if occupied by bats at the time of removal. There would be some potential for habitat impacts on bats as a result of the loss of potentially suitable roosting or foraging habitat. However, BOEM anticipates that impacts on bat habitat from onshore construction activities would be limited because, based on recent proposed offshore wind projects, whenever possible, facilities (including overhead transmission lines) would be co-located with existing developed areas (i.e., roads and existing transmission lines) to limit disturbance. In addition, New York State restricts tree clearing from March through November on Long Island. Where necessary, construction of onshore facilities may require clearing and some permanent removal of some trees along the edge of the construction corridor. Any habitat that may be present within permanent substation/converter station sites or other permanent facilities would be converted to developed land with landscaping for the duration of the NY Bight project's operational lifetime, which would be considered a long-term effect. While BOEM anticipates tree clearing to be minimal due to the likely placement of onshore project components in previously disturbed areas and adherence to requirements to minimize impacts identified through state permitting and ESA consultation, it is possible that areas of forest that support bats could be temporarily and permanently cleared depending on the siting of the NY Bight project's onshore components. Disturbance to the land surface or terrestrial habitat during the course of conceptual decommissioning would be minimal, such as disconnecting and cutting buried cables at the fence site below ground.

Applicants could also leave some onshore facilities in place for future use. Therefore, onshore temporary impacts of conceptual decommissioning would be negligible. Overall, BOEM anticipates habitat loss would be limited, and any potential effects would be indirect and unlikely to affect individual or population levels of bat species. However, the area of suitable bat habitat removed could vary, depending on the specific siting of the onshore project components.

3.5.1.4.2 Impacts of Six Projects

The same noise and presence of structure IPF impact types and mechanisms described under one NY Bight project apply to six NY Bight projects. There would be more potential for impacts for these IPFs due to the greater amount of offshore and onshore development under six NY Bight projects. However, noise impacts are still expected to be minimal because noise has limited effects on bats (see Section 3.5.1.4.1, *Impacts of One Project*), and a greater number of offshore structures are unlikely to change the intensity of the impact because bat presence on the OCS is low. Therefore, noise impacts and offshore structures under six NY Bight projects are anticipated to have negligible impacts on bats.

The same land disturbance IPF impact types and mechanisms described under one NY Bight project apply to six NY Bight projects. Similar to a single NY Bight project, the level of impact of bats from land disturbance depends on the amount of bat habitat affected from the onshore project components, particularly forest habitat. While BOEM anticipates that impacts on bat habitat from onshore construction activities under six NY Bight projects would be limited, it is possible that areas of forest that support bats could be temporarily and permanently cleared. Under six NY Bight projects, the potential for this possibility would be greater compared to one NY Bight project due to the increased amount of offshore wind development that would occur.

3.5.1.4.3 Impacts of Alternative B on ESA-Listed Bats

As stated previously, the presence of northern long-eared bat on the offshore environment would generally be limited, and there would be more potential effects from onshore activities. On June 20, 2024, BOEM initiated consultation with the USFWS on a Programmatic Framework ESA Section 7 consultation.

3.5.1.4.4 Cumulative Impacts of Alternative B

The construction and installation, O&M, and conceptual decommissioning of both onshore and offshore infrastructure for offshore wind activities across the geographic analysis area would also contribute to the primary IPFs of noise, presence of structures, and land disturbance. Given that the use of the OCS by migrating tree bats during spring and fall migration is anticipated to be infrequent and limited and given that cave bats do not typically occur on the OCS, offshore wind activities would not appreciably contribute to impacts on bats. Temporary disturbance and permanent loss of onshore habitat may occur as a result of constructing onshore infrastructure such as onshore substations and onshore export cables for offshore wind development. Any habitat removal is anticipated to be minimal, and any impacts resulting from habitat loss or disturbance would not be expected to result in individual fitness or population-level effects within the geographic analysis area. However, the area of suitable bat habitat removed could vary, depending on the specific siting of the onshore project components.

The cumulative impacts on bats would likely be negligible in the offshore environment because the occurrence of bats offshore is low. This conclusion would not change even if all six of the individual NY Bight projects are constructed all at once or staggered. Onshore habitat loss is expected to be minimal and would result in negligible impacts, but a greater area of habitat loss could result in increased impacts. If construction of the onshore components of the projects is staggered, then there could be less of an effect on bats in the short term than if all six NY Bight projects were constructed at once. In the context of reasonably foreseeable environmental trends, BOEM anticipates the contribution of impacts of six NY Bight projects to the cumulative noise, presence of structures, and land disturbance impacts on bats would be undetectable.

3.5.1.4.5 Conclusions

Impacts of Alternative B. Construction, installation, and conceptual decommissioning of Alternative B, whether one NY Bight project or six NY Bight projects, would likely have **negligible** to **minor** impacts on bats, depending on the amount and quality of forest habitat removed. The main significant risk would be from operation of the offshore WTGs and potential onshore removal of habitat, which could lead to long-term impacts in the form of mortality, although BOEM anticipates this to be rare due to limited bat presence on the OCS in both numbers and time of year. Noise effects from construction are expected to be limited to temporary and localized behavioral avoidance that would cease once construction is complete.

Cumulative Impacts of Alternative B. BOEM anticipates that the cumulative impacts on bats in the geographic analysis area would likely be **negligible** to **minor** under six NY Bight projects. In context of reasonably foreseeable environmental trends, the impact of six NY Bight projects to the cumulative impacts on bats would be undetectable. Because the occurrence of bats offshore is low, six NY Bight projects would contribute to the cumulative impacts primarily through the long-term impacts from onshore habitat loss related to onshore substations and cables.

3.5.1.5 Impacts of Alternative C (Proposed Action) – Identification of AMMM Measures at the Programmatic Stage – Bats

Alternative C, the Proposed Action, considers the potential impacts of future offshore wind development for the NY Bight area with the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts. Alternative C consists of two sub-alternatives – Sub-alternative C1: Previously Applied AMMM Measures, and Sub-alternative C2: Previously Applied and Not Previously Applied AMMM Measures. The analysis for Sub-alternative C1 is presented as the change in impacts from those impacts discussed under Alternative B, and the analysis for Sub-alternative C2 is presented as the change from those impacts discussed in Sub-alternative C1. Refer to Table G-1 in Appendix G, *Mitigation and Monitoring*, for a complete description of AMMM measures that make up the Proposed Action.

3.5.1.5.1 Sub-alternative C1 (Preferred Alternative): Previously Applied AMMM Measures

Sub-alternative C1 analyzes the AMMM measures that BOEM has required as conditions of approval for previous activities proposed by lessees in COPs submitted for the Atlantic OCS or through related consultations (Table 3.5.1-5).

Table 3.5.1-5. Summary of previously applied avoidance, minimization, mitigation, and monitoring measures for bats

Measure ID	Measure Summary
BB-1	This measure proposes requiring that any occurrence of dead or injured ESA-listed birds or bats be reported as soon as practicable, which would improve the understanding of ESA-listed bat interactions with wind farms.
BB-2	This measure proposes annual reporting requirements for dead or injured birds or bats, which would improve the overall understanding of bat interactions with wind farms.
BB-3	This measure proposes lessees prepare and implement a Bird and Bat Post-Construction Monitoring Plan, which would include monitoring, reporting requirements, and adaptive management to reduce impacts on bats from offshore wind farms.

Impacts of One Project

The identification of AMMM measures under Sub-alternative C1 could potentially reduce impacts on bats compared to those under Alternative B for the presence of structures IPF. Impacts for other IPFs would remain the same as described under Alternative B.

Presence of structures: Development and implementation of a *Bird and Bat Post-Construction Monitoring Plan* (BB-3) would support advancement of the understanding of bat interactions with offshore wind farms through monitoring, reporting requirements, and adaptive management. Depending on the results of the post-construction monitoring, new mitigation and monitoring measures may be required by BOEM if impacts on bats in the offshore environment deviate substantially from the impact analysis. The immediate reporting of dead or injured ESA-listed bats and annual reporting of any dead or injured bats would improve overall understanding of bat interactions with offshore wind and may reduce overall impacts on bats over time (BB-1, BB-2). Dead bat reporting could also lead to new mitigation or monitoring methods to reduce impacts on bats.

Overall, while the identification of the AMMM measures under Sub-alternative C1 for this IPF could reduce impacts on bats, BOEM anticipates the impacts from presence of structures from one project in the NY Bight lease areas would be similar to Alternative B and remain negligible. This impact determination is primarily based on the current understanding that bat presence in the offshore environment is low.

Impacts of Six Projects

The same IPF impact types and mechanisms described under one NY Bight project apply to six NY Bight projects. AMMM measures identified under Sub-alternative C1 for six NY Bight projects could similarly reduce impacts on bats as described for a single NY Bight project, but the benefits would apply to more projects and cover a large geographic extent. However, because presence of bats on the OCS is low and because bat habitat impacts in the onshore environment are unknown, the potential impacts on bats for six NY Bight projects under Sub-alternative C1 compared to one NY Bight project are not anticipated to be substantially different. For the same reasons, the potential impacts on bats for six NY Bight projects under Sub-alternative C1 compared to six NY Bight projects under Alternative B are not anticipated to be substantially different and remain negligible to minor.

Impacts of Sub-alternative C1 (Preferred Alternative) on ESA-Listed Bats

The identification of AMMM measures would result in similar reductions in impacts for ESA-listed bats as described for all bats for one NY Bight project and six NY Bight projects, with the exception of AMMM measure BB-1, which is designed specifically to mitigate impacts on ESA-listed bats. BB-1 would improve the understanding of ESA-listed bat interactions with WTGs through immediate reporting requirements. The northern long-eared bat is the only bat species listed as threatened or endangered under the ESA that may be affected by Sub-alternative C1. As stated previously, the presence of northern long-eared bat in the offshore environment would generally be limited, with more potential effects from onshore activities.

Cumulative Impacts of Sub-alternative C1 (Preferred Alternative)

Similar to Alternative B, the cumulative impacts on bats under Sub-alternative C1 would likely be negligible in the offshore environment because the occurrence of bats offshore is low. Onshore habitat loss may be reduced if lessees design the onshore project components to avoid sensitive onshore bat habitat, but there is still the possibility of larger habitat areas removed, which could result in potential minor impacts from land disturbance. In context of reasonably foreseeable environmental trends, the impacts of Sub-alternative C1 to the cumulative noise, presence of structures, and land disturbance impacts on bats would be undetectable.

3.5.1.5.2 Sub-alternative C2: Previously Applied and Not Previously Applied AMMM Measures

Sub-alternative C2 analyzes the AMMM measures under Sub-alternative C1 plus the AMMM measures that have not been previously applied. However, BOEM has not identified any AMMM measures that have not been previously applied for bats, and, therefore, the impacts on bats under Sub-alternative C2 are the same as Sub-alternative C1.

3.5.1.5.3 Conclusions

Impacts of Alternative C. Construction, installation, and conceptual decommissioning of the NY Bight projects under Sub-alternative C1 or Sub-alternative C2, whether one NY Bight project or six NY Bight projects, would likely have **negligible** to **minor** impacts on bats, depending on the amount and quality of forest habitat removed. The AMMM measures under Sub-alternative C1 and Sub-alternative C2 would provide some certainty in reducing impacts on bats in the offshore environment and, therefore, could reduce potential impacts on bats compared to Alternative B. However, bat presence in the offshore environment is low and generally limited to a few months out of the year, and the AMMM measures may not significantly reduce impacts. Onshore habitat impacts under Sub-alternative C1 and Sub-alternative C2 could be reduced by lessees designing the projects to avoid onshore bat habitat. However, because the location of onshore infrastructure is not known, there could still be a range of potential impacts on habitat regardless of the AMMM measures, resulting in **negligible** to **minor** impacts. Noise effects from construction are expected to be limited to temporary and localized behavioral avoidance that would cease once construction is complete.

Cumulative Impacts of Alternative C. BOEM anticipates that the cumulative impacts on bats in the geographic analysis area would likely be **negligible** to **minor** for six NY Bight projects. In context of reasonably foreseeable environmental trends, the impacts contributed by Sub-alternative C1 and Sub-alternative C2 to the cumulative impacts on bats would be undetectable. Because the occurrence of bats offshore is low, Sub-alternative C1 and Sub-alternative C2 would contribute to the cumulative impacts primarily through the long-term impacts from onshore habitat loss related to onshore construction. If the lessees design onshore project components to avoid bat habitat there may be reduced bat impacts onshore, but the extent of this reduction cannot be known at this time.

3.5.1.6 Recommended Practices for Consideration at the Project-Specific Stage

In addition to the AMMM measures identified under Alternative C, BOEM is recommending lessees consider analyzing the RPs in Table 3.5.1-6 to further reduce potential bat impacts. Refer to Table G-2 in Appendix G for a complete description of the RPs.

Table 3.5.1-6. Recommended Practices for bat impacts and related benefits

Recommended Practice	Potential Benefit
BB-4: Prepare a framework for a *Bird and Bat Post-Construction Monitoring Plan* to be submitted with the COP.	Developing a framework for a *Bird and Bat Post-Construction Monitoring Plan* would provide the public and agencies an opportunity to provide early feedback on the plan.
MUL-5: Use equipment, technology, and best practices to produce the least amount of noise possible to reduce noise impacts.	Using noise reduction measures to produce the least amount of noise practicable would likely minimize disturbance/displacement impacts.
MUL-21: Use the best available technology, including new and emerging technology, when possible, to reduce impacts, such as the use of MERLIN radar systems.	Assessing and monitoring bat mortality risk through radar sensors and avian-detection software (e.g., MERLIN) would provide information on avian occurrence in a wind farm area and could be used to inform post-construction operational mitigation.
MUL-23: Avoid or reduce potential impacts on important environmental resources by adjusting project design, which may minimize impacts on bats associated with onshore activities.	Adjusting project design to minimize impacts, such as routing cable in previously disturbed areas, has the potential to reduce impacts on individual bats and their habitats from onshore activities.
MUL-25: Use consistent turbine grid layouts, markings, and lighting in lease areas. Turbines should have one of the two lines of orientation in the grid layout spaced at least 1 nm apart.	Providing more structure-free areas in the lease area and reducing the total number of structures would potentially reduce interactions between bats and WTGs.

Recommended Practice	Potential Benefit
MUL-26: Coordinate regional monitoring and surveys.	Coordinating monitoring and survey efforts across lease areas in the NY Bight to standardize approaches would contribute to understanding potential impacts to bats at a regional scale.

3.5 Biological Resources

3.5.3 Birds

This section discusses potential impacts on bird resources from the Proposed Action, alternatives, and ongoing and planned activities in the geographic analysis area for birds. The geographic analysis area for birds, as shown on Figure 3.5.3-1, includes the United States coastline from Maine to Florida, extending 100 miles (161 kilometers) offshore and 0.5 mile (0.8 kilometer) inland to capture the movement range for species in this group. The geographic analysis area for birds was established to capture resident species and migratory species that winter as far south as South America and the Caribbean, and those that breed in the Arctic or along the Atlantic Coast that travel through the area. The offshore limit was established to cover the migratory movement of most species in this group. The onshore limit was established to cover onshore habitats used by the species that may be affected by onshore and offshore components of the NY Bight projects.

The bird impact analysis in this PEIS is intended to be incorporated by reference into the project-specific environmental analyses for individual COPs expected for each of the NY Bight lease areas. Because the locations of onshore components for the NY Bight projects are not known at this time, the analysis of onshore bird impacts is dependent on a hypothetical project analysis, and impact conclusions consider a maximum-case scenario for onshore development. Additional detailed site-specific analysis will be required for individual COPs. Refer to Appendix C, *Tiering Guidance*, which identifies additional analyses anticipated to be required for the project-specific environmental analysis of individual COPs.

3.5.3.1 Description of the Affected Environment and Future Baseline Conditions

This section discusses bird species that use offshore and onshore habitats, including both resident bird species that use the NY Bight lease areas during all (or portions of) the year and migrating bird species with the potential to pass through the lease areas during fall migration, spring migration, or both. Given the differences in life history characteristics and habitat use between offshore and onshore bird species, the following discusses each group separately. This section also discusses bald and golden eagles, and addresses federally listed threatened and endangered birds, which are further addressed as part of the Programmatic Framework ESA Section 7 consultation that BOEM initiated with the USFWS on June 20, 2024.

The Mid-Atlantic Coast plays an important role in the ecology of many bird species. The Atlantic Flyway, which follows the Atlantic Coast, is an important migratory route for many bird species moving from breeding grounds in New England and eastern Canada to winter habitats in North, Central, and South America. Bays, beaches, coastal forests, marshes, and wetlands provide important stopover and foraging habitat for migrating birds (MMS 2007). Section 4.2.4 of the Atlantic OCS Proposed Geological and Geophysical Activities Programmatic EIS (BOEM 2014a) discusses the use of the Atlantic Coast habitats by migratory birds.

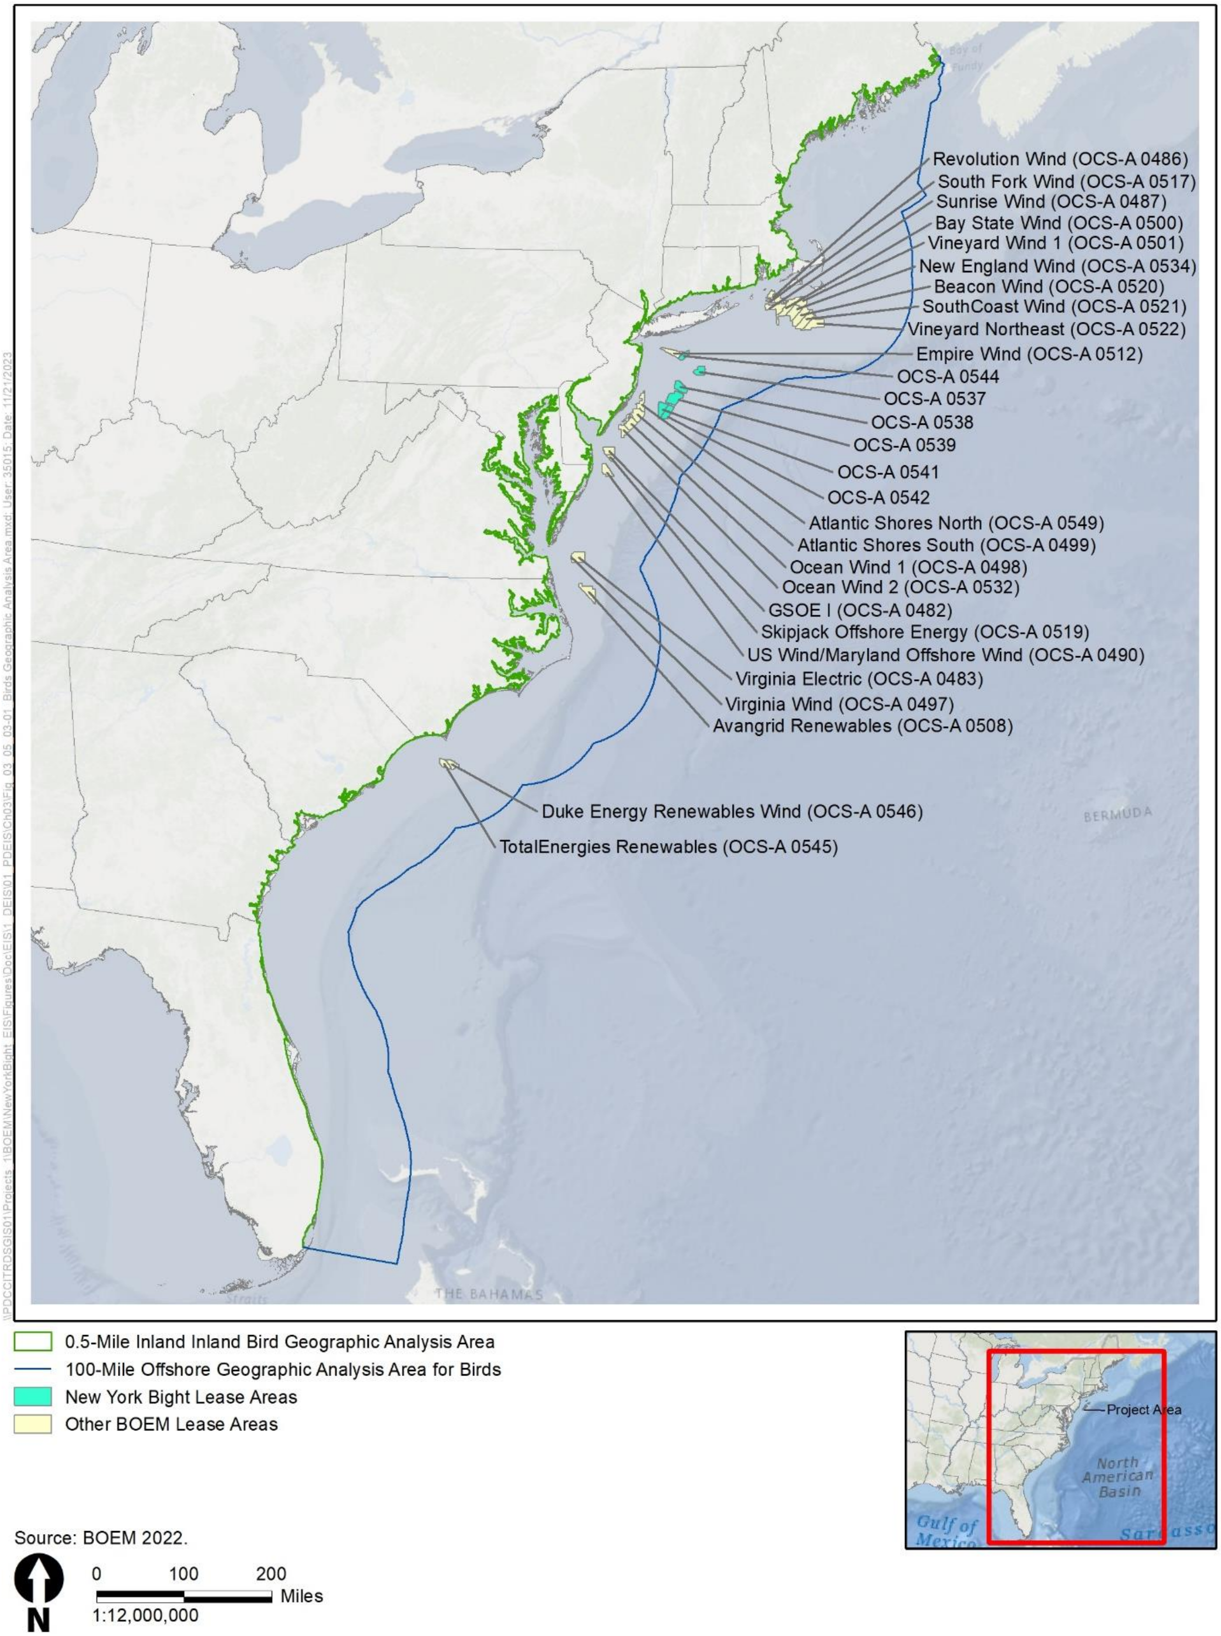


Figure 3.5.3-1. Bird geographic analysis area

Birds in the geographic analysis area are subject to pressure from ongoing activities, such as onshore construction, marine minerals extraction, port expansions, and installation of new structures in the OCS, but particularly from accidental releases; new cable, transmission line, and pipeline emplacement; interactions with fisheries and fishing gear; and climate change. More than one-third of bird species that occur in North America (37 percent, 432 species) are at risk of extinction unless significant conservation actions are taken (NABCI 2016). This is likely representative of the conditions of birds within the geographic analysis area. Species that live or migrate through the Atlantic Flyway have historically been, and will continue to be, subject to a variety of ongoing anthropogenic stressors—including hunting pressure (approximately 86,000 seaducks are harvested annually [Roberts 2019]), commercial fisheries by-catch (approximately 2,600 seabirds are killed annually on the Atlantic [Hatch 2017; Sigourney et al. 2019]), and climate change—which may have adverse impacts on bird species. Additional protections for migratory birds are provided through the Migratory Bird Treaty Act of 1918 (MBTA), which makes it illegal to "take" migratory birds, their eggs, feathers, or nests. The official list of migratory birds protected under the MBTA, and the international treaties that the MBTA implements, is found at 50 CFR 10.13.

According to the North American Bird Conservation Initiative (NABCI), more than half of the offshore bird species (57 percent, 31 species) have been placed on the NABCI watch list as a result of small ranges, small and declining populations, and threats to required habitats. This watch list identified species of high conservation concern based upon high vulnerability to a variety of factors, including population size, breeding distribution, non-breeding distribution, threats to breeding, threats to non-breeding, and population trends (NABCI 2016). Globally, monitored offshore bird populations have declined by nearly 70 percent from 1950 to 2010, which may be representative of the overall population trend of seabirds (Paleczny et al. 2015) including those that forage, breed, and migrate over the Atlantic OCS. Overall, offshore bird populations are decreasing; however, considerable differences in population trajectories of offshore bird families have been documented.

Coastal birds, especially those that nest in coastal marshes and other low-elevation habitats, are vulnerable to sea level rise and the increasing frequency of strong storms as a result of global climate change. According to NABCI, nearly 40 percent of the more than 100 bird species that rely on coastal habitats for breeding or for migration are on the NABCI watch list. Many of these coastal species have small population sizes or restricted distributions, making them especially vulnerable to habitat loss/degradation and other stressors (NABCI 2016). Some of the main drivers of threats to birds include habitat loss, habitat fragmentation, collisions with glass windows and power lines, invasive species, predators, toxic chemicals, and climate change (USFWS 2021a).

Marine-Life Data and Analysis Team (MDAT) marine bird models have been developed to describe regional-scale patterns of bird abundance (Curtice et al. 2016; Winship et al. 2018), including on U.S. Atlantic waters. The MDAT analysis integrates survey data (1978–2016) from the Atlantic Offshore Seabird Dataset Catalog with a range of environmental variables to produce long-term average annual and seasonal models. These models were recently updated by Winship et al. (2023) to include monthly predictions of relative abundance for 49 species from more recent survey data. Like the previous MDAT model, the updated models are based on data collected at much larger geographic and temporal scales than a survey for a particular area (e.g., a digital aerial survey of a lease area) and data that were also collected using a range of survey methods. The larger geographic scale is helpful for determining the importance of the NY Bight lease areas to marine birds relative to other available locations in the Northwest Atlantic and is thus important for determining overall exposure of birds to offshore wind lease areas. Limitations of the model data are described in detail in Winship et al. (2023). Figure 3.5.3-2 shows the MDAT model for total marine avian relative annual abundance distribution in U.S. Atlantic waters and indicates an overall low abundance of birds on the OCS, with much higher abundances along the nearshore areas of the coastline. Table 3.5.3-1 shows the annual percentage of the 49 marine avian species populations that overlap with anticipated offshore wind energy development on the OCS, which indicates that only a small percentage of a species' population would potentially occur in the wind development areas during annual migration. Overall, the MDAT models indicate marine bird presence on the OCS is low, including in the NY Bight lease areas.

NYSERDA conducted four aerial digital surveys for avian and marine wildlife between 2018 and 2019 in the NY Bight area, including surveys in summer 2018 (6 days in August), fall 2018 (4 days in November/December), winter 2018–2019 (3 days in February), and spring 2019 (2 days in April) (NYSERDA 2022). The aerial data provide coverage for all of four NY Bight lease areas (OCS-A 0537, OCS-A 0538, OCS-A 0539, and OCS-A 0544), a portion of OCS-A 0542, and none of OCS-A 0541 (Appendix B, *Supplemental Information and Additional Figures and Tables,* Figure B.2-1). The three most common avian species observed during the surveys were the red phalarope (*Phalaropus fulicarius*), Bonaparte's gull (*Chroicocephalus philadelphia*), and an unknown large shearwater-species.

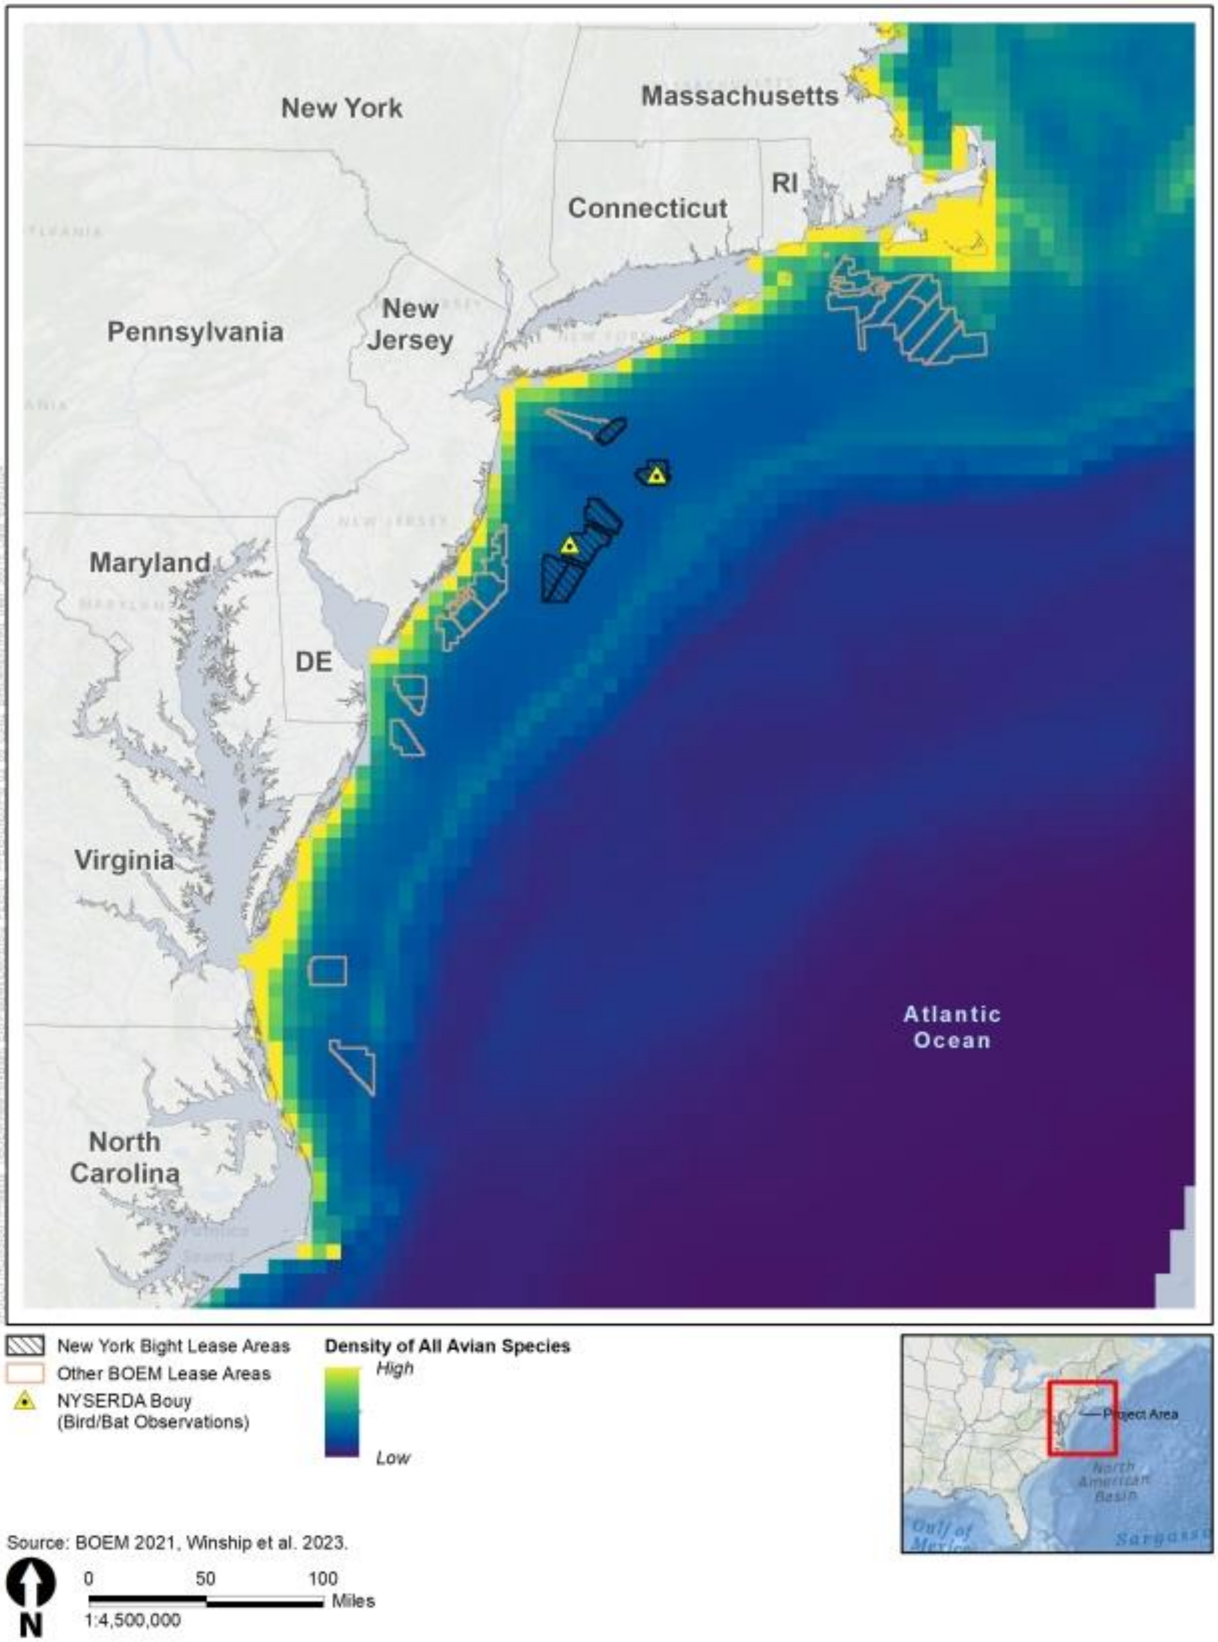

Figure 3.5.3-2. Total avian relative annual abundance distribution map

Table 3.5.3-1. Annual percentage of Atlantic seabird population (1993–2019) that overlaps with anticipated offshore wind energy development on the OCS

Species	Population %	Species	Population %
Artic Tern (*Sterna paradisaea*)	0.97	Long-tailed Ducks (*Clangula hyemalis*)	2.90
Atlantic Puffin (*Fratercula arctica*)	1.10	Manx Shearwater (*Puffinus puffinus*)[1]	1.00
Audubon Shearwater (*Puffinus lherminieri*)[1]	0.08	Northern Fulmar (*Fulmarus glacialis*)	0.63
Black-capped Petrel (*Pterodroma hasitata*)[1]	0	Northern Gannet (*Morus bassanus*)	2.50
Black Guillemot (*Cepphus grille*)	0.64	Parasitic Jaeger (*Stercorarius parasiticus*)	1.40
Black-legged Kittiwake (*Rissa tridactyla*)	2.30	Pomarine Jaeger (*Stercorarius pomarinus*)	0.81
Black Scoter (*Melanitta americana*)	0.92	Razorbill (*Alca torda*)	1.90
Bonaparte's Gull (*Chroicocephalus philadelphia*)	2.80	Ring-billed Gull (*Larus delawarensis*)	0.93
Brown Pelican (*Pelecanus occidentalis*)	0.07	Red-breasted Merganser (*Mergus serrator*)	1.00
Band-rumped Storm-Petrel (*Oceanodroma castro*)[1]	0.03	Red Phalarope (*Phalaropus fulicarius*)	0.89
Common Eider (*Somateria mollissima*)	0.60	Red-necked Phalarope (*Phalaropus lobatus*)	0.73
Common Loon (*Gavia immer*)	4.10	Roseate Tern (*Sterna dougallii*)	1.60
Common Murre (*Uria aalge*)	1.40	Royal Tern (*Thalasseus maximus*)	0.20
Common Tern (*Sterna hirundo*)	1.10	Red-throated Loon (*Gavia stellate*)	2.70
Cory's Shearwater (*Calonectris borealis*)[1]	0.59	Sooty Shearwater (*Ardenna grisea*)	1.10
Double-crested Cormorant (*Phalacrocorax auritus*)	1.40	Sooty Tern (*Onychoprion fuscatus*)	0.03
Dovekie (*Alle alle*)	1.80	South Polar Skua (*Stercorarius maccormicki*)	1.50
Great Black-backed Gull (*Larus marinus*)	1.30	Surf Scoter (*Melanitta perspicillata*)	1.50
Great Shearwater (*Puffinus gravis*)	0.70	Thick-billed Murre (*Uria lomvia*)	0.57
Great Skua (*Stercorarius skua*)	1.60	Wilson's Storm-Petrel (*Oceanites oceanicus*)	0.79
Herring Gull (*Larus argentatus*)	1.30	White-winged Scoter (*Melanitta deglandi*)	3.30
Horned Grebe (*Podiceps auritus*)	1.50	Lesser Black-backed Gull	1.50
Laughing Gull (*Leucophaeus atricilla*)	0.88	Black Tern (*Chlidonias niger*)[1]	0.91
Leach's Storm-Petrel (*Oceanodroma leucorhoa*)	0.13	Forster's Tern (*Sterna forsteri*)	2.40
Least Tern (*Sternula antillarum*)[1]	0.11		

Source: calculated into percentages from Appendix H in Winship et al. (2023).
[1] Species considered Birds of Conservation Concern in Bird Conservation Regions M16, M18, and M19 by USFWS (2021b).

Appendix B, Table B.2-1 identifies the number of observations by species and by lease area from the NYSERDA aerial surveys. Two meteorological buoys deployed by NYSERDA, and located within Lease Areas OCS-A 0537 and OCS-A 0539, have been used to collect avian data. The buoys include nanotag antennas that provide species-specific information gleaned from tagged birds, as well as bird acoustic sensors that constantly record diurnal and nocturnal bird calls. The two buoys detected 215 bird passes, consisting of nine species, between September 2019 and September 2022 (Normandeau Associates Inc. 2022). The most common bird detected at both buoys was the herring gull (*Larus argentatus smithsonianus*), with a total of 203 total pass observations, or 94 percent of all birds passes detected. The remaining 6 percent of birds detected at one or both buoys included American redstart, green heron, least bittern, palm warbler, ring-billed gull, white-throated sparrow, wood thrush, and yellow warbler (refer to Appendix B, Table B.2-2 for full percentages of the species observed).

Satellite telemetry datasets from the Northeast Ocean Data Portal show fine-scale use and movement patterns from three species of diving bird—including the surf scoter (*Melanitta perspicillata*), red-throated loon (*Gavia stellata*), and northern gannet (*Morus bassanus*), over the course of 5 years. The data that was collected represents the utilization distributions for each species throughout the Mid-Atlantic U.S. waters during different times of the year. The utilization distributions represent the probability that an animal will occur within a specific area during a specified time of year. The surf scoter and red-throated loon are less active within the geographic analysis area during fall migration and overwinter distribution, but heavily utilize the Mid-Atlantic Flyway during spring migration. In contrast, the northern gannet utilizes the Mid-Atlantic Flyway and passes through the geographic analysis area year-round for foraging and migration (Northeast Ocean Data Portal 2022; Appendix B, Figures B.2-2, B.2-3, and B.2-4).

Table 3.5.3-2 briefly describes the bird presence in the offshore project area by bird group based on information from other offshore lease areas (e.g., Empire Wind OCS-A 0512, Ocean Wind 1 OCS-A 0498, Atlantic Shores South OCS-A 0499). The table breaks down birds into six groups—shorebirds, wading birds, raptors, songbirds, coastal waterbirds, and marine birds. Marine birds are broken down further by family group.

Table 3.5.3-2. Bird presence in the offshore project area by bird group

Bird Group	Potential Bird Presence in the Offshore Project Area
Shorebirds	Shorebirds (e.g., black-bellied plover, semipalmated plover) are typically coastal breeders and foragers and generally avoid straying out over deep waters during breeding. Primarily, exposure of shorebirds to the offshore infrastructure would be limited to the spring and fall migration periods.
Wading Birds	Most long-legged wading birds, such as herons and egrets, breed and migrate in coastal and inland areas. Like the smaller shorebirds, wading birds are believed to avoid straying out over deep waters but may fly offshore during spring and fall migration periods.
Raptors	The degree to which raptors might occur offshore is dictated primarily by their morphology and flight strategy (i.e., flapping versus soaring), which influences species' ability or willingness to cross large expanses of open water where thermal formation is poor (Kerlinger 1985). Among raptors, falcons are the most likely to be encountered in offshore settings along the Atlantic Flyway (DeSorbo et al. 2012, 2018). Merlins are the most abundant diurnal raptor observed at offshore islands during migration. Both have been observed offshore on vessels and offshore oil platforms considerable distances from shore.
Songbirds	Songbirds (e.g., warblers, sparrows) almost exclusively use terrestrial, freshwater, and coastal habitats and do not use the offshore marine system except during migration. Many North American breeding songbirds migrate to the tropical regions, many in flocks. On their

Bird Group	Potential Bird Presence in the Offshore Project Area
	migrations, neotropical migrants generally travel at night and at high altitudes where favorable winds can aid them along their trip. Songbirds regularly cross large bodies of water (Bruderer and Lietchi 1999; Gauthreaux and Belser 1999), and there is some evidence that species migrate over the northern Atlantic (Adams et al. 2015). Some birds may briefly fly over the water while others, like the blackpoll warbler, are known to migrate over vast expanses of ocean (Faaborg et al. 2010; DeLuca et al. 2015). Evidence for a variety of species suggests that overwater migration in the Atlantic is much more common in fall (than in spring), when the frequency of overwater flights increases perhaps due to consistent tailwinds (Morris et al. 1994; Hatch et al. 2013; Adams et al. 2015; DeLuca et al. 2015).
Coastal Waterbirds	Coastal waterbirds use terrestrial or coastal wetland habitats and rarely use the marine offshore environment. This group includes aquatic species not captured in other groupings, such as grebes and waterfowl, that are generally restricted to freshwater or use saltmarshes or beaches. Waterfowl comprise a broad group of geese and ducks, most of which spend much of the year in terrestrial or coastal wetland habitats. The diving ducks generally winter on open freshwater, as well as brackish or saltwater. Species that regularly winter on saltwater, including mergansers, scaup, and goldeneyes, usually restrict their distributions to shallow, very nearshore waters. Because most coastal waterbirds spend a majority of the year in freshwater aquatic systems and nearshore marine systems, there is little to no use of the offshore environment around lease areas during any season. A subset of diving ducks has a strong affinity for saltwater, either year-round or outside of the breeding season; these species are known as seaducks.
Marine Birds (by family group)	
Loons	Common loons and red-throated loons are known to use the Atlantic OCS in winter. Analysis of satellite-tracked red-throated loons, captured and tagged in the Mid-Atlantic area, found their winter distributions to be largely inshore of the Mid-Atlantic WEAs, although they did overlap with OCS lease areas during spring migration (Gray et al. 2016).
Seaducks	The seaducks (e.g., black scoter, surf scoter, common eider) use the Atlantic OCS heavily in winter. Most of these seaducks dive to forage on mussels and other benthic invertebrates, and generally winter in shallower inshore waters or out over large offshore shoals, where they can access benthic prey. Seaducks tracked with satellite transmitters remained largely inshore of the lease areas (Spiegel et al. 2017). Based on digital aerial survey data and MDAT models, seaduck exposure is expected to be minimal and would be primarily limited to migration or travel between wintering sites.
Petrel group	In the Atlantic, this group consists mostly of shearwaters (e.g., Cory’s shearwater, great shearwater, sooty shearwater) and storm-petrels (e.g., Wilson’s storm-petrel) that breed in the southern hemisphere and visit the northern hemisphere in vast numbers during the austral winter (boreal summer). These species use the Atlantic OCS region so heavily that, in terms of sheer numbers, they easily outnumber the locally breeding species and year-round residents at this time of year. Several of the species (e.g., Cory’s shearwater, Wilson’s storm-petrel) are found in high densities across the broader region, concentrating beyond the Atlantic OCS and in the Gulf of Maine as shown in the MDAT avian abundance models.
Gannets, Cormorants, and Pelicans	Northern gannets use the Atlantic OCS during winter and migration. They are opportunistic foragers, capable of long-distance oceanic movements. The double-crested cormorant is the most likely species of cormorant in the offshore environment of the lease areas, but regional MDAT abundance models show that cormorants are concentrated closer to shore and not commonly encountered well offshore (Curtice et al. 2016; Winship et al. 2018). Brown pelicans are rare in the area, as only one was detected during surveys performed for adjacent OCS locations, and New Jersey is at the northern extent of its range; therefore, they are unlikely to pass through the NY Bight lease areas in any numbers.
Gulls, skuas, and jaegers	The regional MDAT abundance models show that these birds have wide distributions, ranging from near shore (gulls) to offshore (jaegers). Herring gulls and great black-backed

Bird Group	Potential Bird Presence in the Offshore Project Area
	gulls are resident in the region year-round, and are found farther offshore during the non-breeding season. The parasitic jaeger is often observed closer to shore during migration than the other species and great skuas may migrate along the Atlantic OCS outside the breeding season.
Terns	Black tern, least tern, common tern, Forster's tern, roseate tern, and royal tern have been observed in and around the NY Bight lease areas. Terns generally restrict themselves to coastal waters during breeding, although they may pass through the NY Bight lease areas during migration. Roseate terns are federally listed.
Auks	Auk species present are generally northern or Arctic-breeders that winter along the Atlantic OCS (e.g., common murre, dovekie, razorbill). The annual abundance and distribution of auks along the eastern seaboard in winter is erratic and is dependent upon broad climatic conditions and the availability of prey. The MDAT abundance models show that during winter auks are generally concentrated offshore, along the shelf edge, and southwest of Nova Scotia.

MDAT = Marine-life Data and Analysis Team

Within the Atlantic Flyway, much of the bird activity is concentrated along the coastline (Watts 2010). Waterbirds use a corridor between the coast and several kilometers out onto the OCS, whereas land birds tend to use a wider corridor extending from the coastline to tens of kilometers inland (Watts 2010). Although both groups may occur over land or water within the flyway and may extend considerable distances from shore, the highest diversity and density are centered on the shoreline.

There are four species of birds listed as threatened or endangered under the ESA that may occur in the offshore and onshore project areas: the threatened piping plover (*Charadrius m. melodus*), endangered roseate tern (*Sterna d. dougallii*), threatened Rufa subspecies of the red knot (*Calidris canutus rufa*), and the Eastern rail (*Laterallus jamaicensis jamaicensis*) (addressed as part of the Programmatic Framework ESA Section 7 consultation BOEM initiated with USFWS on June 20, 2024). In terms of ESA-listed bird species by state, four are listed under the ESA in New Jersey and three are listed in New York. Currently, there is no designated critical habitat for any ESA-listed bird species in New Jersey, and critical habitat in New York is designated only for piping plover along the Lake Ontario shoreline, which would be outside of the project area for any of the NY Bight lease areas. In April 2023, USFWS issued a proposed rule (88 *Federal Register* 22530) to designate approximately 680,000 acres as critical habitat for rufa red knot across 13 states, including portions of New York and New Jersey in the geographic analysis area.

Bald eagles (*Haliaeetus leucocephalus*) are federally protected by the Bald and Golden Eagle Protection Act (16 USC 668 et seq.), as are golden eagles (*Aquila chrysaetos*). Golden eagles are found throughout the United States, but mostly in the western half of the United States and are rare in the eastern states (Cornell University 2019). Golden eagles do not fly over the ocean. As with bald eagles, the general morphology of golden eagles dissuades long-distance movements in offshore settings (Kerlinger 1985), as the species generally relies upon thermal formations, which develop poorly over the open ocean, during long-distance movements. As such, golden eagles are unlikely to fly through the NY Bight lease areas.

Bald eagles are broadly distributed across North America and generally nest and perch in areas associated with water (lakes, rivers, bays) in both freshwater and marine habitats, often remaining largely within roughly 1,640 feet (500 meters) of the shoreline (Buehler 2000). Bald eagles are year-round residents in New York and New Jersey and occur in a variety of terrestrial environments, typically near water such as coastlines, rivers, and large lakes (New York Natural Heritage Program 2022; NJDEP n.d.). There are high numbers of observations along the New Jersey and New York coastlines with few bald eagles observed offshore, plus one unusual siting in 2020 of a bald eagle about 40 miles offshore New Jersey (eBird 2024). While it is possible that a bald eagle may be found offshore, the general morphology of bald eagles dissuades long-distance movements in offshore settings, as the species generally relies upon thermal formations, which develop poorly over the open ocean, during long-distance movements. As such, bald eagles are unlikely to fly through the NY Bight lease areas.

3.5.3.2 Impact Level Definitions for Birds

Definitions of potential impact levels are provided in Table 3.5.3-3. Beneficial impacts on birds are described using the definitions provided in Section 3.3.2 (Table 3.3-1).

Table 3.5.3-3. Adverse impact level definitions for birds

Impact Level	Definition
Negligible	There would be no measurable impacts, or impacts would be so small that they would be extremely difficult or impossible to discern or measure.
Minor	Most impacts would be avoided; if impacts occur, the loss of one or a few individuals or temporary alteration of habitat could represent a minor impact, depending on the time of year and number of individuals involved.
Moderate	Impacts would be unavoidable but would not result in population-level effects or threaten overall habitat function.
Major	Impacts would result in severe, long-term habitat or population-level effects on species.

Accidental releases, cable emplacement and maintenance, land disturbance, lighting, noise, presence of structures, and traffic are contributing IPFs to impacts on birds. However, these IPFs may not necessarily contribute to each individual issue outlined in Table 3.5.3-4.

Table 3.5.3-4. Issues and indicators to assess impacts on birds

Issue	Impact Indicator
Collision/injury/electrocution	Qualitative estimate of species vulnerability to collision/electrocution
Displacement/barrier effects	Changes to noise levels Projected traffic patterns/volume changes
Habitat loss/modification	Acres of habitat removal or modification

3.5.3.3 Impacts of Alternative A – No Action – Birds

When analyzing the impacts of the No Action Alternative on birds, BOEM considered the impacts of ongoing activities, including ongoing non-offshore-wind and ongoing offshore wind activities on the baseline conditions for birds. The cumulative impacts of the No Action Alternative considered the impacts of the No Action Alternative in combination with other planned non-offshore-wind and offshore wind activities, which are described in Appendix D*, Planned Activities Scenario*.

3.5.3.3.1 Impacts of the No Action Alternative

Under the No Action Alternative, the baseline conditions for birds described in Section 3.5.3.1, *Description of Affected Environment and Future Baseline Conditions*, would continue to follow current regional trends and react to IPFs introduced by other ongoing non-offshore-wind and offshore wind activities. Ongoing non-offshore-wind activities within the geographic analysis area that contribute to impacts on birds are typically associated with onshore construction, coastal lighting, etc. Impacts may also result from activities in the offshore environment (vessel traffic, commercial fisheries, etc.) and climate change. Onshore construction activities and associated impacts are expected to follow current trends and have the potential to affect bird species from temporary and permanent habitat removal or alteration, temporary noise impacts related to construction activities, collisions with proposed structures, and lighting effects, which could cause avoidance behavior and potential displacement as well as injury to or mortality of individual birds. Activities in the offshore environment could result in bird avoidance behavior and displacement; however, local population-level effects are not anticipated for onshore and offshore activities because the level of activity and disturbance is anticipated to remain relatively small compared to total habitat in the geographic analysis area. Impacts of climate change such as increased storm severity and frequency, ocean acidification, altered migration patterns, increased disease frequency, and increased erosion and sediment deposition, have the potential to result in long-term, potentially high-consequence risks to birds and could lead to changes in prey abundance and distribution, changes in nesting and foraging habitat abundance and distribution, and changes to migration patterns and timing.

Ongoing offshore wind activities within the geographic analysis area that contribute to impacts on birds are listed in Table 3.5.3-5. The effects of approved projects have been evaluated through previous NEPA review and are incorporated by reference. Ongoing O&M of the Block Island and Coastal Virginia Offshore Wind Pilot projects and ongoing construction of the Vineyard Wind 1 (OCS-A 0501), South Fork Wind (OCS-A 0517), Ocean Wind 1 (OCS-A 0498), Revolution Wind (OCS-A 0486), Sunrise Wind (OCS-A 0487), New England Wind (OCS-A 0534) Phase 1 and 2, Empire Wind (OCS-A 0512) 1 and 2, and CVOW-Commercial (OCS-A 0483) projects would affect birds through the primary IPFs of accidental releases, lighting, cable emplacement and maintenance, noise, presence of structures, traffic, and land disturbance. Ongoing offshore wind activities would have the same type of impacts from these IPFs that are described in detail in Section 3.5.3.3.3, *Cumulative Impacts of the No Action Alternative,* for ongoing and planned offshore wind activities, but the impacts would be of lower intensity.

3.5.3.3.2 Impacts of the No Action Alternative on ESA-Listed Species

There are four ESA-listed bird species that may occur within the geographic analysis area; however, the potential occurrence of these listed bird species is expected to be low. The IPFs described in Section 3.5.3.3.3 for all birds would also apply to ESA-listed bird species. Any future federal activities that could affect any listed bird species would need to comply with ESA Section 7 to ensure that the proposed activities do not jeopardize the continued existence of the species. Future non-federal activities would be addressed under ESA Section 10 to ensure that proposed activities do not jeopardize the continued existence of the species.

3.5.3.3.3 Cumulative Impacts of the No Action Alternative

The cumulative impact analysis for the No Action Alternative considers the impact of the No Action Alternative in combination with other planned non-offshore-wind activities and planned offshore wind activities (without the NY Bight projects). Other planned non-offshore-wind activities that may affect birds include installation of new submarine pipelines, cables, and transmission systems (e.g., PBI), increasing onshore construction, marine mineral extraction, port expansions, and the installation of new structures on the OCS (see Appendix D for a description of planned activities). These activities may result in temporary and permanent impacts on birds including disturbance, potential displacement, injury, mortality, habitat degradation, and habitat alteration. Table 3.5.3-5 lists the ongoing and planned offshore wind activities in the geographic analysis area for birds.

Table 3.5.3-5. Ongoing and planned offshore wind in the geographic analysis area for birds

Ongoing/Planned	Projects by Region
Ongoing – 12 projects[1] 	**MA/RI** • Block Island (state waters) • Vineyard Wind 1 (OCS-A 0501) • South Fork Wind (OCS-A 0517) • Revolution Wind (OCS-A 0486) • Sunrise Wind (OCS-A 0487) • New England Wind (OCS-A 0534) Phase 1 • New England Wind (OCS-A 0534) Phase 2 **NY/NJ** • Ocean Wind 1 (OCS-A 0498) • Empire Wind 1 (OCS-A 0512) • Empire Wind 2 (OCS-A 0512) **VA/NC** • CVOW-Pilot (OCS-A 0497) • CVOW-Commercial (OCS-A 0483)
Planned – 18 projects[2] 	**MA/RI** • SouthCoast Wind (OCS-A 0521) • Beacon Wind 1 (OCS-A 0520) • Beacon Wind 2 (OCS-A 0520) • Bay State Wind (OCS-A 0500) • OCS-A 0500 remainder • OCS-A 0487 remainder • Vineyard Wind Northeast (OCS-A 0522) **NY/NJ** • Ocean Wind 2 (OCS-A 0532) • Atlantic Shores North (OCS-A 0549) • Atlantic Shores South (OCS-A 0499) **DE/MD** • Skipjack (OCS-A 0519) • US Wind/Maryland Offshore Wind (OCS-A 0490) • GSOE I (OCS-A 0482) • OCS-A 0519 remainder **VA/NC** • Kitty Hawk North (OCS-A 0508)

[1] Refer to footnotes 9 and 10 in PEIS Chapter 1 for additional information on the status of Ocean Wind 1, Empire Wind 1, and Empire Wind 2.

[2] Status as of September 20, 2024.

BOEM expects other offshore wind development activities to affect birds through the following IPFs.

Accidental releases: The accidental release of fuel/fluids, other contaminants, trash, and debris could occur as a result of offshore wind activities. The assumed risk of any type of accidental release would be increased primarily during construction activities, but also during operations and conceptual decommissioning of offshore wind facilities. Ingestion of hazardous contaminants, such as fuel and fluids from vessels, has the potential to result in lethal and sublethal impacts on birds, including decreased hematological function, dehydration, drowning, hypothermia, starvation, and weight loss (Briggs et al. 1997; Haney et al. 2017; Paruk et al. 2016). Additionally, small exposures to vessel fuel/fluids that result in oiling of feathers can lead to sublethal effects such as changes in flight efficiencies that result in increased energy expenditure during daily and seasonal activities. These daily and seasonal activities include, but are not limited to, chick provisioning, commuting, courtship, foraging, long-distance migration, predator evasion, and territory defense (Maggini et al. 2017). Based on the volumes potentially involved (refer to Appendix D), the likely amount of hazardous contaminant releases associated with offshore wind development would fall within the range of accidental releases that already occur on an ongoing basis from non-offshore-wind activities and would represent a minor impact on birds.

Vessel compliance with USCG regulations would minimize trash or other debris; therefore, BOEM expects accidental trash releases from offshore wind vessels to be rare and localized. In the unlikely event of a release, lethal and sublethal impacts on local bird species could occur resulting in blockages caused by both hard and soft plastic debris (Roman et al. 2019). Given that accidental releases are anticipated to occur primarily during construction activities, BOEM expects that accidental releases of trash and debris would have minor impacts on birds.

Air emissions: The secondary standards of the NAAQS (see Section 3.4.1.1) specifically aim to safeguard the environment, including wildlife and their habitats. Air pollution can directly impact birds via physical harm, such as damage to respiratory systems, or indirectly via changes to habitat conditions, food supplies, and/or species interactions (Lianga et al. 2020). Emissions from fossil fuel combustion include NO_X gases, which interact with ultraviolet radiation in sunlight to form surface-level ozone. A recent study found that air quality improvements limiting ozone over the past 4 decades have stemmed the decline in U.S. bird populations, averting the loss of 1.5 billion birds, particularly among land birds smaller than 142 grams (Liang et al. 2020). By limiting ozone precursor pollutants, such as NO_X, the NAAQS helps prevent harmful effects on vegetation, water bodies, and soil, thus ensuring healthier ecosystems. It is reasonable to assume that the displacement of fossil fuels by the generation of electricity by offshore wind would further reduce ozone and consequently result in minor to moderate beneficial impacts on air quality (see Section 3.4.1). This decrease in NO_X emissions and surface-level ozone formation would consequently have a minor to moderate beneficial impact on populations of small land birds.

Lighting: Offshore wind development would result in additional nighttime light from vessels and offshore wind structures. Construction vessels have an array of lights that could attract some birds and potential prey species to construction zones, potentially exposing them to collision risks with vessels during the construction period. The resulting vessel-related lighting impacts would be localized and minor for bird species.

Up to 2,459 WTGs and 66 OSSs from ongoing and planned offshore wind projects would have navigational and FAA hazard lighting in accordance with BOEM's lighting and marking guidelines. This lighting has some potential to result in long-term impacts and may pose an increased collision or predation risk to migrating birds (Hűppop et al. 2006), particularly to night-flying migrants during low-visibility weather conditions. However, this risk would be minimized through the use of red flashing FAA lighting (Kerlinger et al. 2010). Overall, BOEM anticipates lighting impacts related to offshore wind structures and vessels would be minor.

Cable emplacement and maintenance: Generally, emplacement of submarine cables would result in increased suspended sediments that may affect diving birds, displacement of foraging individuals, or decreased foraging success, and have impacts on some prey species (e.g., benthic assemblages) (Cook and Burton 2010). Impacts associated with cable emplacement would be temporary and localized, and birds would be able to successfully forage in adjacent areas not affected by increased suspended sediments. Any dredging necessary prior to cable installation could also contribute to additional impacts. Disturbed seafloor from construction of offshore wind projects may affect some bird prey species; however, assuming planned projects use installation procedures similar to those proposed in other recent COPs (e.g., Empire Wind OCS-A 0512, Ocean Wind 1 OCS-A 0498), the duration and extent of impacts would be short-term and localized, and benthic assemblages would be expected to recover from disturbance. See Section 3.5.2, *Benthic Resources*, and Section 3.5.5, *Finfish, Invertebrates, and Essential Fish Habitat* for additional information on benthic and fish impacts. Once the cables are installed, limited to no maintenance would be required except if repairs are needed to fix a damaged cable, in which case impacts on birds would be similar to those described for construction but more limited in geographic scope. Impacts would be minor because suspended sediments and potential displacement of foraging birds would be short-term and benthic habitats would recover.

Noise: Anthropogenic noise on the OCS associated with offshore wind development, including noise from aircraft, pile-driving activities, G&G surveys, offshore construction, and vessel traffic, has the potential to result in impacts on birds on the OCS. Additionally, onshore construction noise has the potential to result in impacts on birds. BOEM anticipates that these impacts would be localized and temporary. Potential impacts could be greater if avoidance and displacement of birds occurs during seasonal migration periods. Aircraft flying at low altitudes cause birds to flush, resulting in increased energy expenditure. Disturbance, if any, would be temporary and localized, with impacts dissipating once the aircraft has left the area. No individual or population-level effects would be expected.

Construction of up to 1,682 WTGs and 48 OSSs associated with planned offshore wind projects would create noise and may temporarily affect diving birds. The greatest impact of noise is likely to be created by pile-driving activities during construction. Noise transmitted through water has the potential to result in temporary displacement of diving birds but would be localized to the space around each pile. The impacts from such noise can cause short-term stress and behavioral changes ranging from mild annoyance to escape behavior (BOEM 2014b, 2016). Additionally, localized noise impacts on prey species may affect bird foraging success. Similar to pile-driving, G&G site characterization surveys for offshore wind facilities, which would occur sporadically, would produce high-intensity impulsive noise around sites of investigation, leading to similar impacts.

Onshore noise associated with intermittent construction of required offshore wind development infrastructure may also result in localized and short-term impacts, including avoidance and displacement, though no individual fitness or population-level effects would be anticipated to occur. Noise associated with vessel traffic could disturb some individual diving birds, but they would likely acclimate to the noise or retreat, potentially resulting in a temporary loss of habitat (BOEM 2012). However, brief, temporary responses, if any, would be expected to decrease once the vessel has passed or the individual has moved away. No individual fitness or population-level effects would be anticipated. Overall, noise impacts on birds are anticipated to be minor because noise would primarily occur during construction (i.e., be short term) and localized.

Presence of structures: The presence of structures can lead to long-term effects on birds, both beneficial and adverse, through fish aggregation and associated increase in foraging opportunities, as well as entanglement with lost fishing gear, migration disturbances, and WTG strikes and displacement. These impacts may arise from buoys, meteorological towers, foundations, scour and cable protections, and transmission cable infrastructure. BOEM predicts that structures would be added and that they would remain until conceptual decommissioning of each facility is complete, approximately 35 years following construction.

The primary threat to birds from the presence of structures would be from collision with WTGs. The Atlantic Flyway is an important migratory corridor for as many as 164 species of waterbirds, and a similar number of land birds, with the greatest volume of birds using the Atlantic Flyway during spring and fall migration (Watts 2010). Along the Atlantic Flyway, much of the bird activity is concentrated along the coastline (Watts 2010). Waterbirds use a corridor between the coast and several kilometers out onto the OCS, while land birds tend to use a wider corridor extending from the coastline to tens of kilometers inland (Watts 2010). While both groups may occur over land or water within the flyway and may extend considerable distances from shore, the highest diversity and density are centered on the shoreline. Building on this information, Robinson Willmott et al. (2013) evaluated the sensitivity of bird resources to collision and displacement due to offshore wind development on the Atlantic OCS and included the 164 species selected by Watts (2010) plus an additional 13 species, for a total of 177 species that may occur on the Atlantic OCS from Maine to Florida during all or some portion of the year.

As discussed in Robinson Willmott et al. (2013) and consistent with Garthe and Hüppop (2004), Furness and Wade (2012), and Furness et al. (2013), species with high scores for sensitivity for collision include gulls, jaegers, and the northern gannet (*Morus bassanus*). A collision sensitivity ranking of migratory birds near the Nysted wind farm in Denmark by Desholm (2009) also found that waterbirds and birds of prey had higher collision sensitivity scores and passerines had lower collision sensitivity scores. In many cases, high collision sensitivity is driven by high occurrence on the OCS, low avoidance rates with high uncertainty, and time spent in the RSZ. Many of the species addressed in Robinson Willmott et al. (2013) have low collision sensitivity, including passerines that spend very little time on the Atlantic OCS during migration and typically fly above the RSZ. Robinson Willmott et al. (2013) stated that because of identified data gaps and related uncertainty, particularly concerning species-specific flight altitude and avoidance behavior, their results should be interpreted with caution. As discussed by Watts (2010), 55 seabird species could encounter operating WTGs on the Atlantic OCS. However, generally the abundance of bird species that overlap with the anticipated development of wind energy facilities on the Atlantic OCS is relatively small (Figure 3.5.3-2). Of the 55 bird species, 49 have sufficient survey data to calculate the modeled percentage of a species population that would overlap with the anticipated offshore wind development on the Atlantic OCS (Winship et al. 2023); the relative annual exposure of these species is generally very low, ranging from 0.00 to 4.10 percent (Table 3.5.3-1). The estimated percentage of federally listed species and Birds of Conservation Concern populations that overlap offshore wind development areas ranges from only 0.00 to 1.00 percent (Table 3.5.3-1). BOEM assumes that the 49 species (89 percent) with sufficient data to model the relative distribution and abundance on the Atlantic OCS are representative of the 55 species that may overlap with offshore wind development on the Atlantic OCS.

Ongoing and planned offshore wind development would result in up to 2,459 WTGs in the bird geographic analysis area (Appendix D, Tables D.A2-1 and D.A2-2). In the contiguous United States, bird collisions with operating onshore WTGs are relatively rare events. Loss et al. (2013) estimated 140,000 to 328,000 (mean = 234,000) birds killed annually from 44,577 onshore monopile wind turbines across the contiguous United States. Bird collisions with onshore monopile turbines in the eastern United States is estimated at 6.86 birds per turbine per year (Loss et al. 2013). Based on this mortality rate, an estimated 16,869 birds could be killed annually from the 2,459 WTGs that would be added for offshore wind development. This represents a maximum-case scenario and does not consider mitigating factors, such as landscape and weather patterns, or bird species that are expected to occur. Given that the relative density of birds in the OCS is low, relatively few birds are likely to encounter offshore WTGs (see Figure 3.5.3-2). Potential annual bird kills from offshore WTGs would be relatively low compared to other causes of migratory bird deaths in the United States; feral cats are the primary cause of migratory bird deaths in the United States (2.4 billion per year), followed by collisions with building glass (599 million per year), collisions with vehicles (214.5 million per year), poison (72 million per year), collisions with electrical lines (25.5 million per year), collisions with communication towers (6.6 million per year), and electrocutions (5.6 million per year) (USFWS 2021a).

Not all individuals that occur or migrate along the Atlantic Coast are expected to encounter the RSZ of one or more operating WTGs associated with planned offshore wind development. Generally, only a small percentage of a species' seasonal population would potentially encounter operating WTGs (Table 3.5.3-1). The addition of WTGs to the offshore environment may result in increased functional loss of habitat for those species with higher displacement sensitivity. However, a recent study of long-term data collected in the North Sea found that despite the extensive observed displacement of loons in response to the development of 20 wind farms, there was no decline in the region's loon population (Vilela et al. 2021). Furthermore, substantial foraging habitat for resident birds would remain available outside of the proposed offshore lease areas, and no individual fitness or population-level impacts would be expected to occur.

Vattenfall (a European energy company) recently studied bird movements within an offshore wind farm situated 1.9–3 miles (3–4.9 kilometers) off the coast of Aberdeen, Scotland (Vattenfall 2023). The purpose of the study was to improve the understanding of seabird flight behavior inside an offshore wind farm with a focus on the bird breeding period and post-breeding period when densities are highest. The study was robust in that seabirds were tracked inside the array with video cameras and radar tracks, which allowed for measuring avoidance movements (meso- and micro-avoidance)[1] with high confidence and at the species level. Detailed statistical analyses of the seabird flight data were enabled both by the large sample sizes and by the high temporal resolution in the combined radar track and video camera data. Meso-avoidance behavior showed that species avoided the RSZ by flying in between the turbines with very few avoiding by changing their flight altitude in order to fly either below or above the rotors. The most frequently recorded adjustment under micro-avoidance behavior was birds flying along the plane of the rotor; other adjustments included crossing the rotor either obliquely or perpendicularly, and some birds cross the rotor-swept area without making any adjustments to the spinning rotors. The study concluded that, together with the recorded high levels of micro-avoidance in all species (>0.96), it is now evident that seabirds will be exposed to very low risks of collision in offshore wind farms during daylight hours. This was substantiated by the fact that no collisions or even narrow escapes were recorded in over 10,000 bird videos during the 2 years of monitoring covering the April–October period. The study's calculated micro-avoidance rate (above 0.96) is similar to Skov et al. (2018). Further evidence supporting turbine avoidance can be found in Schwemmer et al. (2023), in which 70 percent of approaching 143 Global Positioning System (GPS) tracked Eurasian curlews (*Numenius arquata arquata*) demonstrated horizontal avoidance responses when approaching offshore wind farms in the Baltic and North Seas. While most curlews avoided entire wind farms, others changed their flight altitude to fly below or above the RSZ as they pass through the wind farm (Figure 3.5.3-3, Figure 3.5.3-4, and Figure 3.5.3-5). Given that curlews and red knots are in the same family (Scolopacidae) and are ecologically similar, it is reasonable to expect that red knots would behave similarly to curlews when encountering wind farms and turbines.

[1] Micro-avoidance is flight behavior within and in the immediate vicinity of individual wind turbine rotor-swept areas (i.e., last second action to avoid collision); meso-avoidance is flight behavior within and in the immediate vicinity of the wind farm (i.e., anticipatory/impulsive evasion of rows of turbines in a wind farm).

Source: Figure S4 in Schwemmer et al. (2023).
Note: Left panel: offshore wind farm cluster belonging to Belgium and The Netherlands. The bird entered the North Sea approaching from The Netherlands, performed a loop in the south, entered the cluster and returned to a roost in The Netherlands where it stayed for 9 days before continuing its journey in a straight track. Right panel: "Galloper" and "Greater Gabbard" belonging to the United Kingdom. The bird entered from the north, crossed the cluster, performed a circle in the south, entered the cluster again, performed another circle in the north, entered the cluster for a third time, and left the area towards the southwest. Arrows depict flight directions.

Figure 3.5.3-5. Non-directional flights within or in the vicinity of two offshore wind farm clusters made by two curlews tagged as breeding in north Germany

Because most offshore structures would likely be spaced 0.6 to 1 nm (1.1 to 1.9 kilometers) apart, sufficient space between WTGs should allow birds that are not flying above WTGs to fly through individual lease areas without changing course or to make minor course corrections to avoid the WTGs in operation. The effects of offshore wind farms on bird movement ultimately depends on the bird species, size of the offshore wind farm, spacing of turbines, and extent of extra energy costs incurred by the displacement of flying birds (relative to normal flight costs pre-construction) and their ability to compensate for this degree of added energy expenditure. Little quantitative information is available on how offshore wind farms may act as a barrier to movement, but Madsen et al. (2012) modeled bird movement through offshore wind farms using bird (common eider) movement data collected at the Nysted offshore wind farm in the western Baltic Sea just south of Denmark. After running several hundred thousand simulations for different layouts/configurations for a 100 WTG offshore wind farm, the proportion of birds traveling between the turbines increased as distance between turbines increased. With eight WTG columns at 200 meters (0.1 nm) spacing, no birds passed between the turbines. However, increasing inter-turbine distance to 500 meters (0.27 nm) increased the percentage of birds to more than 20 percent, while a spacing of 1,000 meters (0.54 nm) increased this further to 99 percent. The 0.6 to 1 nm spacing estimated for most structures that will be proposed on the Atlantic OCS is greater than the distance at which 99 percent of the birds passed through in the model. As such, adverse impacts of additional energy expenditure due to minor course corrections or complete avoidance of the lease areas would not be expected to be biologically significant. Any additional flight distances would likely be small for most migrating birds when compared with the overall migratory distances traveled, and no individual fitness or population-level effects would be expected to occur. Similar results were also reported for foraging birds. A recent study based on GPS tracking of sandwich terns (*Thalasseus sandvicensis)* near several European wind farms found that avoidance rates of offshore wind turbines increased with turbine density (van Bemmelen et al. 2023); interestingly, the turbines in those wind farms were much closer to each other than anticipated in the NY Bight, suggesting the proposed turbine spacing may not create a barrier that would displace foraging sandwich terns or other tern species.

The addition of WTGs to the offshore environment may result in increased functional loss of habitat for those species with higher displacement sensitivity. Displacement and avoidance can cause birds to expend more energy and to forage in other areas. However, overall habitat loss due to displacement is unlikely to affect population trends because of the relatively small size of wind farm project areas in relation to the available foraging habitat (Fox and Petersen 2019). A recent study of long-term data collected in the North Sea found that despite the substantial observed displacement of loons in response to the development of 20 wind farms, there was no decline in the region's local loon population (Vilela et al. 2021). Extensive foraging habitat for resident birds would remain available outside of the offshore lease areas; therefore, the impacts on birds due to the presence of operating WTGs would likely be low.

In the Northeast and Mid-Atlantic waters, there are 2,570 seabird fatalities through interaction with commercial fishing gear each year; of those, 84 percent are with gillnets involving shearwaters/fulmars and loons (Hatch 2017). Abandoned or lost fishing nets from commercial fishing may get tangled with foundations, reducing the chance that abandoned gear would cause additional harm to birds and other wildlife if left to drift until sinking or washing ashore. A reduction in derelict fishing gear (in this case by entanglement with foundations) has a beneficial impact on bird populations (Regular et al. 2013). In contrast, the presence of structures may also increase recreational fishing and, thus, expose individual birds to harm from fishing line and hooks.

The presence of new structures could result in increased prey items for some local marine bird species. Offshore wind foundations could increase the mixing of surface waters and deepen the regional thermocline, resulting in the potential increase in pelagic productivity in local areas (English et al. 2017). Additionally, new structure installation may create habitat for structure-oriented or hard-bottom species, typically referred to as "reef effect." This reef effect has been observed around WTGs, which can result in local increases in biomass and diversity (Causon and Gill 2018). Recent studies have revealed increased biomass for benthic fish and invertebrates, and potentially for pelagic fish, marine mammals, and birds (Raoux et al. 2017; Pezy et al. 2018; Wang et al. 2019), indicating that the installation of offshore wind energy facilities can generate beneficial permanent impacts on local ecosystems, resulting in increased foraging opportunities for individuals of local marine bird species. BOEM anticipates that the presence of structures may result in permanent beneficial impacts. Conversely, increased foraging opportunities could attract marine birds, potentially exposing those individuals to increased collision risk associated with operating WTGs.

Overall, the abundance of bird species that overlap with ongoing wind energy facilities on the Atlantic OCS is relatively small, and the presence of structures is anticipated to have minor impacts on birds.

Traffic (aircraft): General aviation traffic is responsible for approximately two bird strikes per 100,000 flights (Dolbeer et al. 2019). Because aircraft flights associated with offshore wind development are anticipated to be minimal, aircraft strikes with birds are highly unlikely to occur. As such, aircraft traffic impacts would be negligible and would not be expected to appreciably contribute to overall impacts on birds.

Land disturbance: Onshore construction of offshore wind and transmission infrastructure has the potential to result in some impacts due to habitat loss or fragmentation. While transmission infrastructure, such as PBI, would likely be primarily co-located with existing roads and rights-of way, habitat alteration from planned non-offshore wind activities may occur. Habitat and/or species surveys may be conducted in accordance with federal and state requirements to support federal and state agency consultation and permitting requirements, and consultation and permitting may require that construction activities be seasonally restricted to occur when impacts to birds can be avoided or minimized. However, onshore construction would be expected to account for only a very small increase in development relative to other ongoing development activities. Further, construction would be expected to generally occur in previously disturbed habitats, and no individual fitness or population-level impacts on birds would be expected to occur. As such, onshore construction associated with planned offshore wind development would be minor and would not be expected to appreciably contribute to overall impacts on birds.

3.5.3.3.4 Conclusions

Impacts of the No Action Alternative. Under the No Action Alternative, birds would continue to be affected by existing environmental trends and ongoing activities. BOEM anticipates ongoing activities to have continuing temporary and permanent impacts (disturbance, displacement, injury, mortality, habitat degradation, habitat alteration) on birds primarily through construction activities and climate change. Given that the abundance of bird species that overlap with ongoing wind energy facilities on the Atlantic OCS is relatively small, ongoing wind activities would not significantly contribute to impacts on birds. Temporary disturbance and permanent loss of onshore habitat may occur as a result of offshore wind development. However, habitat removal is expected to be minimal, and any impacts resulting from habitat loss or disturbance would not be anticipated to result in individual fitness or population-level effects within the geographic analysis area. The No Action Alternative would likely result in **negligible** to **minor** impacts on birds.

Cumulative Impacts of the No Action Alternative. Under the No Action Alternative, existing environmental trends and ongoing activities would continue, and birds would continue to be affected by natural and anthropogenic IPFs. Additionally, planned activities would contribute to the impacts on birds due to habitat loss from increased onshore construction and interactions with offshore developments. BOEM anticipates that the impacts associated with offshore wind activities in the geographic analysis area would result in adverse impacts but could potentially include beneficial impacts because of the presence of structures and reduction in ozone levels from fossil fuel displacement. The majority of offshore structures in the geographic analysis area would be attributable to offshore wind development. Migratory birds that use the offshore wind lease areas during all or parts of the year would either be exposed to new collision risk or experience long-term functional habitat loss due to behavioral avoidance and displacement from wind lease areas on the OCS. The offshore wind development would also be responsible for the majority of impacts related to new cable emplacement and pile-driving noise, but effects on birds resulting from these IPFs would be localized and temporary and would not be expected to be biologically significant. BOEM anticipates that the cumulative impacts of the No Action Alternative would likely have a **negligible** to **moderate** impact on birds but could also include moderate beneficial impacts because of the presence of offshore structures. In addition, the displacement of fossil fuels in the generation of electricity by offshore wind would further reduce ozone and consequently result in minor to moderate beneficial impacts to populations of small land birds. The overall beneficial impact on birds due to presence of offshore structures and displacement of fossil fuels would be **minor beneficial** to **moderate beneficial**.

3.5.3.4 Impacts of Alternative B – No Identification of AMMM Measures at the Programmatic Stage – Birds

3.5.3.4.1 Impacts of One Project

Alternative B considers the potential impacts of future offshore wind development for the NY Bight area without the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts.

Accidental releases: Because a NY Bight project would be required to comply with federal and state requirements related to the prevention and control of accidental releases, the expected impacts of accidental releases associated with one NY Bight project would be negligible and would not increase impacts beyond those described for the No Action Alternative.

Air emissions: Similar to the No Action Alternative, the displacement of fossil fuels in the generation of electricity by offshore wind would contribute toward limiting ozone precursor pollutants (such as NO_X), which would result in healthier ecosystems. This decrease in NO_X emissions and surface-level ozone formation would consequently have a minor to moderate beneficial impact on populations of small land birds.

Lighting: Nighttime lighting associated with up to 280 WTGs, 5 OSSs, and multiple vessels (during construction, operations, and conceptual decommissioning) could represent a source of bird attraction, with the same types of impacts on birds described for the No Action Alternative. Similar to the No Action Alternative, vessel-related lighting impacts during construction and operation would be localized and a low risk for bird species. For offshore structure lighting, in the absence of light reduction measures (e.g., aircraft detection lighting system [ADLS]), potential offshore structure lighting impacts during operations could result in moderate impacts on birds.

Cable emplacement and maintenance: Installation of 1,479 miles (2,380 kilometers) of interarray and export cables from a single NY Bight project would result in increased suspended sediments and disturbed seafloor that may affect diving birds, displacement of foraging individuals, or decreased foraging success, and have impacts on some benthic prey species. However, assuming cable installation and maintenance in the NY Bight lease areas would be similar to the installation methods and maintenance activities employed at adjacent wind projects (e.g., Empire Wind OCS-A 0512, Ocean Wind 1 OCS-A 0498), impacts from suspended sediments would be short term and localized, and birds would be able to successfully forage in adjacent areas not affected by increased suspended sediment. In addition, due to the short term and localized nature of the suspended sediment impact, benthic assemblages would be expected to recover from seafloor disturbance. Therefore, impacts from cable emplacement and maintenance are anticipated to be minor.

Noise: Pile-driving noise from up to 280 WTGs, as well as onshore and offshore construction noise, associated with one NY Bight project is anticipated to result in temporary and highly localized impacts. Dredging vessels and other construction noise could temporarily disturb and displace some bird species, but they are likely already acclimated to noise in an urban environment and would be able to easily avoid the noise impacted areas. Under a single NY Bight project, BOEM anticipates noise impacts on birds to be minor and limited to behavioral avoidance of pile-driving or construction activity.

Presence of structures: The numerous types of impacts on birds that could result from the presence of structures, such as migration disturbance, habitat loss/fragmentation, and turbine strikes, are described in detail in Section 3.5.3.3.3. Between 50–280 WTGs and 1–5 OSSs on the OCS would result from a single NY Bight project where few currently exist. The structures, and related bird impacts, associated with one NY Bight project would remain at least until conceptual decommissioning is complete and could pose long-term effects on birds, both disadvantageous and beneficial.

There are few resources that show the level of bird use of the OCS and the ultimate consequences of mortality, if any, associated with operating WTGs. Migratory birds have the potential to pass through the NY Bight lease areas, but overall, a small number is expected within the lease areas given their distance from shore.

As depicted for the offshore wind lease areas on Figure 3.5.3-2, avoiding areas with high concentrations of birds was a factor in selecting locations for offshore wind lease areas on the OCS. All six NY Bight lease areas are located at least 20 nautical miles (37 kilometers) offshore. Within the Atlantic Flyway along the North American Atlantic Coast, much of the bird activity is concentrated along the coastline (Watts 2010). Waterbirds use a corridor between the coast and several kilometers out onto the OCS, while land birds tend to use a wider corridor extending from the coastline to tens of kilometers inland (Watts 2010). However, operation of WTGs in the NY Bight lease areas could result in impacts on some individuals of offshore bird species and possibly some individuals of coastal and inland bird species during spring and fall migration. These impacts could arise through direct mortality from collisions with WTGs or through behavioral avoidance and habitat loss (Drewitt and Langston 2006; Fox et al. 2006; Goodale and Millman 2016). The predicted activity of bird populations that have a higher sensitivity to collision (as defined by Robinson Willmott et al. [2013]) is relatively low in the OCS during all seasons of the year (Figure 3.5.3-6), suggesting that bird fatalities due to collision are likely to be low. Similarly, the predicted activity of bird populations that have a higher sensitivity to displacement is relatively low in the OCS (Figure 3.5.3-7).

When WTGs are present, many birds would avoid the WTG site altogether, especially the species that ranked “high” in vulnerability to displacement by offshore wind energy development (Robinson Willmott et al. 2013). In addition, many birds would likely adjust their flight paths to avoid WTGs by flying above, below, or between them (e.g., Desholm and Kahlert 2005; Plonczkier and Simms 2012; Skov et al. 2018), and others may take extra precautions to avoid WTGs when the WTGs are moving (Johnston et al. 2014). Several species have very high avoidance rates; for example, the northern gannet, black-legged kittiwake, herring gull, and great black-backed gull have measured avoidance rates of at least 99.6 percent (Skov et al. 2018). As mentioned in Section 3.5.3.3.3, Vattenfall (a European energy company) recently studied bird movements within an offshore wind farm situated 1.9 to 3 miles (3 to 4.9 kilometers) off the coast of Aberdeen, Scotland (Vattenfall 2023). The study’s calculated micro-avoidance rate (>0.96) is similar to Skov et al. (2018). Further evidence supporting turbine avoidance can be found in Schwemmer et al. (2023), in which 70 percent of approaching Eurasian curlews (*Numenius arquata arquata*) demonstrated horizontal avoidance responses when approaching offshore wind farms in the Baltic and North Seas.

Avian collision risk impact assessments have been performed for adjacent OCS lease areas (e.g., Empire Wind OCS-A 0512 and Ocean Wind 1 OCS-A 0498) and provide some insight into the potential collisions risk for the NY Bight lease areas. The majority of the bird species identified in the impact assessment for Empire Wind are expected to have “minimal” to “low” overall exposure risk. Similar to Empire Wind, the avian impact assessment performed for Ocean Wind 1 determined the overall exposure risk to be “minimal” to “low.” Further, coastal birds are considered to have minimal exposure (occurrence) within the NY Bight lease areas because they are far enough offshore to be beyond the range of most breeding terrestrial or coastal bird species. Falcons may be potentially exposed to the NY Bight lease areas during migration; however, the proportion of migrating falcons that may be attracted to offshore wind energy projects for perching, roosting, and foraging is uncertain, as is the extent to which individuals might avoid WTGs or collide with them.

Overall, because the presence of birds in the offshore environment is generally low, and avian risk analyses conducted by nearby lease areas indicate low risk, BOEM anticipates the presence of structures from one project in the NY Bight lease areas would have a minor impact on birds.

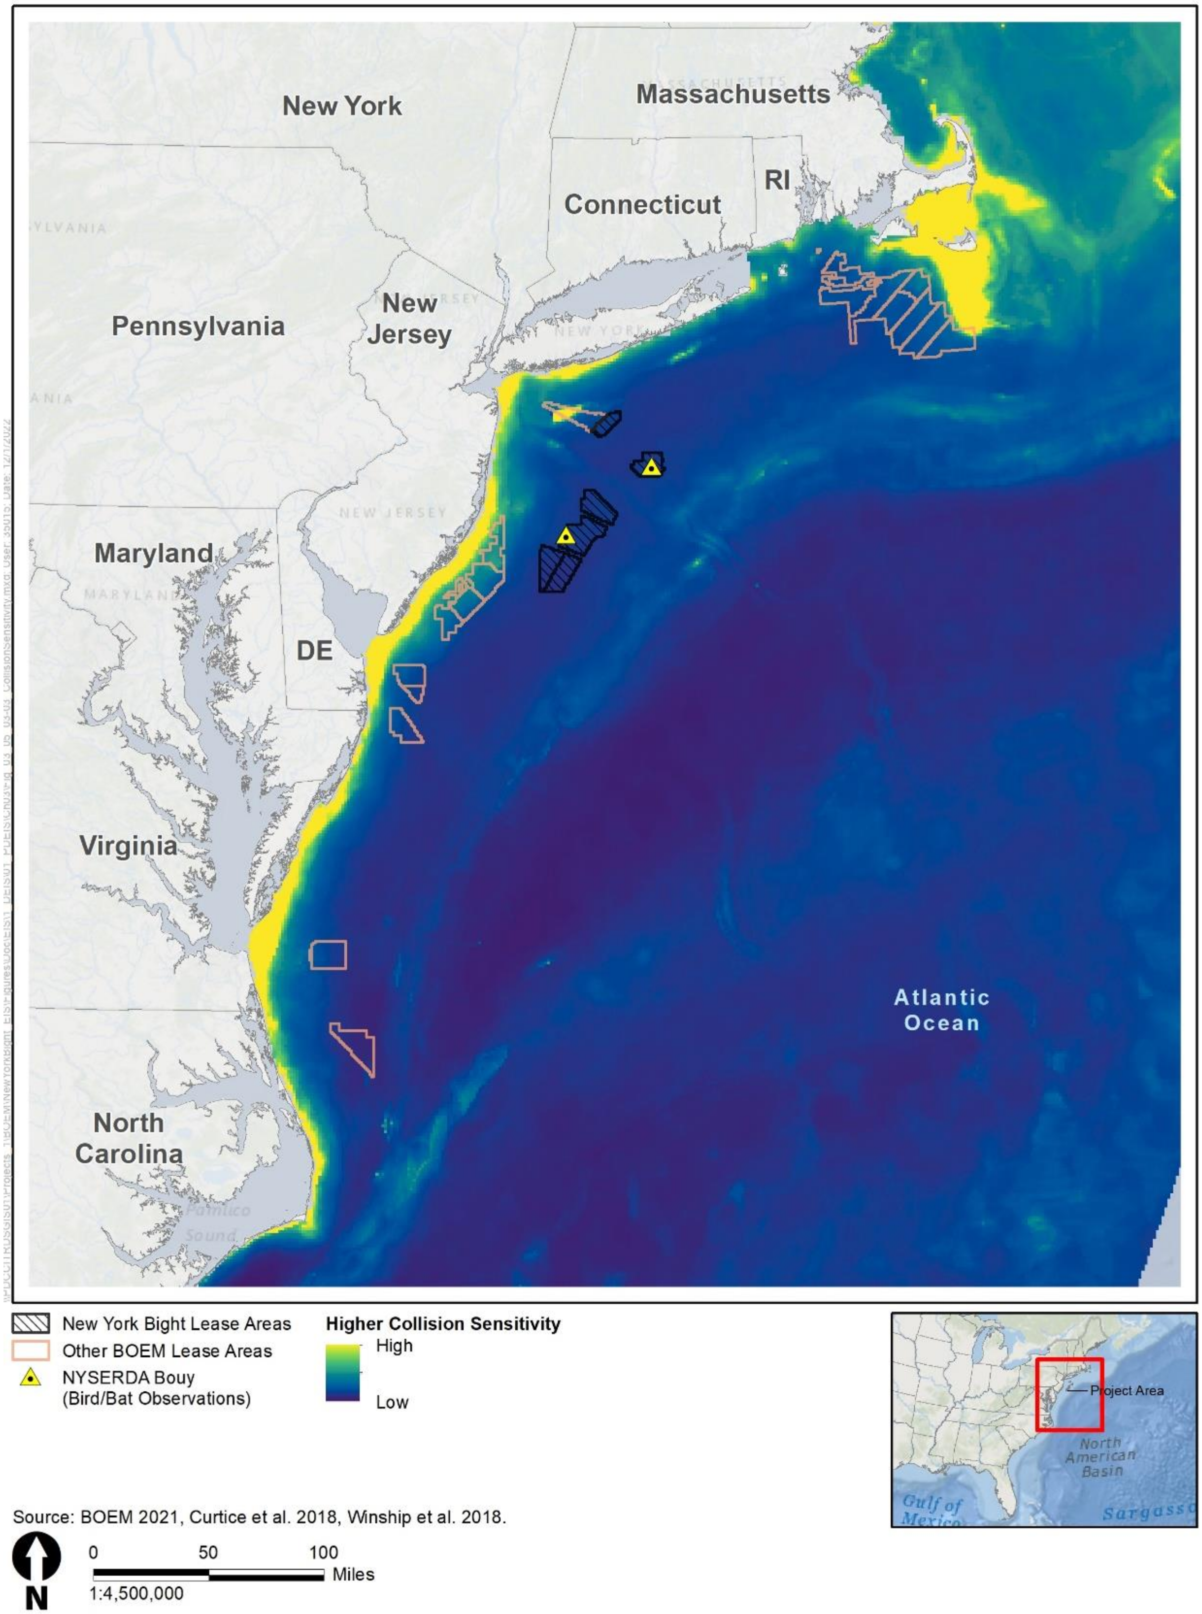

Figure 3.5.3-6.Total avian relative abundance distribution map for the higher collision sensitivity species group

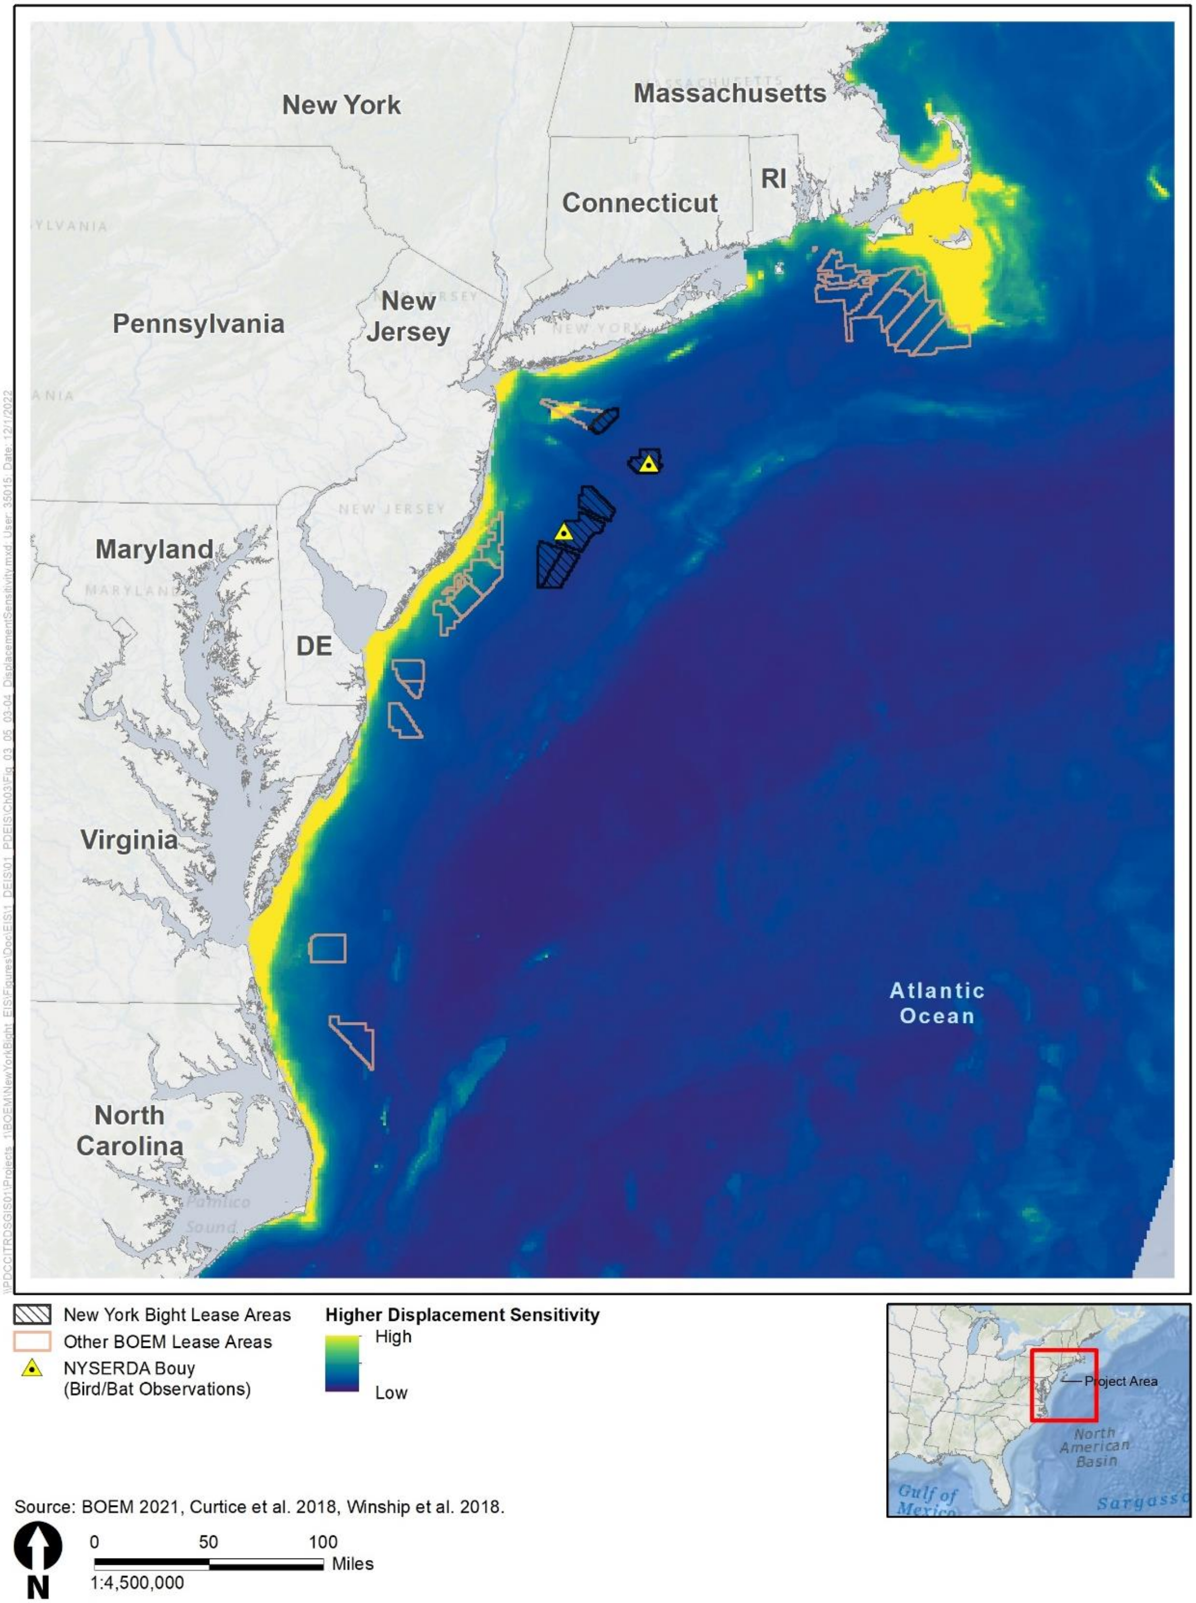

Figure 3.5.3-7. Total avian relative abundance distribution map for the higher displacement sensitivity species group

Traffic (Aircraft): The expected impacts of aircraft traffic associated with a single NY Bight project would not increase beyond the negligible impacts described for the No Action Alternative.

Land disturbance: Impacts associated with construction of onshore elements of one NY Bight project are anticipated to be localized and short term. There would be some potential for habitat impacts on birds as a result of the loss of potentially suitable nesting or foraging habitat. However, BOEM anticipates that impacts on bird habitat from onshore construction activities would be limited because, based on other recent offshore wind projects, whenever possible, facilities (including overhead transmission lines) would be co-located with existing developed areas (i.e., roads and existing transmission lines) to limit disturbance. Any habitat that may be present within permanent substation sites or other permanent facilities would be converted to developed land with landscaping for the duration of the NY Bight project's operational lifetime, which would be considered a long-term effect. While BOEM anticipates habitat clearing to be minimal due to the likely placement of onshore project components in previously disturbed areas, it is possible that larger areas of habitat could be temporarily and permanently cleared. Disturbance to the land surface or terrestrial habitat during the course of conceptual decommissioning would be minimal if onshore components are left in place and abandoned or if minimal disturbance would be required for conceptual decommissioning, such as disconnecting and cutting buried cables at the fence site below ground. If conceptual decommissioning required complete removal of onshore cable, the impacts would be similar to installation impacts. Overall, BOEM anticipates habitat loss would be limited and minor, and any potential effects would be indirect and unlikely to affect individual or population levels of bird species. However, the area of suitable bird habitat removed could vary, depending on the specific siting of the onshore project components, and could result in moderate impacts.

3.5.3.4.2 Impacts of Six Projects

There would be greater potential for impacts under six NY Bight projects due to the greater amount of offshore and onshore development as compared to a single NY Bight project. However, noise impacts are still anticipated to be minimal because noise has limited effects on local birds (see *Impacts of One Project*). The intensity of the impacts from the IPFs related to the offshore environment from a greater number of offshore structures and cables is unlikely to substantially change because bird presence on the OCS is generally low. Therefore, impacts on birds in the offshore environment under six NY Bight projects are anticipated to be negligible to moderate.

The same land disturbance IPF impact types and mechanisms described under one NY Bight project apply to six NY Bight projects. Similar to a single NY Bight project, the level of impact on birds from land disturbance depends on the amount of habitat affected from the onshore project components. While BOEM anticipates that impacts on bird habitat from onshore construction activities under six NY Bight projects would be limited, it is possible that larger areas of habitat could be temporarily and permanently cleared. Under six NY Bight projects, the potential for this possibility would be greater compared to one NY Bight project due to the increased amount of offshore wind development that would occur but would still likely result in a potential negligible to moderate range of impacts.

3.5.3.4.3 Impacts of Alternative B on ESA-Listed Species

The presence of federally protected bird species in the offshore environment would generally be limited. On June 20, 2024, BOEM initiated consultation with the USFWS on a Programmatic Framework ESA Section 7 consultation.

3.5.3.4.4 Cumulative Impacts of Alternative B

The construction and installation, O&M, and conceptual decommissioning of both onshore and offshore infrastructure for offshore wind activities across the geographic analysis area would also contribute to the primary IPFs of accidental releases, air emissions, lighting, cable emplacement and maintenance, noise, presence of structures, traffic (aircraft), and land disturbance. Given that the abundance of bird species that overlap with wind energy facilities on the Atlantic OCS is relatively small, offshore wind activities would not appreciably contribute to impacts on bird populations. Temporary disturbance and permanent loss of habitat onshore may occur as a result of offshore wind development. However, habitat removal is anticipated to be minimal, and any impacts resulting from habitat loss or disturbance would not be expected to result in individual fitness or population-level effects within the geographic analysis area.

The cumulative impacts on birds would likely be moderate because, although bird abundance on the OCS is low, there could be unavoidable impacts offshore and onshore; however, BOEM does not anticipate the impacts to result in population-level effects or threaten overall habitat function. This conclusion would not change even if the six NY Bight projects are constructed at the same time or staggered. In context of reasonably foreseeable environmental trends, the impact of Alternative B to the cumulative accidental releases, air emissions, lighting, cable emplacement and maintenance, presence of structures, traffic (aircraft), and land disturbance impacts on birds would be undetectable.

3.5.3.4.5 Conclusions

Impacts of Alternative B. In summary, construction, installation, and conceptual decommissioning of Alternative B, whether one NY Bight project or six NY Bight projects, would likely have **negligible** to **moderate** impacts on birds, depending on the offshore lighting scheme, amount and quality of habitat removed and the duration of construction activities, as well as the timing and species affected by an activity. The main significant risk would be from operation of the offshore WTGs (including lighting) and potential onshore removal of habitat, which could lead to long-term impacts in the form of mortality, although BOEM anticipates this to be rare. Alternative B would likely also potentially result in **minor beneficial** impacts associated with offshore foraging opportunities for some marine birds, and **minor** to **moderate beneficial** impacts on populations of small land birds due to the reduction in ozone from displacement of fossil fuels in the generation of electricity by offshore wind.

Cumulative Impacts of Alternative B. BOEM anticipates that the cumulative impacts on birds in the geographic analysis area would likely be **negligible** to **moderate** and **minor** to **moderate beneficial** under six NY Bight projects. In context of other reasonably foreseeable environmental trends, the impacts contributed by Alternative B to the cumulative impacts on birds would be undetectable.

Alternative B would contribute to the cumulative impacts primarily through the permanent impacts from the presence of structures and long-term impacts from habitat loss from onshore project components.

3.5.3.5 Impacts of Alternative C (Proposed Action) – Identification of AMMM Measures at the Programmatic Stage – Birds

Alternative C, the Proposed Action, considers the potential impacts of future offshore wind development for the NY Bight area with the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts. Alternative C consists of two sub-alternatives – Sub-alternative C1: Previously Applied AMMM Measures, and Sub-alternative C2: Previously Applied and Not Previously Applied AMMM Measures. The analysis for Sub-alternative C1 is presented as the change in impacts from those impacts discussed under Alternative B, and the analysis for Sub-alternative C2 is presented as the change from those impacts discussed in Sub-alternative C1. Refer to Table G-1 in Appendix G, *Mitigation and Monitoring*, for a complete description of AMMM measures that make up the Proposed Action.

3.5.3.5.1 Sub-alternative C1 (Preferred Alternative): Previously Applied AMMM Measures

Sub-alternative C1 analyzes the AMMM measures that BOEM has required as conditions of approval for previous activities proposed by lessees in COPs submitted for the Atlantic OCS or through related consultations (Table 3.5.3-6).

Table 3.5.3-6. Summary of previously applied avoidance, minimization, mitigation, and monitoring measures for birds

Measure ID	Measure Summary
BB-1	This measure proposes requiring that any occurrence of dead or injured ESA-listed birds or bats (as well as eagles protected under the Bald and Golden Eagle Protection Act) be reported as soon as practicable, which would improve the understanding of ESA-listed bird interactions with wind farms.
BB-2	This measure proposes annual reporting requirements for dead or injured birds or bats, which would improve the overall understanding of bird interactions with wind farms.
BB-3	This measure proposes lessees prepare and implement a *Bird and Bat Post-Construction Monitoring Plan*, which would include monitoring, reporting requirements, and adaptive management to reduce impacts on birds from offshore wind farms.
BIR-1	This measure proposes preparation of a bird perching deterrent plan subject to agency review and implementation of bird perching-deterrents on WTGs and OSSs to reduce potential bird collisions with WTGs.
BIR-2	This measure proposes use of lighting technology that minimizes impacts on avian species to the extent practicable, including lighting designed to minimize upward illumination.
BIR-3	This measure proposes preparation of a *Compensatory Mitigation Plan* and implementation of compensatory mitigation actions to offset take of the ESA-listed piping plover and red knot.
MUL-37	This measure proposes use of an ADLS system on offshore structures to minimize light pollution and species impacts, while ensuring the structures are visible to aircraft.

Impacts of One Project

The identification of AMMM measures under Sub-alternative C1 could potentially reduce impacts on birds compared to those under Alternative B for the lighting and presence of structures IPFs. Impacts for other IPFs would remain the same as described under Alternative B.

Lighting: Implementation of an ADLS system on WTGs (MUL-37) could reduce potential collisions with WTGs. Because WTG lighting can attract some birds and has the potential to pose an increased collision or predation risk to migrating birds, an ADLS system would reduce this risk by significantly reducing the amount of time lights on WTGs would be illuminated. For comparison, the nearby Empire Wind (OCS-A 0512) ADLS-controlled obstruction lights are estimated to be activated for 357 hours, 46 minutes, and 45 seconds over a 1-year period, 7.5 percent of the normal operating time that would occur without ADLS. Using lighting technology on offshore structures that is designed to minimize upward illumination (BIR-2) could also minimize the potential for these lights to be an attractant to migratory birds and reduce the potential for collision with WTGs. While this measure could further minimize potential collisions in addition to implementing an ADLS system (MUL-37), it is unlikely that there would be a substantial additive effect. However, implementing MUL-37 and BIR-2 could reduce the overall potential lighting impacts on birds from moderate to minor.

Presence of structures: The implementation of a *Bird and Bat Post-Construction Monitoring Plan* (BB-3) would support improvement of the overall understanding of bird interactions with offshore wind farms through monitoring, reporting requirements, and adaptive management. Depending on the results of the post-construction monitoring, new mitigation and monitoring measures may be required by BOEM if impacts on birds in the offshore environment are considerably different from the impact analysis. The immediate reporting of dead or injured ESA-listed birds and annual reporting of any dead or injured birds would improve overall understanding of bird interactions with offshore wind and may reduce overall impacts on birds over time (BB-1, BB-2). Dead bird reporting could also lead to new mitigation or monitoring methods to reduce impacts on birds.

In addition to monitoring and reporting measures, Sub-alternative C1 includes measures to avoid direct impacts on birds in the offshore environment. Implementation of bird deterrent devices on WTGs and OSSs (BIR-1), along with adaptive management to modify deterrent design based on ongoing monitoring, would minimize the attraction of birds to WTGs and the potential for collisions.

To mitigate impacts on ESA-listed birds, lessees would be required to develop and implement a Compensatory Mitigation Plan that would include compensatory mitigation actions to offset take of ESA-listed piping plover and red knot (BIR-3). This measure would ensure that impacts on piping plover and red knot are compensated for, which would reduce impacts on ESA-listed species but impacts on other bird species would not be affected.

Overall, while the identification of the AMMM measures under Sub-alternative C1 for this IPF could reduce impacts on birds, BOEM anticipates the bird impacts from presence of structures from one project in the NY Bight lease areas would be similar to Alternative B and remain minor. This impact determination is primarily based on the low presence of birds in the offshore environment and the avian risk analyses conducted by nearby lease areas indicating low risk.

Impacts of Six Projects

Even with the identification of the AMMM measures under Sub-alternative C1, potential impacts on birds within the NY Bight lease areas under six projects is not anticipated to be different compared to a single NY Bight project due to the low presence of birds on the OCS and the unknown bird habitat impacts that could occur in the onshore environment. For the same reasons, the potential impacts on birds for six NY Bight projects under Sub-alternative C1 compared to six NY Bight projects under Alternative B are not anticipated to be substantially different.

Impacts of Sub-Alternative C1 (Preferred Alternative) on ESA-Listed Species

The identification of AMMM measures would result in similar reductions in impacts for ESA-listed birds as described for all birds for one NY Bight project and six NY Bight projects, with the exception of AMMM measures BB-1 and BIR-3, which are designed specifically to mitigate impacts on ESA-listed species. BB-1 and BIR-3 would improve understanding of ESA-listed bird interactions with WTGs through immediate reporting requirements and use compensatory mitigation actions to offset take of piping plover and red knot, respectively. As stated previously, the presence of ESA-listed bird species in the offshore environment would generally be limited, with more potential effects occurring from onshore activities.

Cumulative Impacts of Sub-Alternative C1 (Preferred Alternative)

Under Sub-alternative C1, the cumulative impacts on birds would likely be moderate because, although bird abundance on the OCS is low, there could be unavoidable impacts offshore and onshore. However, BOEM does not anticipate the impacts to result in population-level effects or threaten overall habitat function. In addition, the AMMM measures may not substantially change the potential effect on bird populations. Onshore habitat loss may be reduced if lessees design the onshore project components to avoid sensitive onshore bird habitat, but there is still the possibility of larger habitat areas being removed, which could still result in potential moderate impacts from land disturbance. In the context of other reasonably foreseeable environmental trends, BOEM anticipates the impact of Sub-alternative C1 to the cumulative accidental releases, lighting, cable emplacement and maintenance, noise, presence of structures, traffic (aircraft), and land disturbance impacts on birds would be undetectable.

3.5.3.5.2 Sub-Alternative C2: Previously Applied and Not Previously Applied AMMM Measures

Sub-alternative C2 analyzes the AMMM measures under Sub-alternative C1 plus the AMMM measures that have not been previously applied. However, BOEM has not identified any AMMM measures that have not been previously applied for birds, and, therefore, the impacts on birds under Sub-alternative C2 are the same as Sub-alternative C1 and Alternative B.

3.5.3.5.3 Conclusions

Impacts of Alternative C. Construction, installation, and conceptual decommissioning of one NY Bight project or six NY Bight projects under Sub-alternative C1 or Sub-alternative C2 would likely have **negligible** to **moderate** impacts on birds, depending on the duration of activities performed and how much onshore habitat would be removed. The AMMM measures under Sub-alternative C1 and Sub-alternative C2 would provide some certainty in reducing impacts on birds in the offshore environment and, therefore, could reduce potential impacts on birds compared to those under Alternative B. However, bird presence in the offshore environment is anticipated to be low and the AMMM measures may not significantly reduce impacts. Like Alternative B, onshore habitat impacts under Sub-alternatives C1 and C2 could be reduced by lessees designing the projects to avoid onshore bird habitat. However, because the location of onshore infrastructure is not known, there could still be a range of potential impacts on habitat regardless of the AMMM measures, resulting in negligible to moderate impacts. Noise effects from construction are expected to be limited to temporary and localized behavioral avoidance that would cease once construction is complete. Sub-alternatives C1 and C2 could also result in **minor beneficial** impacts associated with foraging opportunities for some marine birds, and **minor** to **moderate beneficial** impacts on populations of small land birds due to the reduction in ozone from displacement of fossil fuels in the generation of electricity by offshore wind.

Cumulative Impacts of Alternative C. BOEM expects that the cumulative impacts on birds under Sub-alternative C1 and Sub-alternative C2 in the geographic analysis area would likely be **negligible** to **moderate** and **minor** to **moderate beneficial** for six NY Bight projects. In context of reasonably foreseeable environmental trends, the impact of Sub-alternative C1 and Sub-alternative C2 to the cumulative impacts on birds would be undetectable. Because the occurrence of most local bird species offshore is low, Sub-alternative C1 and Sub-alternative C2 would contribute to the cumulative impacts primarily through the long-term impacts from onshore habitat loss related to onshore substations and cables. The extent of onshore habitat impacts is not known at this time because the location of onshore infrastructure is not known, regardless of the absence of land disturbance AMMM measures.

3.5.3.6 Recommended Practices for Consideration at the Project-Specific Stage

In addition to the AMMM measures identified under Alternative C, BOEM is recommending lessees consider analyzing the RPs in Table 3.5.3-7 to further reduce potential bird impacts. Refer to Table G-2 in Appendix G for a complete description of the RPs.

Table 3.5.3-7. Recommended Practices for bird impacts and related benefits

Recommended Practice	Potential Benefit
BB-4: Prepare a framework for a *Bird and Bat Post-Construction Monitoring Plan* to be submitted with the COP.	Developing a framework for a *Bird and Bat Post-Construction Monitoring Plan* would provide the public and agencies an opportunity to provide early feedback on the plan.
MUL-5: Use equipment, technology, and best practices to produce the least amount of noise possible to reduce noise impacts.	Using noise reduction measures to produce the least amount of noise practicable would likely minimize disturbance/displacement impacts.

Recommended Practice	Potential Benefit
MUL-21: Use the best available technology, including new and emerging technology, when possible, to reduce impacts, such as the use of MERLIN radar systems.	Assessing and monitoring bird mortality risk through radar sensors and bird-detection software (e.g., MERLIN) would provide information on avian occurrence in a wind farm area and could be used to inform post-construction operational mitigation.
MUL-23: Consider how to avoid or reduce potential impacts on important environmental resources by adjusting project design as part of COP submittal, which may minimize impacts on birds associated with onshore activities.	Adjusting project design to minimize impacts, such as routing cable in previously disturbed areas, has the potential to reduce impacts on individual birds and their habitats from onshore activities.
MUL-25: Use consistent turbine grid layouts, markings, and lighting in lease areas. Turbines should have one of the two lines of orientation in the grid layout spaced at least 1 nm apart.	Providing more structure-free areas in the lease area and reducing the total number of structures would potentially reduce interactions between birds and WTGs.
MUL-26: Coordinate for regional monitoring and surveys.	Coordinating monitoring and survey efforts across lease areas in the NY Bight to standardize approaches would contribute to understanding potential impacts on birds at a regional scale.
VIS-6: Ensure lighting at onshore and offshore facilities follows night lighting principles and artificial lighting BMPs to avoid light pollution.	Minimizing lighting onshore and offshore would reduce bird attraction to lighting, which would reduce potential collision risk.

3.5 Biological Resources

3.5.4 Coastal Habitat and Fauna

This section discusses potential impacts on coastal habitat and fauna from the Proposed Action, alternatives, and ongoing and planned activities in the geographic analysis area. The coastal habitat and fauna geographic analysis area, as shown on Figure 3.5.4-1, extends from the shoreline inland 1 mile (1.6 kilometers) where onshore infrastructure may be located (e.g., cable landfalls, onshore cable laying, substations/converter stations) and includes the foreshore, backshore, dunes, and interdunal areas as well as vegetation communities. BOEM expects the resources in this area to have small home ranges, and they are unlikely to be affected by impacts outside these home ranges. The 1-mile (1.6-kilometer) inland buffer was used for the analysis area although it is most likely that the onshore infrastructure for future projects would be farther inland. However, because the location of onshore components is unknown, and the existing land use farther inland includes a diverse mix of land use types and previously disturbed areas (see Section 3.6.5, *Land Use and Coastal Infrastructure*), the 1-mile (1.6-kilometer) buffer is used for the geographic analysis area for coastal habitat and fauna. Future project-specific impacts would predominantly be in these already disturbed areas; therefore, at the programmatic level, this 1-mile (1.6-kilometer) buffer is an appropriate geographic analysis area for coastal habitat and fauna.

The affected environment and environmental consequences of project activities that extend into inshore waters (e.g., HDD for cable landfalls) are presented in Section 3.4.2, *Water Quality*; Section 3.5.2, *Benthic Resources* (e.g., soft and hardbottom habitat, mollusk reef biota, submerged aquatic vegetation [SAV]); Section 3.5.5, *Finfish*, *Invertebrates*, *and Essential Fish Habitat*; Section 3.5.6, *Marine Mammals*; and Section 3.5.7, *Sea Turtles*. Additional information on birds, bats, and wetlands is presented in Section 3.5.1, *Bats*; Section 3.5.3, *Birds*; and Section 3.5.8, *Wetlands,* respectively.

The coastal habitat and fauna impact analysis in this PEIS is intended to be incorporated by reference into the project-specific environmental analyses for individual COPs expected for each of the NY Bight lease areas. Because the locations of onshore components for the NY Bight projects are not known at this time, the analysis of onshore coastal habitat and fauna impacts is dependent on a hypothetical project analysis, and impact conclusions consider a maximum-case scenario for onshore development. Additional detailed site-specific analysis will be required for individual COPs. Refer to Appendix C, *Tiering Guidance*, which identifies additional analyses anticipated to be required for the project-specific environmental analysis of individual COPs.

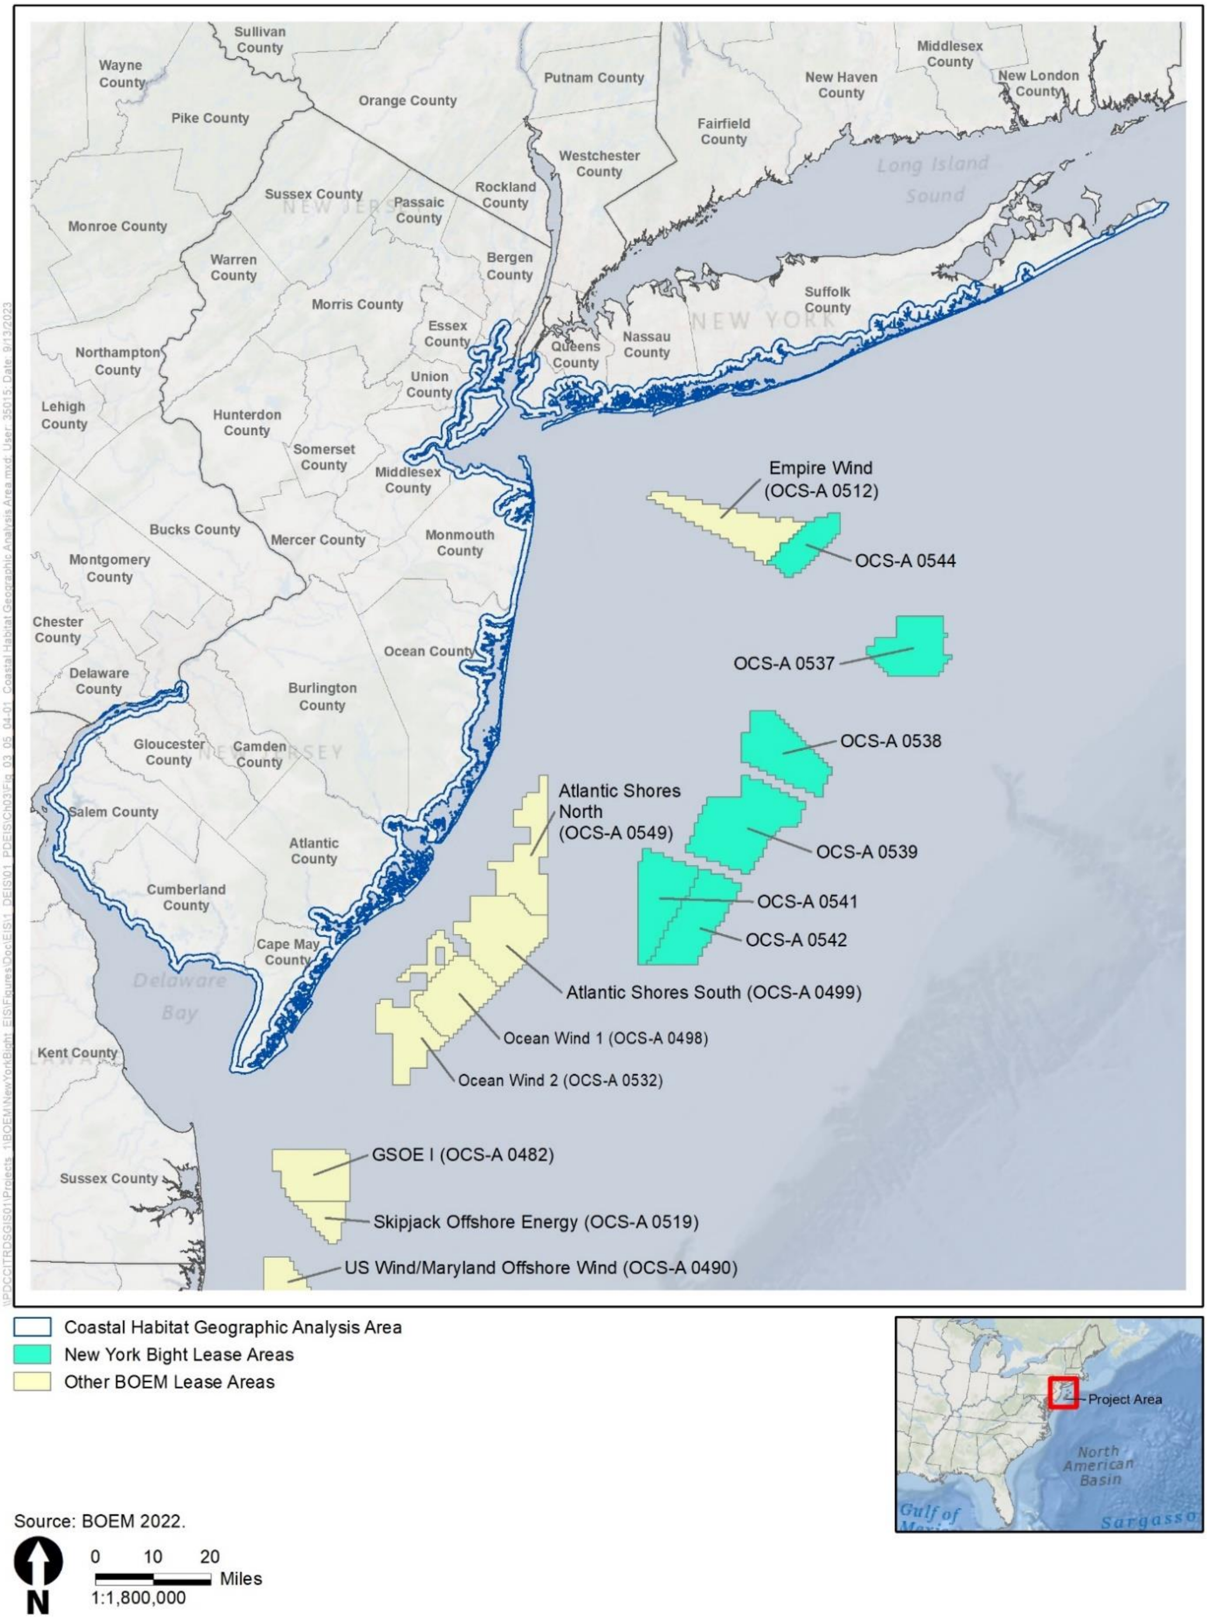

Figure 3.5.4-1. Coastal habitat and fauna geographic analysis area

3.5.4.1 Description of the Affected Environment and Future Baseline Conditions

3.5.4.1.1 Coastal Habitat

This section describes vegetation communities under existing conditions in upland portions of the geographic analysis area and includes information about species and habitats within the onshore area. The *Programmatic Environmental Impact Statement for Alternative Energy Development and Production and Alternate Use of Facilities on the Outer Continental Shelf* (MMS 2007) includes a general description of the affected environment for coastal habitats along the entire Atlantic coast and is hereby incorporated by reference and summarized here. The NY Bight lease areas are located offshore of the Atlantic coastal plain. This plain is a flat stretch of land that borders the Atlantic Ocean for approximately 2,200 miles (3,541 kilometers) from Cape Cod through the southeast United States. The coastal resources of the New York and New Jersey shorelines include sandy beaches, coarse-grained beaches, cliffs, coastal dune systems, and barrier island forests. These habitats and the species present within them are described in detail in the aforementioned PEIS (MMS 2007). Descriptions of site-specific coastal habitats present in the NY Bight are included below.

New York has 120 miles (193 kilometers) of coastline bordering the Atlantic Ocean between Coney Island and Montauk (Tanski 2012). Most of the ocean-facing barrier islands along the south shore of Long Island consist of fine- to medium-grained sand beaches, solid human-made structures (e.g., docks, marinas, jetties, seawalls), and rip-rap (ESI 2009). North-facing shores of the barrier islands border the Great South Bay. Farther west and deeper into the New York-New Jersey harbor, the shoreline is composed of rocky, exposed cliffs, human-made structures, and coarse-grained sand and gravel beaches and eroding scarps (ESI 2001).

New Jersey has 127 miles (204 kilometers) of oceanfront shoreline, much of which is densely populated; however, about 31 miles (50 kilometers) of non-contiguous shoreline between Sandy Hook and Cape May Point has no human-made barriers between land and water (Stockton University 2015). In northern New Jersey, much of the shoreline around Raritan Bay is composed of coarse-grained beaches, mixed-sand and gravel, and rip-rap (NJDEP 2002). Common onshore habitats include forested areas, New Jersey pinelands, Atlantic White Cedar swamp, and beaches and dunes.

Forested Areas

The forested areas of the onshore project area consist of lowland forest and upland forest. Lowland forests are characterized by Atlantic white-cedar (*Chamaecyparis thyoides*) and other broadleaf species. Along the edges of the lowlands are occasional gray birch (*Betula populifolia*), willow oak (*Quercus phellos*), sweet gum (*Liquidambar styraciflua*), and several other water-tolerant lowland species. Lowland forest communities include cedar swamps, hardwood swamps, and pine lowlands. Upland forests are characterized by pines, especially the pitch pine (*Pinus rigida*) and shortleaf pine (*P. echinata*). As compared to the lowlands, the canopy is more varied in composition. Pitch pine is the most abundant, and its associations include shortleaf pine and oaks. Communities within the upland association include pine-black oak (*Q. velutina*), pine-black oak-scrub oak (*Q. berberidifolia*), and oak-pine.

New Jersey Pinelands

Outside of the coastal zone, portions of the onshore geographic analysis area may overlap with mapped New Jersey Pinelands National Reserve. The pinelands ecosystem is an expansive area in southern New Jersey characterized by unconsolidated sand and gravel with a shallow, but characteristically acidic and nutrient-poor aquifer where the plant and animal species have adapted to challenging conditions, particularly wildland fire. Many plant and animal species known to occur in the pinelands require occasional wildfires to maintain habitat conditions and provide opportunities for reproduction. The Pinelands National Reserve area is managed by the Pinelands Commission and is defined by three separate zones: protected areas, managed use areas, and zones of cooperation. The onshore geographic analysis area may overlap with the Pinelands National Reserve areas that are designated as a "Regional Growth Area" which are managed use areas, or Pinelands National Reserve areas designated "protected areas" (State of New Jersey 2021a, 2021b; Pinelands Preservation Alliance 2021).

Atlantic White Cedar Swamp

Atlantic white cedar swamps are prevalent in coastal New Jersey along riverine areas. This community is typically dominated by Atlantic white cedar surrounded by hummocks of sphagnum mosses (*Sphagnum spp*.) with wildflowers, grasses, sedges, rushes, and other species also present (Pinelands Reserve Alliance 2018). Wetlands are further discussed in Section 3.5.8.

Beaches and Dunes

There are many beaches along the New Jersey and New York coastlines. Beach and dune communities are found within the onshore geographic analysis area. These features are generally located along the barrier beach system of the Atlantic shoreline. Dune communities are protected under both New Jersey's and New York's Coastal Zone Management Programs as they provide special protection from coastal storms. Additionally, many beach and dune communities are protected from development if they are located within state parks or wildlife refuges, or if they are federally managed land such as Fire Island National Seashore. In general, while these communities are typically sparsely populated primarily with dune grasses that protect the dunes and assist in sand accretion (USEPA 2012), these habitats are used by many species, including federally and state-listed species such as migratory birds, butterflies, and bats.

Coastal Barrier Resources System

The Coastal Barrier Resources Act (CBRA) protects coastal areas that serve as barriers against wind and tidal forces caused by coastal storms and serve as habitat for aquatic species. The CBRA designated relatively undeveloped coastal barriers along the Atlantic and Gulf coasts as part of the John H. Chafee Coastal Barrier Resources System (BOEM and NOAA 2018). The CBRA encourages the conservation of hurricane-prone, biologically rich coastal barriers by restricting federal expenditures that encourage development (BOEM and NOAA 2018). Several Coastal Barrier Resources Systems are found within the geographic analysis area along coastal New Jersey.

3.5.4.1.2 Coastal Flora

The Atlantic Coast of the United States supports a great diversity of terrestrial biota. This diversity is a function of the combinations of geology, topography, and climate that occur along the coast from the Florida Keys to the Canadian border in Maine and the ecoregions that encompass these areas. The eastern Atlantic Coast falls into six ecoregions, each with a relatively unique ecosystem and biota; three occur in the geographic analysis area and include the Middle Atlantic Coastal Plain, Atlantic Coastal Pine Barrens, and Northeastern Coastal Zone.

Middle Atlantic Coastal Plain (Southern New Jersey)

This ecoregion consists of low elevation flat plains, with many swamps, marshes, and estuaries. Forest cover in the region is mostly loblolly and some shortleaf pine, with patches of oak, gum, and cypress near major streams. Its low terraces, marshes, dunes, barrier islands, and beaches are underlain by unconsolidated sediments (MMS 2007).

Atlantic Coastal Pine Barrens (New Jersey, New York)

This ecoregion is distinguished from the Middle Atlantic Coastal Ecoregion to the south by its coarser-grained soils, cooler climate, and oak-pine potential natural vegetation. The climate is milder than the Northeastern Coastal Ecoregion to the north, which contains Appalachian Oak forests and some Northern hardwood forests. The physiography of this ecoregion is not as flat as that of the Middle Atlantic Coastal Plain, but it is not as irregular as that of the Northeastern Coastal Zone (MMS 2007).

Northeastern Coastal Zone (New York)

This ecoregion contains relatively nutrient-poor soils and concentrations of continental glacial lakes, some of which are sensitive to acidification; however, this ecoregion contains considerably less surface irregularity and much greater concentrations of human population (MMS 2007). Land use now mainly consists of forests and residential development. Land cover and use is further discussed in Section 3.6.5.

3.5.4.1.3 Coastal Fauna

Coastal areas, including beaches and dunes, provide habitat for many different types of fauna. Beaches and dunes are important habitats for migrating and nesting shorebirds and songbirds. The beaches, dunes, and scrub-shrub habitats along the shoreline may support commonly found species such as the double-crested cormorant (*Phalacrocorax auritus*), ring-billed gull (*Larus delawarensis*), great blue heron (*Ardea herodias*), sanderling (*Calidris alba*), and brown pelican (*Pelecanus occidentalis*); see Section 3.5.3, *Birds,* for additional information.

Wildlife expected to be present along the onshore export cable corridor or at the onshore substation construction area include species known to inhabit forested wetlands, forested lowlands, and upland habitats and pinelands, while wildlife expected to be present along the cable landfall sites includes species known to inhabit coastal wetlands, barrier beaches, and bay island habitats.

Typical species found in coastal areas of New Jersey and New York are shown in Table 3.5.4-1, and typical species known to inhabit forested wetland, forested lowland, and upland habitats and pinelands of New Jersey and New York are provided in Table 3.5.4-2.

Table 3.5.4-1. Species typically found in coastal areas of New Jersey and New York

Common Name	Scientific Name	Common Name	Scientific Name
Black Snake	*Pantherophis obsoletus*	Garter Snake	*Thamnophis sirtalis*
Meadow Vole	*Microtus pennsylvanicus*	Porcupine	*Erethizon dorsatum*
Bobcat	*Felis refus*	Deer Mouse	*Peromyscus maniculatus*
Mink	*Neovison vison*	Raccoon	*Procyon lotor*
Bog Lemming	*Synaptomys cooperi*	Northern Diamondback Terrapin	*Malaclemys terrapin*
Eastern Mole	*Scalopus aquaticus*	Red Fox	*Vulpes vulpes*
Bog Turtle	*Glyptemys muhlenbergii*	Eastern Spiny Softshell Turtle	*Apalone spinifera*
Muskrat	*Ondatra zibethicus*	Red Squirrel	*Tamiasciurus hudsonicus*
Box Turtle	*Terrapene carolina carolina*	Eastern Tiger Salamander	*Ambystoma tigrinum*
Northern Scarlet Snake	*Cemophora coccinea copei*	Rice Rat	*Oryzomys palustris*
Brown Bat	*Myotis lucifugus*	Flying Squirrel	*Glaucomys volans*
Norway Rat	*Rattus norvegicus*	River Otter	*Lontra canadensis*
Eastern Chipmunk	*Tamias striatus*	Fowler’s Toad	*Anaxyrus fowleri*
Virginia Opossum	*Didelphis virginiana*	Shrew	*Blarina brevicauda*
Corn Snake	*Pantherophis guttatus*	Skunk	*Mephitis mephitis*
Pine Barrens Tree Frog	*Hyla andersonii*	Gray Tree Frog	*Hyla chrysoscelis*
Cottontail Rabbit	*Sylvilagus floridanus*	Spring Peeper	*Pseudacris crucifer*
Gray Fox	*Urocyon cinereoargenteus*	Gray Squirrel	*Sciurus carolinensis*
Timber Rattlesnake	*Crotalus horridus*	Weasel	*Mustela frenata*
Ground Skink	*Scincella lateralis*	House Mouse	*Mus musculus*
White-footed Mouse	*Peromyscus leucopus*	White-tailed Deer	*Odocoileus virginianus*
Meadow Mouse	*Microtus pennsylvanicus*		

Table 3.5.4-2. Species known to inhabit forested wetland, forested lowland, and upland habitats and pinelands of New Jersey and New York

Common Name	Scientific Name	Common Name	Scientific Name
American Bittern	*Botaurus lentiginosus*	Northern Diamondback Terrapin	*Malaclemys terrapin*
Eastern Chipmunk	*Tamias striatus*	White-tailed Deer	*Odocoileus virginianus*
Red Fox	*Vulpes vulpes*	Virginia Opossum	*Didelphis virginiana*
Gray Fox	*Urocyon cinereoargenteus*	Raccoon	*Procyon lotor*
Red Squirrel	*Tamiasciurus hudsonicus*	Eastern Mole	Scalopus aquaticus
Gray Squirrel	*Sciurus carolinensis*	Northern Harrier	*Circus hudsonius*
Eastern Cottontail	*Sylvilagus floridanus*	Northern Pine Snake	*Pituophis melanoleucus*
Eastern Hognose Snake	*Heterodon platirhinos*	Osprey	*Pandion haliaetus*
Eastern Meadowlark	*Sturnella magna*	Pine Siskins	*Spinus pinus*
Finches	*Fringillidae sp.*	Red Bat	*Lasiurus borealis*
Grasshopper Sparrow	*Ammodramus savannarum*	Red-backed Salamander	*Plethodon cinereus*
Horned Lark	*Eremophila alpestris*	Savannah Sparrow	*Passerculus sandwichensis*

Common Name	Scientific Name	Common Name	Scientific Name
Kinglets	*Regulus spp.*	Little Blue Heron	*Egretta caerulea*
Masked Shrew	*Sorex cinereus*	Woodchuck	*Marmota monax*
Northern Black Racer	*Coluber constrictor*		

For any onshore project components located predominantly within developed lands, the project area would be generally most suitable for species common to urban environments, comprising sparsely vegetated and highly fragmented habitats, including mammals such as Virginia opossum, eastern cottontail, gray squirrel, meadow vole, Norway rat, house mouse, raccoon, and striped skunk. Bird species likely to utilize these urban habitats include house sparrow (*Passer domesticus*), European starling (*Sturnus vulgaris*), gulls, and rock pigeon (*Columba livia*) (see Section 3.5.3 for further discussion of avian species).

3.5.4.1.4 Federal and State-Listed Coastal Species

Under the ESA, the New Jersey Endangered and Nongame Species Program, and the New York Endangered Species Program, species and their habitats potentially impacted by construction and operation of offshore wind projects would require further evaluation to determine presence of habitat and individuals in the geographic analysis area and its immediate vicinity. These evaluations would be required to support federal and state permit requirements.

Special concern species that could potentially occur in these areas include but are not limited to the spotted turtle (*Clemmys guttata*) and the eastern box turtle (*Terrapene carolina carolina*). Seaside sandplant (*Honckenya peploides* var. *robusta*), sea-beach knotweed (*Polygonum glaucum*), seabeach sedge (*Carex silicea*), and sickle-leaf golden-aster (*Pityopsis falcate*) are plant species of concern known to occur in the barrier islands of the geographic analysis area. Federal and state listed threatened and endangered species found in or in the vicinity of the geographic analysis area for coastal habitat and fauna are presented in Table 3.5.4-3. Additional information on other Threatened and Endangered species that may occur in or near the coastal habitat areas can be found in Section 3.5.1, *Bats*; Section 3.5.3, *Birds;* Section 3.5.5, *Finfish*, *Invertebrates*, *and Essential Fish Habitat*; Section 3.5.6, *Marine Mammals*; and Section 3.5.7, *Sea Turtles*.

Table 3.5.4-3. Summary of potential threatened and endangered species in or in the vicinity of the geographic analysis area for coastal habitat and fauna

Common Name	Scientific Name	Taxonomic Group	Federal Status	State Status
Flora				
American Chaffseed	*Schwalbea americana*	Plant	Endangered	Unlisted
Knieskern's Beaked-rush	*Rhynchospora knieskernii*	Plant	Threatened	Unlisted
Sandplain Gerardia	*Agalinis acuta*	Plant	Endangered	NY Endangered
Seabeach Amaranth	*Amaranthus pumilus*	Plant	Threatened	NY Threatened
Sensitive Joint-vetch	*Aeschynomene virginica*	Plant	Threatened	Unlisted
Small whorled pogonia	*Isotria medeoloides*	Plant	Threatened	NY, NJ Endangered
Swamp Pink	*Helonias bullata*	Plant	Threatened	NJ Endangered

Common Name	Scientific Name	Taxonomic Group	Federal Status	State Status
Fauna				
Bobcat	*Lynx rufus*	Mammal	Unlisted	NJ Endangered
Harlequin Duck	*Histrionicus*	Bird	Unlisted	Unlisted
Common Tern	*Sterna hirundo*	Bird	Unlisted	NY Threatened
Forster's Tern	*Sterna forsteri*	Bird	Unlisted	Unlisted
Gull-Billed Tern[1]	*Gelochelidon nilotica*	Bird	Unlisted	Unlisted
Least Tern[1]	*Sterna antillarum*	Bird	Threatened	Unlisted
Black Skimmer[1]	*Rynchops niger*	Bird	Unlisted	Unlisted
Piping Plover	*Charadrius melodus*	Bird	Threatened	NY Endangered
Rufa Red Knot	*Calidris canutus rufa*	Bird	Threatened	NY Threatened
Roseate Tern	*Sterna dougallii*	Bird	Endangered	NY Endangered
Bog Turtle	*Clemys muhlenbergii*	Reptile	Threatened	NJ Endangered
Corn Snake	*Pantherophis guttatus*	Reptile	Unlisted	NJ Endangered
Northern Pine Snake	*Pituophis melanoleucus melanoleucus*	Reptile	Unlisted	NJ Threatened
Timber Rattlesnake	*Crotalus horridus horridus*	Reptile	Unlisted	NJ Endangered
Wood Turtle	*Glyptemus insculpta*	Reptile	Unlisted	NJ Threatened
Cope's Gray Treefrog (southern gray treefrog)	*Hyla chrysoscelis*	Amphibian	Unlisted	NJ Endangered
Pine Barrens Treefrog	*Hyla andersonii*	Amphibian	Unlisted	NJ Threatened
American burying beetle	*Nicrophorus americanus*	Insect	Threatened	NJ Endangered
Monarch Butterfly	*Danaus plexippus plexippus*	Insect	Candidate	Unlisted
Northeastern beach tiger beetle	*Habroscelimorpha dorsalis dorsalis*	Insect	Threatened	NJ Endangered
Rusty patched bumble bee	*Bombus affiniss*	Insect	Endangered	Unlisted

[1] Species considered Birds of Conservation Concern by USFWS (USFWS 2021).

3.5.4.2 Impact Level Definitions for Coastal Habitat and Fauna

Definitions of potential impact levels are provided in Table 3.5.4-4. Beneficial impacts on coastal habitat and fauna are described using the definitions described in Section 3.3.2 (see Table 3.3-1).

Table 3.5.4-4. Adverse impact level definitions for coastal habitat and fauna

Impact Level	Definition
Negligible	There would be no measurable impacts on species or habitat, or impacts would be so small that they would be extremely difficult or impossible to discern or measure.
Minor	Most impacts on species would be avoided; if impacts occur, they may result in the loss of a few individuals. Impacts on sensitive habitats would be avoided; impacts that do occur are temporary or short term in nature.
Moderate	Impacts on species would be unavoidable but would not result in population-level effects. Impacts on habitat may be short term, long term, or permanent and may include impacts on sensitive habitats but would not result in population-level effects on species that rely on them.
Major	Impacts would affect the viability of the population and would not be fully recoverable. Impacts on habitats would result in population-level impacts on species that rely on them.

BOEM expects that planned offshore wind projects in the NY Bight lease area would be designed to avoid important coastal habitat (e.g., wetlands) to the extent feasible, and would be required to comply with federal, state, and local regulations related to the protection of sensitive habitats and species by avoiding or minimizing impacts. Given the extent of sensitive coastal habitats, complete avoidance is often not possible; however, AMMM measures are proposed in Alternative C to minimize and mitigate impacts.

Accidental releases, land disturbance, noise, and traffic are contributing IPFs to impacts on coastal habitat and fauna. However, these IPFs may not necessarily contribute to each individual issue outlined in Table 3.5.4-5.

Table 3.5.4-5. Issues and indicators to assess impacts on coastal habitats and fauna

Issue	Impact Indicator
Habitat loss/ modification	Area of impacted habitat
Disturbance/ displacement	Changes to noise levels Projected traffic patterns/volume changes Qualitative assessment of potential ingestion or ensnarement from trash/debris
Collision/injury	Qualitative estimate of collision risk

3.5.4.3 Impacts of Alternative A – No Action – Coastal Habitat and Fauna

When analyzing the impacts of the No Action Alternative on coastal habitat and fauna, BOEM considered the impacts of ongoing activities, including ongoing non-offshore-wind and ongoing offshore wind activities on the baseline conditions for coastal habitat and fauna. The cumulative impacts of the No Action Alternative considered the impacts of the No Action Alternative in combination with the other planned non-offshore-wind and offshore wind activities, which are described in Appendix D, *Planned Activities Scenario*.

3.5.4.3.1 Impacts of the No Action Alternative

Under the No Action Alternative, baseline conditions for coastal habitat and fauna would continue to follow current regional trends and respond to IPFs introduced by other ongoing activities. Ongoing activities within the geographic analysis area that contribute to impacts on coastal habitat and fauna are generally associated with onshore impacts, including onshore residential, commercial, and industrial development (see Section D.2 in Appendix D for a description of ongoing activities), and climate change. Mainland coastal habitat in the geographic analysis area for coastal habitat and fauna mostly consists of sandy beach and dune vegetation; much of this is developed for the public beach and private residences. Any new structures along the coast, including developments, roads, utilities, marinas and ports, and shoreline protection measures, are anticipated to increase gradually, altering coastal habitat. Development is likely to continue as resident and vacationer populations expand. However, it is important to note that New York and New Jersey State agencies have regulations on coastal development to protect and preserve existing natural resources; while development is likely to continue, much of it will be done in accordance with state regulations to protect the natural environment, including coastal habitat and fauna. Onshore construction activities have the potential to affect coastal habitat and fauna through temporary and permanent habitat removal or conversion and temporary noise impacts during construction, which could cause avoidance behavior and displacement of animals, as well as injury or mortality to individual animals or loss and alteration of vegetation and individual plants. However, population-level effects would not be anticipated. Ongoing offshore wind activities within the geographic analysis area that contribute to impacts on coastal habitat and fauna include ongoing construction of Ocean Wind 1 (OCS-A 0498), South Fork Wind (OCS-A 0517), Sunrise Wind (OCS-A 0487), and Empire Wind (OCS-A 0512) 1 and 2. Ongoing construction of Ocean Wind 1, South Fork Wind, Sunrise Wind, and Empire Wind 1 and 2 would have the same types of impacts on coastal habitat and fauna that are described in Section 3.5.4.3.3, *Cumulative Impacts of the No Action Alternative,* for all ongoing and planned offshore wind activities in the geographic analysis area, but would be of lower intensity.

Climate change and associated sea level rise results in dieback of coastal habitats caused by rising groundwater tables and increased saltwater inundation from storm surges and exceptionally high tides (Sacatelli et al. 2020). Sandy beaches in the geographic analysis area are subject to erosion and vulnerable to the effects of projected climate change and relative sea level rise (Roberts et al. 2015) including ocean acidification and ocean warming. Climate change may also affect coastal habitats through increases in instances and severity of droughts and range expansion of invasive species. Warmer temperatures will cause plants to flower earlier, will not provide needed periods of cold weather, and will likely result in declines in reproductive success of plant and pollinator species (Cassota et al. 2019). Reptile and amphibian populations may experience shifts in distribution, range, reproductive ecology, and habitat availability. Increased temperatures could lead to changes in mating, nesting, reproductive, and foraging behaviors of species, including a change in the sex ratios in reptiles with temperature-dependent sex determination (Cassota et al. 2019).

Climate change factors have accounted for the loss of approximately 3.4 million acres (1.4 million hectares) of forested coastal wetlands across the north Atlantic coastal plain between 1996 and 2016 (White et al. 2021). If sea levels rise approximately 2 feet (0.6 meter) by the end of the century, over 167,000 acres (67,582 hectares) of undeveloped dry land and approximately 161,000 acres (65,154 hectares) of brackish marsh would be lost, replaced in part by over 266,000 acres (107,646 hectares) of newly open water and 50,000 acres (20,234 hectares) of salt marsh (Glick et al. 2008).

3.5.4.3.2 Impacts of the No Action Alternative on ESA-Listed Species

The species discussed in Table 3.5.4-3 may be affected by offshore wind activities. The IPFs described previously for coastal habitat and fauna would also apply to ESA-listed species. Any future federal activities that could affect ESA-listed species would need to comply with ESA Section 7 to ensure that the proposed activities do not jeopardize the continued existence of the species. Future non-federal activities would be addressed under ESA Section 10 to ensure that the proposed activities do not jeopardize the continued existence of individual species.

3.5.4.3.3 Cumulative Impacts of the No Action Alternative

The cumulative impact analysis for the No Action Alternative considers the impacts of the No Action Alternative in combination with other planned non-offshore-wind activities and planned offshore wind activities (without the development of the NY Bight projects).

Planned non-offshore-wind activities that may affect coastal habitat and fauna primarily include increasing onshore development activities (see Section D.2 in Appendix D for a description of ongoing and planned activities). Other planned non-offshore-wind activities that may affect coastal habitat and fauna include new submarine cables, transmission systems (e.g., PBI), and pipelines, oil and gas activities, marine minerals extraction, port expansions, and installation of new structures on the OCS (see Appendix D for a description of planned activities). Planned transmission infrastructure, such as PBI, would likely be primarily co-located with existing roads and rights-of way. These activities may result in temporary or permanent landscape alteration or displacement and injury or mortality to individual plants and animals, but population-level effects would not be expected for flora and fauna. Habitat and plant degradation and loss as well as habitat conversion may also occur. Ongoing and planned offshore wind activities that could potentially overlap the coastal habitat and fauna geographic analysis area are listed in Table 3.5.4-6.

Table 3.5.4-6. Ongoing and planned offshore wind in the geographic analysis area for coastal habitat and fauna

Ongoing/Planned	Projects by Region
Ongoing – 5 projects[1] 	**MA/RI** • South Fork Wind (OCS-A 0517) • Sunrise Wind (OCS-A 0487) **NY/NJ** • Ocean Wind 1 (OCS-A 0498) • Empire Wind 1 (OCS-A 0512) • Empire Wind 2 (OCS-A 0512)
Planned – 3 projects[2] 	**NY/NJ** • Ocean Wind 2 (OCS-A 0532) • Atlantic Shores North (OCS-A 0549) • Atlantic Shores South (OCS-A 0499)

MA = Massachusetts; NJ = New Jersey; NY = New York; RI= Rhode Island
[1] Refer to footnotes 9 and 10 in PEIS Chapter 1 for additional information on the status of Ocean Wind 1, Empire Wind 1, and Empire Wind 2.
[2] Status as of September 20, 2024.

BOEM expects ongoing and planned offshore wind activities to affect coastal habitat and fauna through the following primary IPFs.

Accidental releases: Accidental releases of fuels, lubricating oils, and other petroleum compounds may increase as a result of offshore wind activities. The risk of any type of accidental release would increase primarily during construction, but also could occur during operations and conceptual decommissioning of offshore wind facilities. Onshore, the use of heavy construction equipment could result in releases of fuel and lubricating and hydraulic oils during equipment use or refueling. Accidental releases may cause onshore habitat contamination from releases, cleanup activities, or both, although the volume of spilled material is anticipated to be low. Proper waste handling and cleanup procedures would minimize the potential for accidental releases and ensure spills are cleaned up promptly. There is no evidence that the anticipated volumes of accidental releases combined with cleanup measures would have measurable impacts on coastal habitat and fauna; therefore, impacts would be negligible. See Section 3.4.2.1, *Description of the Affected Environment and Future Baseline Conditions* for water quality, for quantities and details. As described in Section 2.3, *Non-Routine Activities and Events*, accidental releases of chemicals, gases, or man-made debris may occur as a result of a structural failure and could result in impacts on coastal habitat and fauna.

Land disturbance: Ground-disturbing activities from construction of onshore components could contribute to elevated levels of erosion and sedimentation, but usually not to a degree that affects coastal fauna, assuming that industry standard BMPs are implemented. Land disturbance from erosion and sedimentation associated with planned offshore wind activities, including export cables, landfalls, onshore substations/converter stations, and transmission facilities, would likely result in negligible impacts on coastal habitat and fauna in the geographic analysis area.

Land disturbances related to the onshore construction of facilities associated with offshore wind projects could cause removal of vegetation and conversion of natural coastal habitat to developed space. These land use changes are a frequent occurrence in coastal habitat. Land disturbance that results in onshore land use changes associated with planned offshore wind activities may produce minor impacts on coastal habitat and fauna as BOEM expects that most impacts on species would be avoided and, if impacts occur, they may result in the loss of a few individuals.

Some amount of habitat conversion may also result from port expansion activities required to meet the demands for fabrication, construction, transportation, and installation of wind energy structures. The general trend along the coastal region from Virginia to Maine is that port activity will increase modestly and require some conversion of undeveloped land to meet port demand (Lauriat 2022). This conversion will result in permanent habitat loss for local fauna populations. The increase of port facilities from development of planned offshore wind projects would be a minimal contribution of port expansion required to meet increased commercial, industrial, and recreational demand. See Section, 3.5.2, *Benthic Resources,* for more information on port expansion.

Noise: Onshore noise associated with intermittent construction of planned offshore wind development infrastructure (e.g., export cables, landfalls, onshore substations/converter stations, and transmission facilities) may result in highly localized and short-term impacts, including avoidance and displacement of species, as the land-based construction noise is likely sufficient to temporarily drive away local motile fauna, such as wading birds, from the immediate area during construction. No individual fitness or population-level effects would be anticipated to occur. The noise generated from onshore cable installation and trenching would be temporary and localized, and they would extend only a short distance beyond the cable emplacement corridor, therefore, impacts from noise on coastal habitat and fauna would likely be negligible.

Traffic: Impacts on wildlife and their habitat from vehicle traffic associated with planned offshore wind activities are anticipated to be limited as the onshore geographic analysis area is highly developed and experiences regular traffic. Risks of impacts on wildlife from offshore wind-related vehicle traffic may increase in areas that do not currently experience consistent vehicular traffic (e.g., electric utility and pedestrian/bike lanes ROWs). Vehicle traffic associated with the construction and operation of onshore facilities would represent increases in traffic volume mainly during construction and would be concentrated along the onshore cable routes and at the substations. During construction, mechanized equipment traffic could disturb or displace local wildlife, but these impacts would be similar to those caused by human presence, land disturbance, and noise/vibration that already occur. Any vehicle-related impacts on wildlife are expected to be localized and limited to the duration of construction. Limited mobility species, such as snakes and turtles, have a low probability of directly encountering vehicles because of the limited populations of these types of species proximate to the current high traffic use areas within the onshore areas associated with the planned offshore wind activities. Use of standard erosion and sedimentation control BMPs such as silt fences along the limits of construction would prevent these species from entering the construction work areas. Additionally, vehicle-related impacts on wildlife during routine O&M and conceptual decommissioning activities would be accidental and rare. All other species are expected to temporarily avoid areas of higher vehicle traffic but return once activities have ceased. Any impacts are expected to be highly localized, short-term, and not result in any population-level impacts. As there would likely be no measurable impacts on species or habitat, impacts are expected to be negligible.

3.5.4.3.4 Conclusions

Impacts of the No Action Alternative. Under the No Action Alternative, coastal habitat and fauna would continue to be affected by existing environmental trends and ongoing activities. BOEM expects ongoing activities to have continuing temporary, long-term, and permanent impacts (disturbance, displacement, injury, mortality, and habitat conversion) on coastal habitat and fauna primarily through onshore construction impacts, noise, traffic, and climate change. Habitat removal from ongoing activities is anticipated to be minimal, and any impacts resulting from habitat loss or disturbance would not be expected to result in individual fitness or population-level effects within the geographic analysis area. The No Action Alternative would likely result in **negligible** to **moderate** impacts, as climate change is predicted to cause notable impacts on coastal habitat and fauna.

Cumulative Impacts of the No Action Alternative. Under the No Action Alternative, existing environmental trends and ongoing activities would continue, and coastal habitat and fauna would continue to be affected by land disturbance and climate change. In addition to ongoing activities, planned activities may also contribute to impacts on coastal habitat and fauna. Planned activities primarily include increasing onshore construction. BOEM anticipates that the overall impacts associated with the No Action Alternative, when combined with all other planned activities (including offshore wind) in the geographic analysis area, would likely be **negligible** to **moderate** given that any activity would be required to comply with federal, state, and local regulations related to the protection of sensitive habitats and mitigation of impacts, and given the continued impacts of land disturbance and climate change.

3.5.4.4 Impacts of Alternative B – No Identification of AMMM Measures at the Programmatic Stage – Coastal Habitat and Fauna

3.5.4.4.1 Impacts of One Project

Alternative B considers the potential impacts of future offshore wind development for the NY Bight area without the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts.

Accidental releases: One NY Bight project would increase the risk of accidental releases of fuels, lubricating oils, and other petroleum compounds, primarily during construction but also during operations and conceptual decommissioning. Onshore, the use of heavy construction equipment could result in releases of fuel and lubricating and hydraulic oils during equipment use or refueling. These potential accidental releases would be of low risk and small quantity, and combined with the cleanup measures in place, the impacts of accidental releases of fuel, fluids, and hazardous materials on coastal habitat and fauna are expected to be minor; the duration of effects from accidental releases would be short- to long term in nature, and most impacts on species are expected to be avoided.

Land disturbance: Land disturbance associated with onshore construction (clearing, grading and excavations) could cause removal of vegetation, temporary disturbance to adjacent land uses (light, noise, and traffic), and disruption of shoreline access. A single NY Bight project could include land disturbance from onshore construction associated with installation of export cables, landfalls, onshore substations and converter stations, and transmission facilities. Impacts on habitat from onshore construction activities is expected to be limited because, based on BOEM’s experience with other offshore wind projects along the Atlantic coast, facilities would most likely be located in existing developed areas, such as roads, parking lots, and utility ROWs. Lighting associated with new onshore substations or converter stations would increase, but the extent of impacts would likely be limited to the immediate vicinity of the lights, and the intensity of impacts on coastal fauna would likely be unmeasurable at a distance. It is anticipated that direct effects on sensitive environmental resources, such as wetlands and forests, would be avoided or minimized to the maximum extent practicable during the design and construction of the project. Once onshore project details are determined during the project-specific COP NEPA stage, the lessees will obtain the proper permits for land disturbance.

Temporary construction impacts on coastal fauna would be limited (see noise and traffic IPFs), as most individuals would avoid the construction areas (Goodwin and Shriver 2010). Land disturbance that does occur, especially on shoreline parcels, could cause short-term erosion and sedimentation impacts in coastal habitat. Altering dune and beach habitat could increase erosion and sedimentation because dune habitat serves as a crucial buffer zone against flooding. Federal and state agencies work with Atlantic coastal towns and other land managers to develop site-specific beach management plans for the protection of federally and state-listed threatened and endangered species. The project-specific COP NEPA analysis will coordinate with local town and/or beach managers once the landing locations are identified to ensure concurrence with local management plans. Overall impacts from land disturbance on coastal habitat and fauna are expected to be minor.

Noise: One NY Bight project would generate noise during construction of onshore infrastructure. Onshore construction noise levels would primarily be limited to daytime hours. This would include noise associated with the construction of cable landfalls, onshore cable installation, and construction of onshore substations or converter stations. While noise from pile driving will not impact nearshore environments, there is the potential for developers to install cofferdams at HDD exit pit sites. Driving of sheet piles for HDD pit cofferdams, if used, could create noise in the nearshore environment. Onshore construction noise and vibration could lead to the disturbance and temporary displacement of mobile species including insects, birds, reptiles, amphibians, and mammals. The noise generated by construction activities, as well as the physical changes to the space, could render an area temporarily unsuitable for fauna or result in masking effects on communication for fauna that remain in the area (Dooling et al. 2019). Because impacts from onshore construction noise would be short term and primarily only occur in the daytime and since most fauna are able to temporarily leave the area where noise is occurring, BOEM expects that no individual fitness or population-level impacts would occur. Therefore, minor impacts on coastal habitat and fauna from one NY Bight project are expected; lasting impacts on local breeding populations are not anticipated.

Normal operation of onshore substations/converter stations would generate localized continuous noise; however, BOEM expects negligible impacts when considered in the context of the other commercial and industrial noises in the geographic analysis area. No measurable impacts on coastal fauna are expected.

Traffic: Impacts on wildlife and their habitat from vehicle traffic associated with a single NY Bight project are anticipated to be similar to the No Action Alternative. Risks of impacts on wildlife from project-related vehicle traffic may increase along the portions of the onshore project area that occur within areas that do not currently experience consistent vehicular traffic (e.g., electric utility and pedestrian/bike lanes ROWs). During construction, mechanized equipment traffic could disturb or displace local wildlife, but these impacts would be similar to those caused by human presence, land disturbance, and noise/vibration that already occur. Any vehicle-related impacts on wildlife are expected to be localized and limited to the duration of construction. Limited mobility species, such as snakes and turtles, have a low probability of directly encountering vehicles because of the limited populations of these types of species proximate to the current high traffic use areas within the onshore geographic analysis area. Collisions between highly mobile fauna and vehicles or construction equipment have some limited potential to cause mortality. Additionally, vehicle-related impacts on wildlife during routine O&M and conceptual decommissioning activities would be accidental and rare. Any impacts are expected to be highly localized and short-term, would not result in any population-level impacts, and therefore would likely be minor.

3.5.4.4.2 Impacts of Six Projects

The same IPF impact types and mechanisms described under one NY Bight project apply to six NY Bight projects. There would be more potential for impacts for these IPFs due to the greater amount of onshore development under six NY Bight projects. However, accidental releases, land disturbance, noise, and traffic impacts are still expected to be minimal. Therefore, impacts under six NY Bight projects are anticipated to have negligible to minor and short-term impacts on coastal habitat and fauna.

The same land disturbance IPF impact types and mechanisms described under one NY Bight project apply to six NY Bight projects. Similar to one NY Bight project, the level of impact on coastal habitat and fauna depends on the amount, function, impact type, and duration of land disturbance. While BOEM anticipates that impacts on coastal habitat and fauna from onshore construction activities under six NY Bight projects would be minimized to the extent practicable (similar to one NY Bight project), it is reasonable to assume that with six NY Bight projects, larger areas of coastal habitat could be temporarily and permanently impacted. Under six NY Bight projects, the potential for this possibility would be greater compared to one NY Bight project due to the increased amount of onshore development that would occur; however, impacts would likely remain minor.

3.5.4.4.3 Impacts of Alternative B on ESA-Listed Species

On June 20, 2024, BOEM initiated consultation with the USFWS on a Programmatic Framework ESA Section 7 consultation. The species discussed in Table 3.5.4-3 may be affected by Alternative B. The IPFs described previously for all coastal habitat and fauna would also apply to ESA-listed species. Any future federal activities that could affect ESA-listed species would need to comply with ESA Section 7 to ensure that the proposed activities do not jeopardize the continued existence of the species. Future non-federal activities would be addressed under ESA Section 10 to ensure that proposed activities do not jeopardize the continued existence of individual species.

3.5.4.4.4 Cumulative Impacts of Alternative B

The construction and installation, O&M, and conceptual decommissioning of offshore wind projects across the geographic analysis area would contribute to the primary IPFs of accidental releases, land disturbance, noise, and traffic. Temporary disturbance and permanent loss of coastal habitat may occur as a result of constructing onshore infrastructure such as substations. However, the area of coastal habitat altered or removed could vary widely depending on the specific siting of project components.

The cumulative impacts on coastal habitat and fauna would likely be negligible to moderate because coastal habitat is anticipated to be lost or modified and fauna are anticipated to be disturbed or displaced by onshore construction; however, the level of impact would depend on the area of coastal habitat altered or removed. Impacts on species would be unavoidable; impacts on habitat may be short term, long term, or permanent and may include impacts on sensitive habitats. Impacts on habitat would not result in population-level effects on species that rely on them and therefore would range from negligible to moderate. The cumulative coastal habitat loss from ongoing and planned activities, including the six NY Bight projects, is expected to be moderate but would depend on specific construction activities and their proximity to sensitive habitats and species. If construction of project components of the six NY Bight projects is staggered, there could be less of an effect on coastal habitat and fauna in the short term than if all six projects were constructed at once. In context of reasonably foreseeable environmental trends, BOEM anticipates six NY Bight projects would contribute an undetectable increase to cumulative impacts on coastal habitat and fauna.

3.5.4.4.5 Conclusions

Impacts of Alternative B. Construction and installation, O&M, and conceptual decommissioning of Alternative B, whether one NY Bight project or six NY Bight projects, would likely have **negligible** to **minor** impacts on coastal habitat and fauna, depending on the IPF and the amount and quality of coastal habitat altered or removed. No beneficial impacts would occur. The most significant risk would be from potential onshore removal of habitat, which could lead to fauna mortality and habitat alteration, although BOEM anticipates fauna mortality to be rare and the duration of activities resulting in habitat alteration to be short-term. Impacts are expected to be limited because, based on BOEM's experience with other offshore wind projects along the Atlantic coast, facilities would most likely be located in existing developed areas, such as roads, parking lots, and utility ROWs.

Cumulative Impacts of Alternative B. BOEM anticipates that the cumulative impacts on coastal habitat and fauna in the geographic analysis area would likely be **negligible** to **moderate** for six NY Bight projects. In the context of reasonably foreseeable environmental trends, the impacts contributed by six NY Bight projects to the cumulative impacts on coastal habitat and fauna are likely undetectable. Six NY Bight projects would contribute to the cumulative impacts primarily through the short-term to permanent impacts from onshore habitat loss related to onshore substations/converter stations and cables. Existing environmental trends and ongoing activities would continue, and coastal habitat and fauna would continue to be affected by land disturbance unrelated to the six NY Bight projects and climate change.

3.5.4.5 Impacts of Alternative C (Proposed Action) – Identification of AMMM Measures at the Programmatic Stage – Coastal Habitat and Fauna

Alternative C, the Proposed Action, considers the potential impacts of future offshore wind development for the NY Bight area with the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts. Alternative C consists of two sub-alternatives – Sub-alternative C1: Previously Applied AMMM Measures, and Sub-alternative C2: Previously Applied and Not Previously Applied AMMM Measures. The analysis for Sub-alternative C1 is presented as the change in impacts from those impacts discussed under Alternative B, and the analysis for Sub-alternative C2 is presented as the change from Sub-alternative C1. Refer to Table G-1 in Appendix G, *Mitigation and Monitoring*, for a complete description of AMMM measures that make up the Proposed Action.

3.5.4.5.1 Sub-Alternative C1 (Preferred Alternative): Previously Applied AMMM Measures

Sub-alternative C1 analyzes the AMMM measures that BOEM has required as conditions of approval for previous activities proposed by lessees in COPs submitted for the Atlantic OCS and through related consultations. However, BOEM has not identified any AMMM measures for the coastal habitat and fauna; and therefore, the impacts on coastal habitat and fauna under Sub-alternative C1 would be the same as described in Alternative B.

3.5.4.5.2 Sub-Alternative C2: Previously Applied and Not Previously Applied AMMM Measures

Sub-alternative C2 analyzes the AMMM measures under Sub-alternative C1 plus the AMMM measures that have not been previously applied. However, BOEM has not identified any not previously applied AMMM measures for coastal habitat and fauna; therefore, the impacts on coastal habitat and fauna under Sub-alternative C2 are the same as under Sub-alternative C1 (comparable to Alternative B).

3.5.4.5.3 Conclusions

Impacts of Alternative C. BOEM has not identified any AMMM measures for coastal habitat and fauna; therefore, impacts on coastal habitat and fauna under both Sub-alternative C1 and C2 are the same as under Alternative B. Therefore, construction and installation, O&M, and conceptual decommissioning of one NY Bight project or six NY Bight projects under both Sub-alternative C1 and C2 would likely have **negligible** to **minor** impacts.

Cumulative Impacts of Alternative C. BOEM has not identified any AMMM measures for coastal habitat and fauna; therefore, the cumulative impacts on coastal habitat and fauna under both Sub-alternative C1 and C2 are the same as under Alternative B. BOEM anticipates that the cumulative impacts on coastal habitat and fauna in the geographic analysis area would likely be **negligible** to **moderate** for six NY Bight projects.

3.5.4.6 Recommended Practices for Consideration at the Project-Specific Stage

BOEM has not identified any AMMM measures for the coastal habitat and fauna; however, BOEM is recommending lessees consider analyzing the RPs in Table 3.5.4-7 to further reduce potential coastal habitat and fauna impacts. Refer to Table G-2 in Appendix G for a complete description of the RPs.

Table 3.5.4-7. Recommended Practices for coastal habitat and fauna impacts and related benefits

Recommended Practice	Potential Benefit
MUL-5: Use equipment, technology, and best practices to produce the least amount of noise possible to reduce noise impacts.	Minimizing the amount of noise from onshore activities may reduce disturbance and displacement of some coastal fauna species.
MUL-12: Incorporate ecological design elements where practicable. Examples include nature-inclusive design products as an alternative to traditional concrete, which could enhance and encourage the growth of marine flora and fauna (e.g. oyster beds or other artificial reefs).	Ecological design elements could reduce the amount or type of land disturbance.
MUL-18: Coordinate transmission infrastructure among projects by using shared intra- and interregional connections, meshed infrastructure, or parallel routing.	Fewer landfalls and a reduction of onshore cables may reduce land disturbance, noise, and traffic impacts on coastal habitat and fauna because there may be less disturbance of beach, dune, and onshore habitats.
MUL-21: Use best available technology, including new and emerging technology, when possible and consider upgrading/retrofitting equipment.	Using best available technology for onshore construction methods may result in lower noise from onshore activities that could disturb and displace some coastal fauna species and decrease overall impacts on coastal habitats and fauna.
MUL-23: Avoid or reduce potential impacts on important environmental resources by adjusting project design.	The use of HDD for cable installation could help to avoid and minimize impacts on benthic habitats and difficult-to-replace resources by minimizing the amount of land disturbance compared to cable installation methods that use trenching. Adjustments by developers could also include siting onshore cables and substations in developed ROWs, thereby avoiding undisturbed habitat.
MUL-26: Coordinate regional monitoring and survey efforts to standardize approaches, understand potential impacts to resources at a regional scale, and maximize efficiencies in monitoring and survey efforts. Develop monitoring and survey plans that meet regional data requirements and standards.	Coordinating regional monitoring and survey efforts would maximize the monitoring efficiency. The data gathered would be evaluated and considered for future mitigation and monitoring needs, which will serve to reduce impacts.

This page was intentionally left blank.

3.5 Biological Resources

3.5.7 Sea Turtles

This section discusses potential impacts on sea turtles from the Proposed Action, alternatives, and ongoing and planned activities in the sea turtle geographic analysis area. The geographic analysis area for sea turtles, as shown on Figure 3.5.7-1, includes the U.S. Northeast Continental Shelf and Southeast Continental Shelf LMEs to capture the movement range of sea turtles. Due to the size of the geographic analysis area, for analysis purposes in this PEIS, the focus is on sea turtle species likely to occur in the NY Bight area and be affected by NY Bight project activities.

The sea turtles impact analysis in this PEIS is intended to be incorporated by reference into the project-specific environmental analyses for individual COPs expected for each of the NY Bight lease areas. Refer to Appendix C, *Tiering Guidance*, which identifies additional analyses anticipated to be required for the project-specific environmental analysis of individual COPs.

3.5.7.1 Description of the Affected Environment and Future Baseline Conditions

Five species of sea turtles have been documented in U.S. waters of the northwest Atlantic Ocean in the vicinity of the NY Bight area: green (*Chelonia mydas*), hawksbill (*Eretmochelys imbricata*), Kemp's ridley (*Lepidochelys kempii*), leatherback (*Dermochelys coriacea*), and loggerhead (*Caretta caretta*). All five species are listed under the ESA; hawksbill, Kemp's ridley, and leatherback sea turtles are listed as endangered, and green and loggerhead sea turtles are listed as threatened. Critical habitat has been designated for green, hawksbill, leatherback, and loggerhead sea turtles but is not within or in the vicinity of the NY Bight area. Although hawksbill sea turtles have been documented in OCS waters of the northwest Atlantic Ocean, they are rare in this region and have not been documented within New Jersey or New York waters within the last 10 years (Conserve Wildlife Foundation of New Jersey 2022; NMFS 2022a). Therefore, hawksbill sea turtles are considered unlikely to occur within the NY Bight area and thus will not be evaluated further in this PEIS. Three of the four species expected to occur in the NY Bight area are broken out into DPSs, which include the North Atlantic DPS of green sea turtles, the leatherback sea turtle Northwest Atlantic subpopulation, and the Northwest Atlantic DPS of loggerhead sea turtles. A DPS has not been designated for leatherback sea turtles because this species is listed as endangered throughout its global range (85 Fed. Reg. 48332).

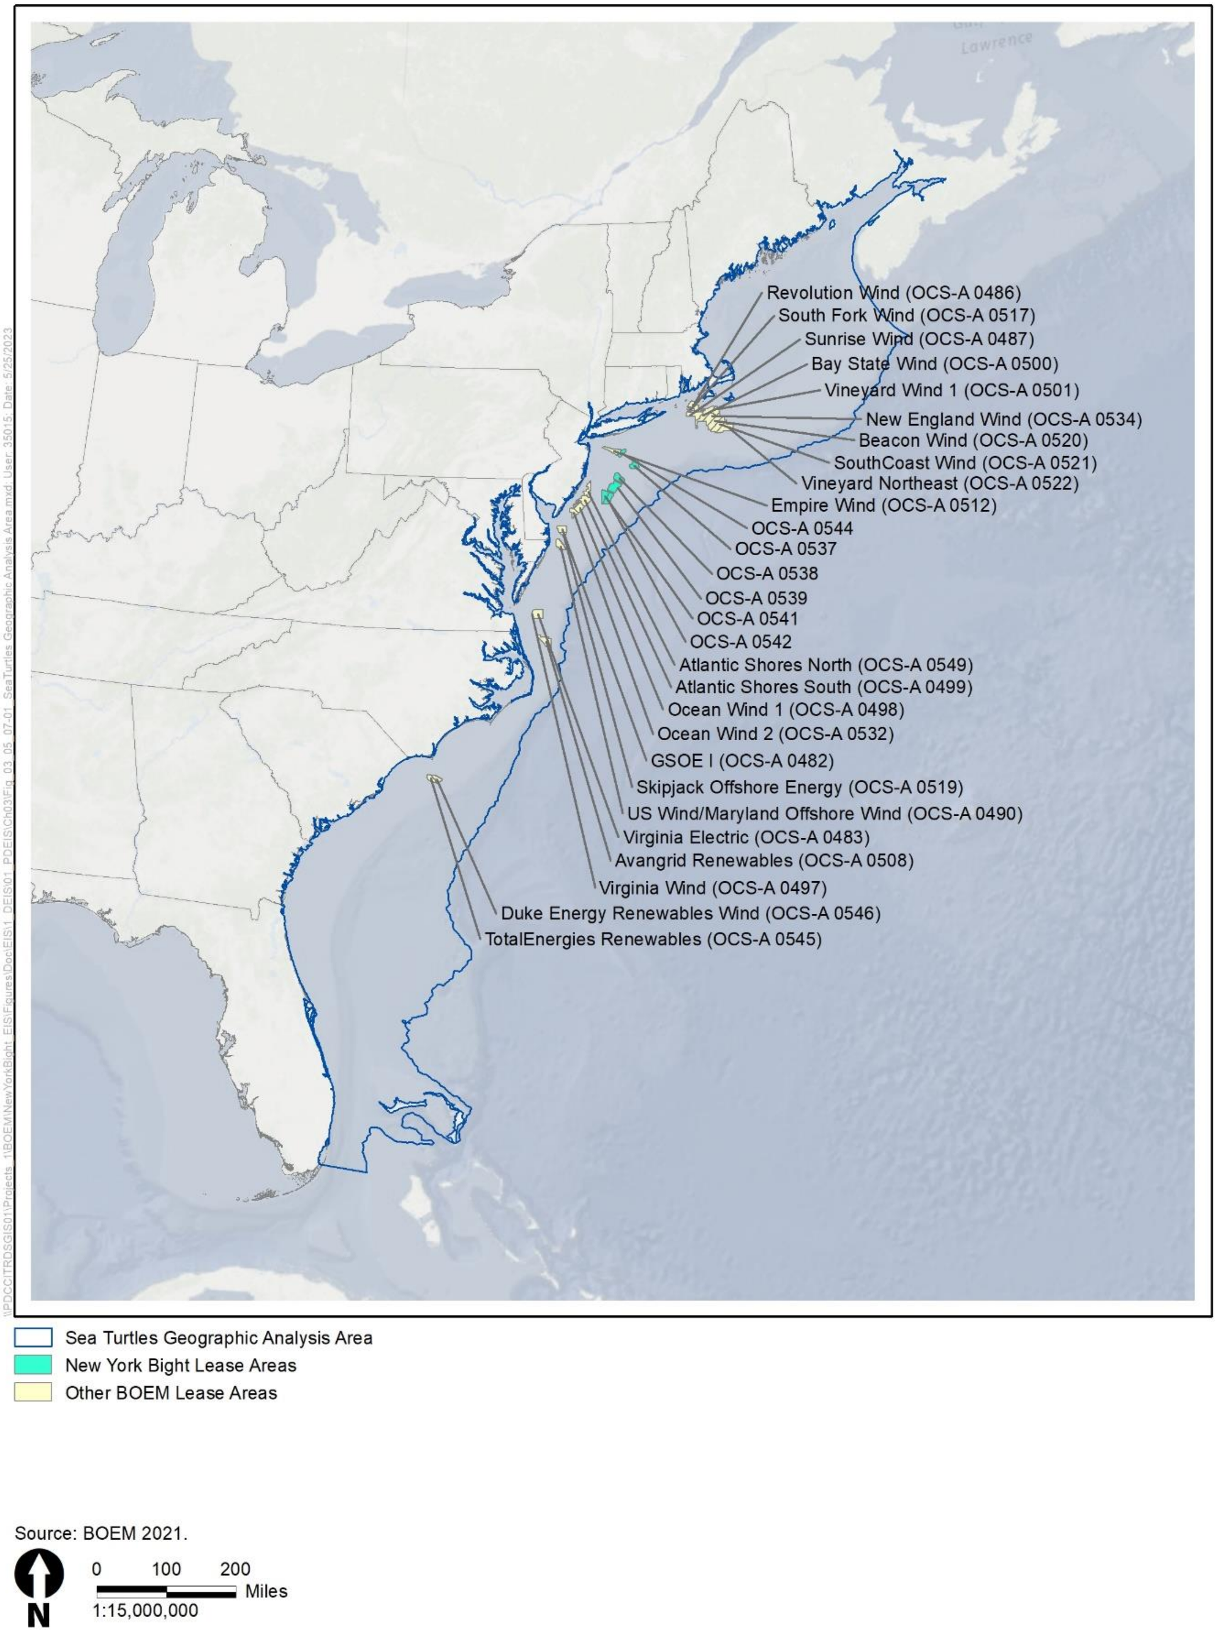

Figure 3.5.7-1. Sea turtles geographic analysis area

Sea turtles generally migrate into or through the NY Bight area as they travel between their northern-latitude feeding grounds and their nesting grounds in the southern United States, Gulf of Mexico, and Caribbean. As ocean waters warm in the spring, sea turtles migrate northward to their feeding grounds in the Mid-Atlantic, typically arriving in the spring or summer and remaining through the fall. As water temperatures cool, most sea turtles begin their return migration to the south. Historically, this southward migration begins in October, and most turtles are gone by the first week in November. Based on this seasonal migration pattern, sea turtles are generally expected to occur in the NY Bight area between late spring and fall (NMFS 2021a). Some individuals may remain in the Mid-Atlantic into the winter when they could experience cold stunning as temperatures drop below 50°F (10°C) (NMFS 2021b), but occurrence is less likely when water temperatures are low (i.e., winter and spring) (BOEM 2012; Greene et al. 2010).

The best available information on the occurrence and distribution of sea turtles in the NY Bight area is provided by a combination of sighting data, technical reports, and academic publications, including:

- Aerial and shipboard survey data collected by the Northwest Atlantic Marine Ecoregional Assessment (Greene et al. 2010);
- Aerial data collected by the NYSERDA (Normandeau Associates Inc. and APEM Inc. 2021a, 2021b);
- PSO monitoring data collected during survey activities for offshore wind projects within or adjacent to the NY Bight area (Gardline 2018, 2021, 2022; RPS 2019, 2020; Smultea 2020);
- Sighting data retrieved from the Ocean Biodiversity Information System (OBIS 2022); and
- Data from the AMAPPS (Palka et al. 2021; NMFS 2021a; NMFS 2022a; NMFS 2022b).

Species occurrence is summarized in Table 3.5.7-1 and described in the following paragraphs. Seasonal density estimates derived from NYSERDA annual reports for their offshore project area (Normandeau Associates Inc. and APEM Inc. 2021a,b) are provided in Table 3.5.7-2. Population estimates are not provided in this section for individual species as sea turtles are wide-ranging and long-lived, making population estimates difficult. Also, survey methods vary depending on species (NMFS and USFWS 2015).

Table 3.5.7-1. Sea turtles likely to occur in the NY Bight area

Common Name	Scientific Name	Distinct Population Segment/ Population[1]	ESA Status	Relative Occurrence in the NY Bight area[2]	Seasonal Occurrence in the NY Bight area
Green sea turtle	*Chelonia mydas*	North Atlantic	Threatened	Regular	Summer through Fall
Kemp's ridley sea turtle	*Lepidochelys kempii*	--	Endangered	Common	Late Spring through Fall
Leatherback sea turtle	*Dermochelys coriacea*	Northwest Atlantic (subpopulation)	Endangered	Common	Late Spring through Fall
Loggerhead sea turtle	*Caretta caretta*	Northwest Atlantic	Threatened	Common	Late Spring through Fall

[1] NMFS 2021a. As a note, the leatherback sea turtle does not have designated Distinct Population Segment because the population is listed as endangered throughout its global range (85 Fed. Reg. 48332).
[2] Regular = occurring in low to moderate numbers on a regular basis or seasonally; Common = occurring consistently in moderate to large numbers.

Table 3.5.7-2. Seasonal sea turtle density estimates in the New York offshore project area[1] derived from NYSERDA annual reports

Species	Density (animals/100 square kilometers)[2]			
	Spring	Summer	Fall	Winter
Green sea turtle	0.0000	0.0003	0.0000	0.0000
Kemp's ridley sea turtle	0.0003	0.0057	0.0016	0.0000
Leatherback sea turtle	0.0000	0.0010	0.0006	0.0000
Loggerhead sea turtle	0.0010	0.1079	0.0016	0.0003

Source: Normandeau Associates Inc. and APEM Inc. 2021b.
[1] The New York offshore project area encompasses the waters of the NY Bight from Long Island southeast to the continental shelf break.
[2] Density estimates are derived from the final NYSERDA report for all surveys between Summer 2016 and Spring 2019 in the New York offshore project area using the most recent year for which data were available for each season or species for which identification was confirmed.

Green sea turtle: Green sea turtles found in the NY Bight area belong to the North Atlantic DPS. This species inhabits tropical and subtropical waters around the globe. In the United States, green sea turtles occur from Texas to Maine, as well as the Caribbean. Late juveniles and adults are typically found in nearshore waters of shallow coastal habitats (NMFS 2022b). In the pelagic environment, green sea turtles are often found in convergence zones (NMFS and USFWS 1991).

No green sea turtle nesting events have been documented on the New Jersey or New York coasts in the NY Bight area. Their diet is largely herbivorous, composed primarily of algae and seagrasses with occasional sponges and invertebrates (NMFS 2022b). Green sea turtles primarily occur offshore within the NY Bight area in summer and fall (Table 3.5.7-2; NMFS 2022b). During the NYSERDA aerial surveys in the New York OPA, only one green sea turtle was observed during the 2016 summer survey (Normandeau Associates Inc. and APEM Inc. 2021b), and results of the AMAPPS visual survey data from 2010 to 2017 indicate green sea turtles are only present in the NY Bight area in the summer and fall (Palka et al. 2017). Data from the sea turtle stranding and salvage network show 73 strandings of green sea turtles in New Jersey and 150 strandings of sea turtles in New York between 2012 and November

2022, largely the result of cold stunning and traditional stranding reasons. Traditional stranding, as defined, occurs when a dead, sick, or injured sea turtle is found washed ashore, floating, or underwater, and when it is not an incidental capture, a post-hatchling, or a cold-stunning event. It specifically excludes healthy, uninjured sea turtles. Out of the recorded strandings, 10 were marked as incidental capture (NMFS 2022a).

PSO monitoring data showed one green sea turtle observed in the Ocean Wind 2 lease area (OCS-A 0532) during surveys between May 2021 and May 2022 (Gardline 2022); one green sea turtle observed nearshore Long Beach, New York in the NY Bight area during surveys between April 2019 and July 2019 (RPS 2019); one green sea turtle observed in the Atlantic Shores South lease area (OCS-A 0499) during surveys from May 2020 to October 2020 (RPS 2020); and two green sea turtles observed offshore Long Island, New York near Montauk during surveys between September 2019 and September 2020 (Smultea Environmental Sciences 2020). There is no population estimate for the North Atlantic DPS of green sea turtles, but the nester abundance for this DPS is estimated to be 167,424, (Seminoff et al. 2015). All major nesting populations in the North Atlantic DPS have shown long-term increases in abundance, but data are lacking to evaluate trends for the South Atlantic DPS (Seminoff et al. 2015).

Kemp's ridley sea turtle: All Kemp's ridley sea turtles, including those found in the NY Bight area, belong to a single population. This species primarily inhabits the Gulf of Mexico, although large juveniles and adults travel along the U.S. Atlantic coast. At these life stages, Kemp's ridley sea turtles occupy nearshore habitats in subtropical to warm temperate waters, including sounds, bays, estuaries, tidal passes, shipping channels, and beachfront waters.

A single Kemp's ridley nest was documented on Queens County's West Beach, New York, in 2018 (Yun 2018). However, this nest was outside the primary nesting range for the species, which is essentially limited to the beaches of the western Gulf of Mexico (NMFS and USFWS 2015). The diet of Kemp's ridley sea turtles is composed primarily of crabs (NMFS 2022c). Kemp's ridley sea turtles primarily occur in the NY Bight area during the spring, summer, and fall (Table 3.5.7-2; NMFS 2022c). Results of the NYSERDA aerial surveys show a total of 64 Kemp's ridley sea turtles were observed in the New York OPA between 2016 and 2018, most of which (57 observations) occurred during the summer surveys (Normandeau Associates Inc. and APEM Inc. 2021b). AMAPPS survey results show similar distributions with a few individuals observed around the NY Bight area in spring which increases in the summer and begins to decrease again in the fall (Palka et al. 2021). Additionally, aerial surveys conducted for the New York Bight Whale Monitoring Program show one observation of Kemp's ridley sea turtles during the summer of 2018 (Tetra Tech and LGL 2020). However, it is noted that visual sighting data may be limited because this small species is difficult to observe using typical aerial survey methods (Kraus et al. 2016). Stranding data from 2012 to 2022 show 102 Kemp's ridley sea turtle strandings in New Jersey and 285 in New York, primarily due to cold stunning or traditional stranding causes (dead, sick, or injured sea turtle), but 51 of these strandings were marked as incidental capture (NMFS 2022a). PSO monitoring data show only one confirmed observation of Kemp's ridley sea turtles in the Ørsted Lease Areas OCS-A 0486, 0487, and 0500 (Smultea Environmental Sciences 2020), which are outside of the NY Bight area. In 2012, the population of individuals aged two and up was estimated at

248,307 turtles (Gallaway et al. 2013). Since 2009, there has been a decline in nest abundance for this population (NMFS and USFWS 2015).

Leatherback sea turtle: Leatherback sea turtles that occur in the NY Bight area belong to the Northwest Atlantic population identified in the 2020 status review for the species (NMFS and USFWS 2020). However, this population has not been identified as a DPS or listed separately under the ESA at this time because the species is considered endangered throughout its global range. This species is found in the Atlantic, Pacific, and Indian Oceans (NMFS 2022d). Leatherback sea turtles can be found throughout the western North Atlantic Ocean as far north as Nova Scotia, Newfoundland, and Labrador. While early life stages prefer oceanic waters, adult leatherback sea turtles are generally found in mid-ocean, continental shelf, and nearshore waters (NMFS and USFWS 1992). Leatherback sea turtle diets are composed primarily of jellyfish and other gelatinous prey, but they may also incidentally consume sea urchins, squid, crustaceans, fish, and vegetation (Eckert et al. 2012). Leatherback sea turtles are known to dive deeper than other sea turtle species while feeding and are therefore more tolerant of cooler oceanic temperatures. Additionally, Bailey et al. (2012) found that mesoscale eddies, convergence zones, and areas of upwelling attract foraging leatherbacks due to the aggregation of jellyfish, their preferred prey, within these features.

There have not been any documented nesting events along the New Jersey or New York coasts within the NY Bight area. Leatherback sea turtles in the NY Bight area primarily occur in the late spring through fall (Table 3.5.7-2; BOEM 2012; Geo-Marine 2010; Palka et al. 2021). During aerial and shipboard surveys for marine mammals and sea turtles off the coast of New Jersey in 2008 and 2009, 12 leatherback sea turtles were sighted during the summer in waters ranging from 59 to 98 feet (18 to 30 meters) deep, located 6.2 to 22.3 miles (10 to 36 kilometers) from shore (Geo-Marine 2010). Leatherback sea turtles were observed 47 times within the New York OPA, which encompasses the waters of the NY Bight from Long Island southeast to the continental shelf break, during the NYSERDA surveys, predominantly in the fall (30 sightings) followed by summer (17 sightings) with no observations in the spring or winter (Normandeau Associates Inc. and APEM Inc. 2021b). AMAPPS and the New York Bight Whale Monitoring Program sightings show a similar trend with higher observations of leatherback sea turtles in the NY Bight area in summer and fall, a few in spring, and none in winter (Tetra Tech and LGL 2020; Palka et al. 2021). Stranding data reported 42 stranded leatherbacks in New Jersey and 109 in New York between 2012 and 2022, primarily due to traditional stranding causes (dead, sick, or injured sea turtle), but 23 of these strandings were marked as incidental capture (NMFS 2022a). PSO monitoring data show one observation of a leatherback sea turtle offshore Block Island, Rhode Island (which is outside the NY Bight area) during surveys between September 2020 and September 2021 (Gardline 2021); 40 leatherbacks observed along the New Jersey coast during surveys between May 2021 and May 2022 (Gardline 2022); 25 leatherback sea turtles observed along the New Jersey coast during surveys between May 2020 to October 2020 (RPS 2020); and 14 leatherback sea turtles observed between the eastern extent of Long Island, New York and Rhode Island during surveys between September 2019 and September 2020 (Smultea Environmental Sciences 2020). The best available estimate of nesting female abundance for the Northwest Atlantic population is 20,659 females. This population is currently exhibiting an overall decreasing trend in annual nesting activity, likely attributed to the destruction or modification of their nesting habitats due to coastal development or erosion (NMFS and USFWS 2020).

Loggerhead sea turtle: Loggerhead sea turtles found in the NY Bight area belong to the Northwest Atlantic DPS. This species inhabits nearshore and offshore habitats throughout the globe. Loggerhead sea turtles occur throughout the Northwest Atlantic as far north as Newfoundland (NMFS 2022e). Coastal waters of the western Atlantic have been identified as foraging habitat for juveniles (USFWS 2020), and the Mid-Atlantic Bight of the Atlantic OCS is an important seasonal foraging ground for approximately 40,000 to 60,000 juvenile and adult loggerheads during summer months (NEFSC and SEFSC 2011). Juvenile loggerhead sea turtles have omnivorous diets, consuming crabs, mollusks, jellyfish, and vegetation. Adults are carnivores, consuming primarily benthic invertebrates (NMFS 2022e).

A single loggerhead nest was documented at Island Beach State Park, New Jersey, in 1979 (Brandner 1983). This nesting event was outside the primary nesting range for the species, which stretches from Texas to Virginia, so no nesting is likely to occur in the NY Bight area (NMFS and USFWS 2008). Loggerhead sea turtles occur in the NY Bight area throughout the year but are more common in the summer and fall (Table 3.5.7-2; BOEM 2012; Geo-Marine 2010; Tetra Tech and LGL 2020; Palka et al. 2021). During aerial and shipboard surveys for marine mammals and sea turtles off the coast of New Jersey in 2008 and 2009, 69 loggerhead sea turtles were sighted between June and October in waters ranging from 30 to 112 feet (9 to 34 meters) deep, located 0.9 to 23.6 miles (1.5 to 38 kilometers) from shore (Geo-Marine 2010). The mean sea surface temperature associated with loggerhead sea turtle sightings was 65.3 degrees Fahrenheit (18.5 degree Celsius). Loggerheads were the most common reported species during NYSERDA aerial surveys in the New York OPA, which reported 1,397 observations (Normandeau Associates Inc. and APEM Inc. 2021b). Most of these sightings were in the summer (1,377) followed by the fall (11), spring (8), and winter (1) (Normandeau Associates Inc. and APEM Inc. 2021b). AMAPPS survey data show loggerheads are most common in the NY Bight area in the summer and fall, with scattered sightings possible further offshore in the spring and winter (Palka et al. 2021). NMFS (2022) reported 397 strandings of loggerhead sea turtles in New Jersey and 339 in New York primarily due to traditional stranding reasons (dead, sick, or injured sea turtle) and cold stunning, but 16 of these were marked as incidental capture. PSO monitoring data show 14 observations of loggerhead turtles along the New Jersey coast during surveys between May 2021 and May 2022 (Gardline 2022); 35 sightings along the New Jersey coast during surveys between May 2020 to October 2020 (RPS 2020); and 14 sightings between the eastern extent of Long Island, New York and Rhode Island during surveys between September 2019 and September 2020 (Smultea Environmental Sciences 2020). The most recent population estimate for the northwest Atlantic continental shelf, calculated in 2010, is 588,000 juvenile and adult loggerhead sea turtles (NEFSC and SEFSC 2011). The Northern recovery unit for the Northwest Atlantic DPS, which is the only recovery unit likely to occur in the NY Bight area, is below the recovery criteria for the number of nests, which required a 2 percent annual increase in the number of nests over a generation time of 50 years; however, the number of nests does correspond to the number of nesting females, which meets the requirement for that recovery criteria (Bolten et al. 2019). All other recovery criteria for this recovery unit—such as abundance on foraging grounds, trends in strandings, and threats to species habitat — have either not been accomplished or there are insufficient data to assess potential recovery (Bolten et al. 2019).

All four sea turtle species likely to occur in the geographic analysis area are subject to regional, ongoing threats. These threats include fisheries bycatch, loss or degradation of nesting and foraging habitat, entanglement in fishing gear, vessel strikes, predation and harvest, disease, and climate change. Green, Kemp's ridley, and loggerhead sea turtles are also susceptible to cold stunning.

3.5.7.1.1 Importance of Sound to Sea Turtles

There are few studies reporting sound production in sea turtles, despite their ability to hear sounds in both air and water. While the general importance of sound to the ecology of sea turtles is not well understood, there is a growing body of knowledge suggesting that sea turtles may use sound in a multitude of ways. Cook and Forest (2005) found that nesting leatherback sea turtles produce sound when breathing in air, but this work suggested the sound was a byproduct of labored breaking rather than a communication signal. Sea turtle embryos and hatchlings have been reported to make airborne sounds, thought to be produced for synchronizing hatching and nest emergence (Montiero et al. 2019, Ferrara et al. 2019, Ferrara et al. 2014a and 2014b, and McKenna et al. 2019). Charrier et al. (2022) noted the production of 10 different underwater sounds in juvenile green sea turtles including those within and above the frequency range of hearing reported for this species. A more comprehensive understanding of sound production, and hearing is needed in sea turtles. However, the limited but growing information available suggests sound may be important to these animals.

Hearing Anatomy of Sea Turtles

The outermost part of the sea turtle ear, or tympanum, is covered by a thick layer of skin covering a fatty layer that conducts sound in water to the middle and inner ear. This is a distinguishing feature from terrestrial and semi-aquatic turtles. This thick outer layer makes it difficult for turtles to hear well in air but it facilitates the transfer of sound from the aqueous environment into the ear (Ketten et al. 1999). The middle ear has two components that are encased by bone, the columella and extracolumella, which provides the pathway for sound from the tympanum on the surface of the turtle head to the inner ear. The middle ear is also connected to the throat by the Eustachian tube. The inner ear consists of the cochlea and basilar membrane. Because there is air in the middle ear, it is generally believed that sea turtles detect sound pressure rather than particle motion. Sea turtle ears are described as being similar to a reptilian ear, but due to the historically limited data in sea turtles and reptiles, fish hearing is often used as an analog when considering potential impacts of underwater sound.

Hearing in sea turtles has been measured through electrophysiological and behavioral studies both in air and in water on a limited number of life stages for each of the five species. In general, sea turtles hear best in water between 200 to 750 Hz and do not hear well above 1 kHz. It is worth noting that there are species-specific and life-stage specific differences in sea turtle hearing (Table 3.5.7-3). Sea turtles are also generally less sensitive to sound than marine mammals, with the most sensitive hearing thresholds underwater measured at or above 75 dB re 1 µPa (Reese et al. 2023; Papale et al. 2020). Loggerhead sea turtles have been studied most thoroughly with respect to other species, including post-hatchlings

(Lavender et al. 2012, 2014), juveniles (Bartol et al. 1999; Lavender et al. 2012, 2014), and adults (Martin et al. 2012).

Table 3.5.7-3. Hearing capabilities, including hearing frequency range and peak sensitivity in sea turtles, by species

Species	Life Stages Tested	Hearing Frequency Range (Hz)	Maximum Sensitivity (Hz)	References
Loggerhead	Post-hatchling, juvenile	100–900 (in air)	500–700	Ketten & Bartol 2006
	Post-hatchling, juvenile, adult	50–1,100 (underwater)	100–400	Bartol & Bartol 2012, Lavender et al. 2014, Martin et al. 2012, Lenhardt 2002, Bartol et al. 1999
Green	Juvenile, sub-adult	50–2,000 (in air)	200–700	Ridgway et al. 1969; Ketten & Bartol 2006; Piniak et al. 2016
	Juvenile	50–1,600 (underwater)	200–400	Piniak et al. 2016
Leatherback	Hatchling	50–1,600 (in air)	300	Piniak 2012, Piniak et al. 2012
	Hatchling	50–1,200 (underwater)	300	Piniak 2012, Piniak et al. 2012
Kemps ridley	Juvenile	100–500 (in air)	100–200	Ketten & Bartol 2006

Source: Summarized from Table 3 in Reese et al. 2023, which was adapted from Papale et al. 2020.
Note: hearing frequency range indicates the widest range of hearing based on the aggregation of results from the references listed, while max sensitivity represents the range of sounds that they can hear best.

Potential Impacts of Underwater Sound

As with marine mammals, sea turtles may experience a range of impacts from underwater sound including non-auditory injury, PTS or TTS, behavioral changes, acoustic masking, or increases in physiological stress. The potential impacts will depend on the physical qualities of the sound source and the environment, as well as the physiological characteristics and the behavioral context of the species of interest. Sound from activities such as pile-driving, seismic surveys, and drilling could have impacts on sea turtles given the overlap between sea turtles' hearing range and the frequency range of these sound sources - yet there is extremely limited data on how their behavior and physiology are impacted. A comprehensive review of the potential impacts of noise on sea turtles can be found in Reese et al. 2023.

While there is no direct evidence of PTS occurring in sea turtles, evidence of underwater noise-induced TTSs in a freshwater turtle species recently have been recorded and suggest turtles may be more sensitive to sound than previously understood (Salas et al. 2023; Mannes et al. 2023). In red eared sliders, Salas et al. (2023) reported the mean predicted TTS onset was 160 dB re 1 μPa^2 s. There was individual variation in susceptibility to TTS, threshold shift magnitude, and recovery rate, which was non-monotonic and occurred on time scales ranging from less than 1 hour to more than 2 days post-exposure (Salas et al. 2023). TTS also has been demonstrated in red eared sliders based on a 24-hour exposure that resulted in a sound exposure level of 160 dB re 1 μPa^2 s, where all animals showed a depression in sensitivity immediately after exposure and a full recovery 3–5 hours after exposure (Mannes et al. 2023). Prolonged or repeated exposure to sound levels sufficient to induce TTS without recovery time can lead to PTS in marine mammals (Southall et al. 2007). Few studies have looked at hair cell damage in reptiles, and do not indicate precisely if sea turtles are able to regenerate injured sensory hair cells (Warchol 2011). While several studies have examined physiological responses of sea turtles to physically stressful events (e.g., incidental or directed capture in fishing nets, cold stunning, handling, transport, etc.), to date, no research has been published on potential stress responses in sea turtles to elevated environmental noise (Reese et al. 2023). Stress response studies characterizing physiological (stress/hormone) responses to sound are ongoing to estimate potential acoustic impacts on sea turtles from industry sound sources. Elevated levels of corticosterone have been observed in Kemp's ridley sea turtles and green sea turtles in response to stressful stimuli such as ground transport for rehabilitation and disease (Aguirre et al. 1995; Hunt et al. 2016). Other physiological impacts due to chronic stress include immunosuppression (Milton and Lutz 2003). Samuel et al. (2005) demonstrated that anthropogenic sound levels from boating and recreational activity near Long Island, New York were over two orders of magnitude greater than when compared with the periods of lowest human activity, and suggested exposure to such levels could affect sea turtle behavior. Chronic exposure to anthropogenic noise may result in increased stress responses in sea turtles, which could have direct consequences on individual fitness (Reese et al. 2023).

The soundscapes and subsequent noise impacts presently experienced by sea turtles in biologically important habitats, and their behavioral and physiological responses may be variable and in general are still not well understood.

Regulation of Underwater Sound for Sea Turtles

There are few empirical data available to form regulatory thresholds for sea turtle sound exposure. For several years, the regulatory community accepted the recommendations of Popper et al. (2014) and used their thresholds for fishes without swim bladders as a proxy for sea turtles. NMFS has adopted the U.S. Navy PTS and TTS thresholds from Finneran et al. (2017) as their own (NMFS 2023). These thresholds include dual criteria (Lpk and SEL) for PTS and TTS, along with auditory weighting functions published by Finneran et al. (2017) used in conjunction with SEL thresholds for PTS and TTS. The behavioral threshold recommended in the GARFO acoustic tool (2020) is an SPL of 175 dB re 1 µPa (Finneran et al. 2017; McCauley et al. 2000) (Table 3.5.7-4). These thresholds apply to all life stages.

Table 3.5.7-4. Acoustic thresholds for sea turtles currently used by NMFS GARFO and BOEM for auditory effects from impulsive and non-impulsive signals, as well as thresholds for behavioral disturbance

Impulsive Signals				Non-impulsive Signals		All
PTS		TTS		PTS	TTS	Behavior
Lp,pk	LE, 24hr	Lp,pk	LE, 24hr	LE, 24hr		Lp,rms
232	204	226	189	220	200	175

Lp,pk = peak sound pressure (dB re 1 µPa); LE =sound exposure level accumulated over 24 hours (dB re 1 µPa2s); Lp =root-mean-square sound pressure (dB re 1 µPa).
PTS = permanent threshold shift; TTS = temporary threshold shift, which is a recoverable hearing effect.
Sources: Finneran et al. 2017; McCauley et al. 2000.

Thresholds for Auditory Injury

As a conservative approach, Popper et al. (2014) recommended using thresholds developed for fishes without swim bladders for sea turtles in response to impulsive sounds. Finneran et al. (2017) agree, that while still unsatisfactory, data from fish provide a better analogy currently due to similar hearing range and that the functioning basilar papilla in the turtle ear is dissimilar to the functioning cochlea in mammals. When exposed to acoustic signals representative of low- and mid-frequency active sonar, Halvorsen et al. (2013); Halvorsen et al. (2012), reported TTS in some species of fish exposed to cumulative SELs of approximately 220 dB re 1 µPa2s between 2 and 3 kHz, and 210 to 215 dB re 1 µPa2s between 170 and 320 Hz, respectively (Finneran et al. 2017). Based on these data the U.S. Navy uses an estimated SEL of 200 dB re 1 µPa2s for TTS onset in sea turtles. An 11 dB difference, on average, was found between SEL-based impulsive and non-impulsive TTS thresholds for marine mammals. By applying the same rule to turtles, (Finneran et al. 2017) derived a weighted SEL-based impulsive TTS threshold of 189 dB re 1 µPa2s which is 3 dB higher than the previously recommended unweighted threshold by Popper et al. (2014) of 186 dB re 1 µPa2s (Finneran et al. 2017). Based on the relatively high SEL-based TTS threshold derived for sea turtles, Finneran et al. (2017) hypothesized that the Lpk based threshold for sea turtles would be higher than that for marine mammals. Consequently, the sea turtle Lpk based TTS threshold for impulsive noise is set to 226 dB re 1 µPa, to match the highest marine mammal value. Sea turtle PTS data from impulsive noise exposures do not exist, therefore PTS onset was estimated by adding 15 dB to the derived SEL-based TTS thresholds and adding 6 dB to the Lpk thresholds (Finneran et al. 2017; Southall et al. 2007). The SEL-based non-impulsive PTS threshold is set to 220 dB re 1 µPa2s in sea turtles (Finneran et al. 2017).

Thresholds for Behavioral Disturbance

There are limited data pertaining to behavioral responses of sea turtles to anthropogenic noise, and none specifically to sounds generated by offshore wind activities. Several publications have attempted to examine sea turtles' immediate behavioral responses mostly focusing on seismic airgun noise. McCauley et al. (2000) observed that one green turtle and one loggerhead sea turtle in an open water pen increased swimming behaviors in response to a single seismic airgun at received levels of 166 dB re 1 µPa and exhibited erratic behavior at received levels greater than 175 dB re 1 µPa. Other empirical work has shown a range of responses, but NMFS developed sea turtle behavioral criteria based on these studies by McCauley et al. (2000). The sound level at which sea turtles are expected to exhibit a behavioral response to both impulsive and non-impulsive sound is a received SPL of 175 dB re 1 µPa.

Thresholds for Non-Auditory Injury

For both turtles and mammals, NMFS has adopted criteria used by the U.S. Navy to assess the potential for non-auditory injury from underwater explosive sources as presented in Finneran et al. (2017). The criteria include thresholds for the following non-auditory effects: mortality, lung injury, and gastrointestinal injury. Unlike auditory thresholds, these depend upon an animal's mass and depth.

The U.S. Navy has published two sets of equations for these thresholds. The first set of equations (Table 3.5.6-6) is usually intended for estimating numbers of animals that may be affected, while the second set of equations (Table 3.5.6-7) is more conservative and normally used for defining mitigation zones. The approach requires choosing a set of representative animal masses to assess.

3.5.7.2 Impact Level Definitions for Sea Turtles

Definitions of potential impact levels are provided in Table 3.5.7-5. Beneficial impacts on sea turtles are described using the definitions described in Section 3.3.2 (see Table 3.3-1).

Table 3.5.7-5. Definitions of potential adverse impact levels for sea turtles

Impact Level	Definition
Negligible	There would be no measurable impacts on individuals or populations of sea turtles, or impacts would be so small that they would be extremely difficult or impossible to discern or measure.
Minor	Impacts on sea turtles are detectable and measurable, but are low intensity, highly localized, and temporary or short term in duration. Impacts would not result in population-level effects.
Moderate	Impacts on sea turtles are detectable and measurable. These impacts could result in loss of individuals, but those effects would likely be recoverable and would not affect population viability.
Major	Impacts on sea turtles are significant and extensive, long term in duration, and could have population-level effects that are not recoverable, even with mitigation.

Contributing IPFs to impacts on sea turtles include accidental releases, cable emplacement and maintenance, discharges/intakes, electric and magnetic fields and cable heat, survey gear utilization, noise, port utilization, presence of structures, and vessel traffic. However, these IPFs may not necessarily contribute to each individual issue outlined in Table 3.5.7-6.

Table 3.5.7-6. Issues and indicators to assess impacts on sea turtles

Issue	Impact Indicator
Underwater noise from construction, operation, and conceptual decommissioning	Extent, frequency, and duration of impacts resulting from noise above established effects thresholds as noted in Section 2.5 (Tables 3–4) in the Construction and Operations Plan Modeling Guidelines.[1]
Vessel collisions	Qualitative estimate of potential collision risk.
Water quality impacts	Quantitative estimate of intensity and duration of suspended sediment effects. Qualitative analysis of impacts from potential discharges (fuel spills, trash, and debris) relative to baseline.
Artificial light	Intensity, frequency, and duration of impacts relative to baseline.
Power transmission	Theoretical extent of detectable electric and magnetic field effects.
Seabed and water column disturbance/alteration	Water column volume and acres of seabed disturbance, loss, or conversion by structure presence.
Habitat alteration	Acres of land disturbance (e.g., nesting habitat), loss, or conversion due to onshore construction or cable landfall.
Prey impacts	Extent, frequency, and duration of impacts resulting from activities associated with offshore wind development on prey species for sea turtles.
Entanglement risk from gear/wind equipment	Qualitative estimate of potential entanglement risk.

3.5.7.3 Impacts of Alternative A – No Action – Sea Turtles

When analyzing the impacts of the No Action Alternative on sea turtles, BOEM considered the impacts of ongoing activities, including ongoing non-offshore-wind and ongoing offshore wind activities on the baseline conditions for sea turtles. The cumulative impacts of the No Action Alternative considered the impacts of the No Action Alternative in combination with the other planned non-offshore-wind and offshore wind activities, which are described in Appendix D, *Planned Activities Scenario*.

3.5.7.3.1 Impacts of the No Action Alternative

Under the No Action Alternative, baseline conditions for sea turtles described in Section 3.5.7.1, *Description of the Affected Environment and Future Baseline Conditions,* would continue to follow current regional trends and respond to IPFs introduced by other ongoing non-offshore-wind and offshore wind activities. Ongoing non-offshore-wind activities in the geographic analysis area that contribute to impacts on sea turtles include undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); ongoing vessel traffic; installation of new structures on the U.S. Continental Shelf; onshore development activities; and global climate change (see Appendix D for a description of ongoing activities). These activities contribute to numerous IPFs including:

- Accidental releases, which can have physiological effects on sea turtles;
- Discharges/intakes, which can result in altered micro-climates of warm water surrounding outfalls and entrainment risk;
- Cable emplacement and maintenance and port utilization, which can disturb benthic habitats, affect water quality, and present an entrainment risk for sea turtles;
- EMFs and heat, which can result in behavioral changes in sea turtles;
- Underwater noise, which can have physiological and behavioral effects on sea turtles;
- Port utilization, which can disturb benthic habitats, affect water quality, and present an entrainment risk for sea turtles during dredging and could introduce additional noise;
- The presence of structures, which can result in behavioral changes in sea turtles and effects on prey species, which can affect prey availability for, and distribution of, sea turtles, and increased risk of interactions with fishing gear;
- Vessel traffic, which increases risk of vessel collision;
- Survey gear utilization, which can result in interactions of gear with sea turtles; and
- Lighting, which has a limited potential to attract sea turtles offshore and to result in disorientation of nesting females and hatchling turtles from artificial lighting on nesting beaches or in nearshore habitats.

Because sea turtles have large ranges and highly migratory behaviors, these IPFs can have impacts on individuals over broad geographical scales. Therefore, in addition to the current conditions and trend of sea turtles in the geographic analysis area, these populations are also affected by factors beyond the geographic analysis area. However, the assessment in this PEIS focuses on those stressors currently present within the geographic analysis area; any effect on the populations outside this region are considered as part of the species' ongoing vulnerability, which affects its risk of impact.

The main known contributors to mortality events include collisions with vessels (ship strikes), entanglement with fishing gear, and fisheries bycatch. Many sea turtle migrations can cover long distances within the geographic analysis area, and these factors can have impacts on individuals over broad geographic and temporal scales.

Global climate change is an ongoing potential risk to sea turtles, although the associated impact mechanisms are complex, not fully understood, and difficult to predict with certainty. Possible impacts on sea turtles due to climate change include increased storm severity and frequency; increased erosion and sediment deposition; increased disease frequency; ocean acidification; and altered habitat, prey availability, ecology, and migration patterns. Over time, climate change, in combination with coastal development, would alter existing habitats and render some areas unsuitable for some species and more suitable for others. Available data also suggests that changing temperatures and sea level rise may lead to changes in the sex ratio of sea turtle populations (e.g., green sea turtle population feminization predicted under IPCC scenarios by 2120), loss of nesting area, and a decline in population growth due to nest incubation temperature reaching lethal levels (Patrício et al. 2019; Varela et al. 2019). In addition to affecting nesting activity, increased sea surface temperatures could have physiological effects on sea turtles during migration (Marn et al. 2017). Higher temperatures in migratory corridors would be especially risky for metabolic rates of female sea turtles post-nesting, as they do not generally forage during breeding periods and their body condition would not be expected to be optimal to withstand unexpected changes in water temperature in their migratory habitat (Hays et al. 2014).

Ongoing offshore wind activities within the geographic analysis area that contribute to impacts on sea turtles are listed in Table 3.5.7-7. Ongoing O&M of the Block Island and CVOW-Pilot (OCS-A 0497) projects and ongoing construction of the Vineyard Wind 1 (OCS-A 0501), South Fork Wind (OCS-A 0517), Ocean Wind 1 (OCS-A 0498), Revolution Wind (OCS-A 0486), Sunrise Wind (OCS-A 0487), Empire Wind 1 and 2 (OCS-A 0512), New England Wind Phase 1 and 2 (OCS-A 0534), and CVOW-C (OCS-A 0483) projects would affect sea turtles primarily through the IPFs of noise, presence of structures, and vessel traffic. Ongoing offshore wind activities would have the same type of impacts from these IPFs that are described in detail in Section 3.5.7.3.3, *Cumulative Impacts of the No Action Alternative* for ongoing and planned offshore wind activities, but the impacts would be of lower intensity.

3.5.7.3.2 Impacts of Alternative A – No Action on ESA-Listed Species

As noted in Section 3.5.7.1, *Description of the Affected Environment and Future Baseline Conditions*, all sea turtle species that are expected to occur regularly in the NY Bight area are listed as either threatened or endangered under the ESA. Therefore, the impacts of the No Action Alternative described in Section 3.5.7.3.1 apply to the ESA-listed sea turtle species in the NY Bight area.

3.5.7.3.3 Cumulative Impacts of the No Action Alternative

The cumulative impact analysis for the No Action Alternative considers the impacts of the No Action Alternative in combination with other planned non-offshore-wind activities and planned offshore wind activities (without the NY Bight projects).

Planned non-offshore-wind activities within the geographic analysis area that contribute to impacts on sea turtles include undersea transmission lines, transmission systems (e.g., PBI), gas pipelines, and other submarine cables; tidal energy projects; marine minerals use and ocean-dredged material disposal; military use; marine transportation; fisheries use and management; oil and gas activities; and onshore development activities. BOEM expects planned activities other than offshore wind to affect sea turtles through several primary IPFs, including accidental releases, EMFs, new cable emplacement and maintenance, port utilization, noise, and the presence of structures. See Appendix D for a summary of potential impacts associated with planned non-offshore-wind activities by IPF for sea turtles.

Ongoing and planned offshore wind activities in the geographic analysis area for sea turtles are listed in Table 3.5.7-7.

Table 3.5.7-7. Ongoing and planned offshore wind in the geographic analysis area for sea turtles

Ongoing/Planned	Projects by Region
Ongoing – 12 projects[1] 	**MA/RI** • Block Island (State waters) • Vineyard Wind 1 (OCS-A 0501) • South Fork Wind (OCS-A 0517) • Revolution Wind (OCS-A 0486) • Sunrise Wind (OCS-A 0487) • New England Wind (OCS-A 0534) Phase 1 • New England Wind (OCS-A 0534) Phase 2 **NY/NJ** • Ocean Wind 1 (OCS-A 0498) • Empire Wind 1 (OCS-A 0512) • Empire Wind 2 (OCS-A 0512) **VA/NC** • CVOW-Pilot (OCS-A 0497) • CVOW-Commercial (OCS-A 0483)

Ongoing/Planned	Projects by Region
Planned – 18 projects[2] 	**MA/RI** • SouthCoast Wind (OCS-A 0521) • Beacon Wind 1 (OCS-A 0520) • Beacon Wind 2 (OCS-A 0520) • Bay State Wind (OCS-A 0500) • OCS-A 0500 remainder • OCS-A 0487 remainder • Vineyard Wind Northeast (OCS-A 0522) **NY/NJ** • Ocean Wind 2 (OCS-A 0532) • Atlantic Shores North (OCS-A 0549) • Atlantic Shores South (OCS-A 0499) **DE/MD** • Skipjack (OCS-A 0519) • US Wind/Maryland Offshore Wind (OCS-A 0490) • GSOE I (OCS-A 0482) • OCS-A 0519 remainder **VA/NC** • Kitty Hawk North (OCS-A 0508) • Kitty Hawk South (OCS-A 0508) **SC** • Duke Energy Renewables Wind (OCS-A 0546) • TotalEnergies Renewables (OCS-A 0545)

CVOW = Coastal Virginia Offshore Wind; DE = Delaware; GSOE = Garden State Offshore Energy; MA = Massachusetts; MD = Maryland; NC = North Carolina; NJ = New Jersey; NY = New York; RI = Rhode Island; SC = South Carolina; VA = Virginia

[1] Refer to footnotes 9 and 10 in PEIS Chapter 1 for additional information on the status of Ocean Wind 1, Empire Wind 1, and Empire Wind 2.

[2] Status as of September 20, 2024.

The following sections summarize the potential impacts of ongoing and planned offshore wind activities on sea turtles during construction and installation, O&M, and conceptual decommissioning of the projects by IPF.

Accidental releases: Ongoing and planned offshore wind activities may increase accidental releases of fuels, fluids, hazardous materials, and trash and debris due to increased vessel traffic and installation of WTGs and other offshore structures. The risk of accidental releases is expected to be highest during construction, but accidental releases could also occur during operation and conceptual decommissioning. As described in Section 2.3, *Non-Routine Activities and Events*, accidental releases of chemicals, gases, or man-made debris may occur as a result of a structural failure and could result in impacts on sea turtles.

In the planned activities scenario (see Appendix D, Table D2-3), there would be a low risk of a leak of fuel, fluids, or hazardous materials from any one of approximately 2,525 WTGs and OSS installed in the geographic analysis area, which would store a total of 10,368,997 gallons (39,250,923 liters) of oils and lubricants in the WTG; 7,493,000 gallons (28,364,090 liters) of oils and lubricants in the OSS; 1,437,208 gallons (5,440,424 liters) of diesel fuel in the WTGs; and 1,519,420 gallons (5,751,630 liters) of diesel fuel in the OSS. According to BOEM's modeling (Bejarano et al. 2013), a release of 128,000 gallons

(20,350,374 liters), which represents all available oils and fluids from 130 WTGs and an OSS, is likely to occur no more often than once per 1,000 years, and a release of 2,000 gallons (317,975 liters) or less is likely to occur every 5 to 20 years. The likelihood of a spill occurring from multiple WTGs and OSS at the same time is very low and, therefore, the potential impacts from a spill larger than 2,000 gallons (317,975 liters) are largely discountable. Based on the volumes potentially involved, the additional risk posed by offshore wind development would fall within the range of accidental releases that already occur on an ongoing basis from non-offshore-wind activities.

Impacts resulting from accidental releases may pose a long-term risk to sea turtles and could potentially lead to mortality and sublethal impacts on individuals present in the vicinity of the spill, including adrenal effects, dehydration, hematological effects, increased disease incidence, liver effects, poor body condition, skin effects, skeletomuscular effects, and several other health effects that can be attributed to oil exposure (Camacho et al. 2013; Bembenek-Bailey et al. 2019; Mitchelmore et al. 2017; Shigenaka et al. 2021; Vargo et al. 1986). Additionally, accidental releases may result in impacts on sea turtles due to effects on prey species, although the analysis provided in Appendix D, Table D1-10 suggests localized, temporary effects that would not impact any invertebrate or finfish populations. Oil and fuels from accidental spills may also be transported away from the initial spill site or undergo weathering processes wherein the chemical composition of the oil is altered, which can have unforeseen effects on marine life following a spill (Passow and Overton 2021). However, the potential for exposure would be minor given the isolated nature of these accidental releases when following available regulations such as those set forth by the International Convention for the Prevention of Pollution from Ships (MARPOL) (IMO 2019) and the variable distribution of sea turtles in the geographic analysis area. Fuel spills from vessels have lesser potential impacts on sea turtles due to their low probability of occurrence and relatively limited spatial extent, although impacts of large spills can be significant. Sea turtle exposure to aquatic contaminants and inhalation of fumes from oil spills can result in mortality (Shigenaka et al. 2021) or sublethal effects on individual fitness.

Trash and debris may be accidentally discharged through fisheries use; dredged material ocean disposal; marine minerals extraction; marine transportation; navigation and traffic; survey activities; cables, lines, and pipeline laying; as well as debris carried in river outflows or windblown from onshore. Accidental releases of trash and debris are expected to be low-quantity, localized, and low-impact events from all ongoing and planned non-offshore-wind and offshore wind activities (Appendix D). Direct ingestion of plastic fragments is well documented and has been observed in all species of sea turtles (Bugoni et al. 2001; Hoarau et al. 2014; Nelms et al. 2016; Schuyler et al. 2014). In addition to plastic debris, ingestion of tar, paper, Styrofoam™, wood, reed, feathers, hooks, lines, and net fragments has also been documented (Thomás et al. 2002). Ingestion can also occur when individuals mistake debris for potential prey items (Gregory 2009; Hoarau et al. 2014; Thomás et al. 2002). Potential ingestion of marine debris varies among species and life history stages due to differing feeding strategies (Nelms et al. 2016). Ingestion of plastics and other marine debris can result in both lethal and sublethal impacts on sea turtles, with sublethal effects more difficult to detect (Gall and Thompson 2015; Hoarau et al. 2014; Nelms et al. 2016; Schuyler et al. 2014). Long-term sublethal effects may include dietary dilution, chemical contamination, depressed immune system function, poor body condition, and reduced growth rates, fecundity, and reproductive success. However, these effects are cryptic and clear causal links between ingestion of marine debris and sublethal effects are difficult to identify (Nelms et al. 2016).

Impacts from accidental releases and discharges from ongoing and planned non-offshore-wind activities would likely be minor for sea turtles. Impacts from accidental releases and discharges from offshore wind activities would also be minor as offshore wind projects would be expected to follow all BOEM BMPs and MARPOL guidance for accidental releases. Though long-term consequences to individuals that are detectable and measurable could occur, it would not lead to population-level effects.

Discharges/intakes: Planned offshore wind projects in the geographic analysis area may use HVDC substations that would convert AC to DC before transmission to onshore project components. As described in a BOEM white paper (Middleton and Barnhart 2022), these HVDC systems are cooled by an open loop system that intakes cool sea water and discharges warmer water back into the ocean. Potential effects resulting from intake and discharge use on sea turtles include altered micro-climates of warm water surrounding outfalls, altered hydrodynamics around intakes/discharges, prey entrainment, and sea turtles scavenging intake screens if prey aggregate on them (Wilcox 1985; Martin and Ernest 2000; Villalba-Guerra 2017). Sea turtles may be attracted to the warm water surrounding the outflow area, especially in fall or early winter when the surrounding water temperatures are cooling and the risk for cold-stunning is heightened. However, the warm water discharged is absorbed by the surrounding water and quickly returned to ambient temperatures, thereby minimizing the extent of a warm water plume. Entrainment of potential prey resources would be minimal given the small number of proposed OSSs per project. Entrainment of sea turtles that may depredate on aggregated prey is unlikely due to physical impedance by intake safety screens. Although it is possible for a sea turtle to be impinged and pulled against an intake screen, which could lead to suffocation and drowning, the likelihood of this is considered small given the small number of HVDC converter stations. Sea turtle attraction to warm-water outflows and entrapment by cooling intake systems is documented for nuclear power plants (Wilcox 1985; Martin and Ernest 2000; Villalba-Guerra 2017). However, HVDC converter substation discharges and intakes are expected to be orders of magnitude smaller than those for nuclear power plants. Additionally, the cooling systems for nuclear power plants often use the nearshore ocean water to cool their reactors, which is taken in using a human-made canal from the ocean to the reactor (Martin and Ernest 2000; Villalba-Guerra 2017). The presence of this canal can contribute to the risk of entrainment in nuclear power plant cooling systems, but they would not be present for HVDC converter substations because they are located offshore and would pull directly from surrounding waters. Given this, and the small number of HVDC converter substations planned for the geographic analysis area, impacts on sea turtles are largely discounted. Impacts from intakes and discharges from ongoing and planned offshore wind activities would therefore be long term, low in intensity, localized, and negligible for sea turtles; measurable effects are not anticipated.

Cable emplacement and maintenance: Cable maintenance activities disturb bottom sediments and cause temporary increases in suspended sediment; these disturbances will be localized and generally limited to the emplacement corridor. Data is not available regarding effects of suspended sediments on adult and juvenile sea turtles, although elevated suspended sediments may cause individuals to alter normal movements and behaviors. However, these changes are expected to be too small to be detected

(NOAA 2020). Sea turtles would be expected to swim away from the sediment plume. Elevated turbidity is most likely to affect sea turtles if a plume causes a barrier to normal behaviors, but no impacts would be expected due to swimming through the plume (NOAA 2020). Turbidity associated with increased sedimentation may result in short-term, temporary impacts on some sea turtle prey species such as benthic fish and invertebrates, as well as any SAV present along potential cable routes. The impact on water quality from accidental sediment suspension during cable emplacement is short term and temporary. If elevated turbidity caused any behavioral responses such as avoidance of the turbidity zone or changes in foraging behavior, such behaviors would be temporary, and therefore any impacts would likely be short term and temporary. Turbidity associated with increased sedimentation may result in short-term, temporary impacts on some sea turtle prey species. Long-term changes in benthic habitat due to the presence of hard protection on top of cables may also affect the presence of sea turtle prey species (Janßen et al. 2013; Hutchison et al. 2020), potentially yielding varying effects on sea turtles' foraging abilities around the cables.

Dredging for sand wave clearance may be necessary in places to ensure cable burial below mobile seabed sediments, which could result in additional impacts on sea turtles related to impingement, entrainment, and capture associated with mechanical and hydraulic dredging techniques. Sea turtles have been known to become entrained in trailing suction hopper dredges or trapped beneath the draghead as it moves across the seabed. Direct impacts, especially for entrainment, typically result in severe injury or mortality (Dickerson et al. 2004; NMFS 2020). About 69 dredging projects using trailing suction hopper dredgers have recorded sea turtle takes within channels in New Jersey, Delaware, and Virginia and there have likely been numerous other instances not officially recorded (Ramirez et al. 2017). However, the risk of interactions between hopper dredges and individual sea turtles is expected to be lower in the open ocean areas where dredging may occur compared to nearshore navigational channels where sea turtles are more concentrated in a constrained operating environment (Michel et al. 2013; NMFS 2020). This may be due to the lower density of sea turtles in these areas as well as differences in behavior and other risk factors. Dredging within nearshore areas could affect green sea turtle habitat by directly removing SAV or creating suspended sediments that may be deposited on top of seagrass (see Section 3.5.2, *Benthic Resources*). Changes in turbidity and suspended sediments could temporarily disrupt normal sea turtle behaviors, especially if turtles rely on vision to forage. Sea turtles may experience behavioral effects upon exposure to turbidity or suspended sediments and become more susceptible to other threats like vessel collision, but this has not been studied or measured. There are also no studies that evaluate the behavioral effects of suspended sediments on mobile prey species. Johnson (2018) suggested that any effects on sea turtle prey species from suspended sediments, sediment deposition, or turbidity may cause turtles to move to other areas and then return to the affected areas at some time in the future. It is not believed that dredging would permanently change the sea turtle prey base (Michel et al. 2013) and wind projects would implement turbidity reduction measures to contain the silt and sediment stirred up by dredging.

Given the available information, sediment disturbances associated with both ongoing and planned non-offshore-wind and offshore wind activities are not likely to result in any discernible effects on sea turtles, and the risk of injury or mortality of individual sea turtles resulting from dredging necessary to support offshore wind projects would be low. Cable emplacement and maintenance would therefore result in minor impacts on sea turtles and population-level effects are unlikely to occur.

Electric and magnetic fields and cable heat: EMFs emanate constantly from installed telecommunication and electrical power transmission cables. During operations of ongoing and planned offshore wind projects (Appendix D), cables would produce EMFs. Submarine power cables in the geographic analysis area for sea turtles are assumed to be installed with appropriate shielding and burial depth to reduce potential EMFs to low levels (BOEM 2007). Although the EMF would exist as long as a cable was in operation, impacts would likely be difficult to detect, if they occur at all. Recent reviews by Bilinski (2021) of the effects of EMFs on marine organisms concluded that though sea turtle species can detect electromagnetic fields and use the earth's magnetic field for migration and navigation, no observed effects from subsea cable EMFs have been reported for any sea turtle species. Additionally, transmission cables using HVAC, emit ten times less magnetic field than HVDC (Taormina et al. 2018), and cable shielding, and burial would further reduce the level of EMF produced.

Sea turtles appear to have a detection threshold of magnetosensitivity and behavioral responses to field intensities ranging from 0.0047 to 4000 µT for loggerhead turtles, and 29.3 to 200 µT for green turtles, with other species likely similar due to anatomical, behavioral, and life history similarities (Normandeau et al. 2011). Juvenile or adult sea turtles foraging on benthic organisms may be able to detect magnetic fields while they are foraging on the bottom near the cables and up to potentially 82 feet (25 meters) in the water column above the cable. Juvenile and adult sea turtles may detect the EMF over relatively small areas near cables (e.g., when resting on the bottom or foraging on benthic organisms near cables or concrete mattresses). There are no data on impacts on sea turtles from EMFs generated by underwater cables, although anthropogenic magnetic fields can influence migratory deviations (Luschi et al. 2007; Snoek et al. 2016, 2020). However, any potential impacts from AC cables on turtle navigation or orientation would likely be undetectable under natural conditions, and thus would be insignificant (Normandeau et al. 2011).

Heat transfer into surrounding sediment associated with buried submarine high-voltage cables is possible (Emeana et al. 2016). However, heat transfer is not expected to extend to any appreciable effect into the water column due to the use of thermal shielding, the cable's burial depth, and additional cable protection such as scour protection or concrete mattresses for cables unable to achieve adequate burial depth. As a result, heat from submarine high-voltage cables is not expected to affect sea turtles.

Impacts from EMFs from ongoing and planned non-offshore-wind activities would likely be negligible for sea turtles as it would be of the lowest level of detection and no perceptible consequences to individuals or populations are expected. Impacts from EMFs from ongoing and planned offshore wind activities would similarly be negligible for sea turtles.

Noise: The siting, construction and installation, O&M, and conceptual decommissioning of ongoing and planned offshore wind farms is expected to introduce several types of underwater sound into the marine environment. Physical descriptions of sounds associated with these activities can be found in Appendix J, *Introduction to Sound and Acoustic Assessment*. As discussed in Section 3.5.7.1, hearing sensitivity of sea turtles is restricted to a range of low frequencies. The expected impacts of each of these sources on sea turtles is discussed below.

Geophysical and Geotechnical Surveys

The active acoustic sources used in site characterization surveys introduce noise into the water in areas around sites of investigation. See Appendix J for a physical description of these sounds. Only a subset of geophysical sources (e.g., boomers, sparkers) are likely to be audible by sea turtles given the frequency range of the sounds and the hearing range of turtles, but they may cause short-term behavioral disturbance, avoidance, or stress (NSF and USGS 2011). Recently, BOEM and USGS characterized underwater sounds produced by high-resolution geophysical sources and their potential to affect marine animals, including sea turtles (Ruppel et al. 2022). In addition to frequency range, other characteristics of the sources—like the source level, duty cycle, and beamwidth—make it very unlikely that these sources would result in behavioral disturbance of sea turtles, even without mitigation (Ruppel et al. 2022). Given the intensity of noise generated by this equipment (Crocker and Frantantonio 2016; Crocker et al. 2019) and short duration of proposed surveys, it is unlikely to result in PTS for any turtle species. Although temporary displacement or behavioral responses may occur, they would not result in biologically notable consequences and impacts on sea turtles would be minor and would have no stock or population-level effects. Likewise, geotechnical surveys may introduce low-level, intermittent, broadband noise into the marine environment, though these sounds are unlikely to result in behavioral disturbance given their low source levels and intermittent use.

Unexploded Ordnance Detonations

There are several options for UXO removal that include stabilizing the UXO for safe relocation without detonation, low-order detonation designed to reduce the net explosive yield of a UXO compared to conventional “blow-in-place” techniques, and high-order detonation in which the full explosive weight is detonated in the place where the object is found. The appropriate method of removal for each project will depend on the condition of the UXO (i.e., how stable it is for potential relocation) and surrounding environmental conditions. For a physical description of the sounds produced by underwater explosions, see Appendix J. Underwater explosions of this type generate shock waves, or a nearly instantaneous wave characterized by extreme changes in pressure, both positive and negative. This shock wave can cause injury and mortality to a sea turtle, depending on how close an animal is to the blast. Similar to effects seen in mammals, the physical range at which injury or mortality could occur will vary based on the amount of explosive material in the UXO, size of the turtle, and the location of the turtle relative to the explosive. Injuries may include hemorrhages or damage to the lungs, liver, brain, or ears, as well as auditory impairment such as PTS and TTS (Ketten 2004; Finneran et al. 2017). Potential impacts from *in-situ* UXO detonation would result from both low- and high-order detonation methods, with less intense pressures and noise produced from the low-order detonations. However, though low-order detonation methods would generally be preferred by projects, they may not always fully eliminate the risk of high-order detonation, so potential impacts from *in-situ* UXO disposal need to be assessed assuming high-order detonations would occur. Noise generated during detonation is dependent on the size and type of UXO, amount of charge used, location, water depth, soil conditions, and burial depth of the UXO. Higher order detonation methods, if they were to occur, would present the greatest risk of impact on sea turtles, as this could result in mortality, non-auditory injuries (e.g., hemorrhages, lung damage, ear damage), and auditory injuries such as PTS or TTS and would present moderate impacts on sea turtles. UXO detonations may result in the loss of individuals but would not be expected to result in population-level effects given the irregular occurrence of high-order detonations expected.

Impact and Vibratory Pile-Driving

The construction of WTG and OSS foundations in the geographic analysis area is expected to occur intermittently over an approximate 9-year period between 2023 and 2030. During the installation of foundations, underwater sound related to pile-driving would likely occur for less than 12 hours per day per project. The sound generated during pile-driving will vary depending on the piling method (impact or vibratory), pile material, size, hammer energy, water depth, and substrate type. A description of the physical qualities of pile-driving noise can be found in Appendix J. These sounds may affect sea turtle species in the area. The impacts would vary in extent and intensity based on the scale and design of each project, as well as the schedule of project activities.

Impulsive noise from impact pile-driving during offshore wind development, due to the anticipated frequency and spatial extent of effect, represents the highest risk of exposure and potential for adverse effects on sea turtles in the geographic analysis area. While these potential effects are acknowledged, their significance is unclear because sea turtle sensitivity and behavioral responses to pile-driving noise are not well known and are subjects of ongoing study. However, several studies conducted on responses to seismic airguns, an impulsive signal that can serve as a proxy, have shown that a range of behavioral effects are possible. In these studies, caged and free-swimming sea turtles are reported as reacting to the sounds by initiating a startle dive (Weir 2007; DeRuiter and Doukara 2012), rising to the surface (Lenhardt 1994), and altering swimming patterns (McCauley et al. 2000). In other studies, sea turtles avoided the airgun source initially, but authors suggested that animals likely habituated to the source over time (Moein et al. 1994; Lenhardt 2002; Hazel et al 2007). This type of noise habituation has been demonstrated even when the repeated exposures were separated by several days (Bartol and Bartol 2012; U.S. Department of the Navy 2018). The accumulated stress and energetic costs of avoiding repeated exposures to pile-driving noise over a season or life stage could have long-term effects on survival and fitness (U.S. Department of the Navy 2018).

Vibratory pile-driving may be used prior to impact pile-driving to reduce the risk of pile run for some offshore wind projects and during export cable installation and port facility construction. The term *pile run* refers to the quick penetration of a pile into the seabed as a result of its high self-weight and low resistance from the seabed. A more detailed description of vibratory pile-driving noise can be found in Appendix J. Vibratory pile-driving is expected to create nearly continuous, non-impulsive, low-frequency noise. Compared to impact pile-driving, this means the most damaging elements of sound exposure (the rapid rise time) would not pose a risk to sea turtles like they would for impulsive noise sources. However, like with any continuous source, if animals remain within the area for long enough, they could still experience auditory fatigue. At larger ranges, acoustic masking is possible. However, vibratory pile-driving activities would be relatively short term, occurring over approximately 4 hours per pile for the foundations, and over several days for export cable installation.

Sea turtles that are exposed to pile-driving have the potential to experience acoustic injury such as TTS or PTS. In theory, reduced hearing sensitivity could limit the ability to detect predators, prey, or potential mates and reduce the survival and fitness of affected individuals. However, the role and importance of sound in these biological functions for sea turtles remains poorly understood (Lavender et al. 2014).

Based on the available information provided above and in Appendix J, impacts on sea turtles from construction-related pile-driving noise would be limited to effects on a small number of individuals. However, given the number of projects anticipated within the geographic analysis area through 2030 (Appendix D), impact pile-driving would have moderate impacts on sea turtles due to the potential for severe effects on individuals but no effects on population viability for any species. Vibratory pile-driving is expected to be less impactful for sea turtles and would result in detectable impacts that are minor and would not result in population-level effects.

Foundation Drilling

Drilling activities for the WTG and OSS foundations used prior to pile-driving activities to remove soil or boulders from inside the piles in cases of pile refusal may produce SPL of 140 dB re μPa at 3,280 feet (975 meters) (Austin et al. 2018). This would exceed the continuous noise threshold of 120 dB re 1 μPa (Table 3.7-3) beyond 3,000 feet (914 meters), but these events are expected to be short term, which limits the sea turtles potentially present during construction. While behavioral responses may occur from drilling, they are not expected to be long lasting or biologically significant to sea turtle populations and are therefore minor.

Vessels

Vessel noise associated with non-offshore-wind activities is likely to be present throughout the sea turtle geographic analysis area at a nearly continuous rate due to the prevalence of commercial shipping, fishing, and recreational boating activities which are ongoing and would be expected to continue in the geographic analysis area. During both the construction and operational phases of ongoing and planned offshore wind projects, several types of vessels would be used to transport crew and supplies, and during construction, dynamic positioning systems may be used to keep the pile-driving vessel in place. A description of the physical qualities of vessel noise can be found in Appendix J. Construction and operational vessel noises are the most broadly distributed source of non-impulsive noise associated with offshore wind projects. Sea turtle exposure to underwater vessel noise would increase as a result of ongoing and planned offshore wind projects, especially during construction periods (Appendix D, Table D1-21). Sea turtles are less sensitive to sound compared to faunal groups like marine mammals and no injury or behavioral effects from vessel noise are anticipated for ongoing and planned offshore wind projects. It is unlikely that received levels of underwater noise from vessel activities would exceed PTS thresholds for sea turtles, as the PTS threshold for non-impulsive sources is an SEL_{24h} of 200 dB re 1 μPa^2 s (NMFS 2023), which is comparable to the maximum source level reported for large shipping vessels (Appendix J). Hazel et al. (2007) demonstrated that sea turtles only appear to respond behaviorally to vessels at approximately 33 feet (10 meters) or closer.

Vessel noise effects for ongoing and planned offshore wind projects are expected to be broadly similar to noise levels from existing vessel traffic in the region. Nonetheless, periodic localized, short-term behavioral impacts on sea turtles could occur, but sea turtle behavioral disturbances are anticipated only to occur within a relatively small area around the vessels and are expected to return to normal when the vessel moves away. Therefore, the effects of vessel noise from offshore wind activities would be minor. No population-level effects are expected to occur.

Dredging, Trenching, and Cable-Laying

Preparing a lease area for turbine installation and cable-laying may require jetting, plowing, or removal of soft sediments, as well as the excavation of rock and other material through various dredging methods. Cable installation vessels are likely to use dynamic positioning systems while laying the cables. The sound associated with dynamic positioning generally dominates over other sound sources present, especially in relation to dredging, trenching, and cable-laying activities. A description of the physical qualities of these sound sources can be found in Appendix J. Given the estimated source levels (Appendix J) and transitory nature of these sources, exceedance of PTS and TTS sound levels are not likely for sea turtles (Heinis et al. 2013), and behavioral disturbances would likely be low-intensity and localized, and result in negligible impacts on sea turtles.

Aircraft

Rotary wing aircraft (helicopters) may be used during initial site surveys, protected species monitoring prior to and during construction, facility monitoring, and crew transfers during construction. Sea turtle sensitivity to airborne noise is not well studied, but available information indicates potential disturbances would likely be minimal. Bevan et al. (2018) observed no evident behavioral responses from sea turtles exposed to drones flown directly overhead at altitudes ranging from 50 to 102 feet (18 to 31 meters). When aircraft travel at relatively low altitude, aircraft noise has the potential to elicit stress or behavioral responses (e.g., diving or swimming away or altered dive patterns) (BOEM 2017; NSF and USGS 2011; Samuel et al. 2005). Aircraft would operate through the NY Bight area at altitudes of 1,000 feet (305 meters) or more except when landing or departing from service vessels. NMFS (2016) determined that noise and disturbance effects on sea turtles from aircraft operations for a single offshore wind project would be negligible, and effects from aircraft use during multiple projects within the geographic analysis area would similarly be expected to be negligible as these noises are not expected to overlap in time or space.

WTG Operations

No biologically notable effects on sea turtles are anticipated from noise produced by WTG operation. Noise associated with operational WTGs would be expected to attenuate below ambient levels at a relatively short distance from WTG foundations (Miller and Potty 2017; Thomsen et al. 2015; Tougaard et al. 2009). Maximum anticipated noise levels produced by operational WTGs are estimated to be between 125 and 130 dB re 1 μPa m (Lindeboom et al. 2011; Tougaard et al. 2009). HDR (2019) measured SPL below 120 dB re 1 µPa at 164 feet (50 meters) from operating turbines at the Block Island Wind Farm, which are below the sound level thresholds expected to cause sea turtle PTS, TTS, and behavioral disturbance (NMFS 2023). Additionally, current generation WTGs use direct drive motors that could result in a sound decrease of approximately 10 dB from WTGs using gear boxes that were considered in prior studies (Stöber and Thomsen 2021). However, a review of published literature also identified an increase in underwater source levels (up to 177 dB re 1 µPa) with increasing power size with a nominal 10 MW WTG (Stöber and Thomsen 2021), and given the number of foundations expected within the sea turtle geographic analysis area through 2030 (Appendix D), the presence of WTG operational noise would be a persistent presence throughout the sea turtle geographic analysis area. Impacts on sea turtles would therefore be minor as the behavioral responses would be detectable but would not be expected to result in any population-level effects.

Port utilization: The development of an offshore wind industry in the sea turtle geographic analysis area may incentivize the expansion or improvement of regional ports to support planned projects. As discussed in Section D.2.5 of Appendix D, a number of dredging and port improvement projects at ports within the NY Bight area have either been proposed or are considered reasonably foreseeable including Port Ivory, the Port of Albany, the Port of Coeymans, the Southern Brooklyn Marine Terminal, the Brooklyn Navy Yard, and Arthur Kill Terminal in New York; the Paulsboro Marine Terminal, Lower Alloways Creek, High Bar Harbor, and Barnegat Light Stake channels in New Jersey; and Barnegat Bay, New Jersey. Further details of each of these proposed or foreseeable projects are provided in Appendix D.

Any port expansion could increase the total amount of disturbed (modified or lost) benthic habitat and result in impacts on some sea turtle prey species. However, given that port expansions would likely occur in subprime areas for foraging and the disturbance would be relatively small in comparison to the overall sea turtle foraging areas in the geographic analysis area, port expansions are not expected to affect sea turtles. Dredging for port facility improvement could lead to additional impacts on turtles from incidental entrainment, impingement, or capture. Most observed injury and mortality events in the United States due to dredging activities were associated with hopper dredging in and around core habitat areas in the southern portion of the geographic analysis area and in the Gulf of Mexico outside the geographic analysis area (Michel et al. 2013; NMFS 2020). Ongoing maintenance dredging of these facilities may increase related risks to individual turtles over the lifetime of the facilities; however, typical mitigation measures such as timing restrictions should minimize this potential. Additionally, the size, scope, and location of the dredging activities conducted for ongoing and planned offshore wind projects would be less than that identified for other projects such as beach nourishment or port deepening, and the type of equipment used reduces the risk of entrainment or impingement. Compared to the dredging activities for ongoing and planned offshore wind projects, navigation dredging projects, which occur primarily in channels close to shore, generally pose a greater risk of entrainment of sea turtles because of their tendency to concentrate in channels (Ramirez et al. 2017). For example, the number of sea turtles entrained by hopper dredging in BOEM offshore borrow areas has historically been relatively low when compared to navigation channel dredging (Ramirez et al. 2017). Between 1995 and 2015, there were 69 reported sea turtle takes in the North Atlantic (i.e., north of North Carolina) by trailing suction hopper dredges, versus approximately 260 taken in hopper dredges operating in the South Atlantic. The takes per project across the entire South Atlantic were estimated to be 0.96 (the North Atlantic was not analyzed). Therefore, given the limited extent and location of offshore wind project dredging in comparison to navigation projects, offshore wind projects are not expected to result in population effects as few to no takes of sea turtles would reasonably be expected. The risk of injury or mortality to individual sea turtles resulting from dredging associated with ongoing and planned offshore wind projects is low.

Port utilization of ongoing and planned non-offshore-wind and offshore wind activities would affect sea turtles through disturbances to benthic habitat, vessel traffic (discussed further in the *Vessel Traffic* IPF), and entrainment risk in dredging equipment. Based on the available information, this would be expected to result in minor impacts on sea turtles; although impacts on individuals would be detectable and measurable, no population-levels effects are expected.

Presence of structures: The Mid-Atlantic region currently has more than 130 artificial reefs. Hard-bottom (scour control and rock mattresses) and vertical structures (bridge foundations, Block Island Wind Farm WTGs, and two WTGs with the CVOW-Pilot project) in a soft-bottom habitat can create artificial reefs, thus inducing the reef effect (Taormina et al. 2018; NMFS 2015). The reef effect is usually considered a beneficial impact associated with higher densities and biomass of fish and decapod crustaceans (Taormina et al. 2018), providing a potential increase in available forage items and shelter for sea turtles compared to the surrounding soft bottoms. The presence of structures associated with non-offshore-wind development in nearshore coastal waters has the potential to provide habitat for sea turtles as well as preferred prey species. This reef effect has the potential to result in long-term, low-intensity, beneficial impacts. Bridge foundations will continue to provide foraging opportunities for sea turtles with measurable benefits to some individuals.

The addition of WTGs offshore in the geographic analysis area could increase sea turtle prey availability through the creation of new hard-bottom habitat, increasing pelagic productivity in local areas, or promoting fish aggregations at foundations (Bailey et al. 2014). Section 3.5.5, *Finfish, Invertebrates, and Essential Fish Habitat*, discusses reef creation and the potential for anthropogenic structures to attract benthic fauna and fish. The enhancement of these resources around new wind farm structures can provide additional foraging opportunities for sea turtles that may result in beneficial effects given the broad geographic range of species during their annual foraging migrations. These beneficial effects could be reversed following project decommissioning, as all project structures could be removed and any artificial reef creation would be reversed. The decision to remove structures or to leave them in place would be a part of the decommissioning application submitted to BSEE and approved or disapproved by BOEM at the project-specific stage.

Additionally, potential beneficial effects may be offset given the increased risk of entanglement due to derelict fishing gear on the structures. The presence of structures during offshore wind project operations has the potential to concentrate recreational fishing around foundations, potentially increasing the risk of sea turtle entanglement in both vertical and horizontal fishing lines and increasing the risk of injury and mortality due to infection, starvation, or drowning. While sea turtles are capable of remaining submerged for long periods, they appear to rapidly consume oxygen stores when entangled and forcibly submerged in fishing gear (Lutcavage and Lutz 1997). If there is an increase in recreational fishing in a wind farm area, it is likely that this will represent a shift in fishing effort from areas outside a wind farm area to within a wind farm area or an increase in overall effort. These structures could also result in fishing vessel displacement or gear shift. The potential impact on sea turtles from these changes is uncertain; however, if a shift from mobile gear (trolling) to fixed gear (hook and line) occurs due to inability of the fishermen to maneuver mobile gear, there would be a potential increase in the number of vertical lines, resulting in an increased risk of sea turtle interactions with fishing gear. Given vessel safety concerns regarding being too close to foundations and other vessels, the likelihood of recreational fishermen aggregating around the same turbine foundation at the same time is low. Due to foraging strategies, leatherback and loggerhead sea turtles are more likely to be exposed to recreational fishing lines in the pelagic WTG area. Conversely, Kemp's ridley and green sea turtles are less likely to be exposed to recreational fishing lines in the pelagic WTG area and are in the geographic analysis area at much lower densities than loggerhead and leatherback sea turtles. Human-made structures, especially tall vertical structures like WTG and OSS foundations, alter local water flow at a fine scale and could result in localized impacts on sea turtle prey distribution and abundance. A discussion of the effects of altered water flow can be found in Section 3.5.6, *Marine Mammals*. The presence of many WTG structures could affect oceanographic and atmospheric conditions in ways that alter local environments and potentially increase primary productivity in the vicinity of these structures (Carpenter et al. 2016; Schultze et al. 2020). However, this may not translate to a beneficial increase in sea turtle prey abundance if the increase in primary productivity is consumed by filter feeders (e.g., mussels) that colonize the surface of the structures (Slavik et al. 2019).

The long-term effects of offshore structure development on ocean productivity and sea turtle prey species, and therefore on sea turtles, are difficult to predict with certainty because they are expected to vary by location, season, and year depending on broader ecosystem dynamics. For example, the presence of new hard surfaces could increase the abundance of associated organisms (e.g., mollusks, crustaceans) on and around the structures, providing a prey resource for sea turtles. Increased primary and secondary productivity in proximity to hard-bottom structures could increase the abundance of prey species like jellyfish (English et al. 2017). Additionally, hard-bottom (scour control, cable protection) and vertical structures (WTG and OSS foundations) in a soft-bottom habitat can create a three-dimensional artificial reef structure, thus inducing the "reef effect" and resulting in higher densities and biomass of mollusks, fish, and decapod crustaceans (Causon and Gill 2018; Taormina et al. 2018). Recent studies have found increased biomass for benthic fish and invertebrates, and possibly for pelagic fish, sea turtles, and birds as well (Raoux et al. 2017; Pezy et al. 2018; Wang et al. 2019), indicating that offshore wind facilities can generate beneficial long-term impacts on local ecosystems, translating to increased foraging opportunities for sea turtle species. Sea turtles may also use vertical structures for shelter from strong currents to conserve energy and for cleaning their carapace (Barnette 2017). In contrast, increased fish biomass around the structures could attract commercial and recreational fishing activity, creating an increased risk of injury or mortality from gear entanglement and ingestion of debris (Berreiros and Raykov 2014; Gregory 2009; Vegter et al. 2014; Shigenaka et al. 2021).

Some level of displacement of sea turtles from ongoing and planned offshore wind lease areas into areas with a greater potential for interactions with ships or fishing gear could occur, particularly during construction phases. However, the addition of structures could locally increase pelagic productivity and prey availability for sea turtles and decrease the likelihood of long-term displacement from the ongoing and planned offshore wind lease areas. While the effect would be present long-term throughout the life of ongoing and planned offshore wind projects, the overall impact is minor and would not be expected to affect the viability of any sea turtle populations.

Traffic: Current activities contributing to traffic in the geographic analysis area include port traffic levels, fairways, TSS, commercial vessel traffic, recreational and fishing activity, and scientific research and surveys. Propeller and collision injuries from boats and ships are common in sea turtles. Vessel strike is an increasing concern for sea turtles, especially in the southeastern United States where development along the coasts is likely to result in increased recreational boat traffic (NMFS and USFWS 2007; Hazel et al. 2007; Barco et al. 2016; Foley et al. 2019). In the United States, the percentage of strandings of loggerhead sea turtles attributed to vessel strikes increased from approximately 10 percent in the 1980s to a record high of 20.5 percent in 2004 (NMFS and USFWS 2007). Sea turtles are most susceptible to vessel collisions in coastal waters, where they forage from May through November. Vessel speed may exceed 10 knots in such waters, and evidence suggests that they cannot reliably avoid being struck by vessels exceeding 2 knots (Hazel et al. 2007). Sea turtle strandings reported to have vessel strike injuries have been reported to be as high as 25 percent in the Chesapeake Bay in Virginia (Barco et al. 2016), and Foley et al. (2019) reported that roughly one-third of stranded sea turtles in Florida had injuries indicative of a vessel strike. Increased vessel traffic associated with ongoing and planned offshore wind activities could result in a higher number of vessel strikes, resulting in sea turtle injury or mortality. However, despite the potential for individual fatalities, no population-level impacts on sea turtles are expected. It is anticipated that projects will adhere to vessel speed restrictions and visual monitoring requirements set forth by NMFS (87 *Federal Register* 46921) which, while geared primarily towards marine mammals, will help reduce the risk of a strike occurring that could result in a serious injury or mortality. PSO sightings data indicate sighting rates for sea turtles during vessel operations were approximately 13 sea turtle detections per 100 hours of vessel effort (Marine Ventures International, Inc. 2022; RPS 2021). These detection rates are relatively high, and even with these high detection rates there were only 18 vessel strike mitigation actions required (2.8 percent of all sea turtle detections) and no strikes were reported.

Therefore, given the risk of impact of vessel strikes on sea turtles and the level of traffic expected from ongoing and planned non-offshore-wind and offshore wind activities, impacts on sea turtles are expected to be moderate as vessel strikes may result in long-term impacts on individuals, but the populations would be expected to recover, and the viability of these populations would not be affected.

Survey gear utilization (biological/fisheries monitoring surveys): A primary threat to sea turtles is their unintended capture in fishing gear, which can result in drowning or cause injuries that lead to mortality (e.g., swallowing hooks). For example, trawl fishing is among the greatest continuing primary threats to the loggerhead turtle (NMFS and USFWS 2019) and sea turtles are also caught as bycatch in other fishing gear including longlines, gillnets, hook and line, pound nets, pot/traps, and dredge fisheries.

A substantial impact of commercial fishing on sea turtles is the entrapment or entanglement that occurs with a variety of fishing gear. Although the requirement for the use of bycatch mitigation measures, such as “turtle excluder devices” in trawl fishing gear, has reduced sea turtle bycatch, Finkbeiner et al. (2011) compiled data on sea turtle bycatch in U.S. fisheries and found that in the Atlantic, a mean estimate of 137,700 interactions, 4,500 of which were lethal, occurred annually since implementation of bycatch mitigation measures. Stationary gear poses a risk of entanglement for ESA-listed sea turtle species due to buoy and anchor lines. Of all the Atlantic sea turtles, the leatherback seems to be the most vulnerable to entanglement in trap/pot fishing gear, possibly due to its physical characteristics, diving and foraging behaviors; distributional overlap with the gear; and the potential attraction to prey items that collect on buoys and buoy lines at or near the surface (NMFS 2016). Individuals entangled in pot gear generally have a reduced ability to forage, dive, surface, breathe, or perform other behaviors essential for survival (Balazs 1985). In addition to mortality, gear entanglement can restrict blood flow to extremities and result in tissue necrosis and death from infection. Individuals that survive may lose limbs or limb function, decreasing their ability to avoid predators and vessel strikes (NMFS 2016). A reduction of sea turtle interactions with fisheries is a priority for sea turtle recovery. The impacts of survey gear utilization associated with biological and fisheries surveys monitoring for ongoing and planned offshore wind activities on sea turtles are expected to be minor given the relatively limited extent and duration of these surveys; impacts on individuals would be detectable and measurable but would not lead to population-level effects.

Lighting: Artificial lighting from ongoing and planned offshore wind and non-offshore-wind projects may be produced by vessel traffic or project structures. Ocean vessels such as ongoing commercial vessel traffic, recreational and fishing activity, and scientific research and survey vessels have an array of lights including navigational, deck lights, and interior lights. Such lights have some limited potential to attract sea turtles although the impacts, if any, are expected to be localized and temporary. Artificial lighting on nesting beaches or in nearshore habitats has the potential to result in disorientation to nesting females and hatchling turtles. Artificial lighting on the OCS does not appear to have the same potential for such effects. Decades of oil and gas platform operation in the Gulf of Mexico, which can have considerably more lighting than offshore WTGs, has not resulted in any known impacts on sea turtles (BOEM 2019). Based on the available information, artificial lighting from ongoing and planned offshore wind and non-offshore-wind projects would be expected to result in negligible impacts on sea turtles; although impacts on individuals would be detectable and measurable, no population-levels effects are expected.

3.5.7.3.4 Conclusions

Impacts of the No Action Alternative. Under the No Action Alternative, sea turtles would continue to be affected by existing environmental trends and ongoing activities. In addition to ongoing climate change, BOEM expects a range of temporary to long-term impacts (disturbance, displacement, injury, mortality, and reduced foraging success) on sea turtles, primarily from exposure to construction-related underwater noise (specifically UXO detonations and impact pile-driving), vessel traffic (i.e., vessel strike), entanglement, seabed disturbance, and changes in habitat from presence of new structures acting as artificial reefs, altering hydrodynamics, and introducing secondary entanglement risk. Ongoing activities are expected to continue to result in **negligible** to **moderate** impacts on sea turtles. Although impacts on individual sea turtles and their habitat are anticipated from pile-driving, vessel traffic, UXO detonation, and other IPFs, they are recoverable and likely would not affect the population viability of any sea turtle species.

Cumulative Impacts of the No Action Alternative. BOEM anticipates that planned offshore wind and non-offshore-wind activities would result in moderate impacts on sea turtles. These impacts are primarily driven by ongoing underwater noise impacts (UXO detonations, impact pile-driving), traffic (i.e., vessel strike), entanglement, and seabed disturbance. Although impacts on individual sea turtles and their habitat are anticipated, populations are expected to recover sufficiently.

Under the No Action Alternative, existing environmental trends and ongoing activities would continue, and sea turtles would continue to be affected by natural and human-caused IPFs. BOEM anticipates that the overall impacts associated with the No Action Alternative, when combined with all other planned activities (including offshore wind without the development of six NY Bight projects), in the geographic analysis area would likely result in **negligible** to **moderate** impacts on sea turtles because the anticipated impact would likely be notable and measurable, but populations are expected to recover and no effects on population viability are anticipated. **Minor beneficial** impacts for sea turtles are expected to result from the presence of structures primarily due to an increase in foraging opportunity as a result of the artificial reef effect, which may be offset given the increased risk of entanglement due to derelict fishing gear on the structures.

3.5.7.4 Impacts of Alternative B – No Identification of AMMM Measures at the Programmatic Stage – Sea Turtles

3.5.7.4.1 Impacts of One Project

Alternative B considers the potential impacts of future offshore wind development for the NY Bight area without the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts.

Accidental releases: Accidental releases of fuel, fluids, hazardous materials, trash, and debris may increase as a result of one project developed in the NY Bight area. The risk of any type of accidental release would be increased primarily during construction when additional vessels are present and during the refueling of primary construction vessels at sea. BOEM prohibits the discharge or disposal of solid debris into offshore waters during any activity associated with construction and operation of offshore energy facilities (30 CFR 250.300). USCG also prohibits dumping of trash or debris capable of posing entanglement or ingestion risk (International Convention for the Prevention of Pollution from Ships, Annex V, Public Law 100–200 [101 Stat. 1458]). Project activities would comply with the federal requirements for the prevention and control of oil and fuel spills, reducing the likelihood of an accidental release. Further, implementation of an OSRP, which is required information with any future project COP submitted for the NY Bight area (30 CFR 585.627(c)), would decrease potential impacts from spills and informational training on proper storage and disposal practices would reduce the likelihood of accidental discharges and spills from occurring. The impacts of one NY Bight project from accidental releases of hazardous materials and trash/debris would, therefore, not increase the risk beyond that described under the No Action Alternative. In the unlikely event of an accidental oil spill, impacts would be sublethal due to quick dispersion, evaporation, and weathering, all of which would limit the amount and duration of exposure of sea turtles to hydrocarbons. The combined regulatory requirements and any additional directives from BOEM and other applicable federal agencies would effectively avoid accidental debris releases and avoid and minimize the impacts from accidental spills such that impacts on sea turtles are unlikely to occur. Therefore, though the consequence to individuals resulting from ingestion of debris could be fatal, the likelihood of this occurring is so low that impacts of accidental releases as a result of one NY Bight project would be of low intensity, short term, and localized. Therefore, the effects on sea turtles from accidental releases and discharges would likely be minor during construction and installation.

The impacts of one NY Bight project during O&M from accidental releases of hazardous materials and trash/debris would be the same, though slightly reduced, as that described above for construction and installation. During O&M, at-sea refueling for construction vessels would not likely occur, thereby reducing overall risk for an accidental spill. All other impacts of accidental releases during O&M would be the same as during construction and installation and would therefore remain minor for sea turtles.

Discharges/intakes: The use of HVDC cables is possible for one NY Bight project, which would require HVDC converter intakes on the up to five OSSs. Therefore, intakes and discharges related to cooling offshore wind converter stations are possible for one NY Bight project. Potential effects resulting from intake and discharge use include altered micro-climates of warm water surrounding outfalls, altered hydrodynamics around intakes/discharges, prey entrainment, association with intakes if prey aggregates on intake screens from which sea turtles scavenge, and direct entrainment or impingement. As discussed in Section 3.5.7.3.3, these impacts on sea turtles are largely discountable given the small number of OSSs. Therefore, the impact as a result of one NY Bight project from discharges and intakes, though long term, would be low in intensity, highly localized, non-measurable, and negligible for sea turtles.

Cable emplacement and maintenance: One NY Bight project would result in seafloor disturbance from installation of up to 280 WTGs, up to 5 OSSs, up to 550 miles (885 kilometers) of interarray cable, and up to 929 miles (1,495 kilometers) of export cable (Section 2.1.2, *Alternative B – No Identification of AMMM Measures at the Programmatic Stage*), which would result in turbidity effects with the potential to have temporary impacts on some sea turtle prey species (see Section 3.5.5, *Finfish, Invertebrates, and Essential Fish Habitat*). Jack-up vessels and vessel anchoring will include additional seafloor disturbance. These effects would be increased primarily during construction and installation activities as cable installation for the offshore export cables and interarray cables are gradually added. As provided in Table 2-2 in Chapter 2 of this PEIS, the most common methods expected for cable emplacement are mechanical or jet plowing. Additional options include jet trencher, precision installation (using a remotely operated vehicle/diver), mechanical cutter, controlled flow excavator, and vertical injection. In general, plumes generated during trenching of offshore areas would likely be limited to within a few feet vertically and a few hundred feet horizontally, and would be expected to settle out of the water column entirely within 24 hours after the completion of jetting operations. The jet plow embedment process for cable installation will, therefore, result in short-term and localized heightened turbidity. Trenching with a jet plow in areas of shallower water depths could cause plumes to nearly reach the surface of the water, and alternate cable emplacement methods may be required for some areas, such as dredging to install cable along sand waves. Dredging using mechanical dredging techniques would also contribute additional impacts on sea turtles due to the risk of impingement and entrainment.

Sea turtles in or near the one NY Bight project area would likely be foraging or migrating between foraging and nesting habitats. Prey species within the one NY Bight project area could include benthic species that could be affected by seabed disturbance associated with installation of the offshore export cables and interarray cables. This disturbance would be short term, and prey species would be expected to return to the area once the cables are installed. Similar levels of impact would be realized during cable maintenance. Because impacts during cable installation or maintenance would be temporary and localized, the impact of project activities on sea turtles would be negligible.

Only intermittent, localized cable maintenance is predicted during the O&M phase of one NY Bight project which would only disturb the seafloor if maintenance required exposing the cables. In case of insufficient burial or cable exposure, whether attributable to natural or human caused issues, appropriate remedial measures will be taken including reburial or placement of additional protective measures. If a cable failure occurs, an appropriate cable repair spread will be mobilized. During these remedial activities, if they occur, sediment plumes would be limited to directly above the seabed and not extend into the water column. Suspended sediments due to jet plowing are expected to remain localized to the area of disturbance and settle quickly to the seafloor. Elevated turbidity levels would be short term, highly localized, and temporary. Therefore, effects to sea turtles would be similar to those described for the construction and installation phase and impacts would be non-measurable and negligible.

Electric and magnetic fields and cable heat: As discussed in Section 3.5.7.3.3, Normandeau et al. (2011) and Bilinski (2021) reviewed the potential effects of EMFs from offshore wind energy projects on sea turtles and other species and concluded that sea turtles would be insensitive to EMF effects from subsea electrical cables. One NY Bight project-related EMFs are likely to be below the threshold detectable to sea turtles and, therefore, indistinguishable from natural variability in the analysis area. Export and interarray cables may be either HVAC or HVDC; potential effects to sea turtles from HVAC cables are considerably reduced compared to HVDC cables. However, Taormina et al. (2018) found that, though EMF from HVDC cables is higher than from HVAC cables, there were no significant differences in resettlement of benthic species over the cable a few years after installation compared to baseline regions, so sea turtles foraging on benthic prey species would not be expected to experience long-term changes in prey availability. Hutchison et al. (2018) found notable behavioral responses of American lobster and little skate in response to EMF from HVDC cables; however, it did not constitute a barrier to movement across the cable for either species, also indicating that long-term changes to sea turtle prey distribution are unlikely to occur. Additionally, export and interarray cables would be buried at a depth ranging from 3 to 19.6 feet (0.9 to 6 meters) and 3 to 9.8 feet (0.9 to 3 meters), respectively, and installed with appropriate cable shielding and scour protection (where needed). These factors will effectively limit sea turtle exposure to both EMFs and heat originating from the project cables. Areas where cable lie exposed on the seafloor could potentially result in EMFs that are detectable by sea turtles, but this area would be small, limited to extending only a few feet from the cable.

These factors indicate that the likelihood of sea turtles encountering detectable EMF and heat effects is low, and any exposure would be below levels associated with measurable biological effects. Therefore, EMF effects on sea turtles would be negligible.

Noise: Activities associated with one NY Bight project that could cause underwater noise effects on sea turtles are UXO detonations, impact and vibratory pile driving (during installation of WTG and OSS foundations), geophysical (i.e., HRG) and geotechnical surveys, vessel traffic, aircraft, cable laying or trenching and dredging, and potential drilling during construction. Project construction activities could generate underwater noise and result in non-auditory injury, auditory injury (i.e., PTS), behavioral disturbance, and masking effects on sea turtles.

Geophysical and Geotechnical Surveys

HRG survey equipment would likely be used during preconstruction surveys to support design finalization. This equipment produces noise in the 1.1 to 200 kilohertz frequency range at sound levels that may exceed sea turtle behavioral thresholds. No injurious impacts are expected for sea turtles from any HRG survey equipment (Baker and Howsen 2021). Behavioral disturbances may occur up to 295 feet (90 meters) from impulsive sources and up to 6.6 feet (2 meters) from non-impulsive sources assuming equipment are operating at the highest power settings (Baker and Howsen 2021). Some low-level behavioral disturbances could potentially occur during project-related HRG surveys; however, due to the relatively short duration of these surveys, risk of exposure to sea turtles is considered minimal. Likewise, geotechnical surveys, which may introduce low-level, intermittent, broadband noise into the marine environment, are unlikely to result in behavioral disturbance given their low source levels and intermittent use. Impacts from G&G surveys from one NY Bight project on sea turtles are therefore expected to be minor, with effects that are of low intensity and detectable but that do not lead to population-level impacts.

G&G surveys may occur irregularly throughout the O&M phase of one NY Bight project to check the integrity of the scour protection around the foundations and ensure the interarray and export cables have not become exposed. The scope of G&G surveys during O&M would be similar to that described for one NY Bight project construction and impacts on all sea turtles would similarly be detectable and minor, with no population-level effects.

Unexploded Ordnance Detonations

As discussed in Section 3.5.7.3.3 and Appendix J, underwater explosions of this type generate high pressure levels that could cause disturbance and both non-auditory and auditory injury to sea turtles. Five UXO locations (shown in Section 3.6.7, *Other Uses (Marine Minerals, Military Use, Aviation, Scientific Research and Surveys*, on Figure 3.6.7-6) and two UXO areas are located within the NY Bight area (Ecology and Environment 2017). While avoidance and non-explosive methods would be preferred and may be employed to lift and move these objects, it may not be possible to avoid all UXOs and some may need to be removed by explosive detonation. Based on acoustic modeling conducted for a nearby wind farm (Ocean Wind 1 OCS-A 0498), the physical range in which detonation of a UXO may exceed the mortality threshold for sea turtles resulting from a UXO at 39-, 66-, 98-, 148-foot (12-, 20-, 30-, and 45-meter) water depths may extend up to 1,903 feet (580 meters) from the source depending on the sea turtle size and location of the detonation (Hannay and Zykov 2022). Modeling included a range of UXO masses from 5 to 1,000 pounds (2.3 to 454 kilograms) based on charge weight "bins" defined by the U.S. Navy (Hannay and Zykov 2022). Modeled distances to non-auditory injury (e.g., gastrointestinal injury, lung injury) thresholds for these UXO masses and depths may extend up to 3,451 feet (1,052 meters) and distances to the PTS threshold may exceed 4,134 feet (1,260 meters) (Hannay and Zykov 2022). Modeled distances to the TTS threshold (which is used to determine potential behavioral disturbances for single detonations) for these UXO masses and depths may extend up to 15,997 feet (4,870 meters) (Hannay and Zykov 2022). The physical range at which injury or mortality could occur will vary based on the amount of explosive material in the UXO, size of the animal, the location of the animal relative to the explosive, whether the UXO is buried, the water depth of the blast, and local seafloor conditions, among other factors. Although acoustic modeling was not conducted for one NY Bight project, the ranges presented above from Hannay and Zykov (2022) are used to approximate the potential risk in this PEIS as the model was conducted for a comparable region in the northeastern United States, which is also likely to encounter similar types of UXO. UXO detonation is anticipated to be infrequent, localized, and temporary as detonation is not the preferred method of removal for any anticipated project. However, given the large ranges to auditory and non-auditory injury, the risk for mortality, and the severity of consequences to an exposed individual, impacts due to an unmitigated UXO detonation would be moderate for sea turtles because this could result in the loss of individuals, but populations would be expected to recover after construction of one NY Bight project.

Impact and Vibratory Pile-Driving

Noise from impact and vibratory pile-driving for the installation of WTG and OSS monopile or jacket foundations would occur intermittently during the installation of offshore structures. Impact pile-driving is anticipated to be used for monopiles and piled jacket foundations; vibratory impact pile-driving would likely only be used for piled jacket foundations. Maximum hammer energy for impact pile-driving is assumed to be less than 5,000 kJ with an estimated duration of up to 4 hours per day. Vibratory pile-driving is predicted to occur over a 1-hour period. If suction bucket or gravity-based foundations are used, no pile-driving would be required; therefore, no impact or vibratory pile-driving noise impacts would occur.

Noise produced by impact pile-driving during installation of WTG and OSS foundations have the potential to result in PTS and behavioral disturbances for all sea turtle species. Although acoustic modeling is not available for one NY Bight project activities, unmitigated ranges to the PTS thresholds for impact pile-driving may exceed 12,139 feet (3,700 meters) for the installation of one monopile per day based on acoustic modeling conducted for similar offshore wind project construction (Empire 2022; Küsel et al. 2022a,b; Tetra Tech 2022). Ranges to the behavioral disturbance threshold for sea turtles may extend to distances from 6,562 to 16,404 feet (2,000 to 5,000 meters) for large-diameter monopile foundations measuring between 30 and 49 feet (9 and 15 meters), which are the foundation type likely to result in the greatest potential for acoustic impacts, depending on the location (Empire 2022; Küsel et al. 2022a,b; Tetra Tech 2022). Vibratory pile-driving is not likely to result in PTS or behavioral disturbance for any species considering threshold ranges are predicted to be very small, extending <164 feet (<50 meters) for PTS thresholds and <656 feet (<200 meters) for behavioral thresholds (Tetra Tech 2022).

Glauconite sands may be present in the NY Bight lease areas. Depending on the classification of the glauconite sands present, there can be challenges associated with potential offshore wind development in these areas. Specifically, some glauconite sands are difficult, or even impossible, to drill through and cause high friction and increased noise during pile-driving. If developers discover glauconite sands during construction and installation, noise levels will likely increase as they determine if the glauconite is passable.

Behavioral and masking effects are more difficult to mitigate with large threshold ranges and are considered likely during impact pile-driving. One NY Bight project includes installation of up to 280 WTG and up to 5 OSS, which would equate to up to 285 days of impact pile-driving (assuming one monopile installation per day). Avoidance of impulsive noise sources by sea turtles has also been inferred from field observations of sea turtle behavior during seismic surveys (DeRuiter and Doukara 2012; Holst et al. 2006; Weir 2007), and other responses include short-term displacement of feeding or migratory activity (NSF and USGS 2011; Samuel et al. 2005). Though sea turtles may temporarily avoid the area, behaviors would be expected to return to normal after construction, and no long-term impacts that would affect stock or population viability are expected.

Impacts from impact pile-driving would be moderate, with effects that are measurable and detectable, but any potential injuries would only affect individuals and would not affect population viability. Impact from vibratory pile-driving would be minor for sea turtles as effects are anticipated to be low intensity, short term, and localized.

Vessels

As discussed in Section 3.5.7.3.3, underwater noise levels produced by construction and maintenance vessels throughout the life of the project are not expected to exceed PTS thresholds for sea turtles given the relatively low noise levels produced. However, sea turtles would be able to detect construction and support vessels associated with one NY Bight project, which could elicit behavioral changes in individual sea turtles present in the project area during vessel operations, but these changes would be limited to evasive maneuvers such as diving, changes in swimming direction, or changes in swimming speed. These changes are not expected to be biologically notable, and impacts on sea turtles from one NY Bight project vessel noise would therefore be minor as population-level effects are not anticipated.

Vessel traffic during the O&M phase of one NY Bight project is expected to be infrequent and limited to the use of smaller vessels which would limit the level of noise produced during maintenance trips and G&G surveys. Given the lower volume of vessel traffic expected during O&M and the smaller size of the vessels expected, impacts on all sea turtles are expected to be barely measurable and, therefore, negligible.

Dredging, Trenching, and Cable-Laying

During one NY Bight project construction, jetting, plowing, or removal of soft sediments may be required prior to installation of the WTGs and OSSs and installation of the interarray cable and export cable. As described in Section 3.5.7.3, these activities may result in behavioral disturbances for some sea turtles, though these are expected to be low-intensity and localized (Heinis et al. 2013). Additionally, because activities associated with one NY Bight project are expected to be short term and localized, impacts on all sea turtles from dredging or trenching noise during cable-laying would be expected to be negligible, with no perceptible consequences to populations.

Drilling

Drilling activities may be used during installation of the WTG foundations in the unlikely event that a pile has been “driven to refusal,” which occurs when five or more blows of an adequate hammer will not budge the pile. Drilling would be used for removal of soils, boulders, or other obstructions from the pile to ensure the foundation is safely and securely installed in the seabed. Drilling activities may produce SPL of 140 dB re μPa at 3,280 feet (1,000 meters) (Austin et al. 2018). This would exceed the continuous noise threshold of 120 dB re 1 μPa beyond 3,280 feet (1,000 meters), but these events are expected to be short term and would not be required for every foundation installed for one NY Bight project, which limits the risk of sea turtles potentially present during construction. While behavioral responses may occur from drilling, they are expected to be short term and of low intensity. Impacts from potential drilling activities on all sea turtles would therefore be minor, as the potential behavioral responses may be detectable, but population-level effects are not anticipated.

Aircraft

Aircraft used during one NY Bight project construction would follow established guidance (BOEM 2019) and would maintain altitudes of 1,000 feet (305 meters) or more above the water surface during normal flight operations, exclusive of takeoffs and landings. As discussed in Section 3.5.7.3.3, there is limited information regarding sea turtle responses to airborne aircraft noise. Based on available information, it is expected that short-term, non-biologically notable behavioral responses may occur (BOEM 2017; NSF and USCG 2011; Samuel et al. 2005). These changes in behavior are expected to end when the aircraft has left the area. Consequently, potential effects on sea turtles from aircraft noise for one NY Bight project are expected to be negligible, with no perceptible consequences to populations.

WTG Operations

As discussed in Section 3.5.7.3.3, operations of the WTG would result in long-term, low-level, continuous noise in the one NY Bight project area, which could result in behavioral disturbances and auditory masking at close distances (Lucke et al. 2007; Tougaard et al. 2009, 2020; Thomsen and Stober 2022). Noise produced by operational WTGs is within the auditory hearing range for all sea turtles, but the potential for impacts is not likely to occur outside a relatively small radius surrounding the project foundations and the audibility of the WTGs may be further limited by the ambient noise conditions of the one NY Bight project area (Jansen and Jong 2016, as an example). Impacts on sea turtles would therefore be minor as the behavioral responses would be detectable but would not be expected to result in any population-level effects.

Port utilization: Use of the port facilities located in New York and New Jersey would increase vessel traffic in the area and potentially require expansion or increased maintenance of port facilities within the sea turtle geographic analysis area. Expansion could result in impacts on coastal and estuarine habitats from shoreline noise during construction and disturbance or loss of habitat for prey species. As discussed in Section 3.5.7.3.3, there are a number of dredging and port improvement activities either planned or considered reasonably foreseeable at the representative ports identified for potential use by any of the NY Bight projects (Section D.2.5, Appendix D). Representative ports in New York and New Jersey include the Port of Albany, Port of Coeymans, Brooklyn Navy Yard, South Brooklyn Marine Terminal, Howland Hook/Port Ivory, Arthur Kill Terminal, Paulsboro Marine Terminal, and New Jersey Wind Port (Section D.2.5, Appendix D).

Increased maintenance such as dredging could expose sea turtles to increased levels of underwater noise, increased turbidity, and entrainment risk, affecting individual sea turtles or their prey. Increased activities associated with port expansion and port maintenance would likely be intermittent but long term. Increased noise associated with dredging was discussed previously under the *Noise* IPF, and vessel traffic associated with the above specified ports is covered in the *Traffic* IPF section. However, as discussed in Section 3.5.7.3.3, most dredging impacts on sea turtles were associated with hopper dredging in the southeastern United States and Gulf of Mexico (Michel et al. 2013; USACE 2020) used for dredging projects that have a much larger scope than what would be associated with one NY Bight project, so any port expansion activities associated with offshore wind projects would have a lower risk of effect on sea turtles. Additionally, most sea turtles occurring in the area would be migrating or foraging offshore, and while one species has been documented nesting in New York, this is considered a rare occurrence and is not common within the NY Bight area (Section 3.5.7.1). Therefore, dredging impacts on sea turtles from port utilization during one NY Bight project construction would be negligible as no perceptible consequences to populations are anticipated.

Port activities beyond routine maintenance of the facilities are not predicted at this time. Therefore, port utilization during the construction and O&M phase of one NY Bight project is likely to have negligible impacts on sea turtles as there would be no perceptible consequences to individuals or populations. Vessel traffic in and out of the ports is considered in the *Traffic* IPF.

Presence of structures: Under one NY Bight project, up to 280 WTGs, up to five OSSs, and new hard scour/cable protection would be installed. The structures and scour/cable protection, and the potential consequential impacts, would remain at least until conceptual decommissioning of the facility is complete. The foundations would be placed in a grid-like pattern with a minimum spacing of 0.6 by 0.6 nautical mile (1.1 by 1.1 kilometers) between WTGs. Based on the space between turbines, one NY Bight project would not present a barrier to movement to sea turtles, and the presence of WTG foundations would pose a negligible risk of displacement effects on sea turtles.

Long-term reef and hydrodynamic effects resulting from one NY Bight project could result in beneficial effects on sea turtles that benefit from increased prey abundance around the structures. However, these beneficial impacts would be reversed following project decommissioning when all project structures would be removed. The decision to remove structures or to leave them in place would be a part of the decommissioning application submitted to BSEE and approved or disapproved by BOEM at the project-specific stage. Conversely, minor impacts due to disruption in hydrodynamics from one NY Bight project could result in impacts on sea turtles that forage on planktonic species such as jellyfish. Sea turtles may also use vertical structures from one NY Bight project for shelter from strong currents to conserve energy and for cleaning their carapace (Barnette 2017). Long-term impacts could occur as a result of increased interaction with active or abandoned fishing gear. This impact is considered minor for sea turtles.

The presence of structures may concentrate recreational fishing around foundations and would also increase the risk of gear loss or damage. This could cause entanglement, especially with monofilament line, and increase the potential for entanglement in both lines and nets leading to injury and mortality due to abrasions, loss of limbs, and increased drag, resulting in reduced foraging efficiency and ability to avoid predators (Barnette 2017; Berreiros and Raykov 2014; Foley et al. 2008). The reef effect may attract recreational fishing effort from inshore areas and attract sea turtles for foraging opportunities, resulting in a small increased risk of sea turtle entanglement and hooking or ingestion of marine debris where fishing activity and turtles are concentrated around the same foundations. Therefore, though the increase in prey availability around the structures may result in long-term benefit for sea turtles, the risk of increased interactions with active or abandoned fishing gear would result in moderate impacts on sea turtles, as impacts on or loss of individuals may occur, but populations are expected to sufficiently recover.

Traffic: A number of vessels will be required to support activities carried out during the construction and installation, O&M, and conceptual decommissioning phases of one NY Bight project. Vessel traffic would be present for surveying activities; foundation, OSS, cable, and WTG installation; and support activities. The majority of the vessels are expected to have conventional propeller- or thruster-based propulsion systems. Smaller vessels designed primarily for crew transfer applications are expected to employ conventional propeller-propulsion systems or water jet-drive-based systems.

It is estimated that one NY Bight project would generate approximately 51 vessels operating in the one NY Bight project area at any one time during the construction and installation phase and approximately the same number of vessel trips per year during conceptual decommissioning as during construction and installation; the O&M phase would result in 8 trips per day primarily from ports identified in the *Port utilization* IPF to the project area (Section 3.6.6, *Navigation and Vessel Traffic*). Crew transfer vessels would account for a majority of vessel types used during O&M followed by supply vessels and jack-up vessels.

The potential effect of a vessel strike on sea turtle populations is considered severe in intensity because potential receptors include listed species and because the NY Bight area and potential vessel transit routes seasonally or annually support sea turtles. The geographic extent is considered localized to the vessel transit routes and the project area. Vessel traffic may also occur after dark or in daylight during periods of poor visibility (e.g., fog) or inclement weather conditions, during which risk of collisions with sea turtles would be higher because both turbid water and darkness would impede turtles' visual detection of approaching boats. Additionally, sea turtles spend time near the surface while resting, feeding, or periodically surfacing to breathe, during which time they would be more susceptible to vessel strikes. Data from Watwood and Buonantony (2012) and Borcuk et al. (2017) suggest loggerhead and green sea turtles spend 60 to 75 percent of the time within 32 feet (10 meters) of the surface and leatherback sea turtles spend about 20 percent of the time within 32 feet (10 meters) of the water surface; there are insufficient data to quantify Kemp's ridley sea turtle activity.

As one NY Bight project vessels would operate throughout the construction and installation, O&M, and conceptual decommissioning phases, the potential for a vessel to strike a sea turtle is considered continuous (life of one NY Bight project). Effects from vessel strikes range from short term in duration for minor injuries to permanent in the case of death of an animal. This impact is considered minor for sea turtles as there is potential for mortality or serious injury to occur to individuals, but it would not affect the viability of any sea turtle populations.

Survey gear utilization: There is currently no specific information regarding biological or fisheries monitoring surveys for one NY Bight project to quantitatively assess in this PEIS. However, unintended capture in fishing gear is a primary threat to sea turtles and is therefore included in this analysis. Sea turtles have the potential to be caught in trawl gear, longlines, gillnets, hook and line, pound nets, pot/traps, and dredge fishing gear. As discussed in Sections 3.5.7.1 and 3.5.7.3.3, impacts of entanglement from fishing gear could occur to all species in the NY Bight area. However, given the relatively limited extent and duration of these surveys, impacts on individuals would be detectable and measurable, but would not lead to population-level effects. The impact of survey gear utilization on sea turtles as a result of one NY Bight project, therefore, is expected to be minor.

Lighting: One NY Bight project would introduce mobile and stationary artificial light sources to the lease area that would persist from dusk to dawn. Artificial light in coastal environments is an established stressor for juvenile sea turtles, which use light to aid in navigation and dispersal and can become disoriented when exposed to artificial lighting sources, but the significance of artificial light in offshore environments is less clear (Gless et al. 2008). Available data suggests that there is the potential for effects on sea turtle species as a result of artificial lighting. While these effects would be localized and limited to the area exposed to operational lights, the effects would persist over the lifetime of the project. Orr et al. (2013) indicate that lights on wind generators flash intermittently for navigation or safety purposes and do not present a continuous light source. Limpus (2006) suggested that intermittent flashing lights with a very short “on” pulse and long “off” interval are non-disruptive to sea turtle behavior, irrespective of the color. Similarly, navigation/anchor lights on top of vessel masts are unlikely to adversely affect sea turtles (Limpus 2006). Orr et al. (2013) summarized available research on potential operational lighting effects from offshore wind energy facilities and concluded that the operational lighting effects on sea turtle distribution, behavior, and habitat use were unknown but likely negligible when recommended design and operating practices are implemented. Therefore, the impact of artificial lighting on sea turtles as a result of one NY Bight project is expected to be negligible.

3.5.7.4.2 *Impacts of Six Projects*

The same IPF impact types and mechanisms described under one project apply to six projects developed for the NY Bight. There would be more potential for impacts for these IPFs due to the greater amount of offshore and onshore development under six NY Bight projects. Impacts for accidental releases, discharges/intakes, EMFs and cable heat, survey gear utilization, and lighting are expected to be the same as those discussed above for one NY Bight project. These IPFs from six projects would not result in combined effects due to the highly localized nature of the individual IPFs, the low probability of any effects for even one project, and no population-level consequences for sea turtles. While individual projects vary in size and individual IPFs for each project may vary, the overall likelihood of impacts resulting from these IPFs for any one project remains the same as described in Section 3.5.7.4.1 regardless of the number of NY Bight projects considered. IPFs that will have a greater potential for impact under six NY Bight projects include cable emplacement and maintenance, noise, port utilization, presence of structures, and traffic.

Cable emplacement and maintenance: Under six NY Bight projects, the total area of seafloor disturbance would increase due to the substantial increase in the number of cables installed and maintained in the NY Bight area. Additionally, construction of six NY Bight projects would increase the amount of dredging equipment and activities used during installation of the cables. As discussed in Sections 3.5.7.3.3 and 3.5.7.4.1, direct impacts from dredging, particularly entrainment, typically result in severe injury or mortality for sea turtles (Dickerson et al. 2004; NMFS 2020). However, the risk of interactions between hopper dredges and individual sea turtles is expected to be lower in the open ocean areas where six NY Bight project cables would likely be installed compared to nearshore navigational channels where sea turtles are more concentrated in a constrained operating environment (Michel et al. 2013; NMFS 2020). The risk of entrainment in dredging associated with cable emplacement for six NY Bight projects would be measurable but impacts would be localized and minor for sea turtles as no population-level effects would occur.

Noise: Under six NY Bight projects, noise generated from impact pile-driving will increase due to the substantial increase in the number of foundations to be installed in the NY Bight area. If the construction of six NY Bight projects does not occur simultaneously, the total sound entering the water column at any given time would approximate that described for one NY Bight project (see *Noise* IPF). However, if construction occurs simultaneously on all six NY Bight projects, this would greatly increase the ensonified region. The impact on sea turtles, however, would remain moderate as PTS cannot be ruled out. The risk to sea turtles from UXO detonations will also increase under six NY Bight projects given the increased area over which UXOs may be encountered that cannot be avoided; the impact, however, will remain the same as for one NY Bight project and is expected to be moderate for sea turtles given the high-consequence severity of this IPF regardless of the number of detonations anticipated. Given the expected substantial increase in vessels operating under six NY Bight projects, impacts on sea turtles due to vessel noise would be elevated to minor for all phases (construction and installation, O&M, conceptual decommissioning), with effects that are detectable and measurable under full buildout of six NY Bight projects but would not lead to population-level effects. The impact on sea turtles from WTG operations under six NY Bight projects would elevate to minor for sea turtles due to potential long-term, localized presence in low-frequency noise that would be restricted to a small radius around each WTG. The impact of six NY Bight projects from all other noise sources (G&G surveys, aircraft, cable laying/trenching, and drilling) would increase marginally, but because the area of effect would also be limited to a relatively small area around the activity for six NY Bight projects, the full build out of projects is not expected to result in prolonged behavioral disturbances that would affect foraging or reproduction for any species, and would not elevate to higher impact levels as compared to one NY Bight project.

Within a concurrent exposure scenario of multiple wind farms under construction, an individual sea turtle in the area has the potential to be exposed to the sounds from more than one pile-driving event within a given season if traveling through more than one lease area during impact pile-driving. However, results from a previous risk assessment for marine mammals conducted for three projects offshore New England showed that concurrent construction of multiple wind farms could in fact minimize the overall risk to sea turtles by reducing the overall duration of impact pile-driving noise present within the NY Bight area (Southall et al. 2021). Therefore, the risk of noise effects on sea turtles is not expected to significantly increase from the construction of six NY Bight projects compared to one project, but the risk of effects of exposure to noise above acoustic thresholds during impact pile-driving cannot be ruled out. This would result in a moderate impact rating for pile-driving for all sea turtles.

Port utilization: Similar to the discussion for cable emplacement and maintenance under six NY Bight projects scenario, port utilization under six NY Bight projects would also increase. This would increase the likelihood of dredging projects occurring that could present the risk of entrainment for sea turtles. With the increase in the number and spatial extent of ports needed to support six NY Bight projects, impacts from potential dredging would be elevated to minor for sea turtles as impacts on individuals would be detectable and measurable, but would not lead to population-level consequences.

Presence of structures: Under six projects, the number of structures in the NY Bight area would be substantially higher than that for one NY Bight project. As a result, the presence of structures IPF has the potential to be more impactful to sea turtles under six NY Bight projects, mainly due to the increased risk of entanglement associated with additional vertical structures in the water column. Sea turtles would be at an increased risk of entanglement and may experience long-term consequences; impacts, however, are expected to remain moderate as effects would be detectable and measurable, though the viability of the species is likely to remain functional or are able to sufficiently recover. Minor beneficial impacts will likely still result due to the reef effect and potential increase in foraging opportunity, which would be measurable, though localized, and may be offset given the increased risk of entanglement due to derelict fishing gear on the structures.

Traffic: The construction of six NY Bight projects will substantially increase the number of vessels operating in the NY Bight area throughout all six NY Bight project phases. This increase in vessel traffic will increase the impact on all sea turtles from minor under one NY Bight project to moderate under six NY Bight projects because the consequences would be detectable and long-term for individuals, but populations are expected to remain viable.

3.5.7.4.3 Impacts of Alternative B on ESA-Listed Species

General impacts of Alternative B on sea turtles were described in the previous subsection. Because all sea turtle species present in the NY Bight area are listed under the ESA, the impact determinations provided in the previous subsections would apply here.

3.5.7.4.4 Cumulative Impacts of Alternative B

The construction and installation, O&M, and conceptual decommissioning of infrastructure for planned non-offshore-wind and planned offshore wind activities across the geographic analysis area would contribute to the primary IPFs of accidental releases, discharges/intakes, cable emplacement and maintenance, electric and magnetic fields and cable heat, noise, port utilization, presence of structures, traffic, and survey gear utilization.

Accidental releases: In the context of ongoing and planned non-offshore-wind and offshore wind activities, the impact contributed by accidental releases from six NY Bight projects would be undetectable. Impacts, therefore, are expected to be temporary and highly localized due to the likely limited extent and duration of a release, resulting in minor impacts for sea turtles, largely driven by ongoing and planned non-offshore-wind activities.

Cable emplacement and maintenance: In the context of reasonably foreseeable environmental trends, the contributions of six NY Bight projects to the combined cable emplacement impacts associated with planned non-offshore-wind and planned offshore wind activities would be undetectable on sea turtles. Impacts are expected to be minor, with short-term, localized consequences to individuals that are detectable and measurable but do not lead to population-level effects.

Discharges/intakes: In the context of reasonably foreseeable environmental trends, the contributions of six NY Bight projects to the combined discharge and intake impacts associated with planned non-offshore-wind and planned offshore wind activities would be undetectable. Impacts, therefore, are expected to be low in intensity, highly localized, and non-measurable, resulting in negligible impacts for sea turtles.

Electric and magnetic fields and cable heat: In the context of reasonably foreseeable environmental trends, the impact contributed by six NY Bight projects, while difficult to detect, would result in a cumulative increase in EMFs in the geographic analysis area beyond that described under the No Action Alternative. However, the combined impacts from EMFs and cable heat on sea turtles would likely still be negligible, localized, and long-term though with no perceptible consequences to individuals or populations.

Noise: In the context of reasonably foreseeable environmental trends, the contributions of six NY Bight projects to the combined noise impacts associated with planned non-offshore-wind and planned offshore wind activities described for Alternative A in Section 3.5.7.3.3 would be noticeable. The most significant sources of noise are expected to be pile-driving and UXO detonation. Impacts from impact pile-driving and UXO detonation would be moderate for all sea turtles due to the potential for severe-intensity effects such as non-auditory injury, but populations would be expected to fully recover. Impacts from vibratory pile-driving, G&G surveys, vessel noise, foundation drilling, and WTG operations would be minor for all sea turtles as impacts would be detectable and measurable but would not lead to population-level effects. Impacts from aircrafts and dredging, trenching, and cable-laying would be negligible for all sea turtles as impacts on individuals would be barely perceptible, short term, and highly localized.

Port utilization: In the context of ongoing and planned non-offshore-wind and offshore wind activities, the impact contributed by six NY Bight projects would result in a noticeable increase in port utilization in the geographic analysis area beyond that described under the No Action Alternative. The cumulative impacts of port utilization would therefore be minor, as impacts on sea turtles are expected to be detectable, but highly localized and intermittent; population-level impacts would not be expected.

Presence of structures: In the context of ongoing and planned non-offshore-wind and offshore wind activities, the impact contributed by six NY Bight projects would result in a noticeable increase in the presence of structures in the geographic analysis area beyond that described under the No Action Alternative. However, the combined impacts from the presence of structures would likely still be moderate for sea turtles, largely due to the risk of secondary entanglement in lost fishing gear, but population-level impacts are not expected. Minor beneficial impacts may result for sea turtles as well due to the reef effect and potential increase in foraging opportunity.

Traffic: In the context of ongoing and planned non-offshore-wind and offshore wind activities, the impact contributed by six NY Bight projects would result in a noticeable increase in vessel traffic in the geographic analysis area. The combined impact would be moderate for sea turtles because vessel strike would result in long-term consequences to individuals that are detectable and measurable but would not affect the viability of any sea turtle populations.

Survey gear utilization: In the context of ongoing and planned non-offshore-wind and offshore wind activities, the impact contributed by six NY Bight projects would be undetectable. Impacts, therefore, are expected to be minor, with short-term, localized consequences to individuals that are detectable and measurable but do not lead to population-level effects.

Lighting: In the context of ongoing and planned non-offshore-wind and offshore wind activities, the impact contributed by six NY Bight projects would result in a noticeable increase in artificial lighting in the geographic analysis area beyond that described under the No Action Alternative. However, the combined impacts from lighting would likely remain negligible for sea turtles, largely due to the limited potential for impacts, if any, and the localized and temporary impacts; although impacts on individuals would be detectable and measurable, no population-levels effects are expected.

3.5.7.4.5 Conclusions

Impacts of Alternative B. Construction and installation, O&M, and conceptual decommissioning of either one or six NY Bight projects, would result in habitat disturbance (presence of structures and new cable emplacement), habitat conversion (presence of structures), underwater and airborne noise, vessel traffic (strikes and noise), and potential discharges/spills and trash under Alternative B. For both one and six NY Bight projects, BOEM expects individual impacts ranging from **negligible** to **moderate** for sea turtles because impacts from most IPFs would likely be noticeable and measurable but would not affect the continued viability of any sea turtle populations. Impacts are expected to result mainly from pile-driving noise, UXO detonations, increased vessel traffic, and the presence of structures related to fishing gear entanglement. **Minor beneficial** impacts for sea turtles are expected to result from the presence of structures primarily due to an increase in foraging opportunity as a result of the artificial reef effect for both one and six NY Bight projects, which may be offset given the increased risk of entanglement due to derelict fishing gear on the structures.

Cumulative Impacts of Alternative B. BOEM anticipates that the cumulative impacts on sea turtles in the geographic analysis area under six NY Bight projects would likely be **negligible** to **moderate** for sea turtles and could include **minor beneficial** impacts. Long-term effects may occur for individual sea turtles, primarily due to UXO detonations, pile-driving noise, vessel traffic, and entanglement risk associated with the presence of structures, but impacts would be recoverable and would not affect the viability of the populations. In the context of other reasonably foreseeable environmental trends, impacts contributed by six NY Bight projects to the cumulative impact on sea turtles would range from undetectable to appreciable. Six NY Bight projects would contribute to the cumulative impacts primarily through pile-driving noise, increased vessel traffic, and the presence of structures as related to fishing gear entanglement.

3.5.7.5 Impacts of Alternative C (Proposed Action) – Identification of AMMM Measures at the Programmatic Stage – Sea Turtles

Alternative C, the Proposed Action, considers the potential impacts of future offshore wind development for the NY Bight Area with the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts. Alternative C consists of two sub-alternatives—Sub-alternative C1: Previously Applied AMMM Measures, and Sub-alternative C2: Previously Applied and Not Previously Applied AMMM Measures. The analysis for Sub-alternative C1 is presented as the change in impacts from those impacts discussed under Alternative B, and the analysis for Sub-alternative C2 is presented as the change from Sub-alternative C1. Refer to Table G-1 in Appendix G, *Mitigation and Monitoring*, for a complete description of AMMM measures that make up the Proposed Action.

3.5.7.5.1 Sub-Alternative C1 (Preferred Alternative): Previously Applied AMMM Measures

Sub-alternative C1 analyzes the AMMM measures that BOEM has previously required as conditions of approval for previous activities proposed by lessees in COPs submitted for the Atlantic OCS and through related consultations (Table 3.5.7-8).

Table 3.5.7-8. Summary of previously applied avoidance, minimization, mitigation, and monitoring measures for sea turtles

Measure ID	Measure Summary
MMST-1	This measure proposes requiring submittal and approval of a Reduced Visibility Monitoring (RVMP)/Nighttime Pile Driving Monitoring Plan to ensure visual monitoring can be achieved.
MMST-2	This measure proposes requiring the submittal and approval of a final pile-driving Marine Mammal and Sea Turtle monitoring plan with PAM and PSO requirements.
MMST-3	This measure proposes adjusting pile-driving clearance zones, shutdown zones, and monitoring and mitigation measures for pile driving based on sound field verification measurements.
MMST-4	This measure proposes requiring time of day restrictions, PSOs, clearance, and shutdown zones for pile-driving activities to reduce impacts from noise.
MMST-5	This measure proposes requiring additional PSO coverage to reliably monitor expanded pile driving clearance or shutdown zones to reduce noise impacts on marine mammals and sea turtles.
MMST-6	This measure proposes requiring that PSOs have effective viewing conditions (e.g., rain, fog, darkness) for visual monitoring during pile-driving to ensure unobstructed visual monitoring.
MMST-7	This measure proposes requiring that PSO coverage and training requirements for pile driving are sufficient to detect protected species.
MMST-9	This measure proposes requiring vessel crew and PSO training for protected species identification to reduce vessel strike risk.
MMST-10	This measure proposes requiring PSO reporting of all protected species in the shutdown zone during active pile driving.
MMST-12	This measure proposes requiring clearance and shutdown zones and related mitigations for marine mammals and sea turtles during geophysical surveys.
MMST-14	This measure proposes requiring that vessel operators and crews maintain a watch for protected species and take mitigative action if sighted to reduce vessel strike risk.
MUL-1	This measure proposes requiring training, recovery, prevention, and reporting to reduce and eliminate trash and debris in order to reduce impacts from entanglement, ingestion, smothering of protected species (including marine mammals, sea turtles, and benthic species), and pollutants in the water column. This measure also proposes requiring surveys to monitor and adaptively mitigate for lost fishing gear accumulated at WTG foundations.
MUL-8	This measure proposes requiring that all trap/pot gear used in fishery surveys would be uniquely marked to distinguish it from commercial or recreational gear and to facilitate identification of gear on any entangled marine mammals, sea turtles, or ESA-listed fish.
MUL-9	This measure proposes requiring recovery and reporting of any lost fishery and benthic monitoring survey gear to reduce entanglement impacts on marine mammals, sea turtles, and ESA-listed fish.
MUL-10d	This measure proposes requiring qualified third-party PSOs to observe Clearance and Shutdown Zones and implement mitigation measures during data collection and site survey activities.
MUL-10e	This measure proposes PSO reporting requirements during site-characterization and site assessment/data collection activities
MUL-13	This measure proposes requiring use of trained observers onboard trawl and trap surveys to mitigate impacts on protected species, including marine mammals, sea turtles, and fish.
MUL-14a	This measure proposes developing and implementing standard protocols for addressing UXOs. Avoidance to the maximum extent practicable is required; a plan must be submitted if avoidance is not possible.
MUL-16	This measure proposes development and implementation of a plan for post-storm event monitoring of facility infrastructure, foundation scour protection, and cables. BSEE reserves the

Measure ID	Measure Summary
	right to require post-storm mitigations to address conditions that could result in safety risks and/or impacts to the environment.
MUL-19	This measure proposes requiring inspecting the cables after installation to determine location, burial, and conditions of the cable and surrounding areas and implementing remedial actions if needed.
MUL-20	This measure proposes requiring implementation of soft start techniques during impact pile-driving to reduce noise impacts on marine mammals, sea turtles, and finfish.
MUL-29	This measure proposes requiring pile-driving sound field verification, a written plan to inform the size of the isopleths for potential injury and harassment, and reporting requirements.
MUL-31	This measure proposes that all fisheries sampling gear is hauled out every 30 days and between seasons to minimize entanglement risk.
MUL-32	This measure outlines PSO reporting requirements (including foundation pile driving).
MUL-33	This measure proposes requiring communication of protected species sightings and detections amongst all project vessels.
MUL-34	This measure proposes requiring reporting of any observations or collections of injured or dead protected species.
MUL-37	This measure proposes requiring use of FAA-approved lighting that will only become active if an aircraft is present in the vicinity of the wind farm to reduce visual impacts at night.
ST-3	This measure proposes requiring vessels deploying fixed fisheries survey gear be equipped with disentanglement equipment and follow Northeast Atlantic Coast STDN Disentanglement Guidelines to reduce impacts on sea turtles from entanglement.
STF-2	This measure proposes requiring identification, data collection, handling, and resuscitation measures for sea turtles and Atlantic sturgeon caught and retrieved in fisheries survey gear to minimize impacts from entanglement.
STF-4	This measure proposes requiring reporting of any potential takes of sea turtles and Atlantic sturgeon during fisheries surveys.

Impacts of One Project

As compared to under Alternative B, implementation of previously applied AMMM measures would reduce impacts on sea turtles for IPFs, including accidental releases, cable emplacement and maintenance, EMF and cable heat, noise, presence of structures, traffic, survey gear utilization, and lighting. Impacts for other IPFs would remain the same as described under Alternative B.

BOEM-proposed mitigation, monitoring, and reporting measures derived from BOEM's *Data Collection and Site Survey Activities for Renewable Energy on the Atlantic OCS* Biological Assessment (Baker and Howsen 2021) and presented in BOEM's *Project Design Criteria and Best Management Practices for Protected Species Associated with Offshore Wind Data Collection* notice (last revised on November 22, 2021) (BOEM 2021) are required under Lease issuance, and are therefore considered standard for preconstruction activities. These measures are primarily related to reducing impacts on sea turtles from G&G survey equipment and vessel traffic during site assessment surveys. Measures that are or will soon be required by federal law, such as USCG discharge rules and the pending NMFS NARW speed rule, are requirements for all vessel operators and not limited to offshore wind or project-specific activities; these measures are accounted for in both Alternative B and Sub-alternative C1 analyses. AMMM measures that are specific to a given IPF or IPFs from Table 3.5.7-8 are discussed further below, except those that are limited to required reporting procedures, which are not expected to reduce expected impacts on sea turtles and therefore are not considered further in this analysis.

Accidental releases: Potential impacts on sea turtles from accidental releases may decrease under Sub-alternative C1 compared to Alternative B. AMMM measure MUL-1 would require standardized marine debris awareness training for project personnel, proper marking and stowage of all materials, equipment, tools and containers, and recovery for all discarded or lost items to the extent practicable. MUL-1 would also require marine debris monitoring around WTG foundations. Additionally, MUL-9, which requires the recovery of lost survey gear, would reduce the amount of marine debris that is in the water as a result of project activities and infrastructure. Implementation of these waste management and mitigation measures, as well as marine debris awareness training, would reduce the likelihood of an accidental release. The impact of accidental releases and discharges under Sub-alternative C1 would be reduced from minor as in Alternative B, to negligible for sea turtles and would be low intensity, short term, and localized and not lead to population-level consequences.

Cable emplacement and maintenance: Potential impacts on sea turtles from cable emplacement and maintenance activities, primarily through increased turbidity in the water column, may be decreased under Sub-alternative C1 compared to Alternative B. AMMM measure MUL-19, which proposes inspection of the cables during operations and implementing remedial actions if needed, could help reduce the potential effects of cable maintenance during operations if additional mitigation measures are deemed necessary. Overall, these measures would only be expected to provide a nominal reduction in potential turbidity effects on sea turtles, and potential impacts are, therefore, not expected to differ under Sub-alternative C1 compared to Alternative B (i.e., negligible).

Electric and magnetic fields and cable heat: AMMM measure MUL-19 would require periodic post-installation cable monitoring. While this measure may identify areas where project HVAC or HVDC cables are exposed on the seabed, it is not anticipated to reduce the level of impact of this IPF on sea turtles compared to Alternative B. The G&G survey efforts and vessel traffic needed to satisfy this AMMM measure could increase risk to sea turtles through both noise and traffic IPFs. However, this potential increase in risk is not anticipated to increase any IPF impact rating; thus, the impact expected on sea turtles remains negligible.

Noise: As discussed in Section 3.5.7.4.1, unmitigated noise has the potential to be highly impactful to sea turtles, especially that originating from UXO detonations and impact pile-driving. As a result, BOEM has developed several AMMM measures that are designed specifically to mitigate the sound exposure levels from impact pile-driving on sea turtles, thereby reducing the potential impact of this IPF.

PSO training, visual monitoring coverage, shutdown procedures, and monitoring equipment effectiveness, procedures, and protocols are critical to monitoring the defined clearance and shutdown zones during noise-generating activities (AMMM measures MMST-3, MMST-4, MMST-5, MMST-6, MMST-7, MMST-10, and MMST-12). These measures—namely those that establish clearance and exclusion zones—establish protocols to effectively monitor them by trained PSOs. Furthermore, the measures require shutdowns for sea turtles detected within these zones that will reduce the overall impact on sea turtles by reducing exposure to sound levels that can cause PTS. Reduction in PTS exposure would reduce the likelihood that a sea turtle is within range to experience these sound levels and would reduce the duration the sea turtle may be exposed to these sound levels.

An RVMP/Nighttime Pile Driving Monitoring Plan (MMST-1) must be prepared and submitted for agency review and approval. Additionally, MMST-2 requires the submittal of a pile-driving monitoring plan, which will need to be consistent with all monitoring and mitigation requirements.

Additionally, the pile-driving sound field measurement requirements proposed under AMMM measures MMST-2, MMST-3, and MUL-29 would confirm the predicted clearance and shutdown zones, adjust these zones or implement additional sound attenuation as needed, and require a pile-driving sound field verification plan to inform the size of the isopleths for potential injury and harassment, respectively. The clearance and exclusion zones will be based on the modeled threshold ranges, and the sound field measurements proposed under these AMMM measures will help ensure the proposed mitigation zones established in the AMMM measures listed previously effectively minimize the risk of PTS, if not eliminating it altogether.

Under Sub-alternative C1, AMMM measure MUL-29 would require the lessee to perform sound field verification of impact pile-driving noise levels during foundation installation. Pile-driving sound field measurement requirements proposed under AMMM measures MMST-3, MUL-22, and MUL-29 would confirm the predicted clearance and shutdown zones in the approved permits, enable adjustment of these zones (MMST-3), and require the lessee to implement additional sound attenuation as needed. Under this AMMM measure, the lessee would be required to prepare and submit for agency review and approval a sound field verification plan before commencement of pile-driving activities. This plan will identify key project parameters, the predicted clearance and shutdown zones, and the lessee’s approach for obtaining the sound field data. The clearance and exclusion zones will be based on the modeled threshold ranges, and the sound field measurements proposed under these AMMM measures will help ensure the proposed mitigation zones established in the AMMM measures effectively minimize the risk of PTS, if not eliminate it altogether.

Preparing and approving an RVMP/Nighttime Pile Driving Monitoring Plan (MMST-1) prior to construction for activities occurring at night or in low-visibility conditions will also ensure sufficient visual PSO coverage for monitoring the clearance and exclusion zones is achieved and implemented for all pile-driving activities. Seasonal restrictions (MMST-4) are primarily designed to avoid pile-driving activities during the period when NARW abundance in the project area is likely to be heightened, which, per this AMMM measure, occurs between January 1 and April 30. However, available data suggests that sea turtles present in the NY Bight area are most likely to occur between spring and fall (Section 3.5.7.1), which largely overlaps with the seasons of low NARW abundances. Therefore, sea turtles are less likely to benefit from this AMMM measure as increased abundances of these species are likely to occur during seasons when impact pile-driving would also occur. Finally, the greatest protections for sea turtles under MMST-4 would be through the implementation of clearance and exclusion zones to be monitored by trained PSOs as described above.

Soft-start procedures (MUL-20) can also be an effective mechanism to reduce the potential for PTS exposures in certain species during impact pile driving by deterring individuals from the ensonified area before the maximum hammer energy, and therefore the maximum sound levels, are reached. However, the efficacy of deterring sea turtle species through pile-driving soft-start procedures is unknown.

Consideration of all AMMM measures for impact pile driving of OSS and WTG foundations under Sub-alternative C1 is expected to reduce the potential impact of pile-driving noise on all sea turtles from the impacts under Alternative B. This would substantially reduce the impact of impact pile-driving to minor for all sea turtles. Impacts would be detectable and measurable, but will be of low intensity, highly localized, and short term in duration; population-level impacts are not anticipated under Sub-alternative C1.

AMMM measure MUL-14a is specifically designed for UXO detonations and proposes avoidance of underwater detonations to the maximum extent practicable and use of the best available technology to avoid or minimize exposure of protected resources to UXO detonations. Additionally, this measure requires consultation with all appropriate state and federal agencies to develop a plan for removal or detonation of a UXO if detonation is demonstrated to be necessary for the project.

The intensity of the effects from UXO detonation is expected to be reduced from severe to medium with the implementation of mitigation and monitoring measures that are applied to pile driving. These measures (PSOs, clearance and shutdown zones, and noise mitigation devices) are expected to limit impacts from extending beyond the immediate project area to a more localized extent that includes just the immediate project area. However, even with monitoring and mitigative measures, there could still be loss of individuals so the impact of UXO detonation would remain as moderate for all sea turtles, but no population-level impacts are anticipated under Sub-alternative C1.

AMMM measures for G&G surveys would include similar measures to those described for impact pile driving such as PSO training, visual monitoring coverage, shutdown procedures, and monitoring equipment effectiveness, procedures, and protocols (AMMM measures MMST-10 and MMST-12). However, under Alternative B (Section 3.5.7.4.1), the main impact from these surveys would be temporary behavioral disturbances, given the acoustic characteristics of these sources and extent of these surveys; the AMMM measures under Sub-alternative C1 would not reduce the impacts to the extent that they are not measurable. Therefore, impacts of G&G surveys would remain detectable and measurable but of low intensity, highly localized, and short-term and therefore minor for all sea turtles.

For noise-producing activities such as vessel operations, aircraft, cable laying or trenching, drilling, and WTG operations, there are no vessel noise-specific AMMM measures for these activities, and impacts under Sub-alternative C1 are unlikely to differ substantially from those under Alternative B (Section 3.5.7.4.1).

Additional discussion of the noise-related AMMM measures and how they may reduce noise impacts can be found in Appendix J.

Presence of structures: The primary impact on sea turtles associated with the presence of structures is due to entanglement risk resulting from an increased interaction with active or abandoned fishing gear. AMMM measures MUL-1, MUL-8, MUL-9, MUL-16, MUL-31, ST-3, ST-2, and STF-4 address this risk by providing guidance for gear use, and monitoring and adaptively mitigating recreational and commercial fishing gear that might be lost at sea. Monitoring and removing lost or derelict fishing gear will reduce exposure to such gear, therefore reducing the risk of entanglement to sea turtles. AMMM measure MUL-31 specifically requires all project-related sampling gear to be hauled at least once every 30 days and removed from the water between sampling seasons and MUL-9 requires the recovery of lost project-related survey gear which would help reduce the amount of gear caught on WTG foundations during O&M. Both measures are expected to reduce entanglement risk to sea turtles by minimizing exposure to and monitoring all survey gear periodically. While required gear marking (MUL-8) would not reduce entanglement risk directly, it would facilitate understanding which sampling gear is highest risk to sea turtles if multiple entanglements were to occur, which could be used to inform future deployments, ideally with minimized risk. BOEM would also require a monitoring plan be developed for post-storm events (MUL-16). While monitoring of cables (and cable protection) and WTG/OSS scour protection would not directly reduce effects on sea turtles, a monitoring plan would provide information about conditions that pose increased entanglement hazards from fishing gear (e.g., unburied cables), and BSEE would retain the ability to require post-storm mitigation to address safety risks and environmental impacts caused by the storm event. Based on these proposed AMMM measures, the impact from the presence of structures due to entanglement risk would be reduced from moderate, as in Alternative B, to minor for sea turtles as impacts would be detectable and measurable but not expected to lead to population-level effects.

Traffic: As discussed in Section 3.5.7.3.3, vessel strikes are a significant concern for all sea turtles. AMMM measures MMST-9, MMST-14, and MUL-33, include vessel strike avoidance procedures such as the use of trained observers, reduced vessel speeds, minimum separation distances, and project-specific training for all vessel crew, and are considered effective at reducing the risk of vessel strike to sea turtles, though they would not completely eliminate it. Speed restrictions designed specifically to reduce strike risk for NARWs (MMST-14), will also be beneficial for sea turtles by reducing the risk of collision as well as serious injury or mortality occurring. Additionally, AMMM measure MMST-14 would specifically require lessees to follow vessel strike avoidance conditions for any construction, operations, or decommissioning vessel transits associated with the project—including trained lookouts searching specifically for sea turtles—and report any sightings. The proposed mitigation outlined above is expected to reduce the risk of vessel strikes occurring or resulting in severe injury or mortality. Therefore, impacts on sea turtles would remain as minor as effects would be detectable and measurable, though would not be expected to lead to population-level consequences.

Survey gear utilization: AMMM measure ST-3 is the primary measure that would reduce the risk of sea turtle entanglement in fisheries monitoring survey gear as it requires projects to have adequate disentanglement equipment onboard when deploying any fixed gear. STF-2 also provides guidelines for safe handling and resuscitation of sea turtles caught in gear which would reduce the risk of long-term impacts or injuries occurring for entangled individuals. AMMM measure MUL-13 would implement a requirement that at least one survey staff onboard trawl and ventless trap surveys be trained in protected species identification and safe handling, and disentanglement procedures would be available onboard. AMMM measure MUL-9 would require that all reasonable efforts are undertaken to recover any survey gear that is lost during any phase of the NY Bight project, including G&G surveys, biological monitoring surveys, and fisheries monitoring surveys. Fast recovery of the lost gear would benefit sea turtles by reducing the amount of time lost gear is in the water and thereby reducing the likelihood of a sea turtle becoming entangled. Additional AMMM measures related to survey gear utilization (MUL-8, STF-2, STF-4) are more focused on tracking gear types and origins and reporting any incidents of entanglement or injury to the proper agencies. While this information is beneficial for tracking take and realized impacts on sea turtle populations, it does not reduce the risk of entanglement occurring and would not lower the impact level.

With the measures laid out in AMMM measures ST-3 and STF-2, the risk of a serious injury or mortality occurring for any sea turtle species during biological or fisheries monitoring surveys under one NY Bight project would be reduced. However, the potential impacts of entanglement would still be detectable and measurable for sea turtles, so impacts under Sub-alternative C1 would remain minor.

Lighting: AMMM measure MUL-37 would propose the use of an FAA-approved vendor for the ADLS, which will activate the FAA hazard lighting only when an aircraft is in the vicinity of the wind farm to reduce visual impacts at night. While this measure is primarily geared towards birds, cultural, and scenic and visual resources, it will indirectly benefit sea turtles by reducing the overall amount of time the safety lights are active on the project turbines. However, as discussed in Section 3.5.7.4.1, the overall effects of artificial lighting from offshore wind projects would be negligible given available data on sea turtle responses to artificial lighting, and the addition of this AMMM measure would result in a nominal reduction in the lighting produced by one NY Bight project. Therefore, the potential impacts of lighting under Sub-alternative C1 would remain negligible.

Impacts of Six Projects

The same IPF impact types and mechanisms described under one NY Bight project also apply to six NY Bight projects. There would be more potential for impacts for these IPFs due to the greater amount of offshore and onshore development under six NY Bight projects. However, with the AMMM measures described in Section 3.5.7.5.1 and Appendix G, impacts under six NY Bight projects are not expected to differ substantially from one NY Bight project. Therefore, impacts from all IPFs are expected to be the same as that discussed in Section 3.5.7.5.1 for one NY Bight project, though over the broader geographic and temporal scale covered by the six NY Bight projects.

Under a concurrent exposure scenario in which multiple NY Bight lease areas are under construction simultaneously, the overall proportion of the NY Bight ensonified by impact pile-driving noise would increase compared to the proportion ensonified by just one project, which could increase the risk of sea turtles in the NY Bight being exposed to above-threshold noise. However, as discussed for one project above, with the AMMM measures identified under Sub-alternative C1 for all six projects—which include monitoring by trained PSOs of designated clearance and exclusion zones and soft-start procedures—the risk of PTS occurring in sea turtles would be minimized by reducing the likelihood and duration of sea turtles being within range of a given pile driving event to encounter sound levels sufficient to result in PTS. Even with concurrent construction of six NY Bight projects, the area over which PTS effects may occur and the risk of sea turtles experiencing above-threshold sound levels would still be limited to a localized area around each pile installation event that would be sufficiently monitored by trained PSOs. Therefore, no additive risk of effects is expected with construction of six projects such that loss of individuals would occur, and impacts would remain minor for impact pile driving of OSS and WTG foundations under Sub-alternative C1.

Similarly with all other IPFs, either the timing or extent of the potential impacts is small enough such that consideration of six projects would not have any additive effects, and no substantial difference in these impacts on sea turtles is expected between one and six projects.

Impacts of Sub-Alternative C1 (Preferred Alternative) on ESA-Listed Species

General impacts of the Sub-alternative C1 on sea turtles were described in the previous subsection. Because all sea turtle species present in the NY Bight area are listed under the ESA, the impact determinations provided in the previous subsections would apply here.

Cumulative Impacts of Sub-Alternative C1 (Preferred Alternative)

Under Sub-alternative C1, the same ongoing and planned non-offshore-wind and offshore wind activities described for Alternative A in Section 3.5.7.3 would continue to contribute to the potential for impacts on sea turtles. In context of reasonably foreseeable environmental trends and planned actions, the cumulative impacts of Sub-alternative C1 (for six NY Bight projects)—when combined with ongoing and planned actions—would be negligible to moderate. Sub-alternative C1 would contribute to the cumulative impacts primarily through impact pile-driving noise, increased vessel traffic, and the presence of structures as related to fishing gear entanglement. Minor beneficial impacts would result from the presence of structures, though this benefit may be offset given the increased risk of entanglement due to derelict fishing gear on the structures.

3.5.7.5.2 Sub-Alternative C2: Previously Applied and Not Previously AMMM Measures

Sub-alternative C2 analyzes the AMMM measures under Sub-alternative C1 plus the AMMM measures that have not been previously applied (Table 3.5.7-9).

Table 3.5.7-9. Summary of not previously applied avoidance, minimization, mitigation, and monitoring measures for sea turtles

Measure ID	Measure Summary
MUL-22	This measure would reduce noise impacts on marine mammals, sea turtles, and finfish by establishing received sound level limits (RSLL) that will require non exceedance of an acoustic threshold at 1,000 or 1,500 meters, depending on the year of pile installation.
STF-5	This measure proposes requiring disengaging trailing suction hopper dredge pumps when dragheads are not in use to prevent impingement or entrainment of sea turtle species.

Impacts of One Project

AMMM measures MUL-22 and STF-5 could reduce impacts on sea turtles compared to those under Sub-alternative C1 for impact pile-driving and cable emplacement. Impacts for other IPFs would remain the same as described under Sub-alternative C1 (Section 3.5.7.5.1).

Cable emplacement and maintenance: AMMM measure STF-5 proposes disengaging dredge pumps when dragheads are not in use for offshore activities requiring the use of a trailing suction hopper dredge to prevent impingement or entrainment of sea turtle species. This would work to keep the dragheads firmly on the bottom to prevent impingement or entrainment of sea turtle species. Pumps would be disengaged when lowering dragheads to the bottom to start dredging, turning, or lifting dragheads off the bottom at the completion of dredging. However, the use of trailing suction hopper dredges for one NY Bight project is not definite, and—given the lower risk of encounters between dredgers and sea turtles in open ocean areas—the risk of entrainment in dredgers is low.

The implementation of this measure would be expected to contribute to the reduction of turbidity and provide an additional measure to reduce entrainment/impingement of sea turtles when added to the previously applied mitigation measures under Sub-alternative C1. The potential effects on sea turtles are therefore unlikely to differ substantially from Sub-alternative C1 (Section 3.5.7.4.1). Therefore, effects from cable emplacement and maintenance would remain negligible under Sub-alternative C2.

Noise: AMMM measure MUL-22 would establish a RSLL such that sound fields generated during impact pile-driving would not exceed thresholds defined by NOAA Fisheries for marine mammal hearing groups. As detailed in Appendix G, the RSLL requirements are specific to a frequency weighted SEL of 183 dB re 1 μPa^2 s (the PTS-onset threshold for low-frequency cetacean species) and an unweighted Lpk of 202 dB re 1 µPa (the PTS-onset threshold for high-frequency cetacean species). In comparison, the PTS-onset threshold for sea turtles is an unweighted SEL of 204 μPa^2 s and an unweighted Lpk of 232 dB re 1 µPa (Table 3.5.7-4). While MUL-22 uses marine mammal acoustic thresholds as the target limit, the area ensonified above the sea turtle PTS-onset thresholds would be expected to fall within the area ensonified above the marine mammal thresholds (since the sea turtles thresholds are higher), so reducing the range over which the marine mammal RSLL may be exceeded to a maximum of 1,500 meters would benefit sea turtles by reducing the range over which their PTS threshold would be exceeded. Additionally, minimizing the PTS ranges would reduce the range to TTS and behavioral disturbance thresholds. Reduction in the size of the PTS ranges in turn reduces the size of clearance and shutdown zones, which improves the ability for trained PSOs or other monitoring technologies to successfully detect sea turtles in and near those zones and reduces the risk of sea turtles being within these zones to experience above-threshold noise. MUL-22 could also minimize noise impacts if developers discover glauconite sands during construction and installation, which may result in increased noise levels as developers determine if the glauconite is passable. Developers would need to use different methodology, technology, or infrastructure, or apply other quieting techniques to reduce their RSLL if glauconite sands are discovered. Therefore, this AMMM measure, though designed specifically for marine mammals, would benefit sea turtles.

The potential reduction in the noise level as a result of these not previously applied AMMM measures would be beneficial for all sea turtles; however, impacts from impact pile-driving under Sub-alternative C2 are unlikely to differ substantially from those under Sub-alternative C1 (Section 3.5.7.4.1). The AMMM measures under Sub-alternative C2 would not reduce potential impacts on sea turtles from impact pile-driving such that impacts are not measurable or are difficult to measure; therefore, they would continue to be detectable and measurable but of low intensity, localized, and short-term like described under Sub-alternative C1. Effects from impact pile-driving would remain minor under Sub-alternative C2.

Impacts of Six Projects

The same IPF impact types and mechanisms described under a single NY Bight project also apply to six NY Bight projects. However, there would be more potential for impacts for these IPFs due to the greater amount of offshore and onshore development under six NY Bight projects, although these impacts could be reduced with the not previously applied AMMM measures under Sub-alternative C2. However, the not previously applied AMMM measures would not change the impact determinations under six projects compared to Sub-alternative C1 (Section 3.5.7.5.1). The only not previously applied AMMM measures under Sub-alternative C2 apply to impact pile-driving noise, so there is no change from Sub-alternative C1 for all other IPFs.

For impact pile-driving, though construction of six NY Bight projects increases the geographic and temporal scale over which pile-driving activities would occur, the implementation of the additional AMMM measures would reduce the likelihood and extent over which sea turtles may be exposed to above-threshold noise. Particularly with MUL-22, the range over which the sea turtle acoustic thresholds may be exceeded would be localized to an immediate area around each pile-driving event such that risk of exposure from six projects would not be additive and would remain the same as that described for one project. Therefore, impact pile-driving impacts associated with six projects under Sub-alternative C2 would remain detectable and measurable but low intensity, localized, and short-term. Because no population-level effects would occur, impacts would remain minor, as assessed under Alternative B and Sub-alternative C1.

Impacts of Sub-Alternative C2 on ESA-Listed Sea Turtles

General impacts of Sub-alternative C2 on sea turtles were described in the previous subsection. All sea turtle species present in the NY Bight area are listed under the ESA; therefore, the impact determinations provided in the previous subsections would apply here.

Cumulative Impacts of Sub-Alternative C2

Under Sub-alternative C2, the same ongoing and planned non-offshore-wind and offshore wind activities described for Alternative A (Section 3.5.7.3) would continue to contribute to the potential impacts on sea turtles. Impacts on sea turtles are anticipated to be similar to those described under Alternative B. While the not previously applied AMMM measures for six NY Bight projects can reduce potential adverse impacts, the impact level determination is not expected to change under Sub-alternative C2. In context of reasonably foreseeable environmental trends and planned actions, the cumulative impacts of Sub-alternative C2 (for six NY Bight projects)—when combined with ongoing and planned actions—would be negligible to moderate. Sub-alternative C2 would contribute to the cumulative impacts primarily through impact pile-driving noise, increased vessel traffic, and the presence of structures as related to fishing gear entanglement. Minor beneficial impacts would result from the presence of structures, though this benefit may be offset given the increased risk of entanglement due to derelict fishing gear on the structures.

3.5.7.5.3 Conclusions

Impacts of Alternative C. Project construction and installation, O&M, and conceptual decommissioning either from one or six NY Bight projects, would result in habitat disturbance (presence of structures and new cable emplacement), habitat conversion (presence of structures), underwater and airborne noise, vessel traffic (strikes and noise), and potential discharges/spills and trash under Sub-alternatives C1 and C2. For both one and six NY Bight projects and Sub-alternatives C1 and C2, BOEM expects individual impacts ranging from **negligible** to **moderate** for sea turtles because impacts from most IPFs would be noticeable and measurable, but likely would not affect the viability of any sea turtle populations; previously applied AMMM measures would reduce some impacts on sea turtles compared to Alternative B for accidental releases, pile driving, and presence of structures. Moderate impact levels would mainly result from UXO detonations. **Minor beneficial** impacts for sea turtles are expected to result from the presence of structures for both one and six NY Bight projects and under Sub-alternatives C1 and C2. AMMM measures that have not been previously applied would further reduce impacts on sea turtles from new cable emplacement and noise, but these reductions would not be sufficient to lower the impact determination from Sub-alternative C1.

Cumulative Impacts of Alternative C. The cumulative impacts of Sub-alternatives C1 and C2 consider the impacts of implementing AMMM measures identified in Appendix G and in combination with other ongoing and planned non-offshore-wind and offshore wind activities described for Alternative A in Section 3.5.6.3. BOEM anticipates that the cumulative impacts on sea turtles in the geographic analysis area under six NY Bight projects would likely be **negligible** to **moderate**. Moderate impact levels would mainly result from impact pile driving and construction noise, UXO detonation, risk of vessel strikes due to non-offshore-wind vessel traffic described under Alternative A, and the presence of structures as related to fishing gear entanglement. **Minor beneficial** impacts for sea turtles are expected to result from the presence of structures, though these beneficial impacts may be offset given the increased risk of entanglement due to derelict fishing gear on the structures. Impacts may be measurable and detectable but would not be expected to affect the viability of any sea turtle populations. In the context of other reasonably foreseeable environmental trends, the impacts contributed by Sub-alternatives C1 and C2 to the cumulative impact on sea turtles would range from undetectable to appreciable for pile-driving noise, increased vessel traffic, and the presence of structures as related to fishing gear entanglement. Implementation of AMMM measures that would have otherwise not been implemented under Alternative B would reduce impact levels to sea turtles for some IPFs.

3.5.7.6 Recommended Practices for Consideration at the Project-Specific Stage

BOEM is recommending that lessees consider analyzing the RPs in Table 3.5.7-10 to further reduce potential sea turtle impacts. Refer to Table G-2 in Appendix G for a complete description of the RPs.

Table 3.5.7-10. Recommended practices for sea turtles impacts and related benefits

Recommended Practice	Potential Benefit
MUL-5: Use equipment, technology, and best practices to produce the least amount of noise possible and reduce noise impacts.	Using noise reduction measures to produce the least amount of noise practicable would likely minimize disturbance/displacement impacts.
MUL-6: Use low noise practices or quieting technology to install foundations, when possible, to limit noise impacts.	The consideration of non-pile-driving foundation types (e.g., suction buckets, gravity-based foundations) first, and the use of the best available quieting technology should be applied to reach the received sound level limit (MUL-22). Using quieting technology (e.g., noise attenuation system [NAS]) reduces the risk of noise impacts on sea turtles by reducing the sound levels that propagate from the pile source. Available studies suggest that when a single or combined NAS is applied to monopile installation, noise reductions ranging from 3 to 17 dB can be achieved, depending on the NAS combination, with some frequency-dependent reductions of over 20 dB (Bellmann et al. 2020).
MUL-7: Use the most current International Maritime Organization's (IMO) Guidelines for the reduction of underwater radiated noise, including propulsion noise, machinery noise, and dynamic positioning systems for project vessels.	Following IMO guidelines would reduce underwater vessel noise.
MUL-10c: Minimize survey vessel interactions with protected species during the use of a moon pool.	Following protocols for moon pool use and monitoring for protected species would minimize vessel interactions with protected species.
MUL-12: Incorporate ecological design elements where practicable.	Using ecological designs elements such as those that could encourage growth of flora or fauna could enhance potential benefits to sea turtles due to the reef effect.
MUL-14b: When MEC avoidance is not possible, submitted UXO/MEC avoidance plans should follow, when finalized, the US Committee on the Marine Transportation System general guidance on MEC.	Following the US Committee on the Marine Transportation System general guidance on MEC would minimize effects from MEC detonation on sea turtles.
MUL-18: Coordinate transmission infrastructure among projects such as by using shared intra- and interregional connections, meshed infrastructure, or parallel routing.	Using a shared infrastructure would consolidate the extent of transmission cables, which could reduce the geographic extent of impacts, from cable emplacement and maintenance and EMF and cable heat. This RP may minimize potential impacts from offshore export cables on sea turtles.
MUL-21: Use the best available technology, including new and emerging technology, when possible and consider upgrading or retrofitting equipment. It may include technology such as jet plows, closed-loop	The use of jet plows would minimize the extent of turbidity plumes associated with cable emplacement as compared to other installation methods. As described in Section 3.4.2, *Water Quality*, a closed-loop subsea cooler system is an emerging technology,

Recommended Practice	Potential Benefit
cooling systems and new foundations designs that do not rely on pile driving.	that, if applied, would eliminate entrainment risks to sea turtles and may minimize localized hydrodynamic and thermal plume impacts because intake and discharge of seawater would not occur. Using foundation designs that do not rely on pile-driving would, if employed, reduce noise exposure to sea turtles.
MUL-23: Avoid or reduce potential impacts on important environmental resources by adjusting project design.	Adjusting project design could include analysis of the turbine layout in order to reduce potential impacts from the presence of structures. MUL-23 could include use of BOEM's risk assessment tool to model potential encounter rates between sea turtles and vessel traffic from offshore wind energy development (i.e., the "vessel strike model"). Use of this tool will serve to identify potential encounter rates between ESA-listed sea turtle species and project vessels; speed and routing variables can be incorporated to assess when and where high strike risk may occur and identify where additional mitigation measures should be focused and reduce the risk of vessel strikes.
MUL-26: Coordinate regional monitoring and survey efforts across lease areas in the NY Bight to standardize approaches, understand potential impacts to resources at a regional scale, and maximize efficiencies in monitoring and survey efforts. Develop monitoring and survey plans that meet regional data requirements and standards.	Coordinating regional monitoring and survey efforts would maximize the monitoring efficiency. The data gathered would be evaluated and considered for future mitigation and monitoring needs, which will serve to reduce impacts.
MUL-27: Employ methods to minimize sediment disturbance such as use of midline buoys to prevent cable sweep and not side-casting materials.	Minimizing sediment disturbance could reduce impacts during cable emplacement and maintenance.
MUL-39: Use of standard underwater cables designs that mitigate the intensity of EMF at the seafloor.	Shielding of cables could reduce the intensity of EMFs, cable heat, and exposure to sea turtles.
STF-1: Monitor tagged sea turtles using technology strategically placed on WTGs to monitor the effect of the presence of structures on sea turtle habitat use and residency around NY Bight project foundations.	Incorporating technologies for detecting tagged sea turtles and monitoring the effect of increases in habitat use and residency around WTG foundations would provide additional information about impacts on sea turtles and could lead to additional mitigation.

This page was intentionally left blank.

3.5 Biological Resources

3.5.8 Wetlands

This section discusses potential impacts on wetlands from the Proposed Action, alternatives, and ongoing and planned activities in the wetlands geographic analysis area. The wetlands geographic analysis area, as shown on Figure 3.5.8-1, includes all 10-digit hydrologic unit code watersheds that could be intersected by the NY Bight projects' onshore infrastructure components. This includes locations along the New Jersey and New York coastline where BOEM anticipates wetland impacts associated with the potential construction of the NY Bight projects' onshore components. A broad geographic analysis area was defined due to the uncertainty of the landfall locations and locations of onshore project components.

The wetlands impact analysis in this PEIS is intended to be incorporated by reference into the project-specific environmental analyses for individual COPs expected for each of the NY Bight lease areas. Because the locations of onshore components for the NY Bight projects are not known at this time, the analysis of onshore wetland impacts is dependent on a hypothetical project analysis, and impact conclusions consider a maximum-case scenario for onshore development. Additional detailed site-specific analysis will be required for individual COPs. Refer to Appendix C, *Tiering Guidance*, which identifies additional analyses anticipated to be required for the project-specific environmental analysis of individual COPs.

3.5.8.1 Description of the Affected Environment and Future Baseline Conditions

Wetlands are areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions (33 CFR 328.3(c)(16)). Wetlands are important features in the landscape that provide numerous beneficial services or functions. Some of these include protecting and improving water quality, providing fish and wildlife habitats, storing floodwaters, providing aesthetic value, ensuring biological productivity, filtering pollutant loads, and maintaining surface water flow during dry periods. The majority of the wetlands in the geographic analysis area are tidally influenced salt marshes, which provide shelter, food, and nursery grounds for coastal fisheries species, including shrimp, crab, and many finfish. Wetlands also protect shorelines from erosion by creating a buffer against wave action and by trapping soils. In flood-prone areas, wetlands reduce the flow of flood water and absorb rainwater. Tidal wetlands also serve as carbon sinks, holding carbon that would otherwise be released into the atmosphere and contribute to climate change. New Jersey and New York's coastal wetlands, including those in the geographic analysis area, protect coastal water quality by acting as a sink for land-derived nutrients and contaminants, constitute an important component of coastal food webs, provide valuable wildlife habitat, and protect upland and shoreline areas from flooding and erosion.

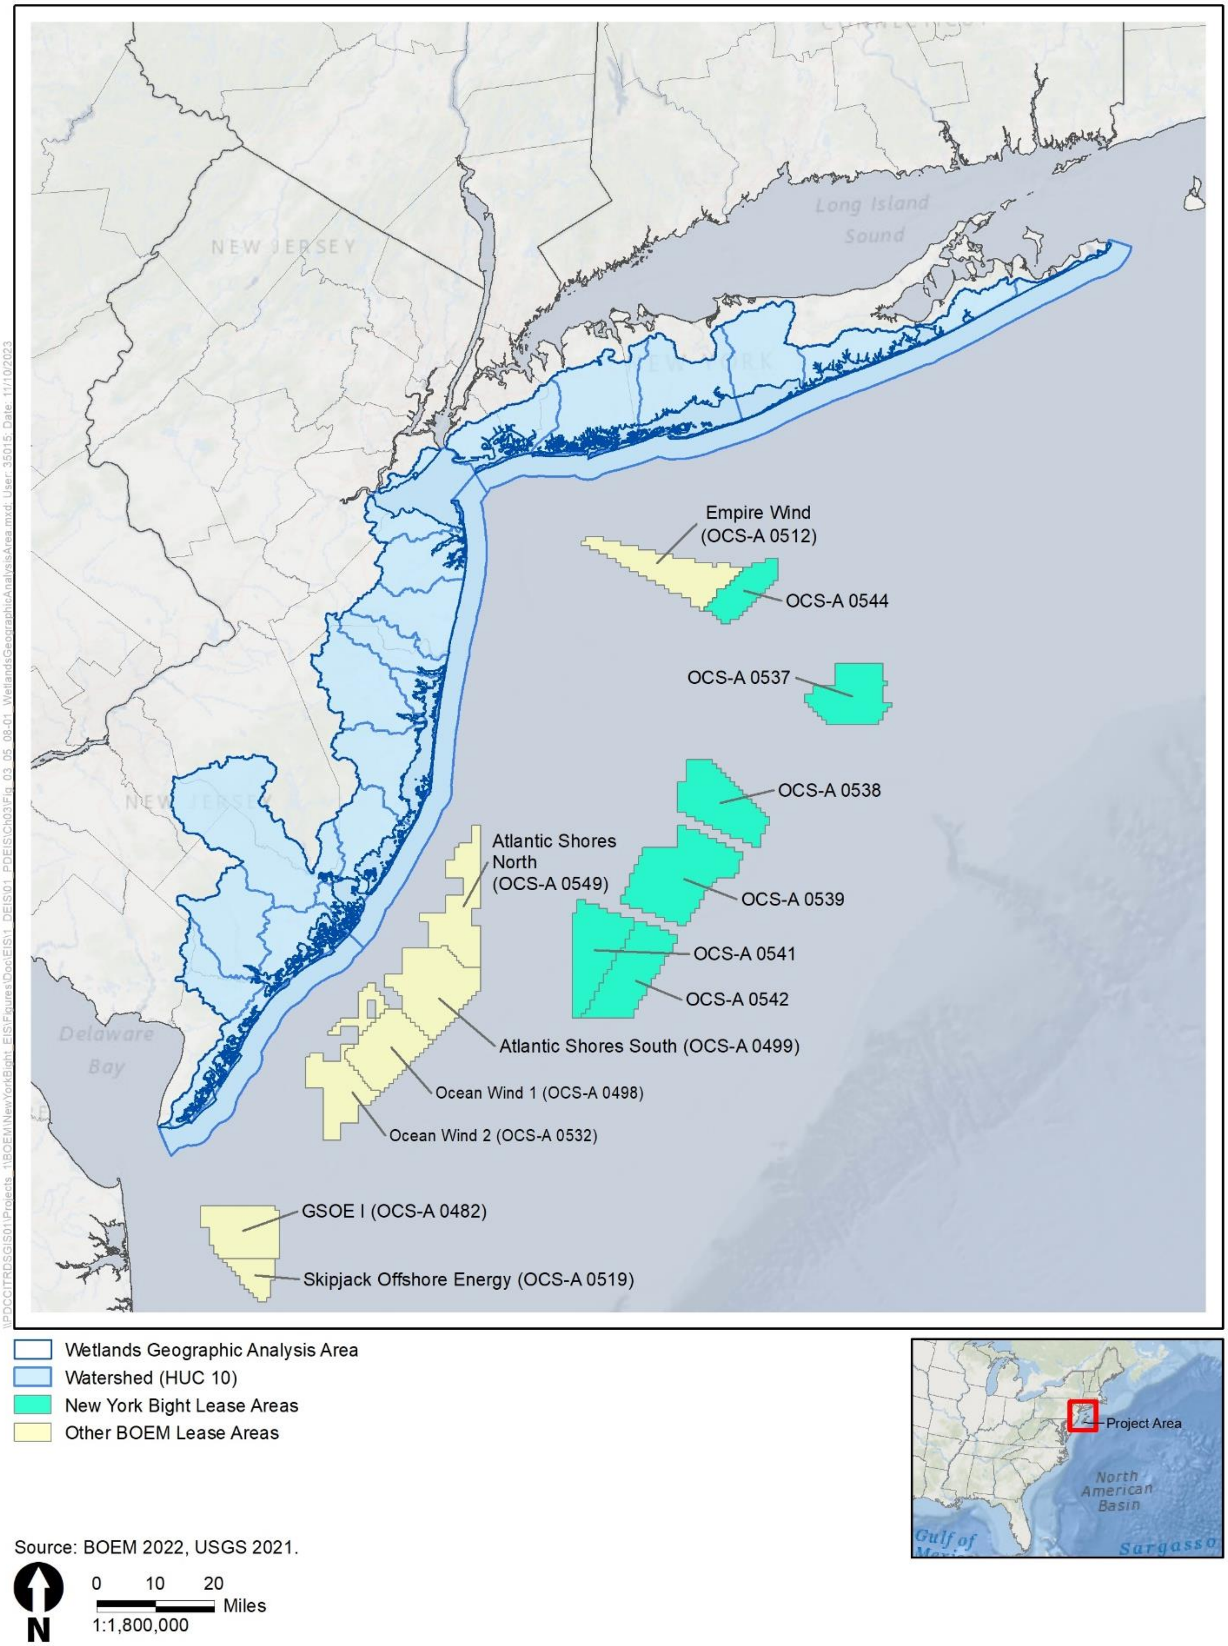

Figure 3.5.8-1. Wetlands geographic analysis area

The NWI, State of NJDEP, and NYSDEC wetland GIS data sets were used to determine the potential presence of wetlands in the geographic analysis area. NWI information is provided in Appendix B, *Supplemental Information and Additional Figures and Tables*, and the NJDEP and NYSDEC information is provided in this section. These datasets map both tidal and non-tidal wetlands. Tidal wetlands in the geographic analysis area are areas where the Atlantic Ocean and estuaries meet land, are found below the spring high tide line, and are subject to regular flooding by the tides. Tidal wetlands are typically categorized into two zones: high marsh and low marsh. Non-tidal wetlands, otherwise referred to as freshwater wetlands, are not influenced directly by tides and are typically categorized based on their hydrology and predominant vegetation. To confirm the extent and presence of regulated wetlands within the onshore project area of the NY Bight projects, a wetland delineation must be conducted to identify the wetlands under jurisdiction of USACE, NJDEP, and NYSDEC. This is expected to occur for each NY Bight project prior to BOEM's decision approving, approving with modifications, or disapproving the COPs.

The New Jersey geographic analysis area contains 332,424 acres of wetlands (Table 3.5.8-1 and Figure 3.5.8-2) (NJDEP 2021). Threats to the state's wetlands include land reclamation, development, dredging, nutrient overload, and sea level rise due to climate change. Sea level rise is considered the largest climate-related threat to salt marshes along the New Jersey shore. New Jersey's climate has warmed by about 3 degrees (F) in the last century, heavy rainstorms are more frequent, and the sea is rising about 1 inch every 6 years. Higher water levels are eroding beaches, submerging lowlands, exacerbating coastal flooding, and increasing the salinity of estuaries and aquifers. Sea level is rising more rapidly along the New Jersey shore than in most coastal areas because the land is sinking (USEPA 2016a).

Table 3.5.8-1. Wetlands in the New Jersey geographic analysis area

Wetland Community	Acres	Percent of Total
Atlantic White-Cedar Wetland	23,842	7.2
Disturbed and Managed Wetlands	12,153	3.7
Freshwater Tidal Marsh	65	0.0
Herbaceous Wetland	3,907	1.2
Phragmites	7,053	2.1
Saline Marsh	100,727	30.3
Scrub/Shrub Wetland	20,078	6.0
Wooded Wetland	164,600	49.5

Figure 3.5.8-2. Wetlands in the New Jersey geographic analysis area

In New York, the NYSDEC identifies and maps two general types of wetlands: tidal wetlands and freshwater wetlands. In the geographic analysis area, tidal wetlands occur around the Long Island coastline, and freshwater wetlands occur inland on Long Island typically on river and lake floodplains (i.e., outside the influence of tidal waters). Both tidal and freshwater wetlands habitats are protected under the state's Tidal Wetland Act (1973) and the Freshwater Wetlands Act (1975). Freshwater wetlands are identified on the basis of vegetation and must be at least 12.4 acres (5 hectares) to be protected under the Freshwater Wetlands Act. Freshwater wetlands smaller than 12.4 acres (5 hectares) would be protected under the CWA (Section 404) if they are determined to be jurisdictional under the CWA by the USACE. Freshwater wetlands are also classified as Class I, II, III, or IV wetlands, which correspond to the benefits the wetland may provide (Class I provides the greatest benefits, Class IV the least benefits). NYSDEC has mapped all tidal and freshwater wetlands in New York, and these wetlands in the geographic analysis area are shown in Figure 3.5.8-3.

New York's climate is changing: most of the state has warmed 1 to 3 degrees (F) in the last century, heavy rainstorms are more frequent, and the sea is rising about 1 inch every decade. Higher sea levels are eroding beaches, submerging lowlands, exacerbating coastal flooding, and threatening coastal wetlands and estuaries. Sea level is rising more rapidly along New York's coast than in most coastal areas because the land surface is sinking (USEPA 2016b).

The New York geographic analysis area contains 36,225 acres (14,659 hectares) of wetlands, according to Cornell University Geospatial Information Repository (2013) and the NYSDEC wetland data (NYSDEC 2005). Table 3.5.8-2 displays the wetlands within the geographic analysis area based on NYSDEC wetland data.

Table 3.5.8-2. Wetlands in the New York geographic analysis area

Wetland Community	Acres	Percent of Total
Freshwater Wetlands		
Freshwater Wetland Class I	8,817	24
Freshwater Wetland Class II	1,327	4
Freshwater Wetland Class III	181	<1
Tidal Wetlands		
Coastal Shoals, Bars and Mudflats	2,136	6
Formerly Connected	542	1
Fresh Marsh	471	1
High Marsh	5,637	16
Intertidal Marsh	11,374	31
Littoral Zone	5,740	16
Total	**36,225**	**100.0**

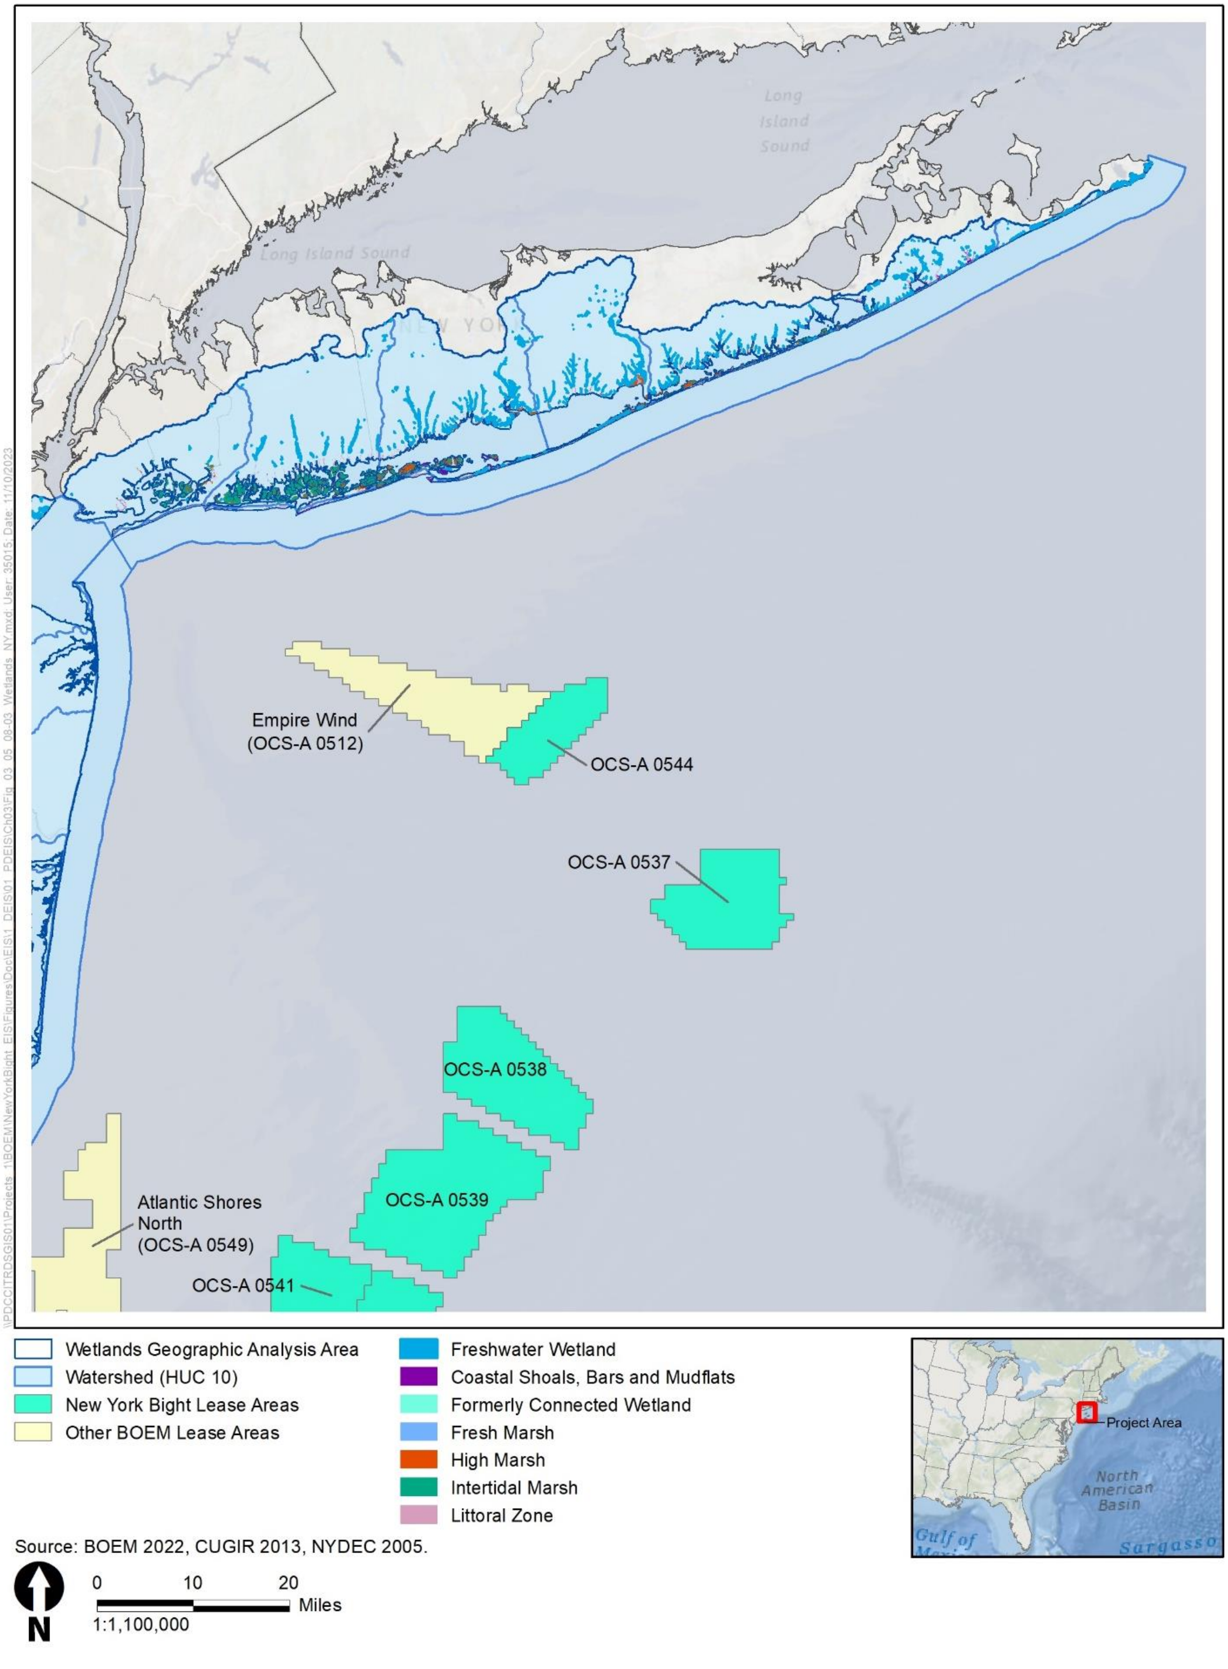

Figure 3.5.8-3. Tidal and freshwater wetlands in the New York geographic analysis area

3.5.8.2 Impact Level Definitions for Wetlands

BOEM's general impact definitions of potential adverse impact levels for wetlands are provided in Table 3.5.8-3. USACE, NJDEP, and NYSDEC define wetland impacts differently than BOEM due to requirements under CWA Section 404, the New Jersey Freshwater Wetlands Protection Act (1987), and the New York State Tidal Wetlands Act (1973) and Freshwater Wetlands Act (1975).

Table 3.5.8-3. Adverse impact level definitions for wetlands

Impact Level	Definition
Negligible	Impacts on wetlands would be so small as to be unmeasurable, and impacts would not result in a detectable change in wetland quality and function.
Minor	Impacts on wetlands would be minimized; and would be relatively small and localized. If impacts occur, wetland functions and values would completely recover.
Moderate	Impacts on wetlands would be minimized; however, permanent impacts would be unavoidable. Compensatory mitigation would be required to offset impacts on wetland functions and values, and mitigation measures would have a high probability of success.
Major	Impacts on wetlands would be minimized; however, permanent impacts would be regionally detectable. Extensive compensatory mitigation would be required to offset impacts on wetland functions and values, and mitigation measures would have a marginal or unknown probability of success.

The New Jersey Freshwater Wetlands Protection Act defines temporary disturbance as a regulated activity that occupies, persists, or occurs on a site for no more than 6 months. Impacts on wetlands that persist longer than 6 months are considered permanent.

USACE defines temporary impacts as those that occur when fill or cut impacts occur in wetlands that are restored to preconstruction contours when construction activities are complete (e.g., stockpile, temporary access). Conversion of a wetland type is also considered a permanent impact.

BOEM expects offshore wind projects in the NY Bight lease areas would be designed to avoid wetlands to the extent feasible, and would be required to comply with federal, state, and local regulations related to the protection of wetlands by avoiding or minimizing impacts. This would include compliance with the New York or New Jersey State Pollutant Discharge Elimination System General Permit for Stormwater Discharges from Construction Activities and implementation of sediment controls and a SWPPP to avoid and minimize water quality impacts during onshore construction. Projects would also need to comply with both tidal and non-tidal wetlands enforceable policies of New Jersey and New York Coastal Management Programs. Any work in wetlands in New Jersey would require a CWA Section 404 permit from USACE or NJDEP (or both) and a Section 401 Water Quality Certification from NJDEP; any wetlands permanently lost would require compensatory mitigation. Any work in wetlands in New York State would require a CWA Section 404 permit from USACE and a Section 401 Water Quality Certification from NYSDEC, as well as authorization from NYSDEC under the Tidal Wetlands Act. If impacts could not be avoided or minimized, mitigation would be anticipated to compensate for lost wetland functions.

Accidental releases and land disturbance are contributing IPFs to impacts on wetlands. However, these IPFs may not necessarily contribute to each individual issue outlined in Table 3.5.8-4.

Table 3.5.8-4. Issues and indicators to assess impacts on wetlands

Issue	Impact Indicator
Wetland fill and disturbance	Areal extent of tidal and non-tidal wetlands impacted and further characterized using the National Wetlands Inventory mapper
Hydrology	Reduced or increased hydrology changes in hydrological regime
Soil erosion and sedimentation	Qualitative assessment of potential impacts resulting from increased sedimentation into wetlands
Discharges/releases	Qualitative assessment of potential impacts from changes in water quality from stormwater runoff or discharges, HDD activity, and spills

3.5.8.3 Impacts of Alternative A – No Action – Wetlands

When analyzing the impacts of the No Action Alternative on wetlands, BOEM considered the impacts of ongoing activities, including ongoing non-offshore-wind and ongoing offshore wind activities on the baseline conditions for wetlands. The cumulative impacts of the No Action Alternative considered the impacts of the No Action Alternative in combination with other planned non-offshore-wind and offshore wind activities, as described in Appendix D, *Planned Activities Scenario*.

3.5.8.3.1 Impacts of the No Action Alternative

Under the No Action Alternative, baseline conditions for wetlands described in Section 3.5.8.1, *Description of the Affected Environment and Future Baseline Conditions*, would continue to follow current regional trends and respond to IPFs introduced by other ongoing non-offshore-wind and offshore wind activities. Ongoing non-offshore-wind activities within the geographic analysis area that may contribute to impacts on wetlands are associated with onshore development activities and climate change.

Ongoing onshore development activities within the geographic analysis area may contribute to impacts by permanently (e.g., fill placement) or temporarily (e.g., stockpile, temporary access) affecting wetlands or areas near wetlands. All projects would be required to comply with existing federal, state, and local regulations related to the protection of wetlands by avoiding or minimizing impacts. If unavoidable permanent wetland impacts (i.e., permanent fill placement) cannot be entirely avoided, then compensatory mitigation would be required to replace lost wetland functions. Climate change–induced sea level rise in the geographic analysis area is also anticipated to continue to affect wetlands. Inundation and rising water levels would result in the conversion of vegetated areas into areas of open water, with a consequent loss of wetland functions associated with the loss of vegetated wetlands. Wetlands have very specific water elevation tolerances and, if water is not deep enough, it is no longer a wetland. Slowly rising waters on a gentle, continuously rising surface can result in wetlands migrating landward. In areas where slopes are not gradual or where there are other features blocking flow (e.g., bulkhead or surrounding developed landscape), wetland migration would be slowed or impeded. Rising coastal waters would also continue to cause saltwater intrusion, which occurs when saltwater starts to move farther inland and creeps into freshwater/non-tidal areas. Saltwater intrusion would continue to change wetland plant communities and habitat (i.e., freshwater species to saltwater species) and overall wetland functions.

As sea level rises along the New Jersey shore, many wetlands will be submerged. Most salt marshes between Cape May and the Meadowlands are unlikely to keep pace if sea level rises 3 feet. Tidal flats are also likely to become open water (USEPA 2016a).

If the oceans and atmosphere continue to warm, tidal waters in New York are likely to rise 1 to 4 feet in the next century. As sea level rises, the lowest dry lands will be submerged and become either tidal wetland or open water. Wetlands can create their own land and keep pace with a slowly rising sea, but if sea level rises 3 feet or more during the next century, most existing wetlands along the south shore of Long Island are likely to be submerged (USEPA 2016b).

There are five ongoing offshore wind projects within the geographic analysis area that could contribute to impacts on wetlands from onshore components (Table 3.5.8-5): South Fork Wind Farm (OCS-A 0517), Ocean Wind 1 (OCS-A 0498), Sunrise Wind (OCS-A 0487), and Empire Wind 1 and 2 (OCS-A 0512). The South Fork Wind Farm includes offshore export cables landing on Long Island, and Ocean Wind 1 includes two offshore export cable routes making landfall in Ocean County, New Jersey and Cape May County, New Jersey. The export cables for Sunrise Wind and Empire Wind would both make landfall on Long Island, New York. These projects' export cable landfall sites are within the geographic analysis area and ongoing construction of the projects could affect wetlands through the primary IPFs of accidental releases and land disturbance; these are described in detail in the following section.

3.5.8.3.2 Cumulative Impacts of the No Action Alternative

The cumulative impact analysis for the No Action Alternative considers the impacts of the No Action Alternative in combination with other planned non-offshore-wind activities and planned offshore wind activities (without the NY Bight projects). Other planned non-offshore-wind activities that may affect wetlands would primarily include increasing onshore construction (see Appendix D for a description of planned activities in the onshore environment). These activities may permanently (e.g., fill placement) and temporarily (e.g., vegetation removal) affect wetland habitat, water quality, and hydrologic functions. All activities would be required to comply with federal, state, and local regulations related to the protection of wetlands by avoiding or minimizing impacts. If impacts would not be entirely avoided, mitigation would be anticipated to compensate for wetland loss.

Planned construction of an offshore wind PBI by the NJBPU could result in impacts on approximately 4 acres of wetlands. Areas with potential impacts include disturbance along the PBI route, HDD entry and exit locations, laydown areas, access roads, and other appurtenant facilities. Because the PBI route would occur mostly within roadways and existing rights-of-way, the footprint of potentially disturbed habitats is relatively small. Through a review of NJDEP's vernal habitat mapping, several areas that are mapped as potential vernal habitat are within the PBI route area (NJDEP 2023). These areas would need to be field-verified to confirm presence and potential impacts. All routes from Sea Girt National Guard Training Center (NGTC) to the Larabee Collector Station must cross the Manasquan River. The furthest upstream potential crossing of the Manasquan River would be along the north side of Hospital Road, and the furthest downstream potential crossing would be along the south side of Lakewood-Allenwood Road. Other stream crossings may include a subset of the following Category 1 waterways: Tarkiln

Brook, Woodcock Brook, Haystack Brook, Dicks Brook, Muddy Ford Brook, Sandyhill Brook, and Judas Creek.

Impacts on wetlands from planned offshore wind projects may occur if onshore activity from these planned offshore wind projects overlaps with the geographic analysis area. Ongoing and planned offshore wind activities that could potentially overlap the wetlands geographic analysis area are listed in Table 3.5.8-5.

Table 3.5.8-5. Ongoing and planned offshore wind in the geographic analysis area for wetlands

Ongoing/Planned	Projects by Region
Ongoing – 5 projects[1] 	**MA/RI** • South Fork Wind (OCS-A 0517) • Sunrise Wind (OCS-A 0487) **NY/NJ** • Ocean Wind 1 (OCS-A 0498) • Empire Wind 1 (OCS-A 0512) • Empire Wind 2 (OCS-A 0512)
Planned – 3 projects[2] 	**NY/NJ** • Ocean Wind 2 (OCS-A 0532) • Atlantic Shores North (OCS-A 0549) • Atlantic Shores South (OCS-A 0499)

MA = Massachusetts; NJ = New Jersey; NY = New York; RI = Rhode Island

[1] Refer to footnotes 9 and 10 in PEIS Chapter 1 for additional information on the status of Ocean Wind 1, Empire Wind 1, and Empire Wind 2.

[2] Status as of September 20, 2024.

Accidental releases: During onshore construction of offshore wind projects in the geographic analysis area, oil leaks and accidental spills from construction equipment are potential sources of wetland water contamination. While many wetlands act to filter out contaminants, any significant increase in contaminant loading could exceed the capacity of a wetland to perform its normal water quality functions. Degradation of water quality in wetlands could occur during construction, conceptual decommissioning, and to a lesser extent O&M. However, due to the small volumes of spilled material anticipated, these impacts would all be short term until the source of the contamination is removed. Compliance with applicable state and federal regulations related to oil spills and waste handling would minimize potential impacts from accidental releases. These include the Resource Conservation and Recovery Act, Department of Transportation Hazardous Material regulations, and implementation of a Spill Prevention, Control, and Countermeasure Plan. Impacts from accidental releases on wetlands would likely be minor because accidental releases would likely be small and localized, and compliance with state and federal regulations would avoid or minimize potential impacts on wetland quality or functions. As described in Section 2.3, *Non-Routine Activities and Events*, accidental releases of chemicals, gases, or man-made debris may occur as a result of a structural failure and could result in impacts on wetlands.

Land disturbance: Construction of onshore components in the geographic analysis area is anticipated to require clearing, excavating, trenching, fill, and grading, which could result in the loss or alteration of wetlands. This may cause adverse effects on wetland habitat, water quality, and flood and storage capacity functions. Table 3.5.8-6 describes impacts on wetlands from other offshore wind projects in the geographic analysis area.

Table 3.5.8-6. Other offshore wind projects' impacts on wetlands in the geographic analysis area

Offshore Wind Project	Wetland Impacts
Ongoing Offshore Wind Project	
South Fork Wind (OCS-A 0517)	One onshore project component for the South Fork Wind Farm (OCS-A 0517) (Hither Hills onshore cable route) could affect up to 2.02 acres (0.89 hectare) of wetland on Long Island (BOEM 2021).
Ocean Wind 1 (OCS-A 0498)	Ocean Wind 1 (OCS-A 0498) has estimated that up to 1 acre (0.4 hectare) of permanent disturbance would occur within wooded wetlands and approximately 0.53 and 11.92 acres (0.21 and 4.82 hectares) of temporary wetland impacts could potentially occur as a result of interconnection cable burial at BL England and Oyster Creek, respectively (BOEM 2022a).
Sunrise Wind (OCS-A 0487)	The landfall and onshore transmission cable route for Sunrise Wind (OCS-A 0487) is anticipated to result in 0.02 acre (0.08 hectare) of wetland impact on Long Island, New York.
Empire Wind (OCS-A 0512)	Based on NWI-mapped wetlands, 13.64 acres (5.51 hectares) of wetlands within the cable corridor could be susceptible to potential impacts as a result of cable installation associated with the Empire Wind lease area (OCS-A 0512). However, this will not necessarily be the area of wetland that would be affected during construction and operations. Empire Wind is evaluating several methods (trenchless, cable bridge) to avoid and minimize wetland impacts at the Reynolds and Barnums Channel crossings. These two channel crossings account for approximately 12.4 acres (5.01 hectares) or 91 percent of the mapped wetland in the cable corridor.
Planned Offshore Wind Projects	
Ocean Wind 2 (OCS-A 0532)	Ørsted is currently planning the Ocean Wind 2 (OCS-A 0532) project, which will develop the remaining portion of its Ocean Wind federal lease area, located adjacent to Ocean Wind 1 (OCS-A 0498). Potential wetland impact information is unavailable at this time.
Atlantic Shores South (OCS-A 0499)	Atlantic Shores South (OCS-A 0499) has estimated that approximately 0.65 acre (0.26 hectare) of temporary and 0.1 acre (0.04 hectare) of permanent disturbance in wetlands may occur as a result of interconnection cable installation (Atlantic Shores Offshore Wind 2022). Approximately 87 percent of the proposed wetland impacts are temporary and would occur in both emergent and forested wetlands.
Atlantic Shores North (OCS-A 0549)	Atlantic Shores North (OCS-A 0549) has estimated approximately 0.8 acre of permanent disturbance and 1.2 acres of temporary disturbance in wetlands (Atlantic Shores Offshore Wind 2024).

Fill material permanently placed in wetlands during construction would result in the permanent loss of wetlands, including any associated habitat, flood and storage capacity, and water quality functions that the wetlands may provide. If a wetland were partially filled and fragmented or if wetland vegetation were trimmed, cleared, or converted to a different vegetation type (e.g., forest to herbaceous), habitat would then be altered and degraded (affecting wildlife use). Additionally, water quality and flood/storage capacity functions would be reduced by changing natural hydrologic flows and reducing the wetland's ability to impede and retain stormwater and floodwater. On a watershed level, any permanent wetland loss or alteration could reduce the capacity of regional wetlands to provide wetland functions.

Temporary wetland impacts, such as rutting, compaction, and mixing of topsoil and subsoil, may occur from a construction activity that crosses or is adjacent to wetlands. Where construction leads to unvegetated or otherwise unstable soils, precipitation events could erode soils, resulting in sedimentation that could affect water quality in nearby wetlands. The extent of wetland impacts would depend on specific construction activities and their proximity to wetlands. These impacts would occur primarily during construction and conceptual decommissioning; impacts during O&M would only occur if new ground disturbance was required, such as to repair a buried component.

Given that the geographic analysis areas for the planned offshore wind projects are within urbanized landscapes in New Jersey and New York and onshore project components would likely be sited in previously disturbed areas (e.g., along existing roadways and ROW), BOEM anticipates wetland impacts would be minimal. In addition, BOEM expects the offshore wind projects would be designed to avoid wetlands to the extent feasible. However, depending on project-specific details and locations of onshore components, wetland impacts could range from negligible to moderate. All offshore wind projects would be required to comply with federal, state, and local regulations related to the protection of wetlands by avoiding or minimizing impacts. Mitigation would be anticipated for projects to compensate for unavoidable wetland impacts.

3.5.8.3.3 Conclusions

Impacts of the No Action Alternative. Under the No Action Alternative, wetlands would continue to follow current regional trends and respond to IPFs introduced by ongoing activities. Land disturbance from onshore construction would cause temporary and permanent loss of wetlands. All activities would be required to comply with federal, state, and local regulations related to the protection of wetlands by avoiding or minimizing impacts. If impacts would not be entirely avoided or minimized, mitigation would be anticipated for projects to compensate for lost wetlands. BOEM anticipates that the No Action Alternative would likely result in **negligible** to **moderate** impacts on wetlands. Impacts would likely be **negligible** to **moderate** because permanent wetland impacts would likely occur, and compensatory mitigation would be required.

Cumulative Impacts of the No Action Alternative. Under the No Action Alternative, existing environmental trends and ongoing activities would continue, and wetlands would continue to be affected by natural and human-caused IPFs. Planned activities would contribute to temporary and permanent impacts on wetlands due to accidental releases and land disturbance. BOEM anticipates that the cumulative impacts associated with the No Action Alternative, when combined with all other planned activities (including offshore wind) in the geographic analysis area would likely be **negligible** to

moderate given that permanent wetland impacts could occur, and any activity would be required to comply with federal, state, and local regulations related to the protection of wetlands and mitigation of impacts.

3.5.8.4 Impacts of Alternative B – No Identification of AMMM Measures at the Programmatic Stage – Wetlands

3.5.8.4.1 Impacts of One Project

Alternative B considers the potential impacts of future offshore wind development for the NY Bight area without the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts.

Accidental releases: Onshore construction activities would require heavy equipment use and HDD activities, and potential spills could occur as a result of an inadvertent release from the machinery or during refueling activities. Applicants would develop and implement a Spill Prevention, Control, and Countermeasure Plan to minimize impacts on water quality (prepared in accordance with applicable NJDEP and NYSDEC regulations). In addition, all waste generated onshore would comply with applicable federal regulations, including the Resource Conservation and Recovery Act and the Department of Transportation Hazardous Material regulations. Therefore, BOEM anticipates a single NY Bight project would result in minor and short-term impacts on wetlands as a result of releases from heavy equipment during construction and other cable installation activities.

Land disturbance: Construction impacts on wetlands and related functions would be similar to those described for the No Action Alternative. The primary wetland impacts would be filling, excavation, rutting, compaction, mixing of topsoil and subsoil, and potential alteration due to clearing. These impacts would be temporary in those locations where onshore project components do not require permanent fill, as restoration would be conducted in accordance with applicable CWA permit requirements. Following installation of interconnection cables within wetlands, topography would be restored, and soils would be de-compacted to avoid long-term impacts on soils and hydrology. Long-term changes from wooded to herbaceous wetlands could occur if clearing is required in wooded wetlands. Placement of fill within a wetland would result in loss of wetlands, and permanent conversion of wooded wetlands to herbaceous or shrub/scrub wetlands would constitute a permanent impact on wetlands because of the conversion to a different vegetation type. Other long-term impacts on wetlands could include clearing wooded wetlands within a temporary workspace. While these would be allowed to revert to forested wetland conditions, after construction, the recovery could take decades or longer and is therefore not considered a temporary impact. Following construction, temporary disturbed areas (e.g., temporary wetland fill, non-forest vegetation clearing) would be restored to pre-existing conditions and revegetated.

Where applicable, onshore interconnection cables would be installed using trenchless technology (e.g., jack-and-bore, pipe jacking, or HDD) beneath wetlands to minimize direct impacts on these resources. Entry/exit work areas would be in disturbed upland areas to further avoid impacts on wetlands. Water quality within wetlands could be affected by sedimentation from nearby exposed soils. To prevent indirect impacts, such as soil erosion and sedimentation from land-disturbing construction activities, on wetlands and waterbodies applicants would need to comply with an approved Soil Erosion and Sediment Control Plan, obtain coverage under a National Pollutant Discharge Elimination System General Permit for Stormwater Discharges from Construction Activities, and prepare a SWPPP for the project. In accordance with these plans, BMPs—including, but not limited to, dust abatement and installation of silt fencing, filter socks, and inlet filters—would be implemented to minimize or avoid potential effects. Additionally, once construction is completed, areas of temporary disturbance would be returned to preconstruction conditions, and at the onshore substations land would be appropriately graded, graveled, or revegetated to prevent future erosion.

Based on recent offshore wind projects under BOEM review, BOEM anticipates that impacts on wetlands from a single NY Bight project would be mostly avoided or minimized by adhering to the requirements of federal, state, and local wetland permitting. However, the area of wetland impacted could vary widely, depending on the specific siting of the onshore project components. Therefore, wetland impacts could range from none to potential permanent filling or clearing of wetlands. Mitigation, if required under federal and state wetland regulations, would likely include a combination of restoration, enhancement, creation, or in-lieu fee (credit purchase). In summary, potential adverse impacts on wetlands from one NY Bight project, should any occur, would be temporary and permanent, and long term and shorter term; this impact would range from negligible to moderate depending on the siting of project components.

3.5.8.4.2 Impacts of Six Projects

The same accidental releases and land disturbance IPF impact types and mechanisms described for one NY Bight project would apply to six NY Bight projects. There would be more potential for impacts from these IPFs due to the greater amount of onshore development under six NY Bight projects. However, accidental release impacts are still expected to be minimal as all six NY Bight projects would develop and implement a Spill Prevention, Control, and Countermeasure Plan to minimize impacts on water quality. Similar to one NY Bight project, the level of impact on wetlands from land disturbance depends on the amount, function, impact type, and duration. While BOEM anticipates that impacts on wetland habitat from onshore construction activities of six NY Bight projects would be minimized to the extent practicable, it is reasonable to assume that larger areas of wetland could be temporarily and permanently affected, resulting in negligible to moderate impacts. The impact of six NY Bight projects would not change the impact conclusion compared to one NY Bight project due to each project requiring federal and state wetland permits.

3.5.8.4.3 Cumulative Impacts of Alternative B

The construction and installation, O&M, and conceptual decommissioning of onshore infrastructure for offshore wind activities across the geographic analysis area would also contribute to the primary IPFs of accidental releases and land disturbance. Temporary disturbance and permanent loss of wetland may occur as a result of constructing infrastructure such as substations and onshore export cables for offshore wind development. Any wetland impact is anticipated to be minimal due to federal, local, and state wetland requirements to avoid and minimize wetland impacts. However, the area of wetland impact could vary widely depending on the specific siting of the onshore project components.

Six NY Bight projects would contribute to the combined accidental release impacts on wetlands from ongoing and planned activities including offshore wind. Impacts would likely be short term and minor due to the low risk and localized nature of the most likely spills, the use of an Oil Spill Response Plan for projects, and regulatory requirements for the protection of wetlands. The development of six NY Bight projects could contribute to the impacts on the land disturbance impacts from ongoing and planned activities including offshore wind. Impacts would likely be temporary to permanent and moderate because permanent wetland impacts would likely occur, and compensatory mitigation would be required. BOEM would not expect normal O&M activities to involve further wetland alteration. Onshore cable routes and associated substation/converter station facilities and POIs generally have no maintenance needs unless a fault or failure occurs; therefore, O&M is not expected to have any notable effects on wetlands.

Although impacts on wetlands would be avoided and minimized, compensatory mitigation would likely be necessary due to unavoidable permanent impacts, and actual wetland impacts could vary widely depending on the locations of specific project components. This conclusion would not change even if six NY Bight projects are constructed all at once or staggered. Therefore, onshore wetland habitat impacts are expected to range from negligible to moderate and would depend on specific construction activities, project component siting, and their proximity to wetlands. If construction of the onshore project components of six NY Bight projects are staggered, then there could be less of an effect on wetlands in the short term than if all six NY Bight projects were constructed at once. In context of reasonably foreseeable environmental trends, BOEM anticipates the impact of six NY Bight projects to the cumulative accidental release impacts would be undetectable; the contribution to cumulative land disturbance impacts would be noticeable on wetlands if greater impacts are incurred based on project-specific siting.

3.5.8.4.4 Conclusions

Impacts of Alternative B. In summary, construction and installation, O&M, and conceptual decommissioning of either one NY Bight project or six NY Bight projects under Alternative B, would likely have **negligible** to **moderate** impacts on wetlands, depending on the area of wetland affected, the types of wetlands affected, and duration of impact. For projects that would incur wetland impacts, the requirements set forth in the CWA Section 404(b)(1) Guidelines of avoidance, minimization, and compensatory mitigation would likely reduce project impacts on wetlands.

Cumulative Impacts of Alternative B. BOEM anticipates that the cumulative impacts on wetlands in the geographic analysis area would likely be **negligible** to **moderate** under six NY Bight projects. In context of other reasonably foreseeable environmental trends, the impacts contributed by six NY Bight projects to the overall impacts on wetlands could be noticeable, depending on site-specific project component siting relative to wetland locations.

3.5.8.5 Impacts of Alternative C (Proposed Action) – Identification of AMMM Measures at the Programmatic Stage – Wetlands

Alternative C, the Proposed Action, considers the potential impacts of future offshore wind development for the NY Bight Area with the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts. Alternative C consists of two sub-alternatives – Sub-alternative C1: Previously Applied AMMM Measures, and Sub-alternative C2: Previously Applied and Not Previously Applied AMMM Measures. The analysis for Sub-alternative C1 is presented as the change in impacts from those impacts discussed under Alternative B, and the analysis for Sub-alternative C2 is presented as the change from those impacts discussed in Sub-alternative C1. Refer to Table G-1 in Appendix G, *Mitigation and Monitoring*, for a complete description of AMMM measures that make up the Proposed Action. BOEM notes that federal, state, and local wetland permitting that would apply to any of the alternatives would contain mitigation measures and permit terms and conditions that would avoid and minimize wetlands impacts and, if needed, compensate for any permanent wetland function loss.

3.5.8.5.1 Sub-alternative C1 (Preferred Alternative): Previously Applied AMMM Measures

Sub-alternative C1 analyzes the AMMM measures that BOEM has required as conditions of approval for previous activities proposed by lessees in COPs submitted for the Atlantic OCS or through related consultations. However, BOEM has not identified any previously applied AMMM measures for wetlands; therefore, the impacts on wetlands under Sub-alternative C1 are the same as for Alternative B.

3.5.8.5.2 Sub-alternative C2: Previously Applied and Not Previously Applied AMMM Measures

Sub-alternative C2 analyzes the AMMM measures under Sub-alternative C1 plus the AMMM measures that have not been previously applied. However, BOEM has not identified any AMMM measures that have not been previously applied for wetlands; therefore, the impacts on wetlands under Sub-alternative C2 are the same as for Sub-alternative C1 and Alternative B.

3.5.8.5.3 Conclusions

Impacts of Alternative C. No AMMM measures are identified for wetlands under Sub-alternative C1 or Sub-alternative C2. Therefore construction and installation, O&M, and conceptual decommissioning activities from either one NY Bight project or six NY Bight projects would be the same as for Alternative B. Impacts on wetlands would likely be **negligible** to **moderate**, depending on the area of wetland affected, the types of wetlands affected, and duration of impact. For projects that would incur wetland impacts, the mitigation requirements set forth in the CWA Section 404(b)(1) guidelines of avoidance, minimization, and compensatory mitigation would likely reduce project impacts on wetlands.

Cumulative Impacts of Alternative C. BOEM anticipates that the cumulative impacts on wetlands in the geographic analysis area would likely be **negligible** to **moderate** under Sub-alternative C1 and Sub-alternative C2. In context of other reasonably foreseeable environmental trends, the impacts contributed by one NY Bight project or six NY Bight projects to the overall impacts on wetlands could be noticeable, depending on site-specific project component siting relative to wetland locations.

3.5.8.6 Recommended Practices for Consideration at the Project-Specific Stage

In addition to the AMMM measures identified under Alternative C, BOEM is recommending lessees consider analyzing the RPs in Table 3.5.8-7 to further reduce potential wetlands impacts. Refer to Table G-2 in Appendix G for a complete description of the RPs.

Table 3.5.8-7. Recommended practices for wetlands impacts and related benefits

Recommended Practice	Potential Benefit
MUL-18: Coordinate transmission infrastructure among projects such as by using shared intra- and interregional connections, meshed infrastructure, or parallel routing.	Using shared transmission infrastructure or following parallel routing with existing and proposed infrastructure could result in the consolidation of export cables from the six NY Bight projects into a reduced number of cable corridors, which could reduce the potential for wetland habitat loss. BOEM also acknowledges that easements and ROWs continue onshore and encourages the use of shared onshore infrastructure where practicable to minimize potential impacts on wetlands.
MUL-23: Avoid or reduce potential impacts on important environmental resources by adjusting project design.	Adjusting project design to minimize impacts on environmental resources, such as by siting onshore infrastructure to avoid wetlands or using HDD to pass underneath wetlands, could reduce overall wetland impacts. The site selection of onshore landfalls and substation locations and the onshore cable routes would have the highest influence on the magnitude of impacts on wetlands.

This page was intentionally left blank.

3.6 Socioeconomic Conditions and Cultural Resources

3.6.3 Demographics, Employment, and Economics

This section discusses the demographics, employment, and economic characteristics in the geographic analysis area and the potential impacts from the Proposed Action, alternatives, and ongoing and planned activities. The geographic analysis area, as shown on Figure 3.6.3-1, includes the counties where onshore infrastructure and potential port cities would be located, as well as the counties closest to the NY Bight lease areas. These counties are the most likely to experience beneficial or adverse economic impacts from the NY Bight projects. Potentially affected counties in New Jersey include Atlantic, Burlington, Camden, Cape May, Cumberland, Essex, Gloucester, Hudson, Middlesex, Monmouth, Ocean, Salem, and Union Counties. Potentially affected counties in New York include Albany, Kings, Nassau, New York, Queens, Rensselaer, Richmond, and Suffolk Counties. This analysis also considers counties that may be affected by visual impacts or impacts on recreation and tourism that may have economic consequences (e.g., on property values, tourism, or recreation), which are discussed in separate sections of this Final PEIS. Refer to Appendix B, *Supplemental Information and Additional Figures and Tables,* for detailed demographic, housing, and employment information for the counties within the geographic analysis area.

The demographics, employment, and economic impact analysis in this PEIS is intended to be incorporated by reference into the project-specific environmental analyses for individual COPs expected for each of the NY Bight lease areas. Refer to Appendix C, *Tiering Guidance*, which identifies additional analyses anticipated to be required for the project-specific environmental analysis of individual COPs.

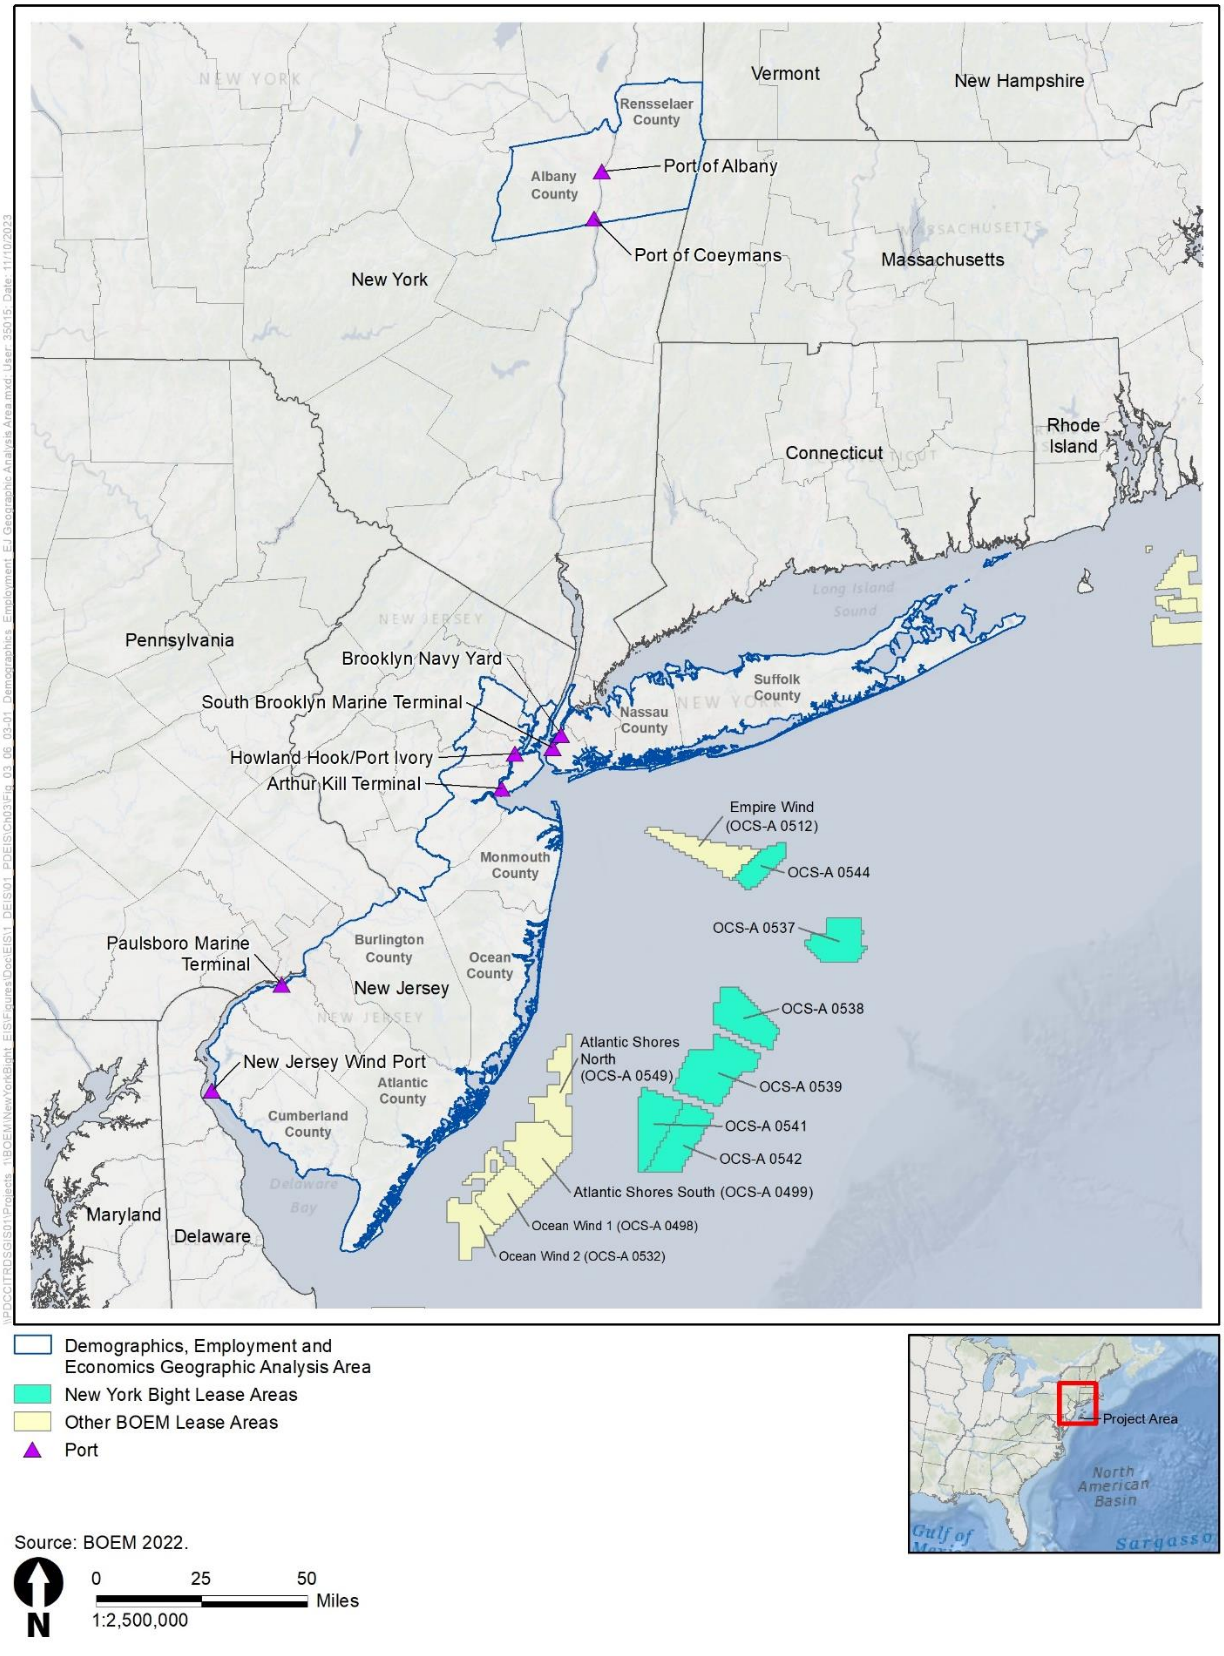

Figure 3.6.3-1. Demographics, employment, and economics geographic analysis area

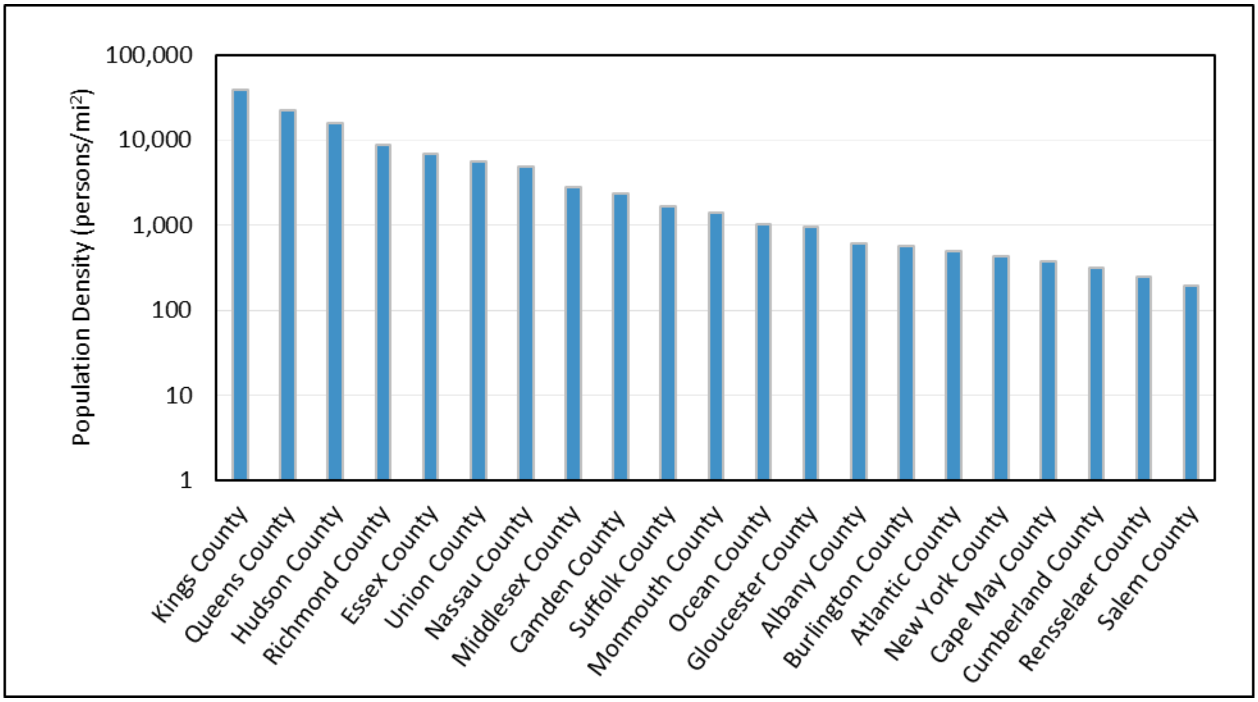
3.6.3.1 Description of the Affected Environment and Future Baseline Conditions

3.6.3.1.1 Demographics

Population

The total population within the geographic analysis area is approximately 15.6 million, with the 8 potentially affected New York counties comprising approximately 9.5 million and the 13 New Jersey counties comprising about 6.1 million. The population within each county varies widely, ranging from 160,000 to 2.7 million in New York and 65,000 to 863,000 in New Jersey (U.S. Census Bureau 2020; Appendix B, Table B.4-1). Population densities are more comparable. The three most densely populated New York counties (Kings, Queens, and Richmond) range from 8,618 to 39,438 persons per square mile; the top three New Jersey counties (Hudson, Essex, Union) range from 5,569 to 15,692 persons per square mile. The two least densely populated counties were inland counties: Rensselaer in New York and Salem in New Jersey, respectively at 247 and 195 persons per square mile (Figure 3.6.3-2).



Source: U.S. Census Bureau 2020.

Figure 3.6.3-2. Population density in New York and New Jersey counties (2020)

Populations trended upwards from 2000 to 2020 for all New York and nearly all New Jersey counties (Appendix B, Table B.4-1). In New Jersey, two counties showed a loss in population: Cape May County between 2000 and 2020, and Cumberland County between 2010 and 2020. Overall, from 2010 to 2020 the population growth of New York and New Jersey counties averaged 4.8 percent and 4.2 percent, respectively; from 2000 to 2020 population growth respectively averaged 7.8 percent and 8.9 percent (U.S. Census Bureau 2000, 2010, 2020).

Population Age Distribution

The age profiles for 2019 for both New York and New Jersey counties show fair consistency across age groups, with the exception of the median age (Appendix B, Table B.4-2). The 0–17 age group is an important demographic as it reflects the opportunity to train and educate the next generation of workers. This age group ranges from 14 percent to 24 percent of the population across all counties in the geographic analysis area, averaging 21 percent. The 18–34 age group ranged from 18 percent to 31 percent, averaging 23 percent. The 35–64 age group ranged from 35 percent to 42 percent, averaging 40 percent. The combined 18–64 age group, which represents the available prime working age population, ranged from 54 percent to 69 percent of the population, averaging 62 percent. The 65+ age group are generally considered retirement age population and ranged from 12 percent to 18 percent, with one outlier at 26 percent, and averaging 23 percent (U.S. Census Bureau 2019).

3.6.3.1.2 Housing

The number of housing units for New York counties in 2019 ranged from 73,011 units to 1,044,493 units, with a median of 524,266 units. The number of housing units for New Jersey counties in 2019 ranged from 27,595 units to 317,314 units, with a median of 202,267 units. The median owner-occupied value per unit for New York counties ranged from $188,700 to $987,700, with a median value of $493,500. The median owner-occupied value per unit for New Jersey counties ranged from $162,500 to $421,900, with a median value of $279,000 (U.S. Census Bureau 2019; Appendix B, Table B.4-4).

Occupancy in 2019 was comparably high for both New York (85 percent to 95 percent, averaging 90 percent) and New Jersey (78 percent to 94 percent, averaging 89 percent) counties (U.S. Census Bureau 2019; Appendix B, Table B.4-4). The figures for New Jersey omit data from Cape May County because of its seasonal population dynamics: some 95,000 year-long residents lived in Cape May County in 2020 (U.S. Census Bureau 2020), but during summer, the population increases to at least eight times that of the permanent winter population due to tourism (Cape May County Planning Board 2022).

The percentages of housing units that are seasonally occupied vary widely between counties. One factor is that tourism and recreation are key economic drivers of coastal counties, whereas the inland counties included in the geographic analysis area (where potential ports are located) are not as dependent on seasonal industries. Thus, Gloucester County and Salem County have seasonally occupied housing unit percentages of 0.3 percent and 0.7 percent, while Atlantic, Ocean, and Cape May Counties have seasonally occupied housing unit percentages of 13.4 percent, 13.8 percent, and 50.8 percent, respectively (U.S. Census Bureau 2019; Appendix B, Table B.4-4).

In 2019, average rents in New Jersey counties in the geographic analysis area ranged from $836 per month to $1,349 per month, with a statewide median rent of $1,087 per month for renter-occupied housing units. Average rents in New York counties in the geographic analysis area in 2019 (with the exception of Queens County, for which no data were available) ranged from $822 per month to $1,651 per month, with a statewide median rent of $1,303 per month (U.S. Census Bureau 2019).

3.6.3.1.3 Employment

Regional Employment

The New York metropolitan area is a major hub of the Nation's commerce. In 2019 total employment in the geographic analysis area counties of New York amounted to approximately 4.25 million jobs and in New Jersey amounted to 3.10 million jobs (U.S. Census Bureau 2019). The number of jobs varied widely by county, ranging from 85,822 to 1,851,947 jobs in New York counties and 31,221 to 429,146 jobs in New Jersey counties. Per capita income in 2019 ranged from $60,231 to $116,100 for counties in New York in the geographic analysis area, compared to a statewide average of $83,134. Per capita income in 2019 ranged from $54,149 to $99,733 for counties in New Jersey in the geographic analysis area, compared to a statewide average of $74,492 (Table 3.6.3-1).

Table 3.6.3-1. New York and New Jersey employment, unemployment, per capita income, and population living below poverty level (2019)

Jurisdiction	Total Employment	Per Capita Income	Unemployment Rate (%)	Population Living Below Poverty Level (%)
New York Counties				
Albany County	168,609	$66,252	4.5	7.1
Kings County	1,308,399	$60,231	6.2	15.9
Nassau County	716,106	$116,100	3.9	3.8
New York County	955,427	$86,553	5.2	11.8
Queens County	1,851,947	$96,631	3.6	12.2
Rensselaer County	85,822	$68,991	4.7	7.8
Richmond County	225,088	$82,783	4.6	9.4
Suffolk County	785,803	$101,031	4.2	4.5
New Jersey Counties				
Atlantic County	139,427	$62,110	8.4	9.9
Burlington County	241,940	$87,416	5.6	4.1
Camden County	267,725	$70,451	6.6	9.1
Cape May County	45,904	$67,074	6.6	6.9
Cumberland County	66,521	$54,149	7.3	11.9
Essex County	411,493	$61,510	8.1	12.8
Gloucester County	158,168	$87,283	5.5	4.4
Hudson County	377,168	$71,189	5.2	11.8
Middlesex County	429,146	$89,533	5.2	6.2
Monmouth County	335,725	$99,733	4.9	4.7
Ocean County	275,104	$70,909	5.1	6.5
Salem County	31,221	$66,842	6	8.6
Union County	299,082	$80,198	5.7	6.9

Source: U.S. Census Bureau 2019.

The New York metropolitan area has a highly diversified economic base. Data on the contribution to the New York and New Jersey GDP for 16 commercial sectors show the breadth of the region's employment summarized at the county level in Table 3.6.3-2. Education/Health Care/Social Assistance is the top commercial sector. Professional/Scientific/Technical Services, Retail Trade, and Finance/Insurance/Real

Estate rounded out the top four positions, which in total accounted for some 60 percent of the total ocean economy employment of the counties.

Table 3.6.3-2. New York and New Jersey employment contribution by commercial sector (2019)

Commercial Sector	New York	New Jersey
Education, Health Care, Social Assistance	29.2%	26.4%
Professional, Scientific, Technical	11.4%	9.6%
Finance, Insurance, Real Estate	10.8%	9.0%
Retail Trade	10.0%	12.1%
Accommodations and Food	7.1%	6.9%
Construction	6.1%	6.8%
Transportation and Warehouse	6.0%	6.5%
Manufacturing	4.5%	7.9%
Information	4.2%	2.8%
Administration, Support, Waste Management	4.0%	4.7%
Arts/Entertainment /Recreation	3.0%	2.5%
Wholesale Trade	2.7%	3.5%
Utilities	0.6%	0.9%
Agriculture, Forestry, Fishing, Hunting	0.2%	0.3%
Management of Companies	0.1%	0.2%
Mining, Quarrying, Oil & Gas	0.0%	0.0%

Source: U.S. Census 2019.

As shown in Table 3.6.3-1, the lowest unemployment levels for New York counties were for Queens County (3.6 percent) and Nassau County (3.9 percent); the highest unemployment levels were in New York County (5.2 percent) and Kings County (6.2 percent) (U.S. Census Bureau 2019). The populations living below poverty levels were lowest for Nassau (3.8 percent) and Suffolk (4.5 percent) Counties and were highest in Queens (12.2 percent) and Kings (15.9 percent) Counties. The lowest unemployment levels for New Jersey counties were in Monmouth, Middlesex, Ocean, and Hudson Counties and ranged from 4.9 percent to 5.2 percent; the highest unemployment levels were in Atlantic (8.4 percent), Essex (8.1 percent), and Cumberland (7.3 percent) Counties. The populations living below poverty levels were lowest for Burlington (4.1 percent) and Gloucester (4.4 percent) Counties and were highest in Hudson (11.8 percent), Cumberland (11.9 percent), and Essex (12.8 percent) Counties (U.S. Census Bureau 2019).

Ocean Industry Employment

Figure 3.6.3-3 presents the contribution of six ocean industry sectors (marine construction, living resources, offshore mineral extraction, ship and boat building, tourism and recreation, and marine transportation) to the ocean industry employment in 2019 for the New Jersey counties within the geographic analysis area. Figure 3.6.3-4 presents the same data for New York counties. Total ocean industry employment for New York counties was 342,047; for New Jersey it was 149,649 (NOEP 2022; Appendix B, Table B.4-8). Considering data for both states within the geographic analysis area, tourism and recreation accounts for 81 percent of the ocean industry economy, marine transportation accounts for 16 percent, and the remaining 3 percent is composed of the other four ocean industry sectors.

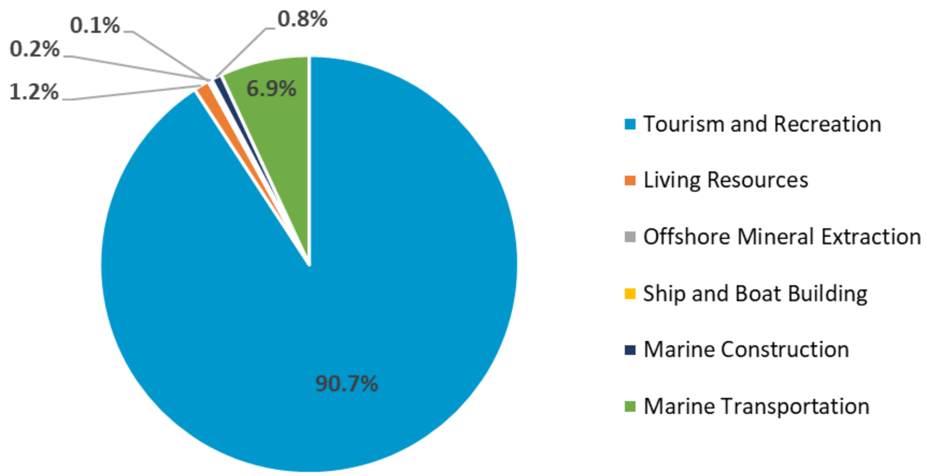
Figure 3.6.3-3. Ocean economy employment, New Jersey counties



Source: NOEP 2022.

Figure 3.6.3-4. Ocean economy employment, New York counties

3.6.3.1.4 Economics

Table 3.6.3-3 presents the data on number of establishments, employment, wages, and GDP attributed to the ocean industry sector for the counties in the geographic analysis area of New York (NOAA 2022). Similar to ocean industry-related employment for New York counties, the number of establishments, wages, and GDP are driven by two ocean industry sectors—tourism and recreation, and marine transportation.

Table 3.6.3-3. Total number of establishments, wages, and GDP for ocean industry economy of New York (2019)

Ocean Sector	Establishments	Employment	Wages, $M	GDP, $M	% NY Coastal Ocean Sector	
					Wages	GDP
Marine Construction	142	2,593	$198	$479	1.9%	1.5%
Living Resources	623	4,264	$8	$497	1.4%	1.6%
Offshore Mineral Extraction	35	90	$16	$14	0.1%	0.0%
Ship and Boat Building	4	190	$12,857	$30	0.1%	0.1%
Tourism and Recreation	20,195	330,693	$696	$29,194	92%	93%
Marine Transportation	397	11,847	$14,047	$1,116	5.0%	3.6%
All Ocean Sectors, Geographic Analysis Area Counties	21,445	349,677	$16,111	$31,330	100%	100%
All Ocean Sectors, State	24,019	398,514	$273	$35,109	87%	89%

Source: NOAA 2022.

Table 3.6.3-4 presents the data on number of establishments, employment, wages, and GDP attributed to the ocean industry sector for the counties in the geographic analysis area of New Jersey for the same six ocean industry sectors (NOAA 2022). Again, two ocean industry sectors—tourism and recreation and marine transportation—drive the ocean industry-related employment, number of establishments, wages, and GDP in New Jersey.

Table 3.6.3-4. Total number of establishments, wages, and GDP for ocean industry economy of New Jersey (2019)

Ocean Sector	Establishments	Employment	Wages, $M	GDP, $M	% NJ Coastal Ocean Sector	
					Wages	GDP
Marine Construction	81	1,869	$183	$369	4.9%	5.6%
Living Resources	152	890	$40	$101	1.1%	1.5%

3.6.3.2 Impact Level Definitions for Demographics, Employment, and Economics

Definitions of adverse impact levels are provided in Table 3.6.3-5. Beneficial impacts on demographics, employment, and economics are described using the definitions described in Section 3.3.2 (see Table 3.3-1).

Table 3.6.3-5. Adverse impact level definitions for demographics, employment, and economics

Impact Level	Definition
Negligible	There would be no measurable impacts, or impacts would be so small that they would be extremely difficult or impossible to discern or measure.
Minor	Adverse impacts would not disrupt the normal or routine functions of the affected activity or geographic place.
Moderate	The affected activity or geographic place would have to adjust somewhat to account for disruptions due to impacts of the project.
Major	The affected activity or geographic place would experience disruptions to a degree beyond what is normally acceptable.

Cable emplacement and maintenance, land disturbance, lighting, noise, port utilization, presence of structures, and traffic are contributing IPFs to impacts on demographics, employment, and economics. However, these IPFs may not necessarily contribute to each individual issue outlined in Table 3.6.3-6.

Table 3.6.3-6. Issues and indicators to assess impacts on demographics, employment, and economics

Issue	Impact Indicator
Impacts on particular demographic and employment sectors of the economy	Qualitative assessment that considers the context and intensity of impacts resulting from the particular IPF on the functioning of the economy (e.g., decrease in full-time equivalent jobs, labor income, gross domestic product, and gross output)

3.6.3.3 Impacts of Alternative A – No Action – Demographics, Employment, and Economics

When analyzing the impacts of the No Action Alternative, BOEM considered the impacts of ongoing activities, including ongoing non-offshore-wind and ongoing offshore wind activities as the baseline conditions for demographics, employment, and economics. The cumulative impacts of the No Action Alternative considered the impacts of the No Action Alternative in combination with other planned non-offshore-wind and offshore wind activities as described in Appendix D, *Planned Activities Scenario*.

3.6.3.3.1 Impacts of the No Action Alternative

Under the No Action Alternative, baseline conditions for demographics, employment, and economics would continue to follow current regional levels and trends and respond to IPFs introduced by other ongoing activities. Tourism, recreation, and marine industries (e.g., fishing) would continue to be important components of the regional economy. Ongoing non-offshore-wind activities in the geographic analysis area that contribute to impacts on demographics, employment, and economics include growth in onshore development; ongoing installation of submarine cables and pipelines; periodic channel dredging; maintenance of piers, pilings, seawalls, and buoys; ongoing commercial shipping; continued port upgrades and maintenance; and ongoing effects from climate change (e.g., damage to property and coastal infrastructure) (see Appendix D for a description of ongoing activities). These ongoing activities contribute to numerous IPFs including cable emplacement and maintenance, which could disrupt fishing; land disturbance, which supports local population growth, employment, and economies; lighting and noise, which can affect residential and other sensitive populations; port utilization, which can affect jobs, populations, and economies; presence of structures, which can affect fishing, navigation, and coastal views; and marine traffic, which can affect commercial fishing/shipping and recreation and tourism economies.

The socioeconomic impact of ongoing activities varies depending on each activity. Activities that generate economic activity, such as port maintenance and channel dredging, would generally benefit the local economy by providing job opportunities and generating indirect economic activity from suppliers and other businesses that support activity along coastal areas. Conversely, ongoing activities that disrupt economic activity, such as climate change, may adversely affect businesses, resulting in impacts on employment and wages. Coasts are sensitive to sea level rise, changes in the frequency and intensity of storms, increases in precipitation, and warmer ocean temperatures. Sea level rise and increased storm frequency and severity could result in property or infrastructure damage, increased insurance cost, and reduction in the economic viability of coastal communities. Impacts on marine life due to ocean acidification, altered habitats and migration patterns, and disease frequency would affect industries that rely on these species. The impacts of climate change are likely over time to worsen problems that coastal areas already face.

Ongoing offshore wind activities within the geographic analysis area that contribute to impacts on demographics, employment, and economics include ongoing construction of Ocean Wind 1 (OCS-A 0498) and Empire Wind 1 and 2 (OCS-A 0512). Ongoing construction of Ocean Wind 1 and Empire Wind 1 and 2 would have the same type of impacts on demographics, employment, and economics that are described in Section 3.6.3.3.2, *Cumulative Impacts of the No Action Alternative* for all ongoing and planned offshore wind activities in the geographic analysis area.

3.6.3.3.2 Cumulative Impacts of the No Action Alternative

The cumulative impact analysis for the No Action Alternative considers the impact of the No Action Alternative in combination with other planned non-offshore-wind activities and planned offshore wind activities (without the NY Bight projects). Offshore wind is a new industry for the Atlantic states and the nation. Although most offshore wind component manufacturing and installation capacity exists outside of the U.S., some studies acknowledge that domestic capacity is poised to increase (BVG 2017; NREL 2023).

A BVG Associates Limited study (BVG 2017) estimated that the percentage of associated jobs that would be sourced in the United States during the initial implementation of offshore wind projects along the U.S. northeast coast would range from 35 to 55 percent. The proportion of jobs projected to be associated with offshore wind within the United States is approximately 65 to 75 percent from 2030 through 2056. Overseas manufacturers of components and specialized ships based overseas would comprise the rest of the offshore wind–related jobs, located outside the United States (BVG 2017).

The American Wind Energy Association (AWEA; now known as American Clean Power) estimates that the offshore wind industry will invest between $80 and $106 billion in U.S. offshore wind development by 2030, of which $28 to $57 billion will be invested within the United States. While most economic and employment impacts would be concentrated in Atlantic coastal states where offshore wind development will occur, there would be nationwide effects as well (AWEA 2020). The AWEA base scenario assumes 20 GW of offshore wind power by 2030, domestic content of 30 percent in 2025, and of 50 percent in 2030; the high scenario assumes 30 GW of offshore wind power by 2030 and domestic content of 40 percent in 2025 and of 60 percent in 2030. Offshore wind energy development will support $14.2 billion in economic output and $7 billion in value added by 2030 under the base scenario and support $25.4 billion in economic output and $12.5 billion in value added under the high scenario.

Compared to the $14.2 to $25.4 billion in offshore wind economic output (AWEA 2020), the 2020 annual GDP for Atlantic states with planned offshore wind projects (Connecticut, Massachusetts, Rhode Island, New York, New Jersey, Delaware, Maryland, Virginia, and North Carolina) ranged from $60.8 billion in Rhode Island to $1.74 trillion in New York (U.S. Bureau of Economic Analysis 2021) and totaled just over $5 trillion. The $14.2 to $25.4 billion in offshore wind industry output would represent 0.3 to 0.5 percent of the combined GDP of these states.

The AWEA estimates that in 2030, offshore wind would support 45,500 (base scenario) to 82,500 (high scenario) full-time equivalent (FTE) jobs nationwide. The Responsible Offshore Development Alliance (RODA) in 2020 estimated that offshore wind projects would create 55,989 to 86,138 job-years through 2030 in construction and 5,003 to 6,994 long-term jobs in O&M (Georgetown Economic Services 2020).

In 2019, employment for New Jersey and New York counties within the geographic analysis area was approximately 3.0 million and 6.1 million jobs, respectively (Table B.4-5 in Appendix B). While the extent to which there will be impacts on the geographic analysis area is unclear due to the geographic versatility of offshore wind jobs, a substantial portion of the jobs supporting planned offshore wind projects in New Jersey and New York would likely be within commuting distance of ports.

Some local economic activity has already begun for the anticipated offshore wind industry. The establishment of a New York State Advisory Council on Offshore Wind Training Institute was launched to develop a plan for deploying public funds and has issued the first solicitation for $3 million to support early training and skills development for disadvantaged communities. The developers of the Sunrise Wind project (OCS-A 0487) have invested $10 million in a National Offshore Wind Training Center at Suffolk County Community College on Long Island to train and certify workers. The Center of Excellence for Offshore Energy at State University of New York’s Maritime College was launched with a grant from New York State to develop classroom and online training programs (NYSERDA 2021).

Ongoing and planned offshore wind activities that may contribute to impacts on demographics, employment, and economics in the geographic analysis area are listed in Table 3.6.3-7.

Table 3.6.3-7. Ongoing and planned offshore wind that may contribute to impacts on demographics, employment, and economics

Ongoing/Planned	Projects by Region
Ongoing – 3 projects[1] 	**NY/NJ** • Ocean Wind 1 (OCS-A 0498) • Empire Wind 1 (OCS-A 0512) • Empire Wind 2 (OCS-A 0512)
Planned – 3 projects[2] 	**NY/NJ** • Ocean Wind 2 (OCS-A 0532) • Atlantic Shores North (OCS-A 0549) • Atlantic Shores South (OCS-A 0499)

NJ = New Jersey; NY = New York
[1] Refer to footnotes 9 and 10 in PEIS Chapter 1 for additional information on the status of Ocean Wind 1, Empire Wind 1, and Empire Wind 2.
[2] Status as of September 20, 2024.

In addition to the regional economic impact of a growing offshore wind industry, BOEM expects ongoing and planned offshore wind activities to affect demographics, employment, and economics through the following primary IPFs.

Cable emplacement and maintenance: Offshore cable emplacement for offshore wind activities could impact commercial fishing and for-hire recreational fishing during cable installation and maintenance, temporarily causing commercial and recreational fishing vessels to relocate away from work areas, disrupting fish stocks, and reducing income or increasing catch per unit effort costs. (See Section 3.6.1.3.2 for additional details.) The economic impact on commercial/for-hire recreational fishing would likely be short term and minor.

Land disturbance: Land disturbance could result in localized, short-term, adverse revenue losses for businesses near construction sites due to construction impacts (e.g., increased noise, traffic, and access disturbances) and beneficial impacts for businesses supporting construction activities. Conceptual decommissioning would create an increased economic activity compared to the O&M phase but is unlikely to cause additional land disturbance. Adverse and beneficial impacts on employment, wages, and GDP would be localized, short term, and minor.

Lighting: Offshore WTGs require aviation warning lighting that could have economic impacts if the lighting influences visitors and residents in selecting coastal locations in which to reside or to visit. No readily available studies characterize the impacts of nighttime offshore lighting on economic activity. Studies cited in Section 3.6.8, *Recreation and Tourism*, suggest that WTGs visible from more than 15 miles (24.1 kilometers) away would have negligible effects on businesses dependent on recreation and tourism activity (Parsons and Firestone 2018).[1] At this distance, the percentage of respondents who indicated that their experience would be improved by the presence of WTGs was the same as the percentage of respondents who indicated that their experience would be worsened by the WTGs. While some WTGs associated with ongoing and planned offshore wind projects in the geographic analysis area would be within 10 miles of shore, the majority of WTGs would be more than 15 miles from coastal locations. The implementation of ADLS would activate a hazard lighting system in response to detecting nearby aircraft and, if ADLS is implemented, would result in shorter-duration night sky impacts. Due to the distance of the WTGs from shore and the expected implementation of ADLS, ongoing and planned offshore wind projects would result in overall negligible impacts. Nighttime transit or construction lighting may be visible from some coastal residences and businesses. Conceptual decommissioning may increase nighttime lighting from vessels in transit but would result in reduced lighting impacts from WTG removals. However, the contribution from offshore wind to existing activity is small and there would likely be a negligible impact on demographics, employment, and economics.

Noise: Noise from vessel traffic during the maintenance and construction phases could affect species important to commercial/for-hire fishing, recreational fishing, and whale watching. Offshore wind-related construction noise from pile-driving, cable laying and trenching, and vessels could drive away species important to tour boat or for-hire recreational fishing businesses. Noise from pile-driving could also affect fish populations important to commercial fishing and marine recreational businesses. These impacts would be greater if multiple construction activities occur in close spatial or temporal proximity. Impacts would likely be temporary, mainly occurring during surveying and construction and, therefore, are expected to be minor. Impacts during O&M would likely be negligible. Onshore construction noise could temporarily inconvenience visitors, workers, and residents, resulting in reduction of economic activity for businesses near cable landfall or substation sites or port improvements. During conceptual decommissioning vessel traffic noise would occur as well as offshore activity-related noise from WTG removal. The location of onshore activities is unknown, so noise impacts from onshore construction currently cannot be determined reliably. Impacts on demographics, employment, and economics from noise is expected to be intermittent, short term, and negligible to minor, like those of typical onshore utility construction activities.

Port utilization: Offshore wind development would require support from nearby port facilities and may need port expansion and improvements. Development activities would bolster port investment and employment, jobs and revenue in port-supporting industries, and port construction/improvement businesses. Port utilization would require a trained workforce for the offshore wind industry, providing local and regional employment and economic activity for onshore and offshore workers. Improvements to existing ports and channels would be beneficial to other port activity. In the O&M phase, the level of port activity would likely be lower but more consistent. Offshore wind development could result in increased demand for port service and result in port expansions. Port construction activities could result in minor short- to long-term adverse impacts on marine transportation and commercial/for-hire/recreational fishing. Overall, however, port utilization from offshore wind is anticipated to result in

[1] This study was based on 100 WTGs using a 0.75-mile grid spacing and a maximum rotor height of 574 feet. The study used visual simulations under clear, hazy, and nighttime (lighted) conditions.

minor beneficial impacts on demographics, employment, and economics both from short-term creation of construction jobs (a few years to a decade, particularly between 2023 and 2030) that likely can be supported by the existing workforce, from minor long-term (decades) job creation during the O&M phase, and from short-term job creation during conceptual decommissioning (a few years to a decade).

Presence of structures: Up to 697 WTGs are projected for the New York/New Jersey region, without any NY Bight development (Appendix D). Businesses that are most likely to be affected by presence of structures include commercial fishing, for-hire recreational fishing, recreational fishing (and for all three, particularly the fisheries using bottom gear) and marine recreation and tourism businesses. Marine transportation could also be affected. Impacts will include both short-term impacts during construction from noise and vessel traffic and long-term impacts from the physical presence of structures by creating areas that fishing vessels may avoid due to safety concerns or potential for gear damage. The areal extent of these areas will increase directly with the number of WTGs installed but will also depend on their location, spacing, and orientation. These potential adverse impacts can be temporary over a timescale of years and minor (e.g., those associated with structure installation) or can be long-term over a timescale of multiple decades and moderate (e.g., resulting from space-use conflicts for fishing or marine transportation). The presence of structures could produce beneficial fish aggregation and reef effect impacts around marine structures for businesses that cater to migratory species and offshore recreational fishing. Damage to gear is a concern and could be worsened if fish aggregate around offshore infrastructure and fishermen engage in higher risk fishing patterns near WTGs. Given the distances from shore, the attraction of recreational anglers to offshore wind structures is more likely to change recreational fishing patterns than to result in an overall increase in recreational fishing. Another beneficial impact could be new business opportunities, e.g., windfarm tourism for those interested in a close-up experience with offshore wind structures, as has occurred for the Block Island Wind Farm. Both adverse and beneficial impacts would be reversed following conceptual decommissioning and WTG removal.

Impacts on commercial fisheries and for-hire recreational fishing are of most concern, with impacts anticipated to range from negligible to major for commercial fisheries and moderate impacts with potential minor beneficial impacts on for-hire recreational fishing (see Section 3.6.1, *Commercial Fisheries and For-Hire Recreational Fishing*). These industries represent only a part of the ocean economy that would be affected by offshore wind, and overall impacts on employment and economics would be minor.

Traffic: Offshore wind construction and conceptual decommissioning and, to a lesser extent, offshore wind operations would generate increased vessel traffic. The magnitude of increased vessel traffic will depend on vessel traffic volumes generated by each offshore wind project and number of WTGs; the extent of concurrent or sequential construction of wind energy projects; and the ports selected for each project. Increased vessel traffic will occur to, from, and in supporting ports and in offshore construction areas. Vessel traffic could adversely affect marine transportation, commercial fishing, and recreational traffic. Impacts of short-term, increased vessel traffic during construction could include increased vessel traffic congestion, delays at ports, and a risk for collisions between vessels. Increased vessel traffic would be localized near affected ports and offshore construction areas. Congestion and delays could increase fuel costs (i.e., for vessels forced to wait for port traffic to pass) and decrease productivity for commercial shipping, fishing, and recreational vessel businesses, whose income depends on the ability to spend time out of port. Collisions could lead to vessel damage and spills, which could have direct costs (i.e., vessel repairs and spill cleanup), as well as indirect costs from damage caused by spills. Beneficially, this increased traffic would support increased employment and economic activity for marine transportation related to offshore wind and supporting businesses and investment in ports.

Beneficial and adverse impacts will be greatest during construction and installation and cover a span of a few years to a decade. The far longer phase of O&M will produce lower and more consistent vessel traffic. Conceptual decommissioning would create a short-term increase in vessel traffic but would be at a lower level of activity than during the construction phase. The increase in vessel trips from offshore wind activity is anticipated to be largely indiscernible from existing levels of vessel traffic. Offshore wind traffic would likely result in short-term, negligible to minor impacts and long-term minor beneficial impacts on employment, wages, and the economy.

3.6.3.3.3 Conclusions

Impacts of the No Action Alternative. Under the No Action Alternative, the demographic and economic trends from ongoing non-offshore-wind activities and ongoing offshore wind construction in the geographic analysis area would continue. Tourism and recreation and marine industries such as marine transportation would continue to be important components of the regional economy. BOEM anticipates that the No Action Alternative would likely have a **negligible** to **minor** impact on the demographics, employment, and economy of the geographic analysis area.

Cumulative Impacts of the No Action Alternative. Under the No Action Alternative, ongoing and planned offshore wind and non-offshore-wind activities would affect ocean-based employment and economics, driven primarily by the continued operation of existing marine industries, especially recreation/tourism and marine shipping. The influence of planned offshore wind development, representing a significant investment in energy production, still presents a small impact in the geographic analysis area whose combined annual state GDPs runs to $2.6 trillion and supports nearly 7.5 million jobs. Although there may be adverse impacts associated with planned offshore wind activities on the region's demographics, employment, and economics, there are also beneficial impacts resulting from these same activities. BOEM concludes the cumulative impact of planned offshore wind development, in combination with ongoing activities, would likely have a **negligible** to **minor** impact and **minor beneficial** impacts on demographics, employment, and economics.

3.6.3.4 Impacts of Alternative B – No Identification of AMMM Measures at the Programmatic Stage – Demographics, Employment, and Economics

3.6.3.4.1 Impacts of One Project

Alternative B considers the potential impacts of future offshore wind development for the NY Bight area without the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts. The development of a single project within the NY Bight lease areas without AMMM measures would result in impacts similar to those described in Section 3.6.3.3.2, *Cumulative Impacts of the No Action Alternative*. Accordingly, the discussion below does not repeat the analyses supplied in Section 3.6.3.3.2 but describes where impacts may differ and reiterates the conclusions of those analyses.

Cable emplacement and maintenance: The development of a single NY Bight project would result in seafloor disturbance due to the installation of interarray and export cables. Cable emplacement could prevent deployment of fixed and mobile fishing gear in limited parts of the NY Bight area from one day up to several months (if simultaneous lay and burial techniques are not used), which may result in the loss of access if alternative fishing locations are not available. The demographic, employment, and economic impact on commercial/for-hire fishing would be localized, short term, and minor.

Land disturbance: Land disturbance could result in localized, short-term, adverse revenue losses for businesses near construction sites and beneficial impacts for businesses supporting construction. During peak tourist season, construction-related impacts associated with land disturbance, including road construction along the offshore export cable routes, could cause traffic delays and inconveniences to local businesses and residents. Temporary blockage of some roads during installation activities may restrict access to some local areas, although it is unlikely that access to specific establishments would be completely inhibited. Conceptual decommissioning is not anticipated to create additional land disturbance. Adverse and beneficial impacts on employment and wages would likely be localized, short term, and minor.

Lighting: One offshore wind project would add new sources of light to onshore and offshore areas, including from nighttime vessel lighting during construction and conceptual decommissioning and fixed lighting at onshore substations/converter stations, and on up to 280 WTGs and up to 5 OSSs. Because of the distance from shore (the NY Bight lease area nearest to shore is 20 nautical miles [37 kilometers] offshore), lighting on the WTGs and OSSs is not anticipated to have a substantial effect on views. However, as described in Section 3.6.9, *Scenic and Visual Resources*, in the absence of an ADLS system, there would be new, constant sources of nighttime lighting in view of the coastline for one NY Bight project. Nighttime lighting could have long-term impacts on demographics, employment, and economics if the lighting influences resident and visitor decisions in selecting coastal locations to visit or reside in. The addition of a single project in the NY Bight area would result in long-term, minor impacts, primarily as a result of offshore lighting on WTGs and OSSs.

Noise: Adverse offshore noise impacts on demographics, employment, and economics during construction/installation and conceptual decommissioning would likely be short term and minor; and impacts during O&M would be negligible. Adverse impacts of onshore noise would likely be intermittent, short term, and minor.

Port utilization: A single NY Bight project's activities at ports would support port investment and employment and would also support jobs and businesses in supporting industries and commerce. Several ports may support a single NY Bight project construction and O&M: Howland Hook/Port Ivory, Port of Albany, Port of Coeymans, South Brooklyn Marine Terminal, Brooklyn Navy Yard, Arthur Kill

Terminal in New York, and New Jersey Wind Port and Paulsboro Marine Terminal in New Jersey. These ports would require a trained workforce for the offshore wind industry including additional shore-based and marine workers that would contribute to local and regional economic activity.

The economic benefits would be greatest during construction and conceptual decommissioning when the most jobs and economic activity at ports supporting the NY Bight project would occur. During operations, activities would be concentrated where the single NY Bight project's onshore O&M facility would be located, and in other ports that may support one NY Bight project-related vessel traffic. Port utilization during construction/installation and conceptual decommissioning is expected to result in short-term minor beneficial impacts on demographics, employment, and economics, and minor beneficial long-term impacts during O&M.

Presence of structures: One NY Bight project would add up to 285 offshore wind structures with foundation scour protection and offshore export cable hard protection, which could affect marine-based businesses (i.e., commercial and for-hire recreational fishing businesses, offshore recreational businesses, and related businesses) through entanglement and gear loss/damage, navigational hazard and risk of allisions, fish aggregation, habitat alteration, and space use conflicts. Adverse impacts could include both short-term minor impacts during construction and long-term minor impacts from the creation of areas that fishing vessels would likely avoid due to the physical presence of structures. The presence of structures could produce long-term beneficial fish aggregation/reef effect impacts that are expected to be negligible to minor. Conceptual decommissioning and WTG removals would reverse both adverse and beneficial impacts from the presence of structures.

Stakeholders have raised questions regarding whether a NY Bight project could affect property values; any impacts on property values could also affect local property tax receipts. Hoen et al. (2013) analyzed housing prices from home sales occurring within 10 miles (16 kilometers) of onshore wind facilities in nine U.S. states and found no statistical evidence that home values were affected in the post-announcement/preconstruction or post-construction periods. The MassCEC also commissioned a report—Relationship between Wind Turbines and Residential Property Values in Massachusetts (Atkinson Palombo & Hoen 2014)—to study if home values were affected by their proximity to onshore WTGs. The study analyzed 122,198 home sales occurring between 1998 and 2012 of homes located within 5 miles (8 kilometers) of 41 Massachusetts wind turbines. Results of this study indicated that there were no effects on nearby home prices resulting from the development of a wind farm in a community. Brunner et al. (2024) found that onshore wind farms in the U.S. had temporary adverse impacts on property values within a limited distance (1–2 miles) and that wind farms further away did not adversely affect property values. A 2017 study found that when placed more than 8 miles (7 nautical miles; 13 kilometers) from shore, there is a minimal effect on vacation rental values associated with offshore wind farms (Lutzeyer et al. 2017). A 2018 study also found that there was no impact on property values when the wind farm is located 5.6 miles (9 kilometers) offshore (Jensen et al. 2018). Dong and Lang (2022) found that the Block Island Wind Farm did not adversely affect property values on Block Island or on the Rhode Island mainland. Since any NY Bight project will be located a substantial distance from shore—with the closest lease area 20 nautical miles from shore and the farthest lease area 35 nautical miles (40 miles) from shore—any impacts on property values are expected to be negligible.

Traffic: Vessel traffic from a single NY Bight project could adversely affect marine transportation, commercial/for-hire fishing, and recreational traffic due to associated increased vessel traffic congestion, delays at ports, and a risk for collisions between vessels. Increased traffic would support increased employment and economic activity for marine transportation and supporting businesses and investment in ports. The highest activity level would occur during the construction phase; lower activity would occur during the conceptual decommissioning phase; and the lowest activity would be during the much longer O&M phase. Offshore wind traffic would likely result in short-term negligible to minor adverse impacts and long-term minor beneficial impacts.

3.6.3.4.2 Impacts of Six Projects

The types of IPFs, impacts, and mechanisms that affect the demographics, employment, and economics of the geographic analysis area as described for one NY Bight project would be the same for six NY Bight projects, but would be of greater intensity or extent because more projects would be constructed and decommissioned. Impacts would be greater due to the higher level of activity and onshore development for six NY Bight projects. The impacts from some IPFs may increase directly proportionally to the amount of construction; for example, seabed disturbance associated with cable emplacement relates directly to the total miles of cable installed for each of the six NY Bight projects. The impacts from other IPFs may be highly dependent on the specific details of how each of the six NY Bight projects would be constructed; for example, the impacts from port utilization for the six NY Bight projects would be highly dependent on the specific ports proposed to be used, their need for improvements, and whether a specific port may be used to serve multiple projects. In addition, if multiple projects are being constructed at the same time, temporary impacts for certain IPFs, such as those associated with traffic and port utilization, could be greater than those identified for a single project. If projects are staggered over a longer period, the intensity of the impacts could be less than if multiple projects were constructed at the same time, but the overall duration of the impacts could be longer. The impacts and benefits for IPFs may increase, but the magnitude change of specific impacts are not known until COPs are developed for each project. Based on the type, nature, and magnitude of impacts expected under one NY Bight project, although impacts from six NY Bight projects would undoubtedly be larger, the overall impact magnitude is not expected to change.

3.6.3.4.3 Cumulative Impacts of Alternative B

The construction and installation, O&M, and conceptual decommissioning of six NY Bight projects would contribute to the impacts on demographics, employment, and economics from ongoing and planned activities in the geographic analysis area. Construction and conceptual decommissioning of six NY Bight projects that overlap with construction and conceptual decommissioning of other ongoing and planned projects would result in temporary impacts from increased vessel traffic and offshore construction that may disrupt maritime businesses. It is not likely that onshore export cables, onshore substations/converter stations, and other project-specific onshore facilities associated with the six NY

Bight projects would overlap spatially with other projects. However, the six NY Bight projects and other ongoing and planned projects may rely on the same ports and construction staging areas, because it is possible that a given port or staging area capacity has sufficient flexibility to accommodate more than one project's requirements. Cumulative impacts would occur if the six NY Bight projects overlap in the use of ports with other offshore wind projects, leading to greater port congestion and greater economic use and employment opportunities.

The presence of structures from the six NY Bight projects combined with the structures from other ongoing and planned offshore wind projects in the region (Ocean Wind 1 [OCS-A 0498], Ocean Wind 2 [OCS-A 0532], Atlantic Shores South [OCS-A 0499], Atlantic Shores North [OCS-A 0549], and Empire Wind 1 and 2 [OCS-A 0512]) would create permanent space-use conflicts that may have negligible to major adverse impacts on commercial fishing and moderate adverse impacts with minor beneficial impacts on for-hire recreational fishing industries. Commercial fishing GDP for New York ranges from approximately $40 million to $69 million, while for New Jersey ranges from approximately $166 million to $191 million (see Section 3.6.1, *Commercial Fisheries and For-Hire Recreational Fishing*). Compared to the ocean sector GDPs of $31 billion for New York and $6.6 billion for New Jersey, although impacts on commercial fishing may be major, such impacts would be negligible to minor on the ocean economies of either state. While the presence of structures would also affect other commercial vessel traffic by requiring most large vessels to navigate around the lease areas, because the lease areas are sited outside of current and proposed vessel traffic lanes (refer to Section 3.6.6, *Navigation and Vessel Traffic*), disruptions to marine transportation and related economic activity would be limited and impacts would be minor. Adverse effects could be counterbalanced by the beneficial effects on the regional economy from increased economic activity and employment associated with the establishment of the New York-New Jersey region as an offshore wind hub, resulting in moderate beneficial impacts on employment and economics. Zhang et al. (2020) estimates that the jobs supported by all development in the New York Bight area are 100 annual development jobs (from 2022 to 2029) and 32,200 annual construction jobs (from 2025 to 2030).

3.6.3.4.4 Conclusions

Impacts of Alternative B. One NY Bight project and six NY Bight projects would likely have **negligible** to **minor** impacts on demographics, employment, and economics. One NY Bight project and six NY Bight projects would affect employment and economics through job creation and increased local business revenue and would likely have **minor beneficial** impacts. The geographic analysis area may experience substantial temporary increased economic activity associated with offshore wind development during the construction and installation phases, a lower and shorter-term increase during conceptual decommissioning, and a low level of increased economic activity over the long-term (35+ years) O&M phase of offshore wind energy production.

While the NY Bight projects' investments in wind energy would largely benefit the local and regional economies through job creation, workforce development, and income and tax revenue, adverse impacts on individual businesses and communities would also occur. Short-term increases in noise during construction, cable emplacement, and conceptual decommissioning; land disturbance; and the long-term presence of offshore lighting and structures would have negligible to minor adverse impacts on demographics, employment, and economics. The commercial fishing industry and other businesses that depend on local seafood production would experience impacts during construction. Overall, the impacts on commercial fishing and onshore seafood businesses would have minor impacts on demographics, employment, and economics for this component of the geographic analysis area's economy. Although commercial fishing is a small component of the regional economy, it is important to the identity of local communities within the region. The IPFs associated with one and six NY Bight projects would also result in impacts on certain recreation and tourism businesses, with an overall minor impact on employment and economic activity for this component of the analysis area's economy.

Cumulative Impacts of Alternative B. In context of reasonably foreseeable environmental trends, the impacts contributed by Alternative B to cumulative impacts on demographics, employment, and economics would be noticeable. BOEM anticipates that cumulative impacts on demographics, employment, and economics from six NY Bight projects when combined with other ongoing and planned activities would likely be **negligible** to **minor** and **moderate beneficial**. The moderate beneficial impacts primarily would be associated with the investment in offshore wind, job creation and workforce development, income and tax revenue, and infrastructure improvements generated from the development of six NY Bight projects plus six ongoing and planned offshore wind projects in the geographic analysis area. The minor adverse effects would result from aviation hazard lighting on WTGs; new cable emplacement and maintenance; the presence of structures; noise and vessel traffic and collisions during construction and conceptual decommissioning; and land disturbance. Impacts on commercial fishing could rise to a major level; however, such impacts would be negligible to minor on the ocean economies of New York and New Jersey because commercial fishing is only one component of the overall ocean economy.

3.6.3.5 Impacts of Alternative C (Proposed Action) – Identification of AMMM Measures at the Programmatic Stage – Demographics, Employment, and Economics

Alternative C, the Proposed Action, considers the potential impacts of future offshore wind development for the NY Bight area with the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts. Alternative C consists of two sub-alternatives – Sub-alternative C1: Previously Applied AMMM Measures, and Sub-alternative C2: Previously Applied and Not Previously Applied AMMM Measures. The analysis for Sub-alternative C1 is presented as the change in impacts from those impacts discussed under Alternative B, and the analysis for Sub-alternative C2 is presented as the change from those impacts discussed in Sub-alternative C1. Refer to Table G-1 in Appendix G, *Mitigation and Monitoring*, for a complete description of AMMM measures that make up the Proposed Action.

3.6.3.5.1 Sub-alternative C1 (Preferred Alternative): Previously Applied AMMM Measures

Sub-alternative C1 analyzes the AMMM measures that BOEM has required as conditions of approval for previous activities proposed by lessees in COPs submitted for the Atlantic OCS or through related consultations.

Although there are no previously applied AMMM measures specific to demographics, employment, and economics, there are many identified for other resources that may indirectly affect demographics, employment, and economics, such as those measures that reduce onshore noise and traffic associated with construction of onshore support facilities or the presence of structure impacts. However, the dynamics of such interactions are complex and not easily quantifiable absent project-specific data. For example, onshore construction can have negative impacts on a local community (e.g., from noise and traffic), but at the same time may use local labor, supplies, or services that positively affect the same community. Thus, the net impact of any AMMM measure on demographics, employment, and economic needs to be assessed when project-specific data are available. Impacts associated with noise, lighting, traffic, and presence of structures would likely be reduced, while impacts for all other IPFs would remain the same as described under Alternative B.

Impacts of One Project

AMMM measures under Sub-alternative C1 that reduce impacts on commercial fisheries and for-hire recreational fishing and recreation and tourism are those most likely to affect employment and economics from a single NY Bight project. As described in Section 3.6.1, *Commercial Fisheries and For-Hire Recreational Fishing*, and Section 3.6.8, *Recreation and Tourism*, AMMM measures may slightly reduce impacts on commercial fishing, for-hire recreational fishing, and recreation and tourism, which would benefit regional employment and economics, but the impact levels would remain the same as projected for Alternative B—negligible to minor adverse impacts and minor beneficial impacts.

Impacts of Six Projects

Impacts of six NY Bight projects under Sub-alternative C1 would be the same as described for one NY Bight project under Sub-alternative C1. AMMM measures may slightly reduce impacts on commercial fisheries and for-hire recreational fishing and on recreation and tourism, but the impact levels would remain the same as projected for Alternative B—negligible to minor adverse impacts and minor beneficial impacts.

Cumulative Impacts of Sub-alternative C1 (Preferred Alternative)

Under Sub-alternative C1, cumulative impacts on demographics, employment, and economics are anticipated to be the same as described under Alternative B.

3.6.3.5.2 Sub-alternative C2: Previously Applied and Not Previously Applied AMMM Measures

Sub-alternative C2 analyzes the AMMM measures under Sub-alternative C1 plus the AMMM measures that have not been previously applied. However, BOEM has not identified any AMMM measures that have not been previously applied for demographics, employment, and economics; therefore, the impacts under Sub-alternative C2 are the same as for Sub-alternative C1.

3.6.3.5.3 Conclusions

Impacts of Alternative C. Impacts on demographics, employment, and economics would be slightly reduced from the AMMM measures that would lessen impacts on other resources like commercial fisheries and for-hire recreational fishing and recreation and tourism. However, under Sub-alternatives C1 and C2, the overall evaluation of impacts would likely remain the same as Alternative B—**negligible** to **minor** impacts and **minor beneficial** impacts from one NY Bight project and six NY Bight projects.

Cumulative Impacts of Alternative C. In context of reasonably foreseeable environmental trends, the impacts contributed by Sub-alternatives C1 and C2 to cumulative impacts on demographics, employment, and economics would be noticeable. The combination of Sub-alternatives C1 and C2 of six NY Bight projects and other ongoing and planned activities would likely result in the same **negligible** to **minor** impacts and **moderate beneficial** impacts on demographics, employment, and economics as Alternative B.

3.6.3.6 Recommended Practices for Consideration at the Project-Specific Stage

BOEM has not identified any RPs for demographics, employment, and economics. However, RPs for other resources that minimize disruptions to businesses—especially those that reduce impacts on commercial fisheries and for-hire recreational fishing and recreation and tourism, while supporting the offshore wind industry—may also benefit demographics, employment, and economics.

3.6 Socioeconomic Conditions and Cultural Resources

3.6.5 Land Use and Coastal Infrastructure

This section discusses potential impacts on land use and coastal infrastructure from the Proposed Action, alternatives, and ongoing and planned activities in the geographic analysis area. The land use and coastal infrastructure geographic analysis area, as shown on Figure 3.6.5-1, includes the counties where onshore infrastructure may be located, the counties with representative ports that may be used by the NY Bight projects, as well as the counties closest to the NY Bight lease areas that may be affected by construction and installation, O&M, and conceptual decommissioning of the NY Bight projects.

The land use and coastal infrastructure impact analysis in this PEIS is intended to be incorporated by reference into the project-specific environmental analyses for individual COPs expected for each of the NY Bight lease areas. Because the locations of onshore components for the NY Bight projects are not known at this time, the analysis of land use impacts is dependent on a hypothetical project analysis and impact conclusions consider a maximum-case scenario for onshore development. Additional detailed site-specific analysis will be required for individual COPs. Refer to Appendix C, *Tiering Guidance*, which identifies additional analyses anticipated to be required for the project-specific environmental analysis of individual COPs.

3.6.5.1 Description of the Affected Environment and Future Baseline Conditions

The geographic analysis area includes a diverse mix of land use types. In New Jersey, land uses in the geographic analysis area include agricultural, barren, urban, riparian lands, forest, and waterbodies (NJDEP 2015). In New York, land uses include agricultural, commercial, industrial, urban, and recreational lands (Long Island Index 2020; NYC Planning 2021). Figure 3.6.5-2 illustrates the diversity of land uses across the geographic analysis area, and Table 3.6.5-1 provides the acreage of each land use type.

New Jersey and New York both have statewide land use laws and regulations in place that regulate land uses and development, particularly along the coast. The Waterfront Development Law authorizes the NJDEP to regulate the construction or alteration of dock, wharf, pier, bulkhead, bridge, pipeline, cable, or other similar development on or adjacent to tidal waterways throughout the state (NJDEP 2022). The Coastal Area Facility Review Act (CAFRA) authorizes NJDEP to regulate residential, commercial, public, or industrial development (such as construction, relocation, and enlargement of buildings and structures; and associated work such as excavation, grading, site preparation, and the installation of shore protection structures) within the CAFRA area, which includes coastal New Jersey along the Delaware Bay (NJDEP 2022).

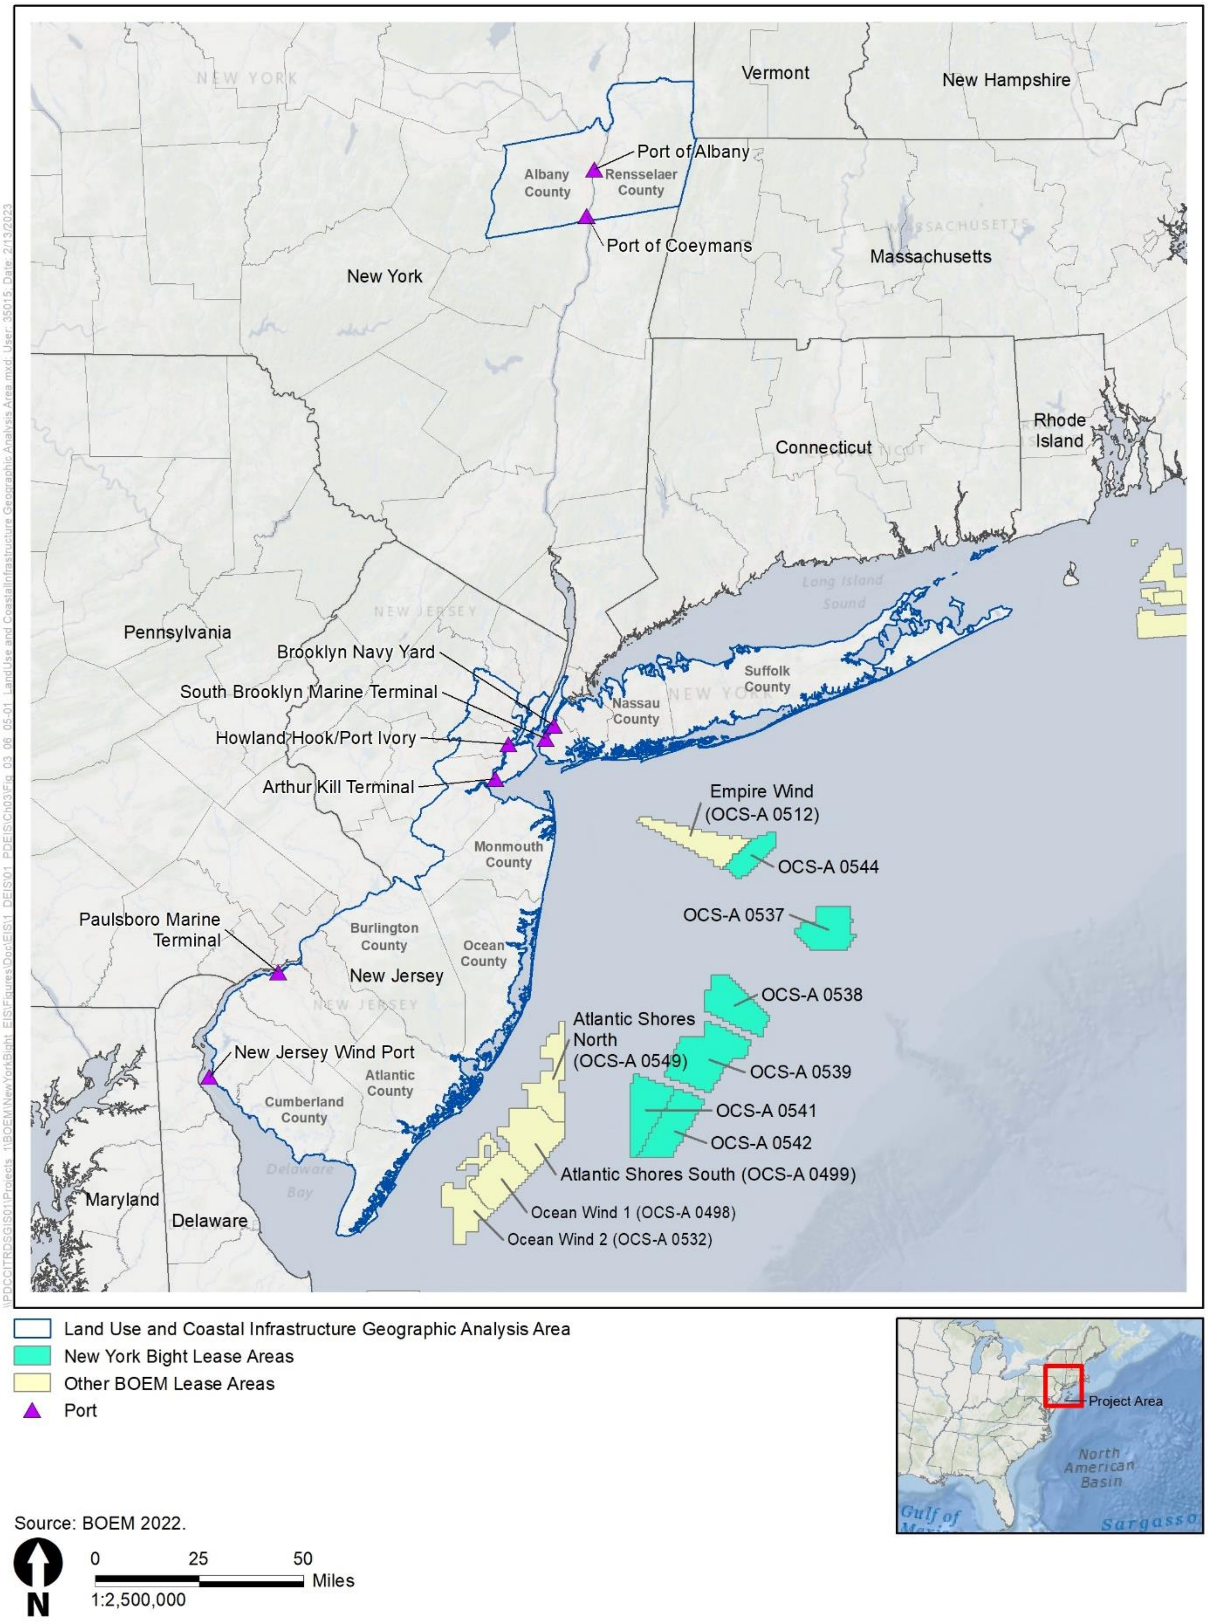

Figure 3.6.5-1. Land use and coastal infrastructure geographic analysis area

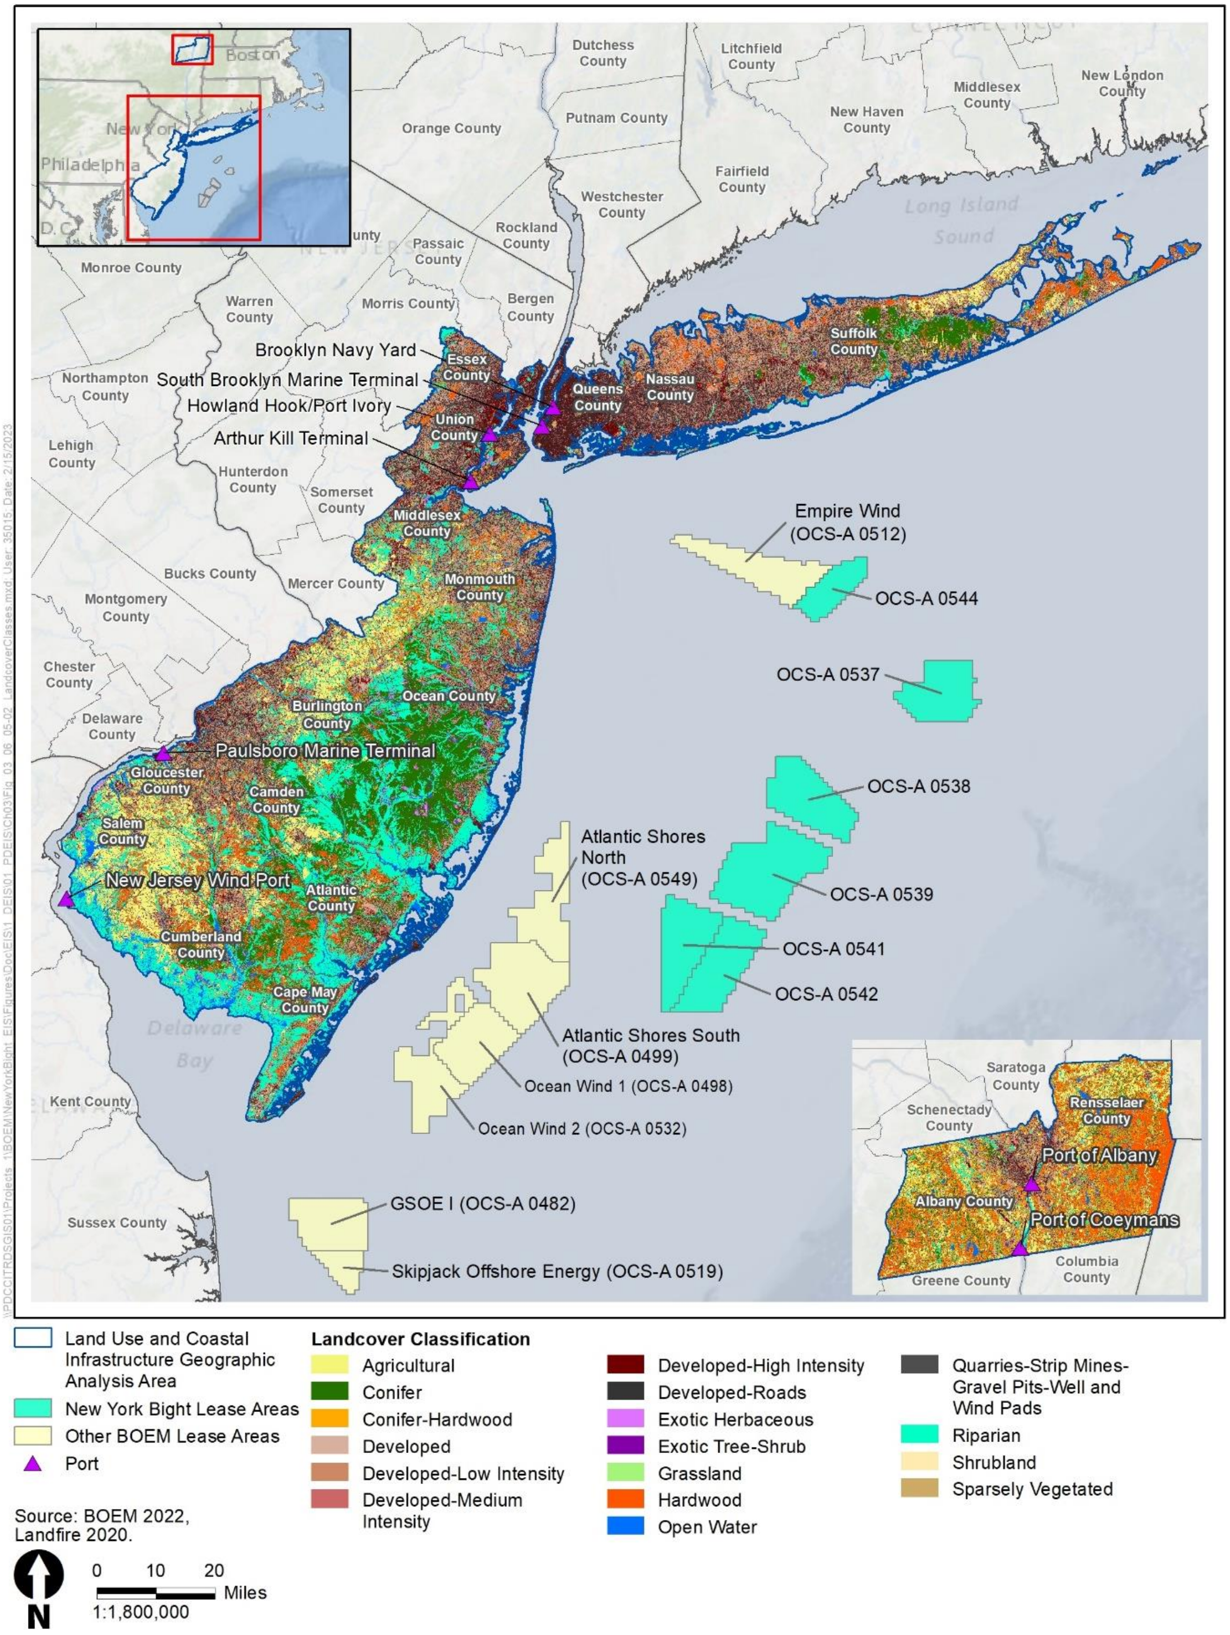

Figure 3.6.5-2. Land uses in geographic analysis area

Table 3.6.5-1. Land use by type

Type of Land Use	Acres	Percent (%)
Agricultural	365,529	9.2%
Conifer	468,544	11.7%
Conifer-Hardwood	70,312	1.8%
Developed	438,403	11.0%
Developed – High Intensity	143,220	3.6%
Developed – Low Intensity	296,394	7.4%
Developed – Medium Intensity	217,279	5.4%
Developed-Roads	652,543	16.4%
Exotic Herbaceous	48,389	1.2%
Exotic Tree-Shrub	8,046	0.2%
Grassland	11,528	0.3%
Hardwood	343,746	8.6%
Open Water	147,372	3.7%
Quarries – Strip Mines – Gravel Pits – Well and Wind Pads	5,908	0.1%
Riparian	758,105	19.0%
Shrubland	1,883	0.0%
Sparsely Vegetated	11,977	0.3%
Total	**3,989,178**	**100.0%**

Source: Landfire 2020.

New York has a Coastal Management Program, which provides a framework for federal, state, and local decision-making that affects coastal land and water areas and uses for actions occurring within the state's coastal boundary. The Coastal Management Program also includes Local Waterfront Revitalization Programs, which allows communities to develop state and federally approved refinements to the state coastal policies to ensure actions are consistent with local planning efforts and special management areas. Related to the federal Coastal Zone Management Act Consistency Review, New York has adopted an approved Renewable Energy Geographic Location Description, which will help make offshore wind project reviews more effective by establishing criteria for automatic review for certain offshore wind projects in the Atlantic Ocean (NYSDOS 2022).

Individual counties and municipalities in New Jersey and New York have individual land use plans and zoning regulations that dictate and govern land uses in the geographic analysis area. Land use is typically regulated through zoning, which is the process local governments use to regulate the use of real property and guide urban growth and development.

Representative ports analyzed in this PEIS that may potentially be used by the NY Bight projects are the New Jersey Wind Port and Paulsboro Marine Terminal in New Jersey and the Port of Albany, Port of Coeymans, Howland Hook/Port Ivory, Arthur Kill Terminal, Brooklyn Navy Yard, and South Brooklyn Marine Terminal in New York. The New Jersey Wind Port is currently being developed as an offshore wind marshalling and assembly port; land use is industrial and undeveloped (NJEDA 2020). The Port of Paulsboro is surrounded by land zoned as marina industrial business (Borough of Paulsboro 2010).

In New York, land use surrounding the Port of Albany is characterized by high-intensity developed land along the Hudson River (NYSERDA 2019a). Land use surrounding the Port of Coeymans is characterized by high-intensity developed land as well as undeveloped land (NYSERDA 2019b). The land use surrounding the Howland Hook/Port of Ivory is primarily industrial (NYSERDA 2019d). The Arthur Kill Terminal, an undeveloped 32-acre parcel on the western shoreline of Staten Island, New York, received federal grants in 2022 to be redeveloped for offshore wind staging and assembly (Empire State Development 2022). The Brooklyn Navy Yard is zoned for industrial uses and is surrounded by commercial, industrial, residential, and open and recreational space (NYSERDA 2022). The land use surrounding the South Brooklyn Marine Terminal is mostly undeveloped (NYSERDA 2019c).

3.6.5.2 Impact Level Definitions for Land Use and Coastal Infrastructure

Definitions of adverse impact levels are provided in Table 3.6.5-2. Beneficial impacts on land use and coastal infrastructure are described using the definitions described in Section 3.3.2, *Impact Terminology,* (Table 3.3-1).

Table 3.6.5-2. Adverse impact level definitions for land use and coastal infrastructure

Impact Level	Definition
Negligible	There would be no measurable impacts on land use, or impacts would be so small that they would be extremely difficult or impossible to discern or measure.
Minor	Impacts would be detectable but would be short term and localized.
Moderate	Impacts would be detectable and broad-based, affecting a variety of land uses, but would be short term and would not result in long-term change.
Major	Impacts would be detectable, long term, and extensive, and result in permanent land use change.

Accidental releases, lighting, port utilization, presence of structures, land disturbance, and traffic are contributing IPFs to impacts on land use and coastal infrastructure. However, these IPFs may not necessarily contribute to each individual issue outlined in Table 3.6.5-3.

Table 3.6.5-3. Issues and indicators to assess impacts on land use and coastal infrastructure

Issue	Impact Indicator
Public health and safety	Construction- or operation-related volume increases, traffic delays, traffic re-routes, and noise
Port improvements and operations	Changes to vehicle, vessel traffic volumes, and working waterfront infrastructure demands
Land use code and zoning	Qualitative assessment of impacts on compliance with local land use regulations

3.6.5.3 Impacts of Alternative A – No Action – Land Use and Coastal Infrastructure

When analyzing the impacts of the No Action Alternative on land use and coastal infrastructure, BOEM considered the impacts of ongoing activities, including ongoing non-offshore-wind and ongoing offshore wind activities on the baseline conditions for land use and coastal infrastructure. The cumulative impacts of the No Action Alternative considered the impacts of the No Action Alternative in combination with other planned non-offshore and offshore wind activities, which are described in Appendix D, *Planned Activities Scenario*.

3.6.5.3.1 Impacts of the No Action Alternative

Under the No Action Alternative, baseline conditions for land use and coastal infrastructure described in Section 3.6.5.1, *Description of the Affected Environment and Future Baseline Conditions*, would continue to follow current regional trends and respond to IPFs introduced by other ongoing non-offshore-wind and offshore wind activities. Ongoing non-offshore-wind activities include onshore development activities. The geographic analysis area lies within developed communities that are likely to continue experiencing commerce and development activity in accordance with established land use patterns and zoning regulations. The geographic analysis area is highly developed, and most construction projects would likely affect land that has already been disturbed from past development, although some development of undeveloped land may also occur. The geographic analysis area is a coastal area that may experience long lasting impacts from climate change such as sea level rise, more frequent and intense storms, and flooding (USEPA 2023). The impact of climate change may require storm hardening and resilience measures to overcome impacts on land use and coastal infrastructure.

Ongoing offshore wind activities that may contribute to impacts on land use and coastal infrastructure include construction of Ocean Wind 1 (OCS-A 0498), South Fork Wind (OCS-A 0517), Sunrise Wind (OCS-A 0487), and Empire Wind 1 and 2 (OCS-A 0512). These projects have landfalls in the geographic analysis area. Ongoing offshore wind activities would have the same types of impacts that are described in detail in Section 3.6.5.3.2, *Cumulative Impacts of the No Action Alternative,* for ongoing and planned offshore wind activities.

3.6.5.3.2 Cumulative Impacts of the No Action Alternative

The cumulative impact analysis for the No Action Alternative considers the impacts of the No Action Alternative in combination with other planned non-offshore-wind activities and planned offshore wind activities (without the NY Bight projects). Planned non-offshore-wind activity that may contribute to land use impacts includes port improvement, dredging projects, transmission systems (e.g., PBI), and onshore development activities; more information regarding these projects can be found in Appendix D, Section D.2.5 and Section D.2.12. Ports in the geographic analysis area would continue to serve marine traffic and industries and experience periodic dredging and improvement projects to meet ongoing needs. Dredging and port improvements would allow larger vessels to use the ports and may result in increased port use and conversion of surrounding land use if the ports are expanded. Planned onshore development, such as commercial/industrial development, would contribute to ongoing construction activities and development in the region. Planned onshore infrastructure would be developed in conformance with existing land use regulations.

Ongoing and planned offshore wind activities that may contribute to impacts on land use and coastal infrastructure in the geographic analysis area are listed in Table 3.6.5-4. The location of known onshore infrastructure from ongoing and planned offshore wind projects in the geographic analysis area includes Long Island, New York, for Empire Wind (OCS-A 0512); Monmouth, New Jersey, and Atlantic City, New

Jersey, for Atlantic Shores South (OCS-A 0499); Upper Township, New Jersey, and Lacey Township, New Jersey, for Ocean Wind 1 (OCS-A 0498); East Hampton, New York for South Fork Wind (OCS-A 0517); and Brookhaven, New York for Sunrise Wind (OCS-A 0487). The locations of onshore infrastructure for other offshore wind projects in the geographic analysis area are not known at this time.

Table 3.6.5-4. Ongoing and planned offshore wind that may contribute to impacts on land use and coastal infrastructure

Ongoing/Planned	Projects by Region
Ongoing – 5 projects[1] 	**MA/RI** • South Fork Wind (OCS-A 0517) • Sunrise Wind (OCS-A 0487) **NY/NJ** • Ocean Wind 1 (OCS-A 0498) • Empire Wind 1 (OCS-A 0512) • Empire Wind 2 (OCS-A 0512)
Planned – 3 projects[2] 	**NY/NJ** • Ocean Wind 2 (OCS-A 0532) • Atlantic Shores North (OCS-A 0549) • Atlantic Shores South (OCS-A 0499)

NJ = New Jersey; NY = New York
[1] Refer to footnotes 9 and 10 in PEIS Chapter 1 for additional information on the status of Ocean Wind 1, Empire Wind 1, and Empire Wind 2.
[2] Status as of September 20, 2024.

Accidental releases: Accidental releases of fuel, fluids, or hazardous materials may increase due to construction of onshore components associated with other offshore wind projects, such as landfalls and onshore export cable routes. Accidental release risks would be highest during construction, but still pose a risk during O&M and decommissioning of offshore wind facilities. BOEM assumes all projects and activities would comply with laws and regulations to minimize releases. Accidental releases could result in temporary restrictions on use of adjacent properties and coastal infrastructure during the cleanup process; however, the impacts would be localized and short term. The exact extent of impacts would depend on the locations of landfall, substations, and cable routes, as well as the ports that support offshore wind energy projects. The impacts of accidental releases on land use and coastal infrastructure would be minor (except in the case of very large spills that affect a large land or coastal area).

Lighting: Aviation obstruction lights on offshore WTGs would be visible from beaches and coastlines within the geographic analysis area. Nighttime lighting for construction and decommissioning of onshore project components could disrupt existing uses on adjacent properties. These impacts would be localized and short term. Nighttime lighting from operation of onshore substations, O&M facilities, and port facilities could disrupt existing or planned uses on adjacent properties in the long term, depending on the specific location of these facilities, the land use and zoning of adjacent properties, and the extent of visual screening incorporated into the design of offshore wind facilities. Given the existing level of development in the geographic analysis area and that facilities would be sited consistent with local zoning regulations, BOEM anticipates the impact of facility lighting would be negligible.

Port utilization: Ports in the geographic analysis area would be improved to support offshore wind projects and other uses (see Appendix D). These improvements would occur within the boundaries of existing port facilities, within areas planned for expansion, or within repurposed industrial facilities, would be similar to existing activities at the existing ports, and would support state strategic plans and local land use goals for the development of waterfront infrastructure. BOEM expects that ports would experience long-term beneficial impacts from greater economic activity and increased employment due to demand for vessel maintenance services and related supplies, vessel berthing, loading and unloading, warehousing and fabrication facilities for offshore wind components, and other business activity related to offshore wind. For example, the Port of Albany estimates that development of a new offshore wind tower manufacturing facility would create approximately 500 construction jobs, 355 direct and full-time new manufacturing jobs, and $350 million in new private investment (Port of Albany 2021). Federal, state, and local agencies would be responsible for minimizing the potential adverse impacts of these future port expansions through zoning regulations and permitting planned improvements and in-water work.

If multiple offshore wind energy projects are constructed at the same time and rely on the same ports, this use could stress port resources and could potentially temporarily increase the marine and road traffic, noise, and air pollution in the area during construction activities. Overall, offshore wind projects would have constant, long-term, minor beneficial impacts on port utilization due to the productive use of ports designated for offshore wind activity, as well as localized, short-term, minor impacts in cases where individual ports are stressed due to project activity.

Presence of structures: Planned and ongoing offshore wind projects would add onshore substations, O&M facilities, and overhead or underground transmission connections to the regional power grid. Improvements to coastal infrastructure such as bulkheads or marinas could also be made to support offshore wind activities. BOEM expects that onshore export cables would generally be buried and would not introduce aboveground structures to the geographic analysis area for land use and coastal infrastructure. Onshore substations, O&M facilities, and overhead electric power transmission lines would be sited consistent with local zoning regulations and ordinances or would be required to obtain a zoning change or other relief.

Non-offshore-wind activities, including transmission systems, could have an impact on existing land use and coastal infrastructure. The Sea Girt NGTC and the adjacent area in Manasquan, New Jersey is one of three major landfall locations in the state of New Jersey for transatlantic and subsea fiber optic and telecommunications cables. The sand replenishment of the beach at the Sea Girt NGTC is a federal civil works project. Construction methods such as HDD may be used to avoid or minimize conflicts between existing and planned coastal infrastructure.

Given the existing level of development in the geographic analysis area and that facilities would be sited consistent with local zoning regulations, BOEM anticipates the addition of onshore infrastructure for offshore wind would have negligible impacts on land use. Improvements made to coastal infrastructure such as bulkheads or marinas to support offshore wind activities would have beneficial impacts on land use and coastal infrastructure.

As described in Section 3.6.9, *Scenic and Visual Resources*, visibility of offshore WTGs would vary with distance from shore, topography, and atmospheric conditions. The presence of WTGs would have negligible impacts on land use because, while WTGs could be visible from some shoreline locations in the geographic analysis area, the presence of WTGs would not be expected to change existing land use patterns.

Land disturbance: Construction and installation of onshore substations, O&M facilities, landfalls, buried onshore export cables, and overhead or underground transmission connections to the regional power grid for offshore wind projects would cause land disturbance and associated impacts (e.g., noise) in the geographic analysis area. Land disturbance for installation of landfalls and buried export cables would be temporary, with areas restored to preexisting conditions following construction. BOEM expects that disturbed areas not occupied by new facilities would be revegetated or otherwise stabilized for erosion control in compliance with stormwater permits for general construction. While the impacts from each individual ongoing and planned offshore wind project would be localized, the combined land disturbance from onshore facilities associated with all ongoing and planned offshore wind projects would affect a variety of land uses across the geographic analysis area, resulting in the potential for moderate impacts.

EMF: Onshore export cables in the geographic analysis area would generate EMF during operation of wind farms. Residents and visitors may be exposed to EMF where cables are installed near businesses, residences, or in public areas. Common household items—including television sets, hair dryers, and electric drills—can emit magnetic fields similar to or higher in intensity than those emitted by power cables (CSA Ocean Sciences, Inc. and Exponent 2019). Based on typical EMF values from submarine cables buried at a depth of 3 feet (1 meter), maximum emissions directly above the onshore export cable would not exceed 165 milliGauss. From 10 to 25 feet (3 to 7.5 meters) away from the onshore export cable, emissions values drop to less than 0.1 to 12 milligauss (Ocean Wind 2023). These values are well below the reported human health reference levels of 2,000 milliGauss for the general population (International Commission on Non-ionizing Radiation Protection 2010). Even if other offshore wind export cables were of higher voltage or buried closer to the surface, EMF levels are still anticipated to be well below the human health reference levels; therefore, EMF impacts on land use would be long-term but negligible.

Traffic: Offshore wind projects could result in increased road traffic and congestion that may affect land use and coastal infrastructure because traffic volumes may dictate where residents and businesses choose to locate. Onshore construction of cables for offshore wind projects would likely disrupt road traffic for a short period of time. The exact extent of impacts would depend on the locations of landfall and onshore transmission cable routes for offshore wind energy projects and traffic management plans developed with local governments. Traffic impacts on land use and coastal infrastructure are anticipated to be negligible.

3.6.5.3.3 Conclusions

Impacts of the No Action Alternative. Under the No Action Alternative, land use and coastal infrastructure would continue to be affected by existing environmental trends and ongoing activities, as well as climate change. BOEM expects ongoing activities under the No Action Alternative to have continuing temporary and permanent **minor** impacts on land use and coastal infrastructure.

Cumulative Impacts of the No Action Alternative. BOEM anticipates that the cumulative impacts associated with the No Action Alternative, when combined with all other planned activities (including offshore wind) in the geographic analysis area, would likely be **moderate** and **minor beneficial**. Offshore wind projects would adversely affect land use through land disturbance (during installation of onshore cable and substations), accidental releases during onshore construction, and traffic (depending on landfall locations, onshore routes, and time of year), as well as through the presence of offshore lighting on wind energy structures and views of the structures themselves that could affect the use and value of onshore properties. Beneficial impacts on land use and coastal infrastructure would result from the productive use of ports and related infrastructure designed or appropriate for offshore wind activity.

3.6.5.4 Impacts of Alternative B – No Identification of AMMM Measures at the Programmatic Stage – Land Use and Coastal Infrastructure

3.6.5.4.1 Impacts of One Project

Alternative B considers the potential impacts of future offshore wind development for the NY Bight area without the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts.

Accidental releases: Accidental releases of fuel, fluids, or hazardous materials could occur during construction and installation, O&M, and conceptual decommissioning of one NY Bight project. The representative NY Bight project's SPCC and OSRP would provide for rapid spill response, cleanup, and other measures to minimize any potential impacts from spills and accidental releases. SPCC is required under the Clean Water Act of 1974 and 40 CFR part 112. OSRP is required under the Oil Pollution Act of 1990 and Executive Order 12777. Should accidental releases occur, there could be temporary restrictions placed on the use of affected properties during the cleanup process. Accordingly, BOEM anticipates that accidental releases from one NY Bight project would have localized, short-term, minor impacts on land use.

Lighting: The types of impacts from lighting from one NY Bight project would be the same as described for the No Action Alternative. The construction and O&M lighting from one individual project is not expected to have a substantial impact on land use and coastal infrastructure. Given the existing level of development in the geographic analysis area and that facilities would be sited consistent with local zoning regulations, BOEM anticipates the impact of facility lighting from one NY Bight project would be negligible.

Port utilization: The Brooklyn Navy Yard, South Brooklyn Marine Terminal, Howland Hook Port Ivory, Arthur Kill Terminal, Paulsboro Marine Terminal, New Jersey Wind Port, Port of Albany, and Port of Coeymans have been identified as representative ports that may be used by the NY Bight projects. While one NY Bight project is not anticipated to require port upgrades, some ports have planned improvements to accommodate offshore wind activities across the region, which are described in Appendix D.

Similar to the No Action Alternative, use of ports by one NY Bight project would result in minor beneficial impacts through greater economic activity and increased employment opportunities. The increase in vessel activity during the construction and installation stage for one NY Bight project would be small and would decrease during operations and decommissioning stages. Therefore, construction and installation, O&M, and conceptual decommissioning would have negligible impacts from port utilization on land use and coastal infrastructure.

Presence of structures: BOEM expects that onshore export cables would generally be buried and would not introduce aboveground structures to the geographic analysis area for land use and coastal infrastructure. Onshore substations, O&M facilities, and overhead electric power transmission lines would be sited consistent with local zoning regulations and ordinances or would be required to obtain a zoning change or other relief. Depending on where the facilities are sited, new aboveground infrastructure could result in the long-term conversion of land from existing conditions to a new use for electric power generation and transmission. Due to the scarcity of waterfront properties in the geographic analysis area, especially in the New York City and Long Island region, electrical facilities that are constructed shoreside could be sited on parcels currently within the public trust (e.g., shorelines, parks), which could pose conflicts with public land uses, such as recreation and coastal resilience projects. Based on BOEM's experience with other offshore wind projects in the region, larger electrical facilities (e.g., substations, O&M facilities) are typically sited on previously disturbed areas and industrial locations, and therefore would not result in long-term changes in land use. Given the existing level of development in the geographic analysis area and that facilities would be sited consistent with local zoning regulations, BOEM anticipates the addition of onshore infrastructure for one NY Bight project would have minor, localized impacts on land use. The presence of one individual project's WTGs would have the same impact as under the No Action Alternative and would likely be negligible.

Land disturbance: Onshore components associated with one NY Bight project are anticipated to include a specific transmission POI in New York or New Jersey and an interconnection point to a regional offshore grid substation. Proper erosion and sedimentation controls would be maintained to avoid and minimize unstable soils that could potentially be moved by wind and runoff. HDD is expected to be used at landfall sites to minimize land disturbance near the shoreline. Land disturbance from onshore construction would produce noise that could affect nearby residential or commercial areas, depending on the location of the facilities, but all noise emissions would be required to comply with local or state noise requirements. Given that the geographic analysis area is highly developed, it is unlikely that one NY Bight project would result in substantial development in previously undisturbed areas. As such, impacts on land use and coastal infrastructure from land disturbance of one NY Bight project would be minor.

EMF: The types of impacts from EMF from one NY Bight project would be the same as described for the No Action Alternative. Onshore export cables in the geographic analysis area would generate EMF during operation of one NY Bight project, but EMF values are anticipated to be well below the reported human health reference levels of 2,000 milliGauss for the general population (International Commission on Non-ionizing Radiation Protection 2010). EMF impacts from onshore cable routes on land use and coastal infrastructure would be long term but negligible.

Traffic: Road traffic associated with one NY Bight project is not anticipated to noticeably add to traffic on the local road system and is therefore anticipated to have the same negligible impact as under the No Action Alternative.

3.6.5.4.2 Impacts of Six Projects

The same IPFs described under one NY Bight project apply to six NY Bight projects. There would be the potential for greater impacts from these IPFs due to the greater amount of onshore development. If multiple projects are being constructed at the same time, temporary impacts associated with land disturbance, traffic, and port utilization could be greater than those identified for one NY Bight project. The development of electric infrastructure for six projects could affect a variety of land uses across the geographic analysis area, reducing the availability of land for other uses. Impacts from six NY Bight projects are anticipated to be moderate, but specific impacts will not be known until COPs are developed for each project, where there will be more detailed project information and analysis.

3.6.5.4.3 Cumulative Impacts of Alternative B

The construction and installation, O&M, and conceptual decommissioning of six NY Bight projects would contribute to the land use impacts from ongoing and planned activities in the geographic analysis area. The greatest cumulative impacts would occur if the landfalls and other electrical infrastructure from six NY Bight projects occur in the same location as other offshore wind projects in the geographic analysis area, including in Long Island, New York, for Empire Wind (OCS-A 0512); Monmouth, New Jersey, and Atlantic City, New Jersey, for Atlantic Shores South (OCS-A 0499); Upper Township, New Jersey, and Lacey Township, New Jersey, for Ocean Wind 1 (OCS-A 0498); East Hampton, New York for South Fork Wind (OCS-A 0517); and Brookhaven, New York for Sunrise Wind (OCS-A 0487). The locations of onshore infrastructure for other offshore wind projects in the geographic analysis area are not known at this time. Cumulative impacts would also occur if six NY Bight projects overlap in the use of ports with other offshore wind projects, leading to greater port congestion but also greater economic use and opportunities. In context of reasonably foreseeable environmental trends, BOEM anticipates that the cumulative impacts associated with six NY Bight projects under Alternative B when combined with past, present, and future activities would be moderate and minor beneficial for land use and coastal infrastructure in the geographic analysis area.

3.6.5.4.4 Conclusions

Impacts of Alternative B. Construction and installation, O&M, and conceptual decommissioning of one NY Bight project under Alternative B would likely have **minor** impacts and **minor beneficial** impacts on land use and coastal infrastructure. Six NY Bight projects would likely have **moderate** impacts because of the increased onshore land disturbance and infrastructure as well as **minor beneficial** impacts from port utilization.

Cumulative Impacts of Alternative B. BOEM anticipates that the impacts associated with Alternative B in the geographic analysis area, combined with ongoing and planned activities, would likely result in **moderate** cumulative impacts and **minor beneficial** cumulative impacts on land use and coastal infrastructure. In context of reasonably foreseeable environmental trends, the impacts contributed by Alternative B to cumulative impacts on land use and coastal infrastructure would likely be noticeable, depending on site-specific project component locations relative to coastal infrastructure locations.

3.6.5.5 Impacts of Alternative C (Proposed Action) – Identification of AMMM measures at the Programmatic Stage – Land Use and Coastal Infrastructure

Alternative C, the Proposed Action, considers the potential impacts of future offshore wind development for the NY Bight area with the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts. Alternative C consists of two sub-alternatives: Sub-alternative C1: Previously Applied AMMM Measures, and Sub-alternative C2: Previously Applied and Not Previously Applied AMMM Measures. The analysis for Sub-alternative C1 is presented as the change in impacts from those impacts discussed under Alternative B, and the analysis for Sub-alternative C2 is presented as the change from those impacts discussed in Sub-alternative C1. Refer to Table G-1 in Appendix G, *Mitigation and Monitoring*, for a complete description of AMMM measures that make up the Proposed Action.

3.6.5.5.1 Sub-alternative C1 (Preferred Alternative): Previously Applied AMMM Measures

Sub-alternative C1 analyzes the AMMM measures that BOEM has required as conditions of approval for previous activities proposed by lessees in COPs submitted for the Atlantic OCS or through related consultations. However, BOEM has not identified any previously applied AMMM measures for land use and coastal infrastructure; therefore, the impacts on land use and coastal infrastructure under Sub-alternative C1 are the same as for Alternative B.

3.6.5.5.2 Sub-alternative C2: Previously Applied and Not Previously Applied AMMM Measures

Sub-alternative C2 analyzes the AMMM measures under Sub-alternative C1 plus the application of AMMM measures that have not been previously applied. Under this sub-alternative, these AMMM measures (Table 3.6.5-5) are analyzed in addition to the AMMM measures applied under Sub-alternative C1. However, as BOEM has not identified any previously applied AMMM measures for land use and coastal infrastructure in Sub-alternative C1, analysis in Sub-alternative C2 is presented as the change in impacts from those discussed under Alternative B.

Table 3.6.5-5. Summary of not previously applied avoidance, minimization, mitigation, and monitoring measures for land use and coastal infrastructure

Measure ID	Measure Summary
EJ-1a	This measure proposes requiring a lessee to create an Environmental Justice Communications Plan that will guide a lessee throughout the project life on meaningful engagement, and will propose a process for what, how, and to whom the lessee plans to communicate during activities described in the COP that may affect populations with environmental justice concerns, including construction, operations, and decommissioning. The Environmental Justice Communications Plan must be specifically designed for populations with environmental justice concerns and be created in coordination with, at minimum, organizations that serve these populations. Residents of these populations should be involved in the creation of the plan and will have the opportunity to review the plan and provide feedback.

Impacts of One Project

AMMM measure EJ-1a could minimize some impacts on land use and coastal infrastructure specifically relating to the land disturbance and traffic IPFs. Impacts for other IPFs would remain the same as described under Alternative B. EJ-1a would require lessees to develop an Environmental Justice Communications Plan that describes how the lessee intends to communicate with environmental justice communities during activities including construction, operations, and decommissioning. The Environmental Justice Communications Plan would allow communities to prepare for construction activities and minimize impacts on sensitive land uses, such as residences, near the onshore construction sites.

While some impacts on land use may be minimized with EJ-1a, the extent of the impacts cannot be determined without project-specific information. BOEM does not anticipate this measure would substantively reduce the overall impact for one NY Bight project compared to Alternative B, which is minor, or increase the overall beneficial impact, which is minor.

Impacts of Six Projects

For six NY Bight projects, the AMMM measure EJ-1a would implemented be the same as described for one NY Bight project but would cover a larger geographic area and affect more land uses. AMMM measure EJ-1a would minimize impacts on the land disturbance and traffic IPFs by limiting some construction impacts. Residents would be notified of upcoming construction activities, but they would not avoid the development activities that could temporarily and permanently affect land use patterns in the geographic analysis area. Therefore, the overall impact magnitude is not anticipated to change.

Cumulative Impacts of Sub-alternative C2

Under Sub-alternative C2, the same ongoing and planned activities (including offshore wind) as those under Alternative B would contribute to impacts on land use and coastal infrastructure. The construction and installation, O&M, and conceptual decommissioning for six NY Bight projects with the AMMM measure that has not been previously applied would still cumulatively affect land use across the geographic analysis area, although at a slightly reduced level.

3.6.5.5.3 Conclusions

Impacts of Alternative C. The construction, installation, and decommissioning of one NY Bight project under Sub-alternative C1 and Sub-alternative C2 would likely have **minor** impacts and **minor beneficial** impacts on land use and coastal infrastructure. Six NY Bight projects would likely have **moderate** impacts and **minor beneficial** impacts. AMMM measure EJ-1a may slightly reduce overall impacts (but not change the impact level) on land uses under Sub-alternative C2 by minimizing temporary construction impacts in communities with environmental justice concerns.

Cumulative Impacts of Alternative C. BOEM anticipates that the cumulative impacts on land use and coastal infrastructure under Sub-alternatives C1 and C2 in the geographic analysis area from six NY Bight projects combined with ongoing and planned activities would likely be **moderate** and **minor beneficial**. AMMM measure EJ-1a would reduce overall impacts under Sub-alternative C2, but it would not change the impact level. In context of reasonably foreseeable environmental trends, the impacts contributed by Sub-alternatives C1 and C2 to cumulative impacts on land use and coastal infrastructure would be noticeable.

3.6.5.6 Recommended Practices for Consideration at the Project-Specific Stage

In addition to the AMMM measure identified under Sub-alternative C2, BOEM is recommending lessees consider analyzing the RPs in Table 3.6.5-6 to further reduce potential land use and coastal infrastructure impacts. Refer to Table G-2 in Appendix G for a complete description of the RPs.

Table 3.6.5-6. Recommended Practices for land use and coastal infrastructure impacts and related benefits

Recommended Practice	Potential Benefit
MUL-5: For onshore and offshore project activities and across all phases of construction and operations, use equipment, technology, and best practices that produce the least amount of noise practicable to avoid and minimize noise impacts on the environment.	Using equipment or technology to reduce noise may help prevent noise impacts on certain land uses that may be sensitive to noise, such as residential land use.
REC-1: Prioritize scheduling of nearshore construction activities for outside the summer tourist season, which is generally between Memorial Day and Labor Day.	Scheduling nearshore construction activities outside of the summer tourist season may reduce traffic and noise impacts that would otherwise contribute to the additional tourist traffic and noise.

This page was intentionally left blank.

3.6 Socioeconomic Conditions and Cultural Resources

3.6.8 Recreation and Tourism

This section discusses potential impacts on recreation and tourism resources and activities from the Proposed Action, alternatives, and ongoing and planned activities in the geographic analysis area. The geographic analysis area, as shown on Figure 3.6.8-1, includes a 47.4-mile (76.2-kilometer) buffer around the NY Bight lease areas in the open ocean (corresponding to the maximum potential visibility of the turbine tips), the ocean-facing coastal counties from which the NY Bight projects would be visible, and counties that may be affected by onshore construction activity. Section 3.6.3, *Demographics, Employment, and Economics*, discusses the economic aspects of recreation and tourism in the geographic analysis area.

The recreation and tourism impact analysis in this PEIS is intended to be incorporated by reference into the project-specific environmental analyses for individual COPs expected for each of the NY Bight lease areas. Refer to Appendix C, *Tiering Guidance*, which identifies additional analyses anticipated to be required for the project-specific environmental analysis of individual COPs.

3.6.8.1 Description of the Affected Environment and Future Baseline Conditions

Recreation and tourism play a major role in New York and New Jersey’s environment and economy. Visitors from all over the world travel to the area to partake in a variety of onshore and marine recreational activities. Marine recreational activities include wildlife viewing tours, scuba diving, and recreational fishing and boating. Popular onshore recreational activities include beach going, surfing, golfing, and scenic viewing. In 2016, the economic value of recreation and tourism for New York State in Nassau and Suffolk County accounted for $2.7 billion (gross domestic product [GDP]), and $1.3 billion in wages; while New Jersey’s Ocean County alone resulted in $569 million (GDP), and $288 million in wages within the state (Center for Blue Economy 2016).

3.6.8.1.1 Project Area and Regional Setting

Coastal areas of New York and New Jersey support ocean-based and onshore recreation and tourism activities, such as recreational and for-hire boating and fishing, guided tours, day use of parks and beaches, outdoor sports, and scenic or wildlife viewing. A 2012 BOEM study identified that the counties within the geographic analysis area are susceptible to impacts on their recreation and tourism economies from offshore wind development (BOEM 2012).

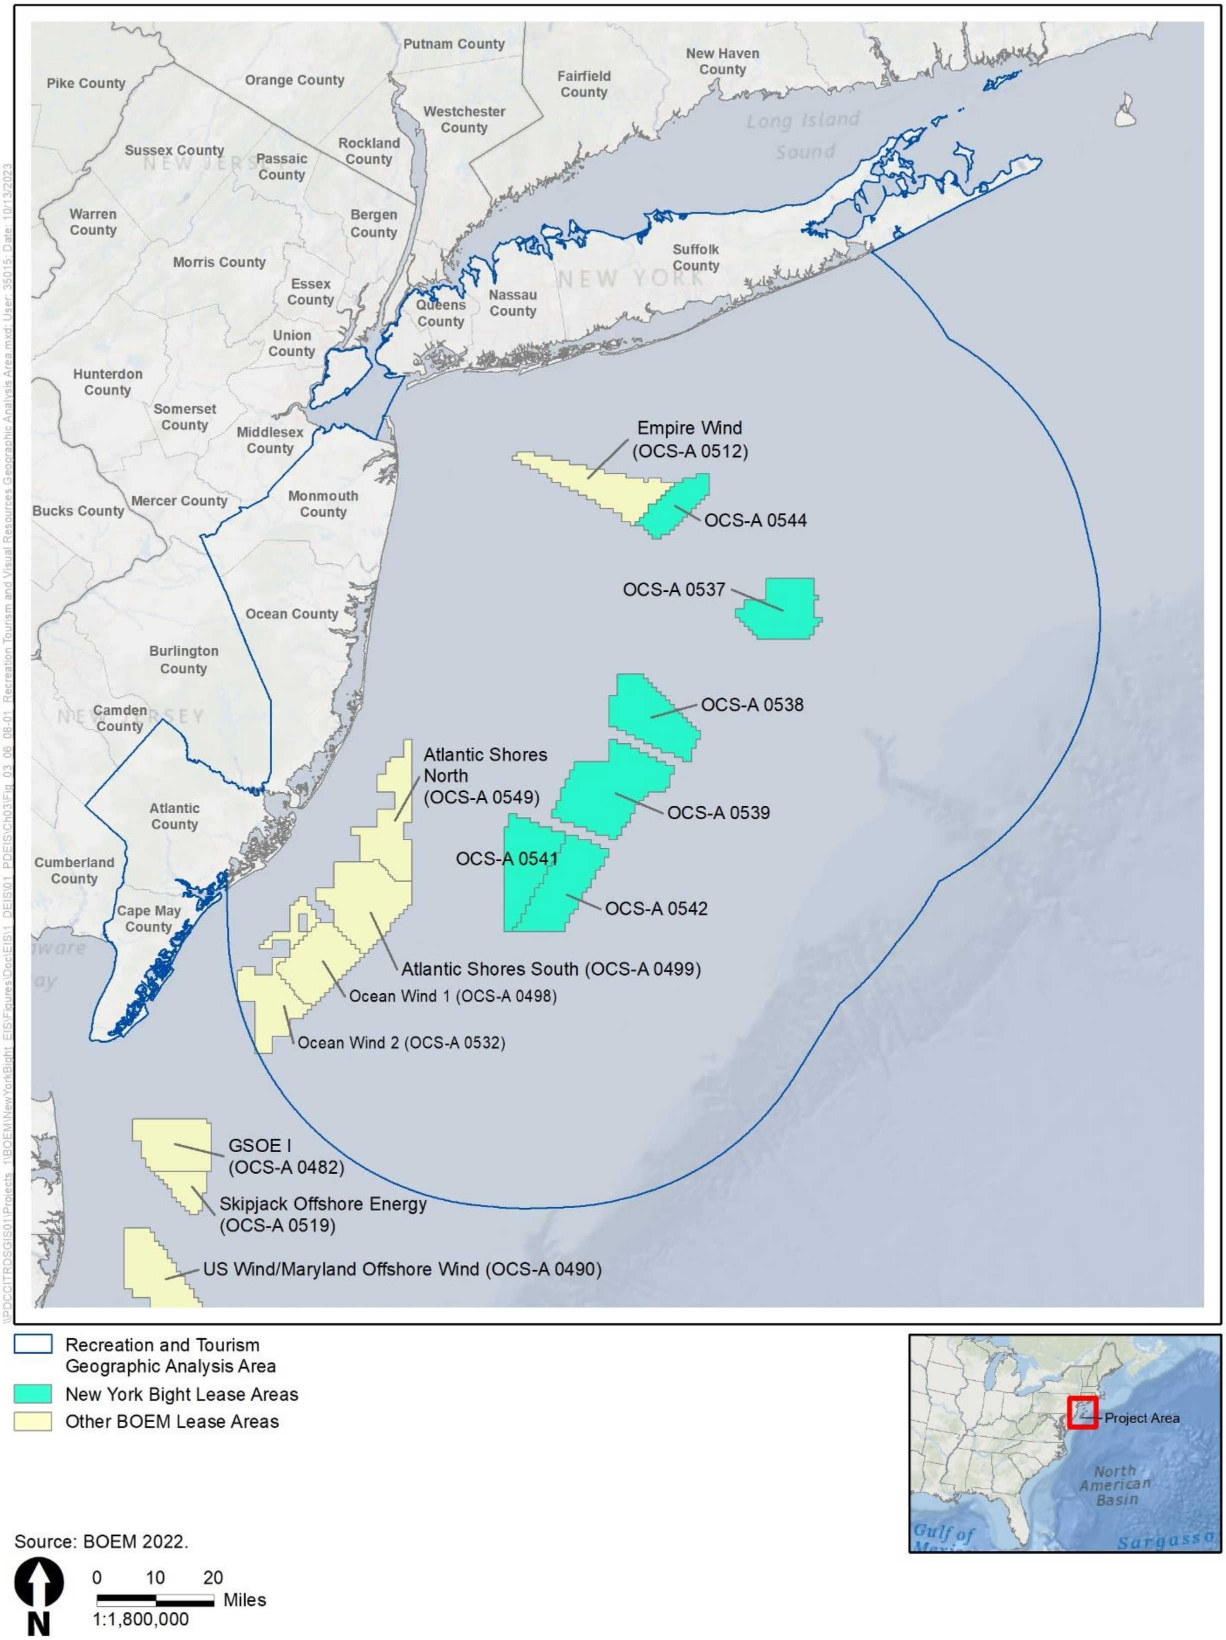

Figure 3.6.8-1. Recreation and tourism geographic analysis area

There are many recreation areas within the geographic analysis area. Though many recreation and tourism opportunities exist in inland portions of coastal counties in New Jersey and New York, this PEIS focuses on areas along the shoreline that have shown a greater dependency on coastal resources. The coastal areas support ocean-based and onshore activities, entertainment, and accommodation, as well as food services related to recreation and tourism. Given the proximity to the Atlantic Ocean, the geographic analysis area has a wide range of characteristics, with communities and landscapes ranging from large cities to small towns, suburbs, rural areas, and wildlife preserves. These coastal areas and shore communities have been extensively developed for water-based recreation and tourism.

The scenic quality of the coastal environment is important to the identity, attraction, and economic health of many coastal communities. Additionally, the recreational and entertainment aspect of outdoor activity on these beaches, within parks, and new and historic coastal towns are important community characteristics. The coastal and ocean amenities, such as beaches, birdwatching, connected trails, and onshore and offshore recreational fishing, are accessible to residents and tourists (whether free or for fee) and function as key drivers for recreation and tourism businesses. Recreational by-product businesses include food, security, water safety, housing, and entertainment.

Given the regional importance and unique attributes of recreational fishing compared to the other types of recreation and tourism, the following discussion is separated into two categories: recreation and tourism, and recreational fishing. Refer to Section 3.6.1, *Commercial Fisheries and For-Hire Recreational Fishing*, for analysis of commercial fisheries and for-hire recreational fishing.

3.6.8.1.2 Recreation and Tourism

Recreation and tourism contribute substantially to the economies of New York and New Jersey's coastal counties. Counties within the geographic analysis area accounted for $29 billion and $4 billion in GDP, respectively, for New York and New Jersey, which represented 89 percent and 56 percent of their entire state's ocean industry economy (NOAA 2022c). In 2019, 265.5 million people visited New York and spent about $73.6 billion, leading to a $117.6 billion total economic impact through tourism (Empire State Development n.d.). Appendix B, *Supplemental Information and Additional Figures and Tables,* Section B.6 describes recreational resources for each county in the geographic analysis area.

There are numerous federal, state, and local recreational areas and recreational trails within the geographic analysis area. Otis Pike Fire Island High Dune Wilderness, a 7-mile stretch of undeveloped barrier island on Fire Island, is the only federally designated wilderness area within the state of New York. Recreation features within the wilderness area include hiking trails, backcountry camping opportunities, fishing, and scenic views and abundant wildlife that attract bird watchers and wildlife viewers. The Gateway National Recreation Area includes three units: the Jamaica Bay Unit (Jamaica Bay and surrounding properties in Brooklyn and Queens including the western end of the Rockaway Peninsula), the Staten Island Unit (Fort Wadsworth, Miller Field, and Great Kills), and the Sandy Hook Unit (the Sandy Hook peninsula). The Gateway National Recreation Area provides visitors green spaces and beaches alongside historic structures and cultural landscapes and provides space for recreation activities such as boating, bicycling, bird watching, archery, camping, fishing, and guided tours.

Recreational trails for biking, birding, dog walking, fishing, inline skating, and walking (with wheelchair accessibility) also exist within the geographic analysis area. Some of these align with beaches, marinas, and national recreational areas, such as the Ocean Parkway Coastal Greenway in New York and the Sandy Hook Multi-Use Pathway in New Jersey.

Beaches are valuable assets for recreation and tourism. Those beaches regarded as undeveloped are important tourist destinations and are often valued for their remoteness (Peregrine Energy Group 2008) and as such may be sensitive to the visual impacts of offshore wind facilities. The National Park Service Atlantic and Gulf Coast Recreation Area Survey reported that in 2007 there were only two undeveloped beaches in the geographic analysis area of New Jersey: Brigantine Inlet North and Absecon Inlet, which are both in Atlantic County (NPS 2007). Of the three New York State Park Beaches (Hoboken, Wildwood, and Jones Beach), only Jones Beach State Park has a direct line of sight to the NY Bight lease areas (NYSERDA 2021). Further, within the last 10 years storms have ravaged areas in and outside of the geographic analysis area, where coastal restoration is ongoing (NY DEC 2022; NJ DEP 2022). Coastal ecosystem and habitat restoration activity, including beach and dune nourishment projects, support recreational opportunities along the New Jersey and New York coastline. In the geographic analysis area, the relatively few remaining undeveloped beaches, combined with a predominantly developed coast, indicates a tolerance or acceptance of coastal development in most coastal communities. Where wetlands plantings are in place to preserve open spaces and improve environmental quality, project-specific NEPA analyses will address potential impacts and ensure compliance with rigorous local controls. Development will likely avoid disturbances in those areas.

Ocean water-oriented recreational activities include boating, jet skiing, beach going, hiking, fishing, shell fishing, and bird and wildlife viewing. New York and New Jersey are identified as within the top five states with the largest contributions to marine-based recreation and tourism employment, and New York is within the top five states contributing to GDP related to marine-based recreation and tourism (NOAA n.d.). Recreation and tourism contribute approximately 90 percent of employment in the ocean sector economy for New York counties in the geographic analysis area and 58 percent in New Jersey counties analyzed (NOAA 2022c) (see Figures 3.6.3-4 and 3.6.3-5 in Section 3.6.3).

Many water-oriented recreational activities in the geographic analysis area include boating. Boating covers a wide range of activities, from the use of ocean-going vessels to small boats used by residents and tourists in sheltered waters, and includes sailing, fishing, shell fishing, kayaking, canoeing, and paddleboarding. Commercial businesses offer rentals of canoes and kayaks, and private charter boats for recreation, fishing, and wildlife viewing. Many of the activities make use of coastal and ocean amenities that are free for public access. Nonetheless, these features function as key drivers for many coastal businesses, particularly those within the recreation and tourism sectors.

Offshore wildlife viewing in charter boats, such as bird and whale watching, is particularly popular off the New York and New Jersey coasts and in the New York Harbor between spring and fall due to migrations. Chartered bird-watching tours occur at New York Harbor during the winter months, while whale watching occurs at New York Harbor and throughout the NY Bight area, especially during the summer months (NYSERDA 2017). Year-round bird watching occurs in areas off the coast of Long Island near Jones Inlet, the waters off Fire Island Inlet, and Moriches Inlet. Another wildlife viewing area stretches over 60 nautical miles from Jones Inlet to Hudson Canyon and is used by charter vessels specifically for pelagic bird watching during the winter (NYSDOS 2022). New York's whale watching operations are concentrated in three general use areas: outside of New York Harbor, south of Long Island, and east of Montauk. Tours are primarily scheduled from spring through fall, typically peaking in June, July, and August, with some New York-based tour companies offering cruises year-round (NYSDOS 2022). The New York State Department of Environmental Conservation has instituted a New York Bight Whale Monitoring Program that extends south from Long Island to the Outer Continental Shelf, within which this tourism activity occurs (NYSDEC n.d.).

Surface-based marine recreational activities popular along the New York coastline, particularly during the summer, include swimming, surfing, kayaking, paddle boarding, windsurfing, and kite boarding. Surfing usually occurs all along Long Island in New York down the Jersey Shore to Cape May (NJ Beaches 2023). Surfing can occur year-round, with the prime season in the fall. Surfers frequent several towns and cities along the coastline, including Ocean City and Atlantic City. Swimming is popular during the summer months along the miles of white sand beaches (New Jersey Department of State 2021a). Underwater recreation happens throughout the year in New York and New Jersey, but it is most popular between May and October. These activities take place from Long Island to Cape May at sites that include shipwrecks, artificial reefs, beach dives, and various inland sites. The sailing season typically runs from May to October in New Jersey (New Jersey Department of State 2021b) and primarily occurs in relatively small areas within the bays and inlets and just along the coastline (NJ DEP 2021; Ocean Wind 2022).

3.6.8.1.3 Recreational Fishing

There is a large and robust recreational fishing industry in New York and New Jersey. Figure 3.6.1-22 in Section 3.6.1, *Commercial Fisheries and For-Hire Recreational Fishing,* depicts popular for-hire recreational fishing areas offshore New York and New Jersey relative to the six NY Bight lease areas. The *Fisheries Economics of the United States Report of 2019* estimates that recreational fishing had a $309 million impact on New York's economy and a $388 million impact on New Jersey's economy in 2019 (NOAA 2022a). In 2019, there were a reported 13.4 million recreational fishing trips in New York and 13.3 million in New Jersey (NOAA 2022a). BOEM estimates approximately 8.6 million recreational fishing trips are made from New York and New Jersey into the NY Bight area (BOEM 2018). Popular recreational saltwater species in the waters off the NY Bight area are primarily caught from May to October, with seasonal extensions from April to November. Annually, national and regional saltwater fishing tournaments in New York and New Jersey target a variety of fish including stripers, fluke, bluefish, black drum, weakfish, northern kingfish, sea bass, tautog, tuna, and shark (NJDEP 2018a). According to NOAA Fisheries One Stop Shop database, recreational anglers off the coast of New York and New Jersey caught 33,322,544 and 21,344,901 pounds of fish, respectively, in 2019 (NOAA n.d.).

NMFS provides statewide annual marine fishing trip (effort) data for New York for 2022. The shore fishing mode accounted for 1,487,534 trips, the party boat mode for 117,214 trips, the charter boat mode for 73,782 trips, and the private/rental boat mode for 1,647,971 trips, for a total of 3,326,501 recreational fishing trips (NMFS 2023). For New Jersey's annual marine fishing trips for 2022, shore fishing mode accounted for 4,265,032 trips, the party boat mode for 101,309 trips, the charter boat mode for 105,540 trips, and the private/rental boat mode for 2,122,013 trips, for a total of 6,593,894 recreational fishing trips (NMFS 2023). For comparison, NMFS reports inland recreational fishing trips in New York totaled nearly 13 million (80 percent of total trips) while inland fishing trips in New Jersey totaled less than 8 million (54% of total trips).

NOAA's social indicator mapping identifies the importance or level of dependence of recreational fishing to coastal communities (NOAA 2022b). Several communities in the geographic analysis area have a high recreational fishing reliance, which measures the presence of recreational fishing in relation to the population size of a community, and high recreational fishing engagement, which measures the presence of recreational fishing through fishing activity estimates. The communities with the highest recreational fishing reliance and recreational fishing engagement would be most affected by impacts on recreational fishing from offshore wind development.

Recreational crabbing is also important to the region and occurs primarily along the bays and creeks on the Jersey Shore, especially in the upper portions of Barnegat Bay, Little Egg Harbor, and the Maurice River estuary, which contribute 65 to 86 percent of the total recreational harvest (NJDEP 2018b). The peak crabbing season occurs from mid-June until early October and is especially good in August.

3.6.8.2 Impact Level Definitions for Recreation and Tourism

Definitions of adverse impact levels are provided in Table 3.6.8-1. Beneficial impacts on recreation and tourism are described using the definitions described in Section 3.3.2 (see Table 3.3-1).

Table 3.6.8-1. Adverse impact level definitions for recreation and tourism

Impact Level	Definition
Negligible	There would be no measurable impacts, or impacts would be so small that they would be extremely difficult or impossible to discern or measure.
Minor	Impacts would not disrupt the normal functions of the affected activities and communities.
Moderate	The affected activity or community would have to adjust somewhat to account for disruptions due to the project.
Major	The affected activity or community would experience unavoidable disruptions due to large local or notable regional adverse impacts of offshore wind development.

Anchoring, cable emplacement and maintenance, land disturbance, lighting, noise, presence of structures, and traffic are contributing IPFs to impacts on recreation and tourism. However, the IPFs described may not necessarily contribute to each individual issue outlined in Table 3.6.8-2.

Table 3.6.8-2. Issues and indicators to assess impacts on recreation and tourism

Issue	Impact Indicator
Changes to recreation and tourism access and opportunity	Qualitative assessment of changes to the following: • Vehicle/vessel traffic volume • Viewshed • Navigation hazards • Access restrictions
Changes to recreational fishing	Qualitative assessment of impacts on the following: • Loss or damage to fishing gear • Change in distribution and catch of target species • Loss of recreational fishing access sites • Impacts on recreational fishing businesses and expenditures

3.6.8.3 Impacts of Alternative A – No Action – Recreation and Tourism

When analyzing the impacts of the No Action Alternative on recreation and tourism, BOEM considered the impacts of ongoing activities, including ongoing non-offshore-wind and ongoing offshore wind activities on the baseline conditions for recreation and tourism. The cumulative impacts of the No Action Alternative considered the impacts of the No Action Alternative in combination with other planned non-offshore and offshore wind activities, which are described in Appendix D, *Planned Activities Scenario*.

3.6.8.3.1 Impacts of the No Action Alternative

Under the No Action Alternative, baseline conditions for recreation and tourism described in Section 3.6.8.1, *Description of the Affected Environment and Future Baseline Conditions*, would continue to follow current regional trends and respond to IPFs introduced by other ongoing non-offshore-wind activities. Ongoing non-offshore-wind activities within the geographic analysis area include ongoing vessel traffic; recreational and commercial fishing; noise and trenching from periodic maintenance or installation of piers, pilings, seawalls, and offshore cables; and onshore development activities. Ongoing activities would contribute to impacts on recreation and tourism through the primary IPFs of anchoring, land disturbance, lighting, cable emplacement and maintenance, noise, presence of structures, and vessel traffic. These activities would contribute to periodic disruptions to recreation and tourism activities but are a typical part of daily life along the New York and New Jersey coastlines and would not substantially affect recreational enjoyment in the geographic analysis area. Visitors would continue to pursue activities that rely on the area's coastal and ocean environment, scenic qualities, natural resources, and establishments that provide services for recreation and tourism. Ongoing offshore wind activities within the geographic analysis area that contribute to impacts on recreation and tourism include ongoing construction of Ocean Wind 1 (OCS-A 0498) and Empire Wind 1 and 2 (OCS-A 0512). Ongoing construction of Ocean Wind 1 and Empire Wind 1 and 2 would have the same type of impacts on recreation and tourism that are described in Section 3.6.8.3.2, *Cumulative Impacts of the No Action Alternative*, for all ongoing and planned offshore wind activities in the geographic analysis area.

3.6.8.3.2 Cumulative Impacts of the No Action Alternative

The cumulative impact analysis for the No Action Alternative considers the impacts of the No Action Alternative in combination with other planned non-offshore-wind activities and planned offshore wind activities (without the NY Bight projects). Planned non-offshore-wind activities that would contribute to periodic disruptions to recreation and tourism activities include tidal energy projects, military use, dredge material disposal, and sand borrowing operations; increased vessel congestion that can pose a risk for collisions or allisions; dredging and port improvements, marine transportation, and oil and gas activities; or activities that pose a risk for gear entanglement such as undersea transmission lines, gas pipelines, and other submarine cables. See Appendix D for a description of planned activities. Like ongoing activities, other planned non-offshore-wind activities may result in periodic disruptions to recreation and tourism activities along the coast. However, visitors are expected to be able to continue to pursue activities that rely on other coastal and ocean environments, scenic qualities, natural resources, and establishments that provide services to recreation and tourism.

Ongoing and planned offshore wind projects in the geographic analysis area are listed in Table 3.6.8-3.

Table 3.6.8-3. Ongoing and planned offshore wind projects in the geographic analysis area for recreation and tourism

Ongoing/Planned	Projects by Region
Ongoing – 3 projects[1] 	**NY/NJ** • Ocean Wind 1 (OCS-A 0498) • Empire Wind 1 (OCS-A 0512) • Empire Wind 2 (OCS-A 0512)
Planned – 3 projects[2] 	**NY/NJ** • Ocean Wind 2 (OCS-A 0532) • Atlantic Shores North (OCS-A 0549) • Atlantic Shores South (OCS-A 0499)

NJ = New Jersey; NY = New York
[1] Refer to footnotes 9 and 10 in PEIS Chapter 1 for additional information on the status of Ocean Wind 1, Empire Wind 1, and Empire Wind 2.
[2] Status as of September 20, 2024.

BOEM expects ongoing and planned offshore wind activities to affect recreation and tourism through the following IPFs.

Anchoring: Anchoring could potentially affect recreational boating in the geographic analysis area both through the presence of an increased number of anchored vessels during offshore wind construction and installation, O&M, and conceptual decommissioning and through the creation of offshore areas with cable or scour protection where anchors of smaller recreational vessels may fail to hold.

Development of offshore wind projects would increase the number of vessels anchored offshore, particularly in offshore work areas during construction and installation. Vessel anchoring would also occur during O&M but at a reduced frequency. Anchored vessels for offshore wind projects would have localized, intermittent, long-term impacts on recreational boating.

Ongoing and planned offshore wind projects would add scour protection for WTGs and would create offshore areas with cable hardcover, which could create resistance to anchoring for recreational boats. Scour and cable protection would have localized, long-term impacts on anchoring for recreational boats. BOEM expects that recreational boaters could navigate around anchored vessels and adjust their locations to avoid cable and scour protection issues with brief inconveniences; therefore, impacts would likely be minor.

Land disturbance: Ongoing and planned offshore wind development would require installation of landfalls, onshore export cable and interconnection cable, and onshore substations, which could result in localized, temporary disturbance to recreational activity or tourism-based businesses near construction sites. BOEM expects these impacts would be localized and temporary during construction and installation, and O&M and conceptual decommissioning impacts would be reduced. The exact extent of impacts would depend on the specific locations chosen for offshore wind projects; however, the impacts would generally be localized, temporary, and minor.

Lighting: Offshore wind projects would add new sources of light to onshore and offshore areas including from nighttime vessel lighting and fixed lighting at onshore substations. BOEM expects that lighting at onshore substations would have negligible impacts on recreation and tourism as onshore lighting is a prevalent feature along the New York and New Jersey coast. Impacts of vessel lighting would be temporary for the duration that the vessel is engaged in construction and installation, O&M, or conceptual decommissioning activities. WTGs would be lit and marked in accordance with FAA and USCG requirements for aviation and navigation obstruction lighting, respectively. The lighting on WTGs would be visible from beaches and coastlines within the geographic analysis area and could have long-term impacts on recreation and tourism in certain locations if the lighting influences visitor decisions in selecting coastal locations to visit. The implementation of ADLS would activate a hazard lighting system in response to detecting nearby aircraft and, if ADLS is implemented, would result in shorter-duration night sky impacts on the seascape, landscape, and viewers relative to the WTG lighting.

The New York and New Jersey shores within the viewshed of ongoing and planned offshore wind projects have been extensively developed, and existing nighttime lighting is prevalent. Elevated boardwalks, jetties, and seawalls afford greater visibility of offshore elements for viewers in tidal beach areas. Nighttime views toward the ocean from the beach and adjacent inland areas are diminished by ambient light levels and glare of shorefront developments. Visible aviation warning lighting would add a developed/industrial visual element to views that were previously characterized by dark, open ocean, broken only by transient lighted vessels and aircraft passing through the view. As a result, although lighting on WTGs would have a continuous, long-term, adverse impact on recreation and tourism, the impact in the geographic analysis area is likely to be limited to individual decisions by visitors to the New York and New Jersey coastline and elevated areas, with less impact on the recreation and tourism industry as a whole. Lighting impacts on recreation and tourism are anticipated to be negligible due to the distance of the offshore wind development projects from shore and the use of ADLS.

Cable emplacement and maintenance: An estimated 3,094 miles (4,979 kilometers) of submarine export cable and interarray cable would be installed in the geographic analysis area between 2023 and 2030 for ongoing and planned offshore wind projects. Offshore cable emplacement for offshore wind development projects would have temporary, localized, adverse impacts on recreational boating while cables are being installed, because vessels would need to navigate around work areas and recreational boaters would likely prefer to avoid the noise and disruption caused by installation. Cable installation could also have temporary impacts on fish and invertebrates of interest for recreational fishing, due to the required dredging, turbulence, and disturbance; however, species would recover upon completion. The degree of temporal and geographic overlap of each cable is unknown, although cables for some projects could be installed simultaneously. Active work would only occur over the cable segment being emplaced at a given time. Once installed, cables would affect recreational boating only during maintenance operations, except that the mattresses covering cables in hard-bottom areas could hinder anchoring and result in gear entanglement or loss. Impacts of cable emplacement and maintenance on recreational boating and tourism would be short term, continuous, adverse, and localized. Disruptions from cable emplacement and maintenance are anticipated to have a minor impact on recreation and tourism.

Noise: Noise during construction (e.g., from pile-driving) or vehicle/vessel traffic could result in adverse impacts on recreation and tourism. Onshore construction noise near beaches, parkland, recreation areas, or other areas of public interest would temporarily disturb the public's quiet enjoyment. Offshore construction noise could cause boaters to avoid construction areas, although safety zones that USCG may establish for construction areas would be off-limits to boaters. Noise from operational WTGs would be expected to have little effect on finfish, invertebrates, and marine mammals, and consequently little effect on recreational fishing or sightseeing.

Adverse impacts of noise, especially from pile-driving, would also affect recreation and tourism due to impacts on species important to recreational fishing and sightseeing. Using information from the Ocean Wind 1 COP, noise from pile-driving, the noisiest aspect of WTG installation, is estimated to be 101 A-weighted decibels (dBA) at 50 feet (COP Volume III, Appendix R-1, Section 2.5; Ocean Wind 2022). Most recreational fishing takes place closer to shore, so construction of WTGs or OSSs would affect only a small proportion of recreational fishing. Temporary impacts from offshore construction noise will more likely affect recreational fishing for offshore species (e.g., tuna, shark, and marlin). Offshore construction noise also could contribute to temporary impacts on marine mammals, with resulting impacts on chartered tours for whale watching or other wildlife viewing. BOEM qualitatively analyzed impacts on recreational fisheries in the Atlantic OCS region during the offshore construction phase and found slightly negative to neutral impacts on recreational fisheries from both direct exclusion of fishing activities and displacement of mobile target species by construction noise (Tougaard 2008).

BOEM expects that offshore wind construction would result in localized, temporary impacts on recreational fishing and marine sightseeing related to fish and marine mammal populations. If multiple offshore wind construction projects are constructed concurrently, this would increase the spatial extent of temporary disturbances to marine species but would also decrease the temporal extent of these impacts. No long-term, adverse impacts are anticipated, provided that mitigation measures are implemented to prevent population-level harm to fish and marine mammal populations.

Presence of structures: The construction and installation of 697 WTGs within the recreation and tourism geographic analysis area would have long-term, adverse impacts on recreational boating and fishing through the risk of allision; risk of gear entanglement, damage, or loss; navigational hazards; space use conflicts; presence of cable infrastructure; and visual impacts. However, ongoing and planned offshore wind structures could potentially increase the number of trips and revenue by creating new locations for recreational or for-hire fishing through fish and sea turtle attraction and reef effects by creating hard-bottom habitat known to attract numerous species of algae, shellfish, finfish, and sea turtles and result in increased recreational boaters traveling farther from shore.

The presence of offshore wind structures would increase the risk of allision and the complexity of navigation within the geographic analysis area. Generally, smaller vessels moving within and near wind farm installations, such as recreational vessels, are at a greater risk of allisions with WTGs or OSSs. Offshore wind development could require recreational boaters, anglers, sailboat races, and sightseeing boats to adjust their routes. Recreational boating routes in the NY Bight area mainly occur within 3 nautical miles (5.5 kilometers) of the coastline (NY State Parks n.d.). Thus, the impact of these offshore structures would be limited by their farther distances from shore.

As it relates to the visual impacts of structures, the vertical presence of WTGs on the offshore horizon may affect recreational experience and tourism in the geographic analysis area. Section 3.6.9, *Scenic and Visual Resources*, describes the visual impacts from offshore wind infrastructure. A study conducted by Parsons and Firestone (2018) suggests that WTGs visible from more than 15 miles (24.1 kilometers) away would have negligible effects on businesses dependent on recreation and tourism activity. At this distance, the percentage of respondents who indicated that their experience would be improved by the presence of WTGs was the same as the percentage of respondents who indicated that their experience would be worsened by the WTGs. The study found proximity of WTGs to shore is correlated to the number of respondents who would expect a worsened coastal experience (Parsons and Firestone 2018). However, the majority of respondents (68 percent) indicated that the visibility of WTGs would neither improve nor worsen their experience. Respondents were shown a visual simulation for this survey, and it should be noted that the turbines depicted were smaller than those proposed for the NY Bight area. Reported trip loss (respondents who stated that they would visit a different beach without offshore wind) averaged 8 percent when wind projects were 12.5 miles (20 kilometers) offshore and 6 percent when 15 miles (24.1 kilometers) offshore. Within the geographic analysis area, while some WTGs associated with ongoing and planned offshore wind projects would be within 10 miles (16 kilometers) of shore, the majority of WTGs would be more than 15 miles (24.1 kilometers) from coastal locations.

Carr-Harris and Lang (2019) assessed the potential impacts of offshore wind energy development on tourism by examining how the Block Island Wind Farm has impacted the vacation rental market. Using data from Airbnb, they compared three nearby tourist destinations in Southern New England before and after construction. The results suggest that construction of the Block Island Wind Farm caused a significant increase in nightly reservations, occupancy rates, and monthly revenues for Airbnb properties during the peak tourism months of July and August but had no effect in other months. The findings indicate that offshore wind farms can act as an attractive feature of a location, rather than a deterrent.

In a 2020 survey-based study, 11.4 percent of participants indicated that they would tour offshore wind facilities 12.5 miles (20 kilometers) offshore (Parsons et al. 2020), but the number of participants decreases as structures move farther offshore. A majority of respondents who would make the trip expect it to be a one-time trip. Although the likelihood of recreational vessels visiting offshore structures decreases with distance from shore, increasing numbers of offshore structures may create increased recreational vessel traffic to these structures. Additional vessel traffic from these fishing and tourism activities would increase the chance of allisions and collisions among recreational, sightseeing, or commercial vessels.

A 2019 survey of over 500 New Hampshire coastal recreation users found 77 percent support for offshore wind development, 12 percent opposition, and 11 percent neutral. Regarding the impact on their outdoor recreation experience, 43 percent anticipated a beneficial impact, 31 percent anticipated a neutral impact, and 26 percent anticipated an adverse impact (Tourism Economics 2019; BOEM 2021).

Additionally, a 2020 survey-based preference study to determine attitude toward offshore wind and if the presence of offshore wind turbines affects the number of trips a beachgoer makes to the beach found that developed beaches with boardwalks and beaches that were designated as local, state, or national parks had the lowest amount of reported trip cancellation (Parsons et al. 2020). Because many of New Jersey's and New York's most visited beaches are quite developed, long-term impacts on recreation and tourism are not expected. The beachgoers at local, state, or national park beaches self-reported as more favorable toward wind power and correspondingly appeared less inclined to cancel a trip due to the presence of wind turbines.

Based on currently available studies and the distance of ongoing and planned offshore wind projects from shore, BOEM anticipates that the WTGs associated with ongoing and planned offshore wind projects in the geographic analysis area could have a minor adverse impact on recreation and tourism when discernible in previously undeveloped views. The impact of visible WTGs on recreation would be long term and continuous. However, Parsons and Firestone (2018) found that beyond 15 miles (24.1 kilometers) from shore, the percentage of people who responded negatively vs. positively to seeing offshore wind infrastructure was nearly equal. In addition, beneficial impacts due to the presence of offshore structures could provide opportunities for fishing and sightseeing due to a reef effect.

Traffic: Offshore wind project construction and conceptual decommissioning and, to a lesser extent, offshore wind project operation would generate increased vessel traffic that could inconvenience recreational vessel traffic. The impacts would occur primarily during construction, along routes between ports and offshore wind construction areas. Vessel traffic for each project is not known but is anticipated to result in a small increase in current vessel traffic for the NY Bight area. BOEM expects that vessel traffic would have minor impacts on recreation and tourism.

3.6.8.3.3 Conclusions

Impacts of the No Action Alternative. Under the No Action Alternative, recreation and tourism would continue to be affected by existing environmental trends and ongoing activities. The impacts of ongoing activities, including ongoing construction of offshore wind, ongoing vessel traffic, presence of structures, and the noise and trenching from periodic maintenance or installation of piers, pilings, seawalls, or offshore cables, would be **negligible** to **minor**.

Cumulative Impacts of the No Action Alternative. Under the No Action Alternative, existing environmental trends and ongoing activities would continue, and recreation and tourism would continue to be affected by the primary IPFs of anchoring, land disturbance, lighting, cable emplacement and maintenance, noise, presence of structures, and vessel traffic. The impacts of planned non-offshore-wind activities would be similar to the impacts of ongoing, non-offshore-wind activities. Impacts on recreation and tourism from planned offshore wind activities would be long term, localized, and negligible for lighting; long term, localized, and minor from anchoring and from presence of structures; and short term, localized, and minor due to land disturbance, noise, traffic, and cable emplacement and maintenance. Planned offshore wind activities in the analysis area would likely also result in minor beneficial impacts due to the presence of offshore structures, which could provide opportunities for fishing and sightseeing due to a reef effect. Overall, the No Action Alternative combined with all planned activities in the geographic analysis area would likely result in **negligible** to **minor** impacts and **minor beneficial** impacts on recreation and tourism.

3.6.8.4 Impacts of Alternative B – No Identification of AMMM Measures at the Programmatic Stage – Recreation and Tourism

Alternative B considers the potential impacts of future offshore wind development for the NY Bight area without the AMMM measures identified in Appendix G, *Mitigation and Monitoring,* that could avoid, minimize, mitigate, and monitor those impacts.

3.6.8.4.1 Impacts of One Project

Anchoring: Construction and installation, O&M, and conceptual decommissioning of a single NY Bight project would increase the number of vessels anchored offshore and would require the addition of scour protection for WTG foundations and cable protections. Anchored vessels for construction and installation, O&M, and conceptual decommissioning of one NY Bight project would have localized, intermittent, temporary impacts on recreational boating. The addition of scour and cable protection would have localized, long-term impacts on anchoring for recreational boats. BOEM expects that recreational boaters could navigate around anchored vessels and adjust the locations for dropping anchor to avoid cable and scour protection with only brief inconvenience. The anticipated impacts from anchoring on recreation, tourism, or recreational fishing in the geographic analysis area for one NY Bight project would be minor.

Land disturbance: One NY Bight project would require one or more cable landfall(s), onshore export cabling, possible substation and converter station construction, and support service facilities, resulting in vehicle traffic, noise, and construction sites that could reduce visitor enjoyment and temporarily restrict access to recreational sites. Impacts associated with construction of onshore elements would be most likely to occur if construction activities take place during the tourism high season (generally May through September) and disrupt access to recreation areas or create disruptive noise. The disruption would likely be localized and temporary so impacts would be minor. While direct disturbance to recreational sites (e.g., beaches, parks) is possible, BOEM anticipates popular recreational areas would likely be avoided and any impacts, if they did occur, would be temporary. Site-specific project information is needed to fully analyze the extent of impacts on recreational sites.

Lighting: One NY Bight project would add new sources of onshore and offshore light, including nighttime vessel lighting, fixed lighting at onshore substation/converter station sites, and at up to 280 WTGs and up to 5 OSSs. As described for the No Action Alternative, lighting at onshore substations/converter stations is anticipated to have a negligible impact on recreation and tourism because onshore lighting is already a prevalent feature along the New York and New Jersey coast.

Because of the distance from shore (the NY Bight lease area nearest to shore is 20 nautical miles [37 kilometers] offshore, lighting on the WTGs and OSS is not anticipated to have a substantial effect on views. However, as described in Section 3.6.9, *Scenic and Visual Resources*, in the absence of an ADLS system, there would be new, constant sources of nighttime lighting in view of the coastline for the NY Bight project. Nighttime lighting could have long-term impacts on recreation and tourism if the lighting influences visitor decisions in selecting coastal locations to visit. The addition of a single project in the NY Bight area would result in long-term, minor impacts on recreation and tourism, primarily as a result of offshore lighting on WTGs and OSS.

Cable emplacement and maintenance: The development of one NY Bight project would result in seafloor disturbance due to the installation of interarray and export cables. Cable emplacement could prevent deployment of fixed and mobile fishing gear in limited parts of the NY Bight area from one day up to several months (if simultaneous lay and burial techniques are not used), which may result in the loss of access if alternative fishing locations are not available. Impacts would be greatest if cables are installed in areas of high recreational fishing activity, as shown on Figure 3.6.1-22. Activities from support vessels, cable emplacement, and routine or emergency maintenance repairs would temporarily impact access to some areas. Overall, cable emplacement and maintenance would not restrict large areas, and navigational impacts on recreational fishing grounds would be on the scale of hours to days. Cable emplacement and maintenance as a result of a single NY Bight project would likely result in localized and temporary minor adverse impacts on recreation and tourism.

Dredging and turbulence during cable installation could also affect fish and marine mammals of interest for recreational fishing and sightseeing, although species would recover upon completion (Section 3.5.7, *Sea Turtles*, and Section 3.5.6, *Marine Mammals*), resulting in localized, short-term, minor impacts on recreation and tourism. Cable emplacement and maintenance that occur near beaches, fishing sites, or nearshore recreational activities could contribute to recreational impacts related to temporary water quality impacts during construction and maintenance. As discussed in Section 3.4.2, *Water Quality*, impacts on water quality from cable installation and maintenance would be short term and minor and are therefore not anticipated to result in substantive impacts on recreation and tourism.

Noise: Noise from operation of construction equipment, pile-driving, HRG surveys, and vehicle or vessel traffic associated with a single NY Bight project could result in adverse impacts on recreation and tourism. Onshore construction noise near beaches, parkland, recreation areas, or other areas of public interest would temporarily disturb the quiet enjoyment of the sites (in locations where such quiet is an expected or typical condition).

Similarly, offshore construction noise would intrude upon the natural sounds of the marine environment, adversely affecting recreational enjoyment of the marine and coastal environments. Using Ocean Wind 1 as representative of pile-driving for a single NY Bight project, noise from pile-driving—the noisiest aspect of WTG installation—is estimated to be 101 dBA at a distance of 50 feet (Ocean Wind 2022). Over water, the piling noise would be barely audible at 7 miles downwind (Ocean Wind 2022). Accordingly, even where areas within or near the offshore export cable route and lease area are available for recreational boating during construction, increased noise from construction would be limited to a small area in the larger NY Bight and would represent only a temporary inconvenience to recreational boaters. The temporary disruptions to or changes in offshore fish, shellfish, and whale populations (see Section 3.5.5, *Finfish, Invertebrates, and Essential Fish Habitat*, and Section 3.5.6, *Marine Mammals*) as a result of construction noise would have a minor impact on recreational fishing or marine sightseeing. The overall impact from one NY Bight project is expected to be minor.

Presence of structures: The construction and installation of between 50 and 280 WTGs and between 1 and 5 OSSs associated with one NY Bight project within the recreation and tourism geographic analysis area would contribute to impacts on recreational fishing and boating. The offshore structures would have long-term, adverse impacts on recreational boating and fishing through the risk of allision; risk of gear entanglement, damage, or loss; navigational hazards; space use conflicts; presence of cable infrastructure; and visual impacts. However, offshore wind structures could have beneficial impacts on recreation through fish aggregation and reef effects. The impact from one NY Bight project would likely be negligible to minor.

As described in Section 3.6.8.3.2, *Cumulative Impacts of the No Action Alternative*, recreation and tourism may benefit from the presence of operational WTGs. Parsons (Parsons et al. 2020) documented large increases in the number of trips to the shoreline to view offshore wind projects in parts of Europe. New studies of the Block Island Wind Farm corroborate positive effects on tourism. In a study relying on trends in summer vacation property rentals, researchers at the University of Rhode Island observed a 19 percent increase in summer monthly revenue for Block Island vacation property landlords compared to other regional summer vacation rental destinations such as Narragansett and Westerly, Rhode Island, and Nantucket, Massachusetts. The factors that may be driving the increase in rental volume are not defined in the study, but the researchers hypothesized that tourists may be curious to see the wind farm or that the recreational fishing near the wind farm has improved significantly, thereby increasing interest in visiting the wind farm itself (Atlantic Shores 2021; Carr-Harris and Lang 2019). Based on a study prepared by Parsons and Firestone (2018), beaches with views of WTGs could gain trips from the estimated 2.6 percent of beach visitors for whom viewing the WTGs would be a positive result, offsetting some lost trips from visitors who consider views of WTGs to be negative and the 8 percent of respondents who stated they would visit a different beach (without offshore wind development).

Recreational anglers may avoid fishing in the NY Bight lease area due to concerns about their ability to safely fish within or navigate through the area. As noted in Section 3.6.1, *Commercial Fisheries and For-Hire Recreational Fishing*, navigational hazards and scour/cable protection due to the presence of structures from one NY Bight project would result in substantial adverse impacts on commercial fisheries and for-hire recreational fishing. Similar impacts would also result for recreational anglers who would travel the minimum of 20 nautical miles (37 kilometers) to the nearest NY Bight lease area (or over 35 nautical miles [65 kilometers] to the farthest NY Bight lease area). However, because most recreational anglers fish much closer to shore (Figure 3.6.1-22), BOEM anticipates impacts on recreational fishing from presence of structures would be minor.

As described more fully in Section 3.5.5, *Finfish, Invertebrates, and Essential Fish Habitat*, the presence of structures and cable protection can create a “reef effect,” providing ecological benefits and habitat diversity. The offshore foundations, scour protection, and cable protection provide habitat for developing new ecosystems and attract species seeking prey or refuge from predators. For example, the creation of structured habitat is expected to benefit species such as striped bass, black sea bass, and Atlantic cod by potentially increasing their habitat. Similarly, the presence of foundations may increase habitat and provide forage and refuge for some migratory finfish targeted by recreational fishermen. Increasing potential habitat for fish and their prey may positively affect recreational fishing within a NY Bight lease area. Additionally, interest in visiting a single NY Bight project lease area may result in an increased number of fishing trips originating from New Jersey and New York ports. These additional vessel trips could support an increase in angler expenditures at shoreside facilities servicing recreational fishermen (Atlantic Shores 2021; Kirkpatrick et al. 2017).

Traffic: A single NY Bight project would generate a small increase in vessel traffic compared to baseline conditions, with a peak during construction and conceptual decommissioning and reduced traffic during O&M. As described in Section 3.6.6, *Navigation and Vessel Traffic*, based on vessel trip estimates from nearby ongoing and planned offshore wind projects (Ocean Wind 1 [OCS-A 0498], Atlantic Shore South [OCS-A 0499], and Empire Wind [OCS-A 0512]), one NY Bight project is anticipated to generate up to 51 vessels at any given time during construction and 8 vessel trips per day during O&M. Construction support vessels, including vessels carrying assembled WTGs or WTG and OSS components, would be present in the waterways between the NY Bight project area and the ports used during construction and installation and during conceptual decommissioning. Recreational vessels may experience delays within the ports serving construction, but most recreational boaters in the geographic analysis area would experience only minor inconvenience from construction-related vessel traffic. Vessel travel requiring a specific route that crosses or approaches the offshore export cable routes could experience minor impacts. Recreational boating and fishing activities would be required to avoid project vessels and restricted safety zones through routine adjustments to navigation. Although tourists may experience increased transit times in some situations, these situations are spatially and temporally limited. O&M activities would only periodically be present in the NY Bight lease areas.

Section 2.3, *Non-Routine Activities and Events*, describes the non-routine activities associated with a NY Bight project. Activities requiring repair of WTGs, equipment, or cables, or spills from maintenance or repair vessels, which could affect water quality, would generally require intense, temporary activity to address emergency conditions or respond to an oil spill. Additionally, accidental releases of chemicals, gases, or man-made debris may occur as a result of a structural failure. Non-routine activities could temporarily prevent or deter recreation or tourist activities near the site of a given non-routine event, but these impacts would be temporary. Overall, BOEM expects vessel activities in the open waters between the project area and ports and along the cable corridor to result in a small increase in current levels of vessel traffic and have only minor impacts on recreation and tourism.

3.6.8.4.2 Impacts of Six Projects

The same impact types and mechanisms described for a single NY Bight project apply to six NY Bight projects for anchoring, land disturbance, cable emplacement and maintenance, noise, presence of structures, and vessel traffic. However, there would be more potential for impacts due to the larger number of projects occurring and the subsequent greater amount of offshore and onshore development. Impacts from anchoring are still expected to remain minor because anchoring is not expected to substantially affect or disrupt recreational fishing. Land disturbance from six NY Bight projects would increase compared to one NY Bight project, but the impact would remain minor as impacts are anticipated to be temporary during construction.

The amount of nighttime lighting that would be visible from WTGs and OSSs would increase with six NY Bight projects without the use of ADLS. However, because of the distance from shore from any of the NY Bight leases (the closest lease area is 20 nautical miles [37 kilometers] offshore) and the pervasive light sources already present along the New York and New Jersey coastline, impacts from lighting would likely remain minor. Noise impacts would increase in duration and geographic extent and therefore would affect more recreational boaters and anglers. However, because most recreational boating activity occurs closer to shore than the NY Bight lease areas, impacts would remain minor. Disruptions to fish and whale populations as a result of construction noise could also increase impacts on recreational fishing or marine sightseeing, but impacts would be temporary and remain minor.

Impacts from cable emplacement and maintenance under six NY Bight projects would range from minor to moderate, an increase from minor impacts under a single NY Bight project. The increased impacts would be due to multiple areas of cable installation potentially occurring simultaneously, increasing the potential for temporary access limitations on recreational fishing vessels. However, the area used by installation vessels would still be small relative to the size of available access to other fishing grounds, and recreational fishing vessels would be able to make temporary adjustments during construction and O&M.

Because of the increased number of WTGs and OSSs across the six NY Bight lease areas, the impact from the presence of structures would increase to moderate. The increased impacts would be due to the larger area where recreational boating and fishing would be at risk of allision, gear entanglement, increased navigational hazards, and space use conflicts, requiring recreational boaters to make adjustments when traveling to or nearby the NY Bight lease areas. In addition, a greater number of structures would be visible from the coastline and to recreational boaters with six NY Bight projects, potentially affecting recreational experience. Beneficial impacts from fish aggregation and reef effect would remain minor.

Impacts from vessel traffic would increase under six NY Bight projects due to the higher number of vessels that would be required as compared to one NY Bight project during installation, O&M, and conceptual decommissioning. The number of vessels would increase the likelihood that tourism charters and recreational fishing vessels would change their travel routes, times, or other routines, which could negatively impact their catch or result in increased expenses. However, given the incremental increase in vessel traffic from wind energy development compared to regional vessel traffic, the impact would remain minor**.**

3.6.8.4.3 Cumulative Impacts of Alternative B

The construction and installation, O&M, and conceptual decommissioning of six NY Bight projects would contribute to the impacts on recreation and tourism from ongoing and planned activities in the geographic analysis area. BOEM anticipates that the cumulative impacts associated with six NY Bight projects when combined with past, present, and planned activities would be temporarily disruptive during the construction and conceptual decommissioning phases and would result in some long-term impacts associated with the presence of structures. The cumulative impacts would be similar to the impacts discussed for six NY Bight projects above. If construction of the six NY Bight projects is staggered or geographically dispersed onshore, impacts would be further minimized. The six NY Bight projects would contribute a noticeable increase to the minor to moderate and minor beneficial impacts on recreation and tourism from the combination of the six NY Bight projects and other ongoing and planned activities.

3.6.8.4.4 Conclusions

Impacts of Alternative B. Construction and installation, O&M, and conceptual decommissioning of one NY Bight project under Alternative B would likely have **negligible** to **minor** impacts and **minor beneficial** impacts on recreation and tourism. Short-term impacts would occur during construction related to noise, anchored vessels, and hindrances to navigation from the installation of the export cable and WTGs. The long-term presence of cable hardcover and structures in the lease area during operations would also result in impacts on recreational vessel navigation and visual quality. Six NY Bight projects would likely have increased **minor** to **moderate** impacts, as result of the increased number of WTGs and increased construction impacts, and **minor beneficial** impacts.

Cumulative Impacts of Alternative B: In context of reasonably foreseeable environmental trends, the impacts contributed by six NY Bight projects to the cumulative impacts on recreation and tourism would be noticeable and would likely contribute to the **minor** to **moderate** impacts and **minor beneficial** impacts. The main drivers for this impact rating are the impacts on fishing and other recreational activity from noise, vessel traffic, and cable emplacement during construction; visual impacts associated with the presence of structures and lighting; and beneficial impacts on fishing from the reef effect.

3.6.8.5 Impacts of Alternative C (Proposed Action) – Identification of AMMM Measures at the Programmatic Stage – Recreation and Tourism

Alternative C, the Proposed Action, considers the potential impacts of future offshore wind development for the NY Bight Area with the AMMM measures identified in Appendix G, *Mitigation and Monitoring*, that could avoid, minimize, mitigate, and monitor those impacts. Alternative C consists of two sub-alternatives – Sub-alternative C1: Previously Applied AMMM Measures, and Sub-alternative C2: Previously Applied and Not Previously Applied AMMM Measures. The analysis for Sub-alternative C1 is presented as the change in impacts from those impacts discussed under Alternative B, and the analysis for Sub-alternative C2 is presented as the change from those impacts discussed in Sub-alternative C1. Refer to Table G-1 in Appendix G, *Mitigation and Monitoring*, for a complete description of AMMM measures that make up the Proposed Action.

3.6.8.5.1 Sub-alternative C1 (Preferred Alternative): Previously Applied AMMM Measures

Sub-alternative C1 analyzes AMMM measures that BOEM has required as conditions of approval for previous activities proposed by lessees in COPs submitted for the Atlantic OCS and through related consultations (Table 3.6.8-4).

Table 3.6.8-4. Summary of previously applied avoidance, minimization, mitigation, and monitoring measures for recreation and tourism

Measure ID	Measure Summary
MUL-37	This measure requires implementation of ADLS to turn aviation obstruction lights on and off in response to detection of nearby aircraft, which would reduce total nighttime lighting on WTGs and OSSs.

Impacts of One Project

The implementation of MUL-37 could reduce some of the impacts from lighting associated with Alternative B on recreation and tourism. Impacts for other IPFs would remain the same as described under Alternative B. An ADLS system (MUL-37) would activate a hazard lighting system in response to detecting nearby aircraft and would result in shorter-duration night sky impacts. For comparison, the nearby Empire Wind (OCS-A 0512) ADLS-controlled obstruction lights are estimated to be activated for 357 hours, 46 minutes, and 45 seconds over a 1-year period, 7.5 percent of the normal operating time that would occur without ADLS. This would likely reduce the potential impacts from nighttime lighting on recreational viewer experience from minor to negligible.

Impacts of Six Projects

For six NY Bight projects, MUL-37 would be implemented the same as described for one NY Bight project but would cover a larger geographic area and potentially affect more tourism-based businesses and recreational activities. ADLS on WTGs/OSSs of all six NY Bight leases (MUL-37) would substantially reduce the amount of nighttime lighting compared to Alternative B, reducing the impact from lighting to negligible.

Cumulative Impacts of Sub-alternative C1 (Preferred Alternative)

Under Sub-alternative C1, cumulative impacts on recreation and tourism are anticipated to be similar as described under Alternative B, except that implementation of ADLS on six NY Bight projects (MUL-37) in combination with ongoing and planned projects would reduce offshore lighting impacts to negligible.

3.6.8.5.2 Sub-alternative C2: Previously Applied and Not Previously Applied AMMM Measures

Sub-alternative C2 analyzes the AMMM measures under Sub-alternative C1 plus the AMMM measures that have not been previously applied. However, BOEM has not identified any AMMM measures under Sub-alternative C2 that were not previously applied. Therefore, the impacts on recreation and tourism under Sub-alternative C2 are the same as for Sub-alternative C1.

3.6.8.5.3 Conclusions

Impacts of Alternative C. The construction, installation, and conceptual decommissioning for one NY Bight project under Sub-alternative C1 and Sub-alternative C2 would likely have **negligible** to **minor** impacts and **minor beneficial** impacts on recreation and tourism, while impacts on recreation and tourism for six NY Bight projects would be **minor** to **moderate** and **minor beneficial** under Sub-alternative C1 and Sub-alternative C2. The AMMM measure that would be implemented under Sub-alternative C1 and Sub-alternative C2 would reduce lighting impacts but would not reduce the overall impact level.

Cumulative Impacts of Alternative C. In context of reasonably foreseeable environmental trends, the impacts contributed by Sub-alternative C1 and Sub-alternative C2 to cumulative impacts on recreation and tourism would be noticeable. The AMMM measure that would be implemented under Sub-alternative C1 and Sub-alternative C2 would minimize impacts from lighting. BOEM anticipates that the cumulative impacts on recreation and tourism in the geographic analysis area from six NY Bight projects under Sub-alternative C1 and Sub-alternative C2 combined with ongoing and planned activities would likely be **negligible** to **moderate** and **minor beneficial**.

3.6.8.6 Recommended Practices for Consideration at the Project-Specific Stage

BOEM is recommending that lessees consider analyzing RPs in Table 3.6.8-5 to further reduce potential recreation and tourism impacts. Refer to Table G-2 in Appendix G for a complete description of the RPs.

Table 3.6.8-5. Recommended practices for recreation and tourism impacts and related benefits

Recommended Practice	Potential Benefit
MUL-5: Use equipment, technology, and best practices to produce the least amount of noise possible to reduce noise impacts.	Using equipment and technology to limit noise levels could reduce interference with recreational activity near onshore construction sites as a result of construction noise. The NY Bight projects would also have to comply with applicable state or local noise regulations, which would ensure noise levels are within appropriate limits.
REC-1: Schedule nearshore construction activities outside of the summer months to avoid tourist season.	Scheduling onshore and nearshore construction outside of the busy summer tourist season would minimize effects on recreational activities and tourism-based businesses. Increased vehicle traffic, road closures, and potential limitations on recreational access would still occur, but they would affect fewer visitors and summertime recreational activities.

This page was intentionally left blank.

Appendix G: Mitigation and Monitoring

The Final Programmatic Environmental Impact Statement (PEIS) assesses the potential physical, biological, socioeconomic, and cultural impacts that could result from the construction and installation, operations and maintenance (O&M), and conceptual decommissioning of wind energy projects within the six New York Bight (NY Bight) lease areas, as well as the change in those impacts with avoidance, minimization, mitigation, and monitoring (AMMM) measures. The Proposed Action (Sub-alternative C1 [Preferred Alternative] and Sub-alternative C2) for the Final PEIS is the identification of AMMM measures at the programmatic stage that could avoid, minimize, mitigate, and monitor impacts. The Bureau of Ocean Energy Management (BOEM) may require some or all of these measures as conditions of approval for activities proposed by lessees in Construction and Operations Plans (COPs) submitted for the six NY Bight lease areas. BOEM may require additional or different measures based on future, site-specific National Environmental Policy Act (NEPA) analysis or the parameters of specific COPs. BOEM may also modify the measures at the COP specific NEPA stage to tailor them to the characteristics of the proposed project and the site(s) of proposed activities, and to ensure conformity with project-specific consultations and authorizations. The AMMM measures analyzed in the Final PEIS under the Proposed Action are presented in Table G-1.

BOEM identified the AMMM measures analyzed in the Final PEIS from review of offshore wind COPs; COP environmental impact statements (EISs); scoping comment letters; input from cooperating and participating agencies, and Cooperating Tribal Governments; public comments on the Draft PEIS; internal input; and through previous consultations. BOEM analyzed AMMM measures that would be applicable to more than one NY Bight lease area, are reasonable and enforceable, and allow for flexibility where appropriate. These AMMM measures are considered programmatic insofar as they may be applied to COPs for the six NY Bight lease areas, not because they necessarily will apply to COPs under BOEM's renewable energy program outside of the NY Bight lease areas.

Most of the AMMM measures included in this appendix have been previously required by BOEM as conditions of approval for previous activities proposed by lessees in COPs submitted for the Atlantic OCS or through related consultations while a smaller number of measures have not been previously applied. Table G-1 identifies these measures as "Previously Applied" and "Not Previously Applied" in the last column of the table. As part of the Proposed Action, Sub-alternative C1 includes previously applied measures, and Sub-alternative C2 includes previously applied measures and not previously applied measures.

In addition to the AMMM measures, BOEM has identified Recommended Practices (RPs) for the offshore wind industry in Table G-2. These RPs are not part of the Proposed Action. Please note that not all of these RPs are within BOEM's statutory and regulatory authority; those that are not may be adopted and imposed by other governmental agencies at the subsequent COP NEPA stage.

The environmental decision document for each COP-specific NEPA review will describe the specific terms and conditions of the AMMM measures for which compliance is required (40 Code of Federal

Regulations [CFR] 1505.3). All NY Bight lessees will be required to certify compliance with their COP terms and conditions, under 30 CFR 285.633(a). Furthermore, pursuant to 30 CFR 585.634(b), BOEM will periodically review the activities conducted under the approved COPs for the six NY Bight lease areas with the frequency and extent of the review based on the significance of any changes in available information and on onshore or offshore conditions affecting, or affected by, the activities conducted under the COPs.

Monitoring may be required to evaluate the effectiveness of AMMM measures or to identify if resources are responding as predicted to impacts from each NY Bight project. This monitoring would typically be developed in coordination among BOEM and agencies with jurisdiction over the resource to be monitored. The information generated by monitoring may be used to (1) alter how an AMMM measure identified in the ROD is being implemented, (2) revise or develop new mitigation or monitoring measures for which compliance would be required under the COPs for the six NY Bight lease areas in accordance with 30 CFR 285.633(b)(2), (3) develop measures for future projects, or (4) contribute to regional efforts for better understanding of the impacts and benefits resulting from offshore wind energy projects in the Atlantic (e.g., potential cumulative impact assessment tool).

Table G-1. Proposed Action AMMM Measures

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
Previously Applied					
BB-1	Immediate reporting of injured/dead ESA-listed birds and bats	Any occurrence of dead or injured ESA-listed birds or bats, or eagles protected under the Bald and Golden Eagle Protection Act, must be reported to BOEM, BSEE, and USFWS as soon as practicable (taking into account crew and vessel safety), ideally within 24 hours and no more than 72 hours after the sighting. If practicable, the Lessee must carefully collect the dead specimen and preserve the material in the best possible state, contingent on the acquisition of any necessary wildlife permits and compliance with the Lessee's health and safety standards. Occurrences of bird and bat carcasses must also be reported in the Injury and Mortality Reporting (IMR) System.	Bats, Birds	BOEM, BSEE, and USFWS	Previously Applied
BB-2	Injured/dead bird and bat reporting	The Lessee must submit an annual report covering each calendar year, due by January 31, documenting any dead or injured birds or bats found on vessels and structures during construction, operations, and decommissioning in the preceding year. The report must be submitted to BOEM, BSEE, and USFWS. The report must contain the following information: the name of species, date found, location, a picture to confirm species' identity (if possible), and any other relevant information. Carcasses with federal or research bands must be reported to the United States Geological Survey Bird Band Laboratory. Developers should also report any other form of tag such as MOTUS or satellite. Occurrences of bird and bat carcasses must also be reported in the Injury and Mortality Reporting (IMR) System.	Bats, Birds	BOEM, BSEE, and USFWS	Previously Applied
BB-3	Bird and bat monitoring	**Bird and Bat Post-Construction Monitoring Plan.** The Lessee must develop and implement a Bird and Bat Post-Construction Monitoring Plan (BBPCMP) based on the Lessee's Bird and Bat Post-Construction Monitoring Framework (RP BB-4), in coordination with USFWS, and other relevant regulatory agencies. Prior to, or concurrent with, offshore construction activities, including seabed preparation activities, the Lessee must submit a BBPCMP for BOEM, BSEE and USFWS (New York and New Jersey Field Offices) review. BOEM, BSEE, and USFWS will review the BBPCMP and provide any comments on the plan within 60 days of its submittal. The Lessee must resolve all comments on the BBPCMP to BOEM's and BSEE's satisfaction before implementing the plan and before commissioning the first WTG. **Monitoring.** The Lessee must conduct monitoring as outlined in the BBPCMP, which must include use of radio-tags to monitor movement of ESA-listed birds in the vicinity of the project. The BBPCMP will allow for changing methods over time in order to regularly update and refine collision estimates for listed birds. Specific to this purpose, the plan must include an initial monitoring phase involving deployment of Motus radio tags, or similar technology, on listed birds or other species of concern in conjunction with installation and operation of Motus receiving stations on WTGs in the lease area following offshore Motus recommendations (https://motus.org/groups/atlantic-offshore-wind/). The initial phase, which will last for the first few years of operation, may also include deployment of satellite-based tracking technologies (e.g., Global Positioning System [GPS], Argos tags, acoustic bat detectors, or integrated multi-sensor systems). The monitoring may also include measurement of avoidance behavior and densities. **Annual Monitoring Reports.** The Lessee must submit to BOEM (at renewable_reporting@boem.gov), USFWS, and BSEE (via TIMSWeb and at protectedspecies@bsee.gov) a comprehensive report after each full year of monitoring within 12 months. The report must include all data, analyses, and summaries regarding ESA-listed and non-ESA-listed birds and bats. BOEM, BSEE, and the USFWS shall use the annual monitoring reports to assess the need for reasonable revisions (based on subject matter expert analysis) to the BBPCMP. BOEM and BSEE reserve the right to require reasonable revisions to the BBPCMP and may require the use of new technologies as they become available for use in offshore environments. **Post-Construction Quarterly Progress Reports**. The Lessee must submit quarterly progress reports during the implementation of the BBPCMP to BOEM (at renewable_reporting@boem.gov), BSEE, and USFWS by the 15th day of the month following the end of each quarter during the first full year that the project is operational. The progress reports must include a summary of all post-construction monitoring performed, an explanation of overall progress, and any technical problems encountered. **Monitoring Plan Revisions.** Within 30 days of submitting the annual monitoring report, the Lessee must meet with BOEM, BSEE, USFWS, and appropriate state agencies to discuss the following: the monitoring results; the potential need for revisions to the BBPCMP, including technical refinements or additional monitoring; and the potential need for any additional efforts to reduce impacts. If, based on this annual review meeting, BOEM, in consultation with USFWS, determines that revisions to the BBPCMP are necessary, BOEM will require the Lessee to modify the BBPCMP. If the projected collision levels, as informed by monitoring results, deviate substantially from the Final COP NEPA effects analysis, the Lessee must transmit recommendations for new mitigation measures and/or monitoring methods to BOEM. In consultation with USFWS, BOEM and BSEE may adjust the frequency, duration, and methods for various monitoring efforts in future revisions of the BBPCMP based on current technology (including its cost) and the evolving weight of evidence regarding the likely levels of collision mortality for each listed bird species. **Operational Reporting (Operations)**. The Lessee must submit to BOEM (at renewable_reporting@boem.gov) and BSEE (via TIMSWeb and at protectedspecies@bsee.gov) an annual report summarizing monthly operational data calculated from 10-minute supervisory control and data acquisition data for all WTGs together in tabular format: the proportion of time the WTGs were operational (monthly revolutions per minute [rpm]), the average rotor speed (rpm) of spinning WTGs plus 1 standard deviation, and the average pitch angle of blades (degrees relative to rotor plane) plus 1 standard deviation. Any operational data considered by the Lessee to be privileged or confidential must be clearly marked as confidential business information and will be handled by BOEM and BSEE in a manner consistent with 30 CFR 585.114. **Raw Data.** The Lessee must store the raw data from all avian and bat surveys and monitoring activities according to accepted archiving practices. Such data must remain accessible to BOEM, BSEE and USFWS upon request for the duration of the lease. The Lessee must work with BOEM to ensure the data are publicly available. All avian tracking data (i.e., from radio and satellite transmitters) must be stored, managed, and made available to BOEM, BSEE, and USFWS following the protocols and procedures outlined in the agency document entitled *Guidance for Coordination of Data from Avian Tracking Studies*, or its successor applicable at the time the particular data is being stored. All bat data must be stored in the North American Bat Monitoring Program (NABat) database.	Bats, Birds	BOEM, BSEE, and USFWS	Previously Applied

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
BEN-1	Boulder avoidance, identification, and relocation	The Lessee must avoid boulders greater than 0.5 m in diameter within the lease area and along the export cable corridor; if avoidance is not possible, the Lessee must minimize the distance a boulder must be relocated if necessary for the installation of facilities. If the Lessee needs to relocate boulders, it must submit a Boulder Identification and Relocation Plan. The plan must detail, to the extent technically and/or economically practicable or feasible for the project, how the Lessee will relocate boulders as close as practicable to areas immediately adjacent to existing similar habitat. The plan must be submitted to BOEM and BSEE to coordinate with NMFS for review prior to boulder relocation activities. The Lessee must resolve all comments on the Boulder Relocation Plan to BOEM and BSEE's satisfaction prior to implementation of the plan. If BOEM or BSEE do not provide comments on the plan within 60 days of its submittal, then the Lessee may presume concurrence with the plan. The plan must include sufficient scope to mitigate boulders for facility installation and operation risks.	Benthic; Finfish, Invertebrates, and EFH; Commercial and For-Hire Fishing	BOEM, BSEE, and NMFS	Previously Applied
MUL-41 (Previously BEN-2)	Foundation scour protection monitoring	The Lessee must inspect scour protection performance. The Lessee must submit an Inspection Plan to BSEE with the appropriate FDR submittal. BSEE will review the Inspection Plan and provide comments, if any, on the plan within 60 days of its submittal. The Lessee must resolve all comments on the Inspection Plan to BSEE's satisfaction and receive BSEE's concurrence prior to initiating the inspection program. If BSEE does not send comments within 60 days, the Lessee may presume concurrence. • The Lessee must carry out an initial foundation scour inspection of each foundation within 6 months of completing installation of that foundation, thereafter at intervals not greater than 5 years, and within 180 days after a storm event (as defined by the Post-Storm Event Monitoring Plan, described in MUL-16). • The Lessee must provide BSEE with a foundation scour monitoring report within 90 days of completing each foundation scour inspection. If multiple foundation locations are inspected within a single survey effort, the foundation scour monitoring reports for those locations may be combined into a single foundation scour monitoring report to be provided within 90 days of completing the last foundation scour inspection within this single survey effort. The schedule of reporting must be included in the Inspection Plan and concurred with by BSEE. • If scour protection losses develop within 10% of the maximum loss allowance, edge scour develops within 10% of the maximum allowance, or if spud depressions from installation affect scour protection stability, the Lessee must submit a plan for additional monitoring and/or mitigation to BSEE for review and concurrence.	Benthic; Finfish, Invertebrates, and EFH	BOEM, BSEE, and NMFS	Previously Applied
BIR-1	Bird-Deterrent Devices and Plan	To minimize attracting birds to operating WTGs, the Lessee must install bird perching-deterrent device(s) on each WTG and OSS. The Lessee must submit a plan to deter perching on offshore infrastructure by roseate terns and other marine birds for BOEM and BSEE to review in coordination with USFWS and with the FIR ("Bird Perching Deterrent Plan"). BOEM, BSEE, and USFWS will review the Bird Perching Deterrent Plan and provide any comments on the plan within 60 days of its submittal. The Lessee must resolve all comments on the Bird Perching Deterrent Plan to the satisfaction of BOEM and BSEE before implementing the plan. The Bird Perching Deterrent Plan must include the type(s) and locations of bird perching-deterrent devices and a monitoring plan for the life of the project, must allow for modifications and updates as new information and technology becomes available, and must track the efficacy of the deterrents. The plan must be based on best available science regarding the effectiveness of perching-deterrent devices on minimizing collision risk. The location of bird perching-deterrent devices must be proposed by the Lessee based on BMPs applicable to the appropriate operation, effectiveness, and safe installation of the devices. The Lessee must also provide the location and type of bird-deterrent devices as part of the as-built submittals to BSEE.	Birds	BOEM, BSEE, and USFWS	Previously Applied
BIR-2	Light impact reduction for birds	Nothing in this condition supersedes or is intended to conflict with lighting, marking, and signaling requirements of FAA, USCG, or BOEM. The Lessee must use lighting technology that minimizes impacts on avian species to the extent practicable, including lighting designed to minimize upward illumination. The Lessee must provide USFWS with a courtesy copy of the final Lighting, Marking, and Signaling Plan, and the Lessee's approved application to USCG to establish Private Aids to Navigation (PATON).	Birds	FAA, USCG, BOEM, and BSEE	Previously Applied
BIR-3	Compensatory Mitigation Plan for Piping Plover and Red Knot	At least 180 days prior to the start of commissioning of the first WTG, the Lessee would distribute a Compensatory Mitigation Plan for piping plovers and red knot to BOEM, BSEE, and USFWS for review and comment. BOEM, BSEE, and USFWS would review the Compensatory Mitigation Plan and provide any comments on the plan to the Lessee within 60 days of its submittal. The Lessee would resolve all comments on the Compensatory Mitigation Plan to BOEM, BSEE, and USFWS's satisfaction before implementing the plan and before commissioning of the first WTG. The Compensatory Mitigation Plan would provide compensatory mitigation actions to fully offset the impact of the incidental take of piping plover and red knot. The Compensatory Mitigation Plan would require that the compensatory mitigation be implemented by the fifth year of WTG operation. The Lessee will review the effectiveness of the plan with BOEM, BSEE and USFWS at regular (5-year) intervals thereafter or as new information becomes available, during which alternative and adaptive strategies might be considered. The Compensatory Mitigation Plan would include: (1) a quantification of the level of offsets to fully offset the impact of the incidental take expressed in the Incidental Take Statement, based on scientifically recognized techniques and methodologies for each of the impacted species: piping plover and red knot; (2) detailed description of the mitigation actions for each species (Piping plover examples: Habitat enhancement, predator control, reduction of disturbance at wintering sites, etc. Rufa red knot examples: habitat restoration, reduce displacement from peregrine falcons, red tide rehabilitation, etc.); (3) the specific location for each mitigation action; (4) a timeline for completion of the mitigation measures; (5) details of the mitigation mechanisms (e.g., conservation bank, in-lieu fee, applicant-proposed mitigation); (6) best available science linking the compensatory mitigation action(s) to the projected level of collision mortality; and (7) monitoring and reporting to ensure the effectiveness of the mitigation actions in offsetting take.	Birds	BOEM, BSEE, and USFWS	Previously Applied
COMFIS-2	Scour and cable protection plan	The Lessee must prepare and implement a Scour and Cable Protection Plan(s) that includes descriptions and specifications for all scour and cable protection materials. The plan(s) must include depictions of the location and extent of scour and cable protection, the habitat delineations for the areas of cable protection measures, and detailed information on the proposed scour or cable protection materials for each area and habitat type. The Scour and Cable Protection Plan(s) must demonstrate consistency with the Micrositing Plan(s) and Sequencing Plan(s), as appropriate. a. The Lessee must avoid the use of engineered stone or concrete mattresses in complex habitat, as practicable and feasible. The Lessee must ensure that all materials used for scour and cable protection measures consist of natural or engineered stone that does not inhibit epibenthic growth and provides three-	Commercial and For-Hire Fishing	BOEM and BSEE	Previously Applied

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		dimensional complexity in height and in interstitial spaces, as practicable and feasible. If concrete mattresses are necessary, bioactive concrete (i.e., with bio-enhancing admixtures) must be used as practicable as the primary scour protection (e.g., concrete mattresses) or veneer to support biotic growth. b. Cable protection measures must have tapered or sloped edges to reduce hangs for mobile fishing gear. The Lessee must avoid the use of plastics/recycled polyesters/net material (i.e., rock-filled mesh bags, fronded mattresses) for scour protection. c. The Scour and Cable Protection Plan(s) must be submitted to BOEM and BSEE for coordination with other agencies as appropriate for review prior to placement of scour and cable protection within the area covered by the scope of the Plan(s). The Scour and Cable Protection Plan(s) must be concurred with by BOEM and BSEE prior to BSEE issuing a no-objection to the relevant FDR. d. The Lessee must resolve all comments on each Plan to BOEM's and BSEE's satisfaction before placement of the scour and cable protection materials. The final version of the Scour and Cable Protection Plan(s) must be provided to BOEM, BSEE, NMFS and USACE.			
COMFIS-3	Fisheries & Benthic Habitat Monitoring Plan	The Lessee shall develop and implement a Fisheries and Benthic Habitat Monitoring Plan that should include shellfish, such as surfclam and scallop. The Lessee must submit to BOEM and BSEE a Fisheries and Benthic Habitat Monitoring Plan (FBHMP). The Lessee must conduct fisheries and benthic monitoring according to their FBHMP to assess fisheries and benthic habitat status in the project area.	Commercial and For-Hire Fishing; Benthic	BOEM, BSEE, and NMFS	Previously Applied
COMFIS-6	Fisheries compensatory mitigation	The Lessee will implement the following compensation programs consistent with BOEM's draft guidance for mitigating impacts on commercial fisheries and for-hire recreational fishing (https://www.boem.gov/sites/default/files/documents/renewable-energy/DRAFT%20Fisheries%20Mitigation%20Guidance%2006232022_0.pdf): • A gear loss and damage compensation program to address the impact-producing factor for presence of structures during construction, operations, and decommissioning by reducing impacts resulting from loss of gear associated with uncharted obstructions resulting from the proposed project. • A compensation program for lost income from commercial fisheries and for-hire recreational fishing activities and other eligible fishing interests for lost income during construction and a minimum of 5 years post-construction. ○ The Lessee shall establish a compensation/mitigation fund consistent with BOEM's draft Guidance for Mitigating Impacts to Commercial and Recreational Fisheries on the Outer Continental Shelf Pursuant to 30 CFR 585 to compensate commercial and for-hire recreational fishermen for loss of income due to unrecovered economic activity resulting from displacement from fishing grounds due to project construction and operations and to shoreside businesses for losses indirectly related to the project. For losses to commercial and for-hire recreational fishermen, the fund shall be based on the revenue exposure for fisheries based out of ports listed in an individual project's EIS. For losses to shoreside businesses, the Lessee shall analyze the impacts on shoreside seafood businesses adjacent to ports listed in an individual project's EIS.	Commercial and For-Hire Fishing	BOEM, BSEE, NJDEP, and NYDEP	Previously Applied
CUL-2	Marine cultural resources avoidance or additional investigation	BOEM will establish, and the Lessee must comply with, requirements for all avoidance buffers required by BOEM for each marine cultural resource (i.e., archaeological resource and ASLFs) based on the size and dimension of the resource. Avoidance buffers will extend outward from the maximum discernable limit of each resource and are intended to minimize the risk of disturbance during construction. If an adverse effect cannot be avoided, the Lessee will be required to conduct further investigations to minimize or resolve effects on these historic properties. If avoidance of an unevaluated resource is infeasible, additional investigations must be conducted for the purpose of determining eligibility for listing in the NRHP.	Cultural Resources	BOEM or BSEE	Previously Applied
CUL-3	Ancient submerged landform feature (ASLF) monitoring program and marine archaeological post-review discovery plan	BOEM will establish, and the Lessee must comply with, monitoring and post-review discovery plans outlining processes to document and review impacts of construction or any seabed-disturbing activities on marine cultural resources. Such plans may be developed in the course of BOEM's project-level NEPA review and Section 106 consultation on marine archaeological resources. A post-review discovery plan approved by BOEM is also required in the event that an unanticipated discovery and/or inadvertent impact of a marine archaeological resource occurs.	Cultural Resources	BOEM, BSEE, or other agencies that have statutory enforcement authority over cultural resources	Previously Applied
CUL-4	Terrestrial archaeological resource avoidance or additional investigation	BOEM will establish avoidance criteria for any identified terrestrial archaeological historic property or any unevaluated terrestrial archaeological resource. The Lessee must avoid impacts on identified terrestrial archaeological historic properties or unevaluated resources. If avoidance is infeasible, the Lessee must develop a plan to be submitted to BOEM that addresses the adverse effect on the terrestrial archaeological resource. The Lessee may develop this plan in the course of BOEM's project-level NEPA review and Section 106 consultation on terrestrial archaeological resources. Avoidance would entail the development and implementation of avoidance buffers around each historic property and unevaluated resource. If avoidance of an unevaluated resource is infeasible, additional investigations must be conducted for the purpose of determining eligibility for listing in the NRHP.	Cultural Resources	BOEM, BSEE, or other agencies that have statutory enforcement authority over cultural resources	Previously Applied
CUL-5	Terrestrial archaeological resource monitoring program and terrestrial archaeological post-review discovery plan	BOEM will establish, and the Lessee must comply with, monitoring and post-review discovery plans outlining processes to document and review impacts of construction or any ground-disturbing activities on terrestrial archaeological resources. A monitoring plan may be developed in the course of BOEM's project-level NEPA review and Section 106 consultation on terrestrial archaeological resources. A monitoring plan may be required for certain areas, identified through consultation, to ensure impacts on resources are avoided or minimized. A post-review discovery plan will be required for the purposes of establishing a protocol in the event of an unanticipated discovery and/or inadvertent impact on a terrestrial archaeological resource.	Cultural Resources	BOEM, BSEE, or other agencies that have statutory enforcement authority over cultural resources	Previously Applied
MM-1	Reporting of all NARW detections	If a NARW is observed at any time by PSOs or personnel on any project vessels, or during any project-related activity including during vessel transit, the Lessee must immediately report the sighting information to BOEM (renewable_reporting@boem.gov), BSEE (TIMSWeb and notification email to protectedspecies@bsee.gov), the NMFS hotline, the WhaleAlert App (https://www.whalealert.org/), and to the USCG via channel 16, as soon as feasible but no later than 24 hours after the sighting. • If in the Greater Atlantic Region (ME to VA/NC border), call (866-755-6622); • If in the Southeast Region (NC to FL), call (877-WHALE-HELP or 877-942-5343); or • If calling the hotline is not possible, reports can also be made to the U.S. Coast Guard via channel 16. The sighting report must include the time in Coordinated Universal Time (UTC; HH:MM), date (YYYY-MM-DD), location (latitude/longitude in decimal degrees; coordinate system used) of the sighting, number of whales, animal description/certainty of sighting (provide photos/video if taken), closest point of approach,	Marine Mammals	BOEM, BSEE, and NMFS	Previously Applied

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		activities at time of detection, vessel speed, animal behavior, lease area/project name, PSO/personnel name, PSO provider company [if applicable], and reporter's contact info. If a NARW is detected via PAM, the date, time, location (i.e., latitude and longitude of recorder) of the detection as well as the recording platform that had the detection must be reported to nmfs.pacmdata@noaa.gov as soon as feasible, but no longer than 24 hours after the detection. Full detection data and metadata must be submitted monthly on the 15th of every month for the previous month via the webform on the NMFS North Atlantic Right Whale Passive Acoustic Reporting System website at https://www.fisheries.noaa.gov/resource/document/passive-acoustic-reporting-system-templates. The Lessee must send a summary report within 24 hours to NMFS GARFO-PRD and NMFS-OPR with the information submitted to the hotline/template and confirmation the sighting/detection was reported to the respective hotline, the vessel/platform from which the sighting/detection was made, activity the vessel/platform was engaged in at time of sighting/detection, project construction and/or survey activity ongoing at time of sighting/detection (e.g., pile driving, cable installation, HRG survey), distance from vessel/platform to animal at time of initial sighting/detection, closest point of approach of whale to vessel/platform, vessel speed, and any mitigation actions taken in response to the sighting/detection.			
MM-3	Long-term PAM monitoring	The Lessee must conduct long-term monitoring of ambient noise as well as baleen whale and commercially-important fish vocalizations in the lease area before, during, and following construction. The Lessee must conduct continuous recording at least 1 year before construction, during construction, initial operation, and for at least 3 but no more than 10 full calendar years of operation to monitor for potential noise impacts. The Lessee must meet with BOEM and BSEE at least 60 days prior to conclusion of the third full calendar year of operation monitoring (and at least 60 days prior to the conclusion of each subsequent year until monitoring is concluded) to discuss: 1) monitoring conducted to-date, 2) the need for continued monitoring, and 3) if monitoring is continued, whether adjustments to the monitoring are warranted. The instrument(s) must be configured to ensure that the specific locations of vocalizing NARW anywhere within the lease area could be identified, based on the assumption of a 10 km detection range for their calls. The lessee may execute the implementation of this condition through Option 1 or Option 2, as below, but must notify BOEM of its choice at least 120 days before pile driving is scheduled to begin. The timing requirement (i.e., monitoring for at least 3 but no more than 10 full calendar years of operation) will be reevaluated by BOEM and BSEE at the end of the third year and each year subsequently thereafter at the request of the Lessee (at a maximum frequency of requests of once per year). **A. Option 1 - Lessee Conducts Long-term Passive Acoustic Monitoring (PAM).** The Lessee must conduct PAM, including data processing and archiving following the Regional Wildlife Science Collaborative (RWSC) best practices to ensure data comparability and transparency. PAM instrumentation must be deployed to allow for identification of any NARW that vocalize anywhere within the lease area. The sampling rate (minimum 10 kHz) of the recorders must prioritize baleen whale detections, but must also have a minimum capability to record noise from vessels, pile driving, and WTG operation in the lease area. The system must be configured for continuous recording over the entire year. If temporal gaps in recording are expected, the Lessee must ensure that additional recorders can be deployed to fill gaps. The Lessee must use trawl-resistant moorings to ensure that instruments are not lost and must replace any lost instruments as soon as possible. The Lessee must also notify BOEM if such loss and replacement occur. The Lessee must follow the best practices outlined in the RWSC best practices document, unless otherwise required through conditions of COP approval or related consultation. The best practices include engaging with the RWSC, calibrating the instruments, running QA/QC on the raw data, following the templates for reporting species vocalizations, and preparing the data for archiving at National Centers for Ecological Information (NCEI). In terms of data processing, the Lessee must document the occurrence of whale vocalizations (calls of NARW, humpback, sei, fin, and minke whales, as well as odontocete clicks, as available based on sample rate) using automatic or manual detection methods. In addition, data must be processed with either manual or automatic detection software to detect vocalizations of spawning cod. The Lessee must submit a log of these detections as well as the detection methodology to BOEM (at renewable_reporting@boem.gov), BSEE (at protectedspecies@bsee.gov) and NMFS (at nmfs.nec.pacmdata@noaa.gov.) within 120 days following each recorder retrieval. All raw data must be sent to the NCEI Passive Acoustic Data archive on an annual basis and the Lessee must follow NCEI guidance for packaging the data and must pay the fee. • Long-term Passive Acoustic Monitoring Plan. The Lessee must prepare and implement a Long-term PAM Plan under this option. No later than 120 days prior to instrument deployment and before any construction begins, the Lessee must submit to BOEM and BSEE (renewable_reporting@boem.gov and OSWsubmittals@bsee.gov) the Long-term PAM Plan that describes all proposed equipment (including number and configuration of instruments), deployment locations, mooring design, detection review methodology, and other procedures and protocols related to the required use of PAM. As the Lessee prepares the Long-term PAM Plan, it must coordinate with the RWSC. BOEM and BSEE will review the Long-term PAM Plan and provide comments, if any, on the plan within 45 days of its submittal. The Lessee may be required to submit a modified Long-term PAM Plan based on feedback from BOEM and BSEE. The Lessee must address all outstanding comments to BOEM's and BSEE's satisfaction and will need to receive written concurrence from BOEM and BSEE. If BOEM or BSEE do not provide comments on the Long-term PAM Plan within 45 days of its submittal, the Lessee may conclusively presume BOEM's and BSEE's concurrence with the Long-term PAM Plan. **B. Option 2 – Economic and Other Contributions to BOEM's Environmental Studies Program.** As an alternative to conducting Long-term PAM in the lease area, the Lessee may opt to make an economic contribution to BOEM's Environmental Studies Partnership for an Offshore Wind Energy Regional Observation Network (POWERON) initiative on an annual basis and cooperate with the POWERON team to allow access to the lease area for deployment, regular servicing, and retrieval of instruments. In the event the Lessee selects this option, BOEM and the Lessee will enter into a separate agreement. The Lessee's economic contribution will provide for all activities necessary to conduct PAM within the lease area, such as vessel and staff time for regular servicing of instruments, QA/QC on data, data processing to obtain vocalizations of sound-producing species and ambient noise metrics, as well as long-term archiving of data at NCEI. At the Lessee's request, the amount of the economic contribution will be estimated by BOEM's Environmental Studies Program. The Lessee will also be invited to contribute to discussions about the scientific approach of the POWERON initiative via the RWSC. The Lessee may request temporary withholding of the public release (placement into the NCEI public data archive) of raw acoustic data collected within the lease area for up to 180 days after it is collected. During this temporary hold, the Lessee may be provided a copy of the raw PAM data that was collected in the lease area or ROW after it has been cleared for any national security concerns under the RWSC best practices document.	Marine Mammals	BOEM, BSEE, and NMFS	Previously Applied

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
MM-5	Marine Mammal Vessel Strike Management Plan	All project vessels transiting between the operations and maintenance facility and the lease area must travel at 10 knots (18.5 kilometers per hour) or less while operating in a Seasonal Management Area (SMA), unless the Lessee receives concurrence from BOEM and BSEE on its Marine Mammal Vessel Strike Management Plan. The Lessee must submit the Marine Mammal Vessel Strike Management Plan to BOEM, BSEE, and NMFS at least 180 days prior to the Plan's implementation. The plan must describe the location of each transit corridor (with a map); how PAM, in combination with visual observations, will be conducted to ensure highly effective monitoring for the presence of right whales in the transit corridor; and the protocols that will be in place for vessel speed restrictions following detection of a right whale via PAM or visual observation. The Lessee should coordinate with NMFS and monitor updates to the 2022 Proposed Rule, Amendments to the North Atlantic Right Whale Vessel Strike Reduction Rule, on additional vessel speed restrictions (https://www.fisheries.noaa.gov/action/amendments-north-atlantic-right-whale-vessel-strike-reduction-rule). This measure does not supersede any regulatory requirements.	Marine Mammals	BOEM, BSEE, and NMFS	Previously Applied
MMST-1	Reduced Visibility Monitoring Plan/Nighttime Pile Driving Monitoring Plan	The Lessee must submit the Reduced Visibility Monitoring (RVMP)/ Nighttime Pile Driving Monitoring Plan (or plans if submitted separately) to BOEM, BSEE, USACE, and NMFS GARFO PRD at least 180 days before pile driving is planned to begin unless a different time period is identified in the project-specific MMPA LOA. BOEM, BSEE, and NMFS will provide comments to the Lessee within 45 days of receipt of the plan. If issues are identified, the Lessee must submit a modified plan to BOEM, BSEE, USACE, and NMFS GARFO PRD within 30 days of the receipt of the comments and at least 15 days before the start of pile driving and associated activity. The plan may not be implemented, and therefore pile driving may not begin, until BOEM and BSEE inform the Lessee that they concur with the plan. • The plan must contain a thorough description of how the Lessee will monitor pile-driving activities during reduced visibility conditions (e.g. rain, fog) and at night, including proof of the efficacy of monitoring devices (e.g., mounted thermal/infrared camera systems, hand-held or wearable night vision devices, spotlights) in detecting ESA-listed marine mammals and sea turtles over the full extent of the required clearance and shutdown zones, including demonstration that the full extent of the minimum visibility zones (determined at the project-specific stage) can be effectively and reliably monitored in reduced visibility conditions. The plan must identify the efficacy of the technology at detecting marine mammals and sea turtles in the clearance and shutdown zones. The plan must include a full description of the proposed technology, monitoring methodology, and data demonstrating that marine mammals and sea turtles can reliably and effectively be detected within the clearance and shutdown zones for monopiles before, during, and after impact pile driving at night. Additionally, this plan must contain a thorough description of how the Lessee will monitor pile-driving activities during daytime when unexpected changes to lighting or weather occur during pile driving that prevent visual monitoring of the full extent of the clearance and shutdown zones. Without concurrence on this plan, no pile driving may be initiated later than 1.5 hours prior to civil sunset.	Marine Mammals, Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied
MMST-2	Marine Mammal and Sea Turtle Monitoring Plan for Pile Driving	The Lessee must submit a Marine Mammal and Sea Turtle Monitoring Plan for Pile Driving to BOEM, BSEE, USACE, NMFS GARFO PRD, and NMFS OPR at least 180 days before any foundation pile driving is planned. BOEM, BSEE, NMFS GARFO PRD, and NMFS OPR will review the plan and provide comments within 45 days of receipt of the plan. If the plan is determined to be insufficient, the Lessee must submit a modified plan that addresses the identified issues no more than 30 days after receipt of comments from NMFS; at that time, BOEM, BSEE, NMFS GARFO PRD, and NMFS OPR will discuss a timeline for review and approval of the modified plan to meet the Lessee's schedule to the maximum extent practicable. The Lessee must obtain BOEM's and BSEE's concurrence with the Marine Mammal and Sea Turtle Monitoring Plan before starting any pile driving. The plan(s) must include: a description of how all relevant mitigation and monitoring requirements contained in the project-specific NMFS BiOp ITS will be implemented, a pile driving installation summary and sequence of events, a description of all training protocols for all project personnel (PSOs, PAM Operators, trained crew lookouts, etc.), a description of all monitoring equipment and evidence (i.e., manufacturer's specifications, reports, testing) that the Lessee can use to effectively monitor and detect ESA-listed marine mammals and sea turtles in the identified clearance and shutdown zones (i.e., field data demonstrating reliable and consistent ability to detect ESA-listed large whales and sea turtles at the relevant distances in the conditions planned for use), communications and reporting details, and PSO monitoring and mitigation protocols (including number and location of PSOs) for effective observation and documentation of sea turtles and ESA-listed marine mammals during all pile-driving events. The plan(s) must demonstrate sufficient PSO and PAM Operator staffing (in accordance with watch shifts), PSO and PAM Operator schedules, and contingency plans for instances if additional PSOs and PAM Operators are required. The Plan must detail all plans and procedures for sound attenuation, including procedures for adjusting the noise attenuation system(s) and available contingency noise attenuation measures/systems if distances to modeled isopleths of concern are exceeded during SFV. The plan must also describe how the Lessee would determine the number of sea turtles exposed to noise above the 175 dB harassment threshold during impact pile driving of WTG and OSS foundations and how the Lessee would determine the number of ESA-listed whales exposed to noise above the Level B harassment threshold during impact pile driving of WTG and OSS foundations. If any clearance or shutdown zones are expanded, the Lessee must submit a proposed monitoring plan describing the location of all PSOs to NMFS, BOEM, and BSEE for review. The Lessee must resolve BOEM's and BSEE's comments to the proposed monitoring plan to the Bureaus' satisfaction and must conduct activities in accordance with the plan.	Marine Mammals, Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied
MMST-3	Pile-driving clearance and shutdown zone adjustments	Based on sound field verification results, the agencies (BOEM, BSEE, NMFS, and USACE, when applicable) will discuss the possibility of either increasing or decreasing the clearance zones, shutdown zones, and monitoring and mitigation measures for pile driving. The agencies will communicate with the Lessee about how to proceed.	Marine Mammals, Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied
MMST-4	Establishment of foundation pile-driving measures	1. If shutdown is called for but the Lessee determines shutdown is not technically feasible due to human safety concerns or to maintain installation feasibility, reduced hammer energy must be implemented when the lead engineer determines it is technically feasible to do so. 2. Time of Day Restrictions: Foundation pile driving may commence only during daylight hours, unless an RVMP/Nighttime Pile Driving Monitoring Plan has been submitted and approved (see MMST-1). Foundation pile driving may begin no earlier than 1 hour after (civil) sunrise. Foundation pile driving may not be initiated any later than 1.5 hours before (civil) sunset. Foundation pile driving may continue after dark only when the installation of the same pile began during daylight hours (1.5 hours before civil sunset), when clearance zones were fully visible for at least 30 minutes and only when they must proceed for human safety or installation feasibility reasons. 3. The Lessee must deploy at least two PSOs on duty on the foundation pile-driving platform, or nearby construction vessel in the immediate vicinity of the foundation pile-driving platform, at all times during foundation pile driving to visually monitor for marine mammals.	Marine Mammals, Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		4. Monitoring must take place from 60 minutes immediately prior to initiation of foundation pile-driving activity through 30 minutes post-completion of foundation pile-driving activity. Acoustic PSOs (at least one PAM operator) must review data from at least 24 hours prior to pile driving and actively monitor hydrophones for 60 minutes prior to pile driving. 5. For all foundation pile-driving activity, the Lessee must implement designated clearance zones. 6. Foundation pile driving may only commence when the clearance zones are fully visible (e.g., not obscured by darkness, rain, fog), unless an RVMP/Nighttime Pile Driving Monitoring Plan (see MMST-1) has been submitted and approved, and only when clearance zones are clear of marine mammals for at least 30 minutes immediately prior to foundation pile driving, as determined by the lead PSO. 7. If a marine mammal is visually detected entering or within designated shutdown zones after foundation pile driving has commenced, a shutdown of foundation pile driving must be implemented. 8. Following a shutdown, foundation pile driving may not commence until appropriate conditions (i.e., measures 1–5 above) have been met. 9. Pile driving of wind turbine foundations and OSSs in the lease area must not occur from January 1 through April 30. Impact pile driving must not occur in December unless unanticipated delays due to weather or technical problems arise, notified to and approved by BOEM, that necessitate extending impact pile driving into December. **For sea turtles:** To ensure that foundation pile-driving operations are carried out in a way that minimizes the exposure of listed sea turtles to noise that may result in injury or behavioral disturbance, PSOs will establish a shutdown zone (determined at the project-specific stage) for all foundation pile-driving activities. Adherence to the shutdown zones must be reflected in the PSO reports. Any visual detection of sea turtles within the shutdown zones must trigger the required shutdown in pile installation. Upon a visual detection of a sea turtle entering or within the shutdown zone during foundation pile driving, the Lessee must shut down the pile-driving hammer (unless activities must proceed for human safety or for concerns of installation feasibility) from when the PSO observes, until: • The lead PSO verifies that the animal(s) voluntarily left and headed away from the clearance area; or • 30 minutes have elapsed without re-detection of the sea turtle(s) or detection of any sea turtles by the lead PSO.			
MMST-5	PSO coverage of expanded pile-driving clearance/shutdown zones	The Lessee must ensure that, if the clearance and/or shutdown zones are expanded due to sound field verification results (see MMST-3), PSO coverage is sufficient to reliably monitor the expanded clearance and/or shutdown zones. Additional observers must be deployed on additional platforms for every 4,921 feet (1,500 meters) that a clearance or shutdown zone is expanded beyond the distances modeled prior to verification. In the event that the clearance or shutdown zone for sea turtles needs to be expanded, the Lessee must submit a proposed monitoring plan for the expanded zones to BOEM and BSEE, who will coordinate with NMFS GARFO-PRD prior to granting approval. Expansion of the zones will be reconsidered after additional sound attenuation measures are in place that reduce distances to at or below those modeled assuming 10 dB, as verified by SFV. The implementation of expanded clearance/shutdown zone monitoring must be described in the Marine Mammal and Sea Turtle Monitoring Plan (MMST-2).	Marine Mammals, Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied
MMST-6	Pile-driving visibility requirements	PSOs must have effective visual monitoring in all directions, and pile driving must not commence until all clearance zones are fully visible (i.e., are not obscured by darkness, rain, fog, etc.) for at least 30 minutes. Unless otherwise authorized under an approved RVMP/ Nighttime Pile Driving Monitoring Plan (see MMST-1), construction activities must not be initiated until the full extent of all clearance zones are fully visible if conditions (e.g., darkness, rain, fog) prevent the visual detection of marine mammals in the clearance zones. The lead PSO will make a determination as to when there is sufficient visibility to ensure effective visual monitoring can be accomplished in all directions.	Marine Mammals, Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied
MMST-7	PSO coverage and training requirements for pile driving	The Lessee must ensure that PSO coverage is sufficient to reliably detect whales and sea turtles at the surface in clearance and shutdown zones to execute any pile driving delays or shutdown requirements. If, at any point prior to or during construction, BOEM and BSEE determine the PSO coverage that is included as part of the Proposed Action for the COP NEPA analysis is not sufficient to reliably detect ESA-listed whales and sea turtles within the clearance and shutdown zones, additional PSOs and/or platforms will be deployed. Determinations prior to construction will be based on review of the Marine Mammal and Sea Turtle Monitoring Plan for Pile Driving (MMST-2). Determinations during construction will be based on review of the weekly pile-driving reports and other information, as appropriate. The Lessee must use independent, dedicated, qualified PSOs provided by a third party. The PSOs' sole project-related duty must be to observe, collect and report data, and communicate with and instruct relevant vessel crew regarding the presence of protected species and mitigation requirements (including brief alerts regarding maritime hazards). PSOs or any PAM operators serving as PSOs must have completed a commercial PSO training program for the Atlantic with an overall examination score of 80% or greater.[1] Training certificates for individual PSOs must be provided to BOEM or BSEE upon request. PSOs and PAM operators must be approved by NMFS prior to the start of construction activities. Application requirements to become an NMFS-approved PSO for construction activities can be found on the NOAA website[2]. The Lessee must provide to BOEM, upon request, documentation of NMFS approval for individual PSOs. At least one lead PSO must be on duty at any given time as the lead PSO or PSO monitoring coordinator during pile driving. Any required lead PSOs must have prior approval from NMFS to be a lead or unconditionally approved PSO. PSOs on duty must be clearly listed on daily data logs for each shift. A sufficient number of PSOs must be deployed to record data in real time and effectively monitor the affected area for the project, including visual surveys in all directions around a pile, PAM, and continuous monitoring of sighted NARWs in the area. The number of PSOs must meet the requirements for enhanced seasonal monitoring.	Marine Mammals, Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		PSOs must not be on watch for more than 4 consecutive hours, with at least a 2-hour break after a 4-hour watch. PSOs must not work for more than 12 hours in any 24-hour period (Baker et al. 2013) unless an alternative schedule is approved by BOEM. Visual monitoring must occur from the most appropriate vantage point on the associated operational platforms that allows for 360-degree visual coverage around a vessel. The Lessee must ensure that suitable equipment is available to PSOs including binoculars, range-finding equipment, a digital camera, and electronic data recording devices (e.g., a tablet) to adequately monitor the distance of the clearance and shutdown zones, to determine the distance to protected species during surveys, to record sightings and verify species identification, and to record data. PSOs must conduct observations while free from distractions and in a consistent, systematic, and diligent manner.			
MMST-9	Vessel crew and Protected Species Observer (PSO) training requirements	The Lessee must provide project-specific training to all vessel crew members, PSOs, and trained lookouts on the identification of sea turtles and marine mammals, vessel strike avoidance and reporting protocols, how and when to communicate with the vessel operator, the authority of the PSOs, and the associated regulations for avoiding vessel collisions with protected species prior to the start of in-water construction or detonation activities. The Lessee must make available aboard all project vessels reference materials for identifying sea turtles and marine mammals, copies of the Marine Mammal and Sea Turtle Monitoring Plan (MMST-1) and the Marine Mammal Vessel Strike Management Plan (MM-5). Confirmation of the training and understanding of the requirements must be documented on a training course log sheet, and the Lessee must provide the log sheets to BOEM and BSEE upon request. The Lessee must communicate to all crew members its expectation for them to report sightings of sea turtles and marine mammals to the designated vessel contacts. The Lessee must communicate the process for reporting sea turtles and marine mammals (including live, entangled, and dead individuals) to the designated vessel contact and all crew members. The Lessee must post the reporting instructions, including communication channels, in highly visible locations aboard all project vessels.	Marine Mammals, Sea Turtles	BOEM and BSEE	Previously Applied
MMST-10	Reporting of ESA-Listed Species within Shutdown Zone During Active Pile Driving	The Lessee must report any threatened or endangered species that is observed within the identified shutdown zone during active pile driving (vibratory or impact) or drilling. The Lessee must file a report within 48 hours of the incident and include the following: description of the activity (i.e., drilling, vibratory or impact pile driving) and duration of pile driving or drilling prior to the detection of the animal(s), location of PSOs and any factors that impaired visibility or detection ability, time of first and last detection of the animal(s), distance of animal at first detection, closest point of approach of animal to pile, behavioral observations of the animal(s), time the PSO called for shutdown, hammer log (number of strikes, hammer energy), time the pile driving began and stopped, and any measures implemented (e.g., reduced hammer energy) prior to shutdown. If shutdown was determined not to be feasible, the report must include an explanation for that determination and the measures that were implemented (e.g., reduced hammer energy).	Marine Mammals, Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied
MMST-12	Marine mammal and sea turtle geophysical survey clearance and shutdown zones and mitigations	To avoid injury of and minimize any potential disturbance to protected species, the Lessee must implement the following measures for all vessels using boomer, sparker, bubble gun, and chirp sub-bottom profiler categories of equipment. Shutdown, pre-start clearance, and ramp-up procedures are not required during HRG survey operations using only other sources (e.g., ultra-short baselines, fathometers, parametric shallow penetration sub-bottom profilers, hull-mounted non-parametric SBP, side-scan sonars, pingers, acoustic releases, echosounders, and instruments attached to submersible vehicles (HOV/AUV/ROVs)). • For situational awareness of marine mammals and ESA-listed species that may be in the survey area, during times third-party protected species observers (PSOs) are on duty, they must monitor to the farthest extent practicable, with a primary focus being 200 m around geophysical survey vessels (i.e., the Clearance Zone). At all times PSOs are on duty, any observed species must be recorded (see reporting requirements below). • Any observations of a marine mammal or ESA-listed species by crew members aboard any vessel associated with the survey must be relayed to the PSO on duty. • To minimize exposure of ESA-listed species of marine mammal to noise that could be disturbing, a 200 m Shutdown Zone for North Atlantic right whales and unidentified whales, and a 100-m Shutdown Zone for all other ESA-listed whales visible at the surface must be established around the sound source operating boomer, sparker, or bubble gun equipment. If the Shutdown Zone(s) cannot be adequately monitored for ESA-listed species presence (i.e., PSO discretion determines conditions, including night or other low visibility conditions, are such that listed species cannot be reliably sighted within the Shutdown Zone(s) with the available monitoring equipment), no equipment that requires PSO monitoring can be deployed until such time that the Shutdown Zone(s) can be effectively monitored. • The Shutdown Zone(s) must be monitored by third-party PSOs at all times when boomer, sparker, bubble gun, or Chirp sub-bottom profiler categories of equipment are being operated and all observed ESA-listed species must be recorded. • If an ESA-listed whale is detected within or entering the respective Shutdown Zone, any boomer, sparker, or bubble gun categories of equipment that requires PSOs must be shut off until the minimum separation distance is re-established, and the clearance measures are carried out (200 m for North Atlantic right whales and 100 m for other ESA-listed whales). • A PSO must notify the survey crew that a shutdown of all active boomer, sparker, and bubble gun acoustic sources is immediately required. The vessel operator and crew must comply immediately with any call for a shutdown by the PSO. Any disagreement or discussion must occur only after shutdown. • For all protected species, Clearance Zones of 200 m for all ESA-listed species of marine mammal must be clear of all animals for 30 minutes before ramp-up or any deployed survey equipment is activated. • If any protected species is observed within the respective Clearance Zone during the 30-minute pre-clearance period, the relevant acoustic sources must not be initiated until the ESA-listed whale (or unidentified whale) is confirmed by visual observation to have exited the relevant zone, or, until 30 minutes have elapsed with no further sighting of the animal. • A "ramp up" of the boomer, sparker, or bubble gun survey equipment must occur at the start or re-start of geophysical survey activities when technically feasible. A ramp up must begin with the power for the geophysical survey equipment ramped up to half power for 5 minutes, and then to full power. • Following a shutdown for any reason, ramp up of the equipment may begin immediately only if: (a) the shutdown is less than 30 minutes, (b) visual monitoring of the Shutdown Zone(s) continued throughout the shutdown, (c) the animal(s) causing the shutdown was visually followed and confirmed by PSOs to be outside of	Marine Mammals, Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		the Shutdown Zone(s) and heading away from the vessel, and (d) the Shutdown Zone(s) remains clear of all ESA-listed species. If all the conditions above (a, b, c, and d) are not met, the Clearance Zone distance must be monitored for all ESA-listed species for 30 minutes of pre-clearance observation before noise-producing equipment can be turned back on. • No geophysical surveys may be conducted at night or during low-visibility conditions unless PSOs are able to effectively monitor the full extent of the Clearance and Shutdown Zone(s). • An Alternative Monitoring Plan (AMP) for geophysical surveys must be included with a survey plan detailing the monitoring methodology that will be used during nighttime and low-visibility conditions. The AMP must demonstrate how it will support effective monitoring for the presence of whales and sea turtles in the Clearance and Shutdown Zone(s). The AMP should include information about the distances that whales can be effectively detected using the identified technology/equipment, and any limitations posed by sea state(s) or vessel equipment (e.g., deck lights) that may inhibit the field of view. • The AMP must include technologies that have the technical feasibility to detect all ESA-listed species in the Clearance and Shutdown Zone(s). Low-light equipment (i.e., night-vision goggles and/or infrared technology) must be available for use during low visibility (e.g., inclement weather, nighttime) monitoring. • PSOs must be trained and experienced with any AMP technology used. The AMP must describe how calibration will be performed, for example, by including observations of known objects at set distances and under various lighting conditions. This calibration should be performed during mobilization and periodically throughout the survey operation. • PSOs shall make nighttime observations from a platform with no visual barriers, due to the potential for the reflectivity from bridge windows or other structures to interfere with the use of the night vision optics. • Boomer, sparker, bubble gun, or Chirp sub-bottom profiler sound sources used within the Southeast Right Whale Critical Habitat Unit 2 during the calving and nursing season (December-March) shall not operate at frequencies between 7 kHz and 35 kHz at night or poor visibility (i.e., anytime AMP methods are required). • During good conditions (e.g., daylight hours; Beaufort scale 3 or less) when survey equipment is not operating, to the maximum extent practicable (accounting for recommended shift schedules and vessel activities), PSOs should conduct observations for listed species for comparison of sighting rates and behavior with and without use of active geophysical survey equipment. Any observed listed species must be recorded regardless of any mitigation actions required.			

MMST-14	Vessel strike mitigation measures for marine mammals and sea turtles	The Lessee must comply with the following vessel strike avoidance conditions for any construction, operations, or decommissioning vessel transits associated with the project, unless the safety of the vessel or crew necessitates deviation from these requirements. The Lessee must report any such deviations as set forth in MUL-32.
		• PSO Requirements. The Lessee must ensure that vessel operators and crew members maintain a vigilant watch for marine mammals and sea turtles, and reduce vessel speed, alter the vessel's course, or stop the vessel as necessary to avoid striking marine mammals or sea turtles, consistent with identified requirements.
		  ○ All vessels must have a visual observer on board who is responsible for monitoring the vessel strike avoidance zone for marine mammals and sea turtles. Visual observers may be PSO or Trained Lookouts (if PSOs are not required), but Trained Lookouts responsible for these duties must be provided sufficient training by the Lessee to distinguish marine mammals and sea turtles from other phenomena and must be able to identify a marine mammal as a NARW, other whale (defined in this context as sperm whales or baleen whales other than NARW), or other marine mammal, as well as sea turtles. Any crew designated as Trained Lookouts must also receive training on vessel strike minimization procedures, how and when to communicate with the vessel captain, and reporting requirements. All observations must be recorded per reporting requirements.
		  ○ If the Trained Lookout is a vessel crew member, this must be their designated role and primary responsibility on shift. Crew members serving as visual observers must not have other duties while observing for marine mammals while the vessel is operating over 10 knots.
		• Vessel captains/ operators must reduce vessel speed to 10 knots (18.5 kilometers per hour) or less for the remainder of that day when mother/calf pairs, pods, or large assemblages of cetaceans are observed near an underway vessel when safety permits. The presence of a single individual at the surface may indicate the presence of submerged animals in the vicinity of the vessel; therefore, precautionary measures should always be exercised.
		• Alternative monitoring technology (e.g., night vision, thermal cameras) must be available on all vessels to maintain a vigilant watch at night and in any other low-visibility conditions. All observations must be recorded per reporting requirements. The trained lookout must check the Sea Turtle Sighting Hotline (https://seaturtlesightings.org/) before each trip and report any detections of sea turtles in the vicinity of the planned transit to all vessel operators or captains and lookouts on duty that day.
		• Vessel captain and crew must maintain a vigilant watch for all protected species and reduce speed, stop their vessel, or alter course, as appropriate and regardless of vessel size, to avoid striking any listed species. If pinnipeds or small delphinids of Delphinus, Lagenorhynchus, Stenella, or Tursiops are visually detected approaching the vessel (i.e., to bow ride) or towed equipment, vessel speed reduction, course alteration, and shutdown are not required.
		• If a vessel is underway, a PSO must monitor a protected species separation distance of 100 m for sea turtles and 500 m or greater for marine mammals visible at the surface, to ensure detection of that animal in time to take necessary measures to avoid striking the animal. If the vessel does not require a PSO for the type of activity being conducted, crew may be used as a Trained Lookout to meet this requirement.
		• All vessel crew members must be briefed in the identification of protected species that may occur in the survey area and in regulations and best practices for avoiding vessel collisions. Reference materials must be available aboard all project vessels for identification of listed species. The expectation and process for reporting protected species sightings during surveys must be clearly communicated and posted in highly visible locations aboard all project vessels, so that there is an expectation for reporting to the designated vessel contact (such as the lookout or the vessel captain), as well as a communication channel and process for crew members to do so. Vessel crew members must be provided with an Atlantic reference guide to help identify marine mammals and sea turtles that may be encountered. Vessel personnel must also be provided material regarding NARW SMAs, DMAs, visually triggered Slow Zones, sightings information, and reporting.
		• A minimum separation distance of 500 m from all ESA-listed whales (including unidentified large whales) must be maintained around all surface vessels at all times.
			Marine Mammals, Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		• If a large whale is identified within 500 m of the forward path of any vessel, the vessel operator must steer a course away from the whale at 10 knots (18.5 km/hr) or less until the 500 m minimum separation distance has been established. Vessels may also shift to idle if feasible. • If a large whale is sighted within 200 m of the forward path of a vessel, the vessel operator must reduce speed and shift the engine to neutral. Engines must not be engaged until the whale has moved outside of the vessel's path and beyond 500 m. If stationary, the vessel must not engage engines until the large whale has moved beyond 500 m. • If a sea turtle or manta ray is sighted at any distance within the operating vessel's forward path, the vessel operator must slow down to 4 knots and steer away (unless unsafe to do so). The vessel may resume normal vessel operations once the vessel has passed the turtle or ray. • On vessels operating north of the Virginia/North Carolina border between June 1 and November 30, the Lessee must post a trained lookout on all vessel transits during all phases of the project to observe for sea turtles. The trained lookout must communicate any sightings, in real time, to the vessel operator so that the requirements can be implemented. • On vessels operating south of the Virginia/North Carolina border, the Lessee must post a trained lookout on all vessel transits during all phases of the project to observe for sea turtles. The trained lookout must communicate any sightings, in real time, to the vessel operator so that the requirements can be implemented. • The trained lookout must maintain a vigilant watch and monitor a Vessel Strike Avoidance Zone (500 m) at all times to avoid potential vessel strikes of ESA-listed sea turtle species. Alternative monitoring technology (e.g., night vision, thermal cameras, etc.) must be available and utilized by the lookout to ensure effective watch at night and in any other low visibility conditions. If the trained lookout is a vessel crew member, this must be their designated role and primary responsibility while the vessel is transiting. Any designated crew lookouts must receive training on protected species identification, vessel strike minimization procedures, how and when to communicate with the vessel captain, and reporting requirements. • If a sea turtle is sighted within 100 m or less of the operating vessel's forward path, the vessel operator must slow down to 4 knots (unless unsafe to do so) and then proceed away from the turtle at a speed of 4 knots or less until there is a separation distance of at least 100 m at which time the vessel may resume normal operations. Vessel transits to and from the wind project area that require PSOs must maintain a speed that will allow, considering weather conditions, effective detection of sea turtles prior to reaching the 100 m avoidance measure. If a sea turtle is sighted within 50 m of the forward path of the operating vessel, the vessel operator must shift to neutral when safe to do so and then proceed away from the turtle at a speed of 4 knots. The vessel may resume normal operations once it has passed the turtle. • Vessel captains/ operators must avoid transiting through areas of visible jellyfish aggregations or floating Sargassum lines or mats. In the event that operational safety prevents avoidance of such areas, vessels must slow to 4 knots while transiting through such areas. • Vessels operating in water depths with less than four feet of clearance between the vessel and the bottom should maintain speeds no greater than 4 kts to minimize risk of vessel strikes on sturgeon and sawfish. • All vessel crew members must be briefed in the identification of sea turtles and in regulations and best practices for avoiding vessel collisions. Reference materials must be available aboard all project vessels for identification of sea turtles. The expectation and process for reporting of sea turtles (including live, entangled, and dead individuals) must be clearly communicated and posted in highly visible locations aboard all project vessels, so that there is an expectation for reporting to the designated vessel contact (such as the lookout or the vessel captain), as well as a communication channel and process for crew members to do so. • The only exception to the requirements regarding vessel speed and avoiding jellyfish, Sargassum, and/or sea turtles is when the safety of the vessel or crew during an emergency necessitates deviation from these requirements. If any such incidents occur, they must be reported to BSEE and NMFS GARFO-PRD within 24 hours. • If a vessel is carrying a PSO or trained lookout for the purposes of maintaining watch for NARWs, an additional lookout is not required and this PSO or trained lookout must maintain watch for whales and sea turtles. • Vessel transits to and from the project area that require PSOs must maintain a speed commensurate with weather conditions and effectively detecting sea turtles prior to reaching the 100 m separation distance mentioned above, at which point the vessel must reduce speed and avoid sea turtles. • Any observations of a marine mammal or ESA-listed species by crew members aboard any vessel associated with the project must be relayed to the PSO on duty and/or captain of the vessel. • Regardless of monitoring duties, all crew members responsible for navigation duties must receive site-specific training on ESA-listed species sighting/reporting and vessel strike avoidance measures. • Vessels underway must not divert their course to approach any ESA-listed species and marine mammals. • Regardless of vessel size, vessel operators must reduce vessel speed to 10 knots (18.5 kph) or less while operating in any Seasonal Management Area (SMA) and Dynamic Management Area (DMA) or Slow Zone for North Atlantic right whales, unless the vessel is operating in a designated DMA or Slow Zone where right whales have not been detected and it is not reasonable to expect the presence of North Atlantic right whales (e.g., Long Island Sound, shallow harbors). Information about active SMAs, DMAs, and Slow Zones can be accessed at: https://www.fisheries.noaa.gov/national/endangered-species-conservation/reducing-vessel-strikes-north-atlantic-right-whales. • Year-round, all vessel operators must monitor the project's Situational Awareness System, WhaleAlert, USCG VHF Channel 16, and the Right Whale Sighting Advisory System (RWSAS) for the presence of NARWs once every 4-hour shift during project-related activities. The PSO and PAM operator monitoring teams for all activities must also monitor these systems no less frequently than every 12 hours. If a vessel operator is alerted to a NARW detection within the project area, the operator must immediately convey this information to the PSO and PAM teams. For any UXO/MEC detonation, vessel operators must monitor these systems for 24 hours prior to detonating any UXO/MEC.			

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		The following measures, in addition to the PSO measures outlined in MUL-10d, also apply to all vessels associated with any survey activities (transiting or actively surveying): • For monitoring around ASVs controlled from a manned vessel, regardless of the equipment the vessel may be operating, a dual thermal/HD camera must be installed on the mother vessel facing forward and angled in a direction so as to provide a field of view ahead of the vessel and around the ASV. A dedicated operator must be able to monitor the real-time output of the camera on hand-held computer tablets. Images from the cameras must be able to be captured and reviewed to assist in verifying species identification. A monitor must also be installed in the bridge displaying the real-time images from the thermal/HD camera installed on the front of the ASV itself, providing a further forward view of the craft. In addition, night-vision goggles with thermal clip-ons and a handheld spotlight must be provided and used such that PSOs can focus observations in any direction around the mother vessel and/or the ASV. • Survey plans must include identification for vessel strike avoidance measures, including procedures for equipment shut down and retrieval, communication between PSOs/Trained Lookouts, equipment operators, and the captain, and other measures necessary to avoid vessel strikes while maintaining vessel and crew safety. If any circumstances are anticipated that may preclude the implementation of this measure, they must be clearly identified in the survey plan and alternative procedures outlined in the plan to ensure minimum distances are maintained and vessel strikes can be avoided. • To monitor the minimum separation distance, a PSO (or Trained Lookout if PSOs are not required) must be posted during all times a vessel is underway (transiting or surveying) to monitor for listed species within a 180-degree direction of the forward path of the vessel (90 degrees port to 90 degrees starboard). • Visual observers monitoring the minimum separation distance can be either PSOs or Trained Lookouts (if PSOs are not required). If the Trained Lookout is a vessel crew member, this must be their designated role and primary responsibility on shift. Any crew designated as Trained Lookouts must receive training on protected species identification, vessel strike minimization procedures, how and when to communicate with the vessel captain, and reporting requirements. All observations must be recorded per reporting requirements.			
MUL-1	Marine debris awareness and elimination	“Marine trash and debris” is defined as any object or fragment of wood, metal, glass, rubber, plastic, cloth, paper or any other solid, human-made item or material that is lost or discarded in the marine environment by the Lessee or an authorized representative of the Lessee (collectively, the “Lessee”) while conducting activities on the OCS in connection with a lease, grant, or approval issued by the BOEM or BSEE. To understand the type and amount of marine debris that may be generated, and to minimize the risk of entanglement in and/or ingestion of marine debris by protected species, the Lessee must implement the following: • Marine Debris Awareness Training and Certification: The Lessee must ensure that all vessel operators, employees, and contractors engaged in a project’s offshore activities complete marine trash and debris awareness training initially (i.e., prior to engaging in offshore activities pursuant to the approved COP) and annually. Operators must implement a marine debris awareness training and certification process that ensures that their employees and contractors are adequately trained. The training and certification process must include the following elements: (1) viewing of either a marine debris video or training slide pack posted on the BSEE website (https://www.bsee.gov/debris) or by contacting BSEE; (2) receiving an explanation from management personnel that emphasizes their commitment to the requirements; and (3) documented certification that all personnel listed above have completed their initial and annual training. The Lessee must make this certification available for inspection by BSEE upon request. The marine trash and debris training videos, training slide packs, and other marine debris related educational material may be obtained at https://www.bsee.gov/debris or by contacting BSEE at marinedebris@bsee.gov. The training videos, slides, and related material may be downloaded directly from the website. • Training Compliance Report: By January 31 of each year, the Lessee must submit to BSEE an annual report that describes its marine trash and debris awareness training process and certifies that the training process has been followed for the previous calendar year. • Marking: Any materials, equipment, tools, containers, and other items that are used in OCS activities and that are of such shape or configuration that make them likely to snag or damage fishing devices or be lost or discarded overboard, must be clearly marked with the vessel or facility identification number, and must be properly secured to prevent loss overboard. All markings must clearly identify the owner and must be able to resist the effects of the environmental conditions to which they may be exposed. • Recovery and Prevention: Discarding trash or debris in the marine environment is prohibited. Debris accidentally released by the Lessee into the marine environment while performing any activities associated with the project must be recovered within 24 hours when the marine debris is likely to (a) cause undue harm or damage to natural resources (e.g., entanglement or ingestion by protected species); or (b) interfere with OCS uses (e.g., snagging or damaging fishing equipment, or presenting a hazard to navigation). If the marine debris was lost within the boundaries of an archaeological resource/avoidance area, or a sensitive ecological/benthic resource area, the Lessee must contact BSEE for concurrence before conducting any recovery efforts. The Lessee must take steps to prevent similar releases of marine debris and must submit a description of these preventative actions to BSEE within 30 days from the date on which the release of marine debris occurred. • Notification: The Lessee must notify BSEE within 24 hours of any releases of marine debris and indicate whether the released marine debris was immediately recovered. If the marine debris was not recovered, the Lessee must provide its rationale for not recovering the marine debris (e.g., marine debris is located within the boundaries of a sensitive area, recovery was not possible because conditions were unsafe, or recovery was not practicable and warranted because the released marine debris is not likely to result in items (a) or (b) listed in above). • Remedial Recovery: After reviewing the notification and rationale for any decision by the Lessee to forgo recovery, BSEE may order the Lessee to recover the marine debris if BSEE finds that the reasons provided by the Lessee in the notification are insufficient and the marine debris would cause undue harm or damage to natural resources or interfere with OCS uses. • Recovery Plan: If BSEE requires the Lessee to recover the marine debris, the Lessee must submit a Recovery Plan to BSEE within 10 days after receiving BSEE’s order. Unless BSEE objects within 48 hours after the Recovery Plan has been accepted or is in review status by BSEE in TIMSWeb, the Lessee may proceed with the	Benthic; Finfish, Invertebrates, and EFH; Marine Mammals; Water Quality; Sea Turtles	BOEM and BSEE	Previously Applied

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		activities described in the Recovery Plan. Recovery activities must be completed 30 days from the date on which marine debris was released, unless BSEE grants the Lessee an extension. • Recovery Completion Notification: Within 30 days after the marine debris is recovered, the Lessee must provide notification to BSEE that recovery was completed and, if applicable, describe any substantial variance from the activities described in the Recovery Plan that was required during the recovery efforts. • Monthly Reporting: The Lessee must submit to BSEE a monthly report, no later than the fifth day of the month, of all marine debris lost or discarded during the preceding month, including, if applicable, information related to 24 Hour Reporting and Recovery Plan and the referenced TIMSWeb Submittal ID (SID). The Lessee is not required to submit a report for those months in which no marine debris was lost or discarded. The monthly report must include the following: a. Project identification and contact information for the Lessee and for any operators or contractors involved; b. Date and time of the incident; c. Lease number, OCS area and block, and coordinates of the object's location (latitude and longitude in decimal degrees); d. A detailed description of the dropped object to include dimensions (approximate length, width, height, and weight), composition (e.g., plastic, aluminum, steel, wood or paper), and buoyancy (floats or sinks); e. Pictures, data imagery, data streams, and/or a schematic or illustration of the object, if available; f. Indication of whether the lost or discarded item could be detected as a magnetic anomaly of greater than 50 nanotesla (nT), a seafloor target of greater than 1.6 feet (0.5 meter), or a sub-bottom anomaly of greater than 1.6 feet (0.5 meter) when operating a magnetometer or gradiometer, side scan sonar, or sub-bottom profiler; g. Explanation of how the object was lost; and h. Description of immediate recovery efforts and results, including photos. • Annual Surveying and Reporting – Periodic Underwater Surveys, Reporting of Monofilament and Other Fishing Gear Around WTG Foundations: The Lessee must monitor indirect impacts associated with charter and recreational fishing gear lost from expected increases in fishing around WTG foundations by annually surveying at least 10 of the WTGs in the lease area for the first three years following COP approval and every 5 years thereafter. The Lessee may conduct surveys by remotely operated vehicles, divers, or other means to determine the frequency and locations of marine debris. The Lessee must report the results of the surveys to BOEM and BSEE in an annual report, submitted by January 31, for the preceding calendar year. Annual reports must be submitted in both Microsoft Word and Adobe PDF format. Photographic and videographic materials (TIFF or Motion JPEG 2000) must be provided in TIMSWeb with the submittal of the annual report. Photographic and videographic files can also be submitted to marinedebris@bsee.gov if the files cannot be uploaded in TIMSWeb. Survey design and effort (i.e., the number of WTGs and frequency of reporting) may be modified only upon review and concurrence by BOEM and BSEE. a. Annual reports must include a summary of the survey reports that includes survey date(s); contact information of the operator; location and pile identification number; photographic and/or video documentation of the survey and debris encountered; any animals sighted; and the disposition of any located debris (i.e., removed or left in place). Annual reports must also include claim data attributable to the project from the Lessee's corporate gear loss compensation policy and procedures. Required data and reports may be archived, analyzed, published, and disseminated by BOEM and BSEE. • Site Clearance and Decommissioning: The Lessee must include and address information on unrecovered marine debris in the description of the site clearance activities provided in the decommissioning application required under 30 C.F.R. § 285.906.			
MUL-2	Anchoring plan	The Lessee must prepare and implement an Anchoring Plan(s) for all areas where anchoring or buoy placement occurs and jack-up barges are used during construction and operations/maintenance within 1,640 feet (500 meters) of habitats, resources, and submerged infrastructure that are sensitive, including sensitive benthic habitats; boulders greater than or equal to 0.5 m; ancient submerged landform features (ASLFs); known and potential shipwrecks; potentially significant debris fields; potential hazards; third-party infrastructure; and any related facility installation activities (such as cable, WTG, and ESP installation). The plan will require that the Lessee consider any new data on benthic habitats and cultural resources to avoid/minimize impacts on these resources to the maximum extent practicable. It will require all vessels deploying anchors to use, whenever feasible and safe, mid-line anchor buoys to reduce the amount of anchor chain or line that touches the seafloor. The Lessee must provide the anchoring plan to BOEM and BSEE to coordinate with NMFS for review before anchoring activities and construction begin. The Lessee must resolve all comments on the anchoring plan to BOEM and BSEE's satisfaction before conducting any OCS seabed-disturbing activities that require anchoring. For operations and decommissioning, the Lessee must provide proposed anchoring plats to BOEM and BSEE for review and concurrence before anchoring activities occur. The proposed anchoring plats must include avoidances identified above and as-placed anchor plats must be submitted to BOEM and BSEE after completion of an activity (including during operations) or construction of a major facility component (e.g., buoys, export cable installation, WTG or OSS installation and interarray cable installation) or decommissioning to demonstrate that seabed-disturbing activities complied with avoidance requirements for seabed features and hazards, archaeological resources, and/or anomalies. As-placed plats must show the "as-placed" location of all anchors and any associated anchor chains and/or wire ropes and relevant locations of interest or avoidance on the seabed for all seabed-disturbing activities. The plats must be at a scale of 1 inch = 1,000 feet (300 meters) with Differential GPS accuracy.	Benthic; Commercial and For-Hire Fishing; Cultural Resources; Finfish, Invertebrates, and EFH; Water Quality	BOEM, BSEE, and NMFS	Previously Applied
MUL-3	Berm survey and report	Where plows, jets, grapnel runs, or other similar methods are used, post-construction geophysical surveys required as part of the Post-Installation Cable Monitoring must be capable of detecting bathymetry changes of 0.5 meters or less and must be completed to determine the height and width of any created berms. The Lessee must capture bathymetry changes greater than 3 feet during the first and second post-installation surveys along the cable routes. If there are bathymetric changes in berm height greater than 1 meter above grade after the second survey, the Lessee must develop and implement a Berm Remediation Plan to restore created berms to match adjacent natural bathymetric contours (isobaths), as technically and/or economically practical or feasible. The Lessee must submit the Berm Remediation Plan to BOEM and BSEE for a review (in coordination with NMFS) within 90 days of completion of the post-construction survey where the change was detected. The Lessee	Benthic; Finfish, Invertebrates, and EFH	BOEM and BSEE	Previously Applied

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		must resolve all comments on the Berm Remediation Plan to BOEM's and BSEE's satisfaction prior to initiating restoration activities. The final version of the Berm Remediation Plan must be provided to BOEM, BSEE, NMFS, and USACE.			
MUL-4	Final cable protection in hardbottom	The Lessee must avoid the use of engineered stone or concrete mattresses in complex habitat, as practicable and/or feasible. The Lessee must ensure that all materials used for scour and cable protection measures consist of natural or engineered stone that does not inhibit epibenthic growth and provides three-dimensional complexity in height and in interstitial spaces, as practicable and feasible. If concrete mattresses are necessary, bioactive concrete (i.e., with bio-enhancing admixtures) must be used as practicable as the primary scour protection (e.g., concrete mattresses) or veneer to support biotic growth.	Benthic; Finfish, Invertebrates, and EFH	BOEM, BSEE, and NMFS	Previously Applied
MUL-8	Gear identification	To facilitate identification of gear on any entangled animals, all trap/pot gear used in the surveys must be uniquely marked to distinguish it from other commercial or recreational gear. Using yellow and black striped duct tape, place a 3-foot-long mark within 2 fathoms of a buoy. In addition, using black and white paint or duct tape, place three additional marks on the top, middle, and bottom of the line. These gear marking colors are proposed as they are not gear markings used in other fisheries and are therefore distinct. Any changes in marking would not be made without notification and approval from NMFS.	Finfish, Invertebrates, and EFH; Marine Mammals; Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied
MUL-9	Lost survey gear	The Lessee must ensure that any lost fishery and benthic monitoring survey gear is reported and recovered according to the Marine Debris Awareness and Elimination (MUL-1) measure. All lost gear must also be reported to NMFS GARFO-PRD and BSEE within 24 hours (or as required in the MMPA Incidental Take Authorization (ITA)) of the documented time when gear is discovered to be missing or lost. This report must include information on any markings on the gear and any efforts undertaken or planned to recover the gear.	Finfish, Invertebrates, and EFH; Marine Mammals; Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied
MUL-10a	Avoid live bottom features during data collection and site survey activities	All vessel anchoring and any seafloor-sampling activities are restricted from seafloor areas with deep/cold-water coral reefs and shallow/mesophotic reefs. All vessel anchoring and seafloor sampling must also occur at least 150 m from any known locations of threatened or endangered coral species. All sensitive live bottom habitats (eelgrass, cold-water corals, etc.) should be avoided as practicable. All vessels in coastal waters will operate in a manner to minimize propeller wash and seafloor disturbance and transiting vessels should follow deep-water routes (e.g., marked channels), as practicable, to reduce disturbance to sturgeon habitat.	Finfish, Invertebrates, and EFH; Benthic	BOEM, BSEE, and NMFS	Previously Applied
MUL-10d	Third-party PSO requirements during data collection and site survey activities	The Lessee must use qualified third-party PSOs to observe Clearance and Shutdown Zones, and implement mitigation measures as outlined in the conditions in MMST-12 and MMST-14. Additionally: • All PSOs must have completed a training program with BOEM-approved PSO training materials. PSOs must also have received NMFS approval to act as a PSO for geophysical surveys. Application requirements to become an NMFS-approved PSO for surveys are available by sending an inquiry to nmfs.psoreview@noaa.gov. The Lessee must provide to BOEM upon request, documentation of NMFS approval as PSOs for geophysical activities in the Atlantic and copies of the most recent training certificates of individual PSOs' successful completion of a commercial PSO training course with an overall examination score of 80% or greater. Instructions and application requirements to become a NMFS- approved PSO can be found at: https://www.fisheries.noaa.gov/national/endangered-species-conservation/protected-species-observers. • For situations where Trained Lookouts are used when PSOs are not required, training must include protected species identification, vessel strike minimization procedures, how and when to communicate with the vessel captain, and reporting requirements. • PSOs deployed for mitigation, monitoring, and reporting of geophysical survey activities must be employed by a third-party observer provider. While the vessel is underway, they must have no other tasks other than to conduct observational effort, record data, communicate with and instruct relevant vessel crew to the presence of listed species and implement required mitigation and monitoring measures. PSOs on duty must be clearly listed on daily data logs for each shift. ○ Non-third-party observers may be approved by NMFS on a case-by-case basis for limited, specific duties in support of approved, third-party PSOs. • A minimum of one PSO must be on duty for observing listed species on each vessel at all times, including times with low visibility (e.g., night time, fog) that noise-producing equipment is operating, or the survey vessel is actively transiting. The Lessee must include a PSO schedule showing that the number of PSOs used is sufficient to effectively monitor the affected area for the project (e.g., surveys) and record the required data. PSOs must not be on watch for more than 4 consecutive hours, with at least a 2-hour break after a 4-hour watch. PSOs must not work for more than 12 hours in any 24-hour period. • Visual monitoring must occur from the most appropriate vantage point on the associated operational platform that allows for maximum possible 360-degree field of view around the sound source and vessel. If 360-degree field of view is not possible from a single vantage point, multiple PSOs must be on watch to ensure such coverage to ensure both geophysical survey and vessel strike avoidance requirements for ESA-listed species can be implemented. • The Lessee must ensure that suitable equipment is available to each PSO to adequately observe the full extent of the Clearance and Shutdown Zones prior to and during all geophysical survey activity respectively and meet all reporting requirements. The following equipment must be available. ○ Visual observations must be conducted using binoculars and the naked eye while free from distractions and in a consistent, systematic, and diligent manner. ○ Rangefinders (at least one per PSO, plus backups) or reticle binoculars (e.g., 7 x 50) of appropriate quality (at least one per PSO, plus backups) to estimate distances to listed species located in proximity to the Clearance and Shutdown Zone(s). ○ Digital cameras with a telephoto lens that is at least 300 mm or equivalent on a full-frame single lens reflex (SLR). The camera or lens should also have an image stabilization system. Used to record sightings and verify species identification when possible. ○ A laptop or tablet to collect and record data electronically. ○ Global Positioning Units (GPS) if data collection/reporting software does not have built-in positioning functionality. ○ Any other tools deemed necessary to adequately perform PSO tasks.	Marine Mammals; Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
MUL-10e	PSO Reporting requirements during site characterization and site assessment/data collection activities	These reporting requirements pertain to site characterization (HRG, geotechnical, and biological surveys) and site assessment/data collection (deployment, operation, and retrieval of meteorological and oceanographic data buoys) activities associated with Atlantic OCS leases. To ensure compliance and evaluate effectiveness of mitigation measures, regular reporting of survey activities and information on listed species will be required as follows. Only vessel surveys which require third-party PSOs will be required to meet reporting requirements. Reporting requirements must be completed if applicable regardless of survey type or type of observer. PSO data must be collected in accordance with standard data reporting, software tools, and electronic data submission standards approved by BOEM and NMFS for the particular activity. • **Monthly Survey Reports.** Monthly reporting of raw PSO data collected during geophysical survey activities must be submitted to BOEM (renewable_reporting@boem.gov) and BSEE (via TIMS Web Portal and protectedspecies@bsee.gov) by the PSO provider on the 15th of each month for each vessel conducting survey work. Any editing, review, and quality assurance checks must be completed only by the PSO provider prior to submission to BOEM and ensure use of standard field codes and formats. Monthly data reporting from all PSO observations must be recorded based on standard PSO collection and reporting requirements. PSOs must use standardized electronic data forms to record data. The PSOs may record data electronically in data collection software, but the data fields listed below must be recorded and exported to an Excel file for submittal. Alternatively, BOEM has developed an Excel spreadsheet with all the necessary data fields that is available upon request. • **Final Survey Reports.** Final survey reports must be submitted to BOEM in coordination with PSO Providers within 90 calendar days following completion of a survey. Final reports must contain all survey activity included under each submitted survey plan, but include individual vessel departure and return ports, PSO names and training certifications, the PSO provider contact information, dates of the survey, a vessel track, a summary of all PSO documented sightings of protected species, survey equipment shutdowns that occurred, any vessel strike-avoidance measures taken, takes of protected species that occurred, and any observed injured or dead protected species. The DOI will work with the Lessee to ensure that DOI does not release confidential business information found in the monitoring reports. • **Instructions for Geophysical Survey Reports**. The following data fields for PSO reports of geophysical surveys must be reported in Excel format (.xml file) along with metadata defining all data fields. **Survey Information:** ○ Project name ○ Lease number ○ State Coastal Zones ○ Survey Contractor ○ Survey Type ○ Reporting start and end dates ○ Visual monitoring equipment used (e.g., bionics, magnification, IR cameras, etc.); ○ Distance finding method used ○ PSO names (last, first), training certification, and affiliation ○ PSO location and observation height above sea surface **Operations Information:** ○ Vessel name(s) ○ Sound sources including equipment type, power levels, and frequencies used ○ Greatest RMS source level ○ Dates of departures and returns to port with port name **Monitoring Effort Information:** ○ Date (YYYY-MM-DD) ○ Source status at time of observation (on/off) ○ Number of PSOs on duty ○ Start time of observations for each shift in UTC (YY-MM-DDT HH:MM) ○ End time of observations for each shift in UTC (YY-MM-DDT HH:MM) ○ Duration of visual observations of protected species ○ Weather ○ Wind speed (knots), direction (cardinal direction) ○ Beaufort Scale sea state ○ Water depth (meters) ○ Visibility (km) ○ Glare severity related to monitoring area (none, slight, moderate, extreme) ○ Time pre-clearance visual monitoring began in UTC (YY-MM-DDT HH:MM) ○ Time pre-clearance monitoring ended in UTC (YY-MM-DDT HH:MM)	Marine Mammals; Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		○ Duration of pre-clearance visual monitoring ○ Time of day of pre-clearance began (day/night) ○ Time power-up/ramp-up began ○ Time equipment full power was reached ○ Duration of power-up/ramp-up (if conducted) ○ Time survey activity began (equipment on) in UTC ○ Time survey activity ended (equipment off) in UTC ○ Survey Duration ○ Did a shutdown/power-down occur? • Time shutdown was called for (UTC) • Time equipment was shut down (UTC) ○ Vessel location (latitude/longitude, decimal degrees) when survey effort begins and ends; vessel location at beginning and end of visual PSO duty shifts; recorded at :30 intervals if obtainable from data collection software ○ Habitat or prey observations (narrative) ○ Marine debris sightings (narrative) **Detection Information (in addition to the Survey, Operation, and Monitoring fields)** ○ Date (YYYY-MM-DD) ○ Sighting ID (multiple sightings of the same animal or group should use the same ID) ○ Time at first detection in UTC (YY-MMDDT HH:MM) ○ Time at last detection in UTC (YY-MM-DDT HH:MM) ○ PSO name(s) (Last, First) on duty ○ Observer location ○ Number of observes on duty ○ Watch Status (On effort PSO, off effort PSO, opportunistic, crew, alternate vessel/platform) ○ Effort (ON=Device On; OFF=Device Off) ○ Start time of observations ○ End time of observations ○ Location of vessel when detection occurs: Latitude and Longitude (decimal degrees) ○ Compass heading of vessel (degrees) ○ Beaufort sea state ○ Wind speed (knots/direction) ○ Swell Height (meters) ○ Weather/Precipitation ○ Visibility (kilometers) ○ Cloud coverage (%) ○ Glare severity related to monitoring area (none, slight, moderate, extreme) ○ Species (Species Code) ○ Certainty of identification ○ Number of adults (high, low, best) ○ Number of juveniles (high, low, best) ○ Total number of animals or estimated group size ○ Sighting cue (Blow, Breach, White water, Flukes, Body) ○ Bearing to animal(s) when first detected (ship heading in degrees + clock face direction to animal) ○ Distance determination method (use code) ○ Distance from vessel (e.g., reticle distance in meters) ○ Description of unidentified animals (include features such as overall size; shape of head; color and pattern; size, shape, and position of dorsal fin; height, direction, and shape of blow, etc.) ○ Detection narrative (note behavior, especially changes in relation to survey activity and distance from source vessel) ○ Direction of travel/first approach (relative to vessel) ○ Behaviors observed: indicate behaviors and behavioral changes observed in sequential order (use behavioral codes)			

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		○ If any bow-riding behavior observed, record total duration during detection (YY-MM-DDT HH:MM) ○ Initial heading of animal(s) (ship heading in degrees + clock face direction to animal) ○ Final heading of animal(s) (ship heading in degrees + clock face direction to animal) ○ Shutdown zone size during detection (meters) ○ Was the animal inside the shutdown zone? (Y/N) ○ Closest distance to vessel (reticle distance in meters) ○ Time at closest approach (UTC YY-MM-DDT HH:MM) ○ Time animal entered shutdown zone (UTC YY-MM-DDT HH:MM) ○ Time animal left shutdown zone (UTC YY-MM-DDT HH:MM) ○ If observed/detected during ramp-up/power-up: first distance (reticle distance in meters), closest distance (reticle distance in meters), last distance (reticle distance in meters), behavior at final detection ○ Did a shutdown/power-down occur? (Y/N) ○ Time shutdown was called for (UTC) ○ Time equipment was shut down (UTC)			
MUL-13	Protected Species Training for trawl and trap survey staff	The Lessee must ensure all vessels have at least one survey team member onboard each trawl survey and ventless trap survey who has completed Northeast Fisheries Observer Program training (within the last 5 years) or equivalent training (i.e., another training in protected species identification, safe handling, inclusive of taking genetic samples from Atlantic sturgeon). Reference materials for identification, disentanglement, safe handling, and genetic sampling procedures must be available on board each survey vessel. The Lessee must provide documentation of training to NMFS and BSEE at least 7 days prior to the start of the trawl surveys and at any later time that a different observer is deployed on the survey. If the Lessee will deploy non-NEFOP trained observers, the Lessee must submit a training plan to BSEE, BOEM and NMFS GARFO-PRD describing the training that will be provided to the survey observers. The Lessee must submit the PSO Training Plan for Trawl Surveys no later than 7 days prior to the start of trawl surveys. This plan must include a description of the elements of the training (i.e., curriculum, virtual or hands on, etc.) and identify who will carry out the training and their qualifications. Once the training is complete, confirmation of the training and a list of trained survey staff must be submitted to NMFS; this list must be updated if additional staff are trained for future surveys. The Lessee must submit a list of trained survey staff to NMFS GARFO-PRD at least one business day prior to the beginning of the survey. The Lessee must obtain BOEM and BSEE's concurrence with this plan before starting any trawl surveys.	Finfish, Invertebrates, and EFH; Marine Mammals; Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied
MUL-14a	UXO/MEC avoidance	The Lessee must develop and implement standard protocols for addressing unexploded ordnance (UXOs) risks, including implementation of best available technology to avoid or minimize exposure of protected species and sensitive habitats. Where *in situ* disposal is demonstrated to be necessary for the project, the Lessee must consult with state and federal agencies regarding seasonal restriction windows or other precautions. The Lessee must avoid, to the maximum extent practicable, interactions with UXO/Munitions and Explosives of Concern (MEC). If avoidance is not possible, submitted plans should follow all guidance (see Munitions and Explosives of Concern Survey Methodology and In-Field Testing for Wind Energy Areas on the Atlantic Outer Continental Shelf (pnnl.gov) at: https://tethys.pnnl.gov/sites/default/files/publications/Carton-et-al-2017-BOEM.pdf; Supporting National Environmental Policy Act Documentation for Offshore Wind Energy Development Related to Munitions and Explosives of Concern and Unexploded Ordinances (MEC-UXO White Paper [boem.gov]) at: https://www.boem.gov/sites/default/files/documents/renewable-energy/state-activities/MEC-UXO%20White%20Paper.pdf; or any other applicable regulation regarding interaction with UXO/MEC).	Commercial and For-Hire Fishing; Finfish, Invertebrates, and EFH; Marine Mammals; Sea Turtles	BOEM, BSEE, and USACE	Previously Applied
MUL-16	Post-storm event monitoring plan	The Lessee must provide a plan for post-storm event monitoring of the facility infrastructure, foundation scour protection, and cables to BSEE with the relevant FDR. The plan must describe how the Lessee will measure and monitor environmental conditions and duration of storm events; specify the environmental condition thresholds (and their associated technical justification) above which post-storm event monitoring or mitigation is necessary; describe potential monitoring, mitigation, and damage identification methods; and state when the Lessee must notify BSEE of post-storm event related activities. At a minimum, initial post-storm event inspections must be conducted for each OSS, met tower, and 10% of the WTGs including associated scour protection, following each storm where any condition(s) exceed one-half the design return period. For example, a WTG platform designed for 50-year environmental conditions must be inspected following a storm event that exceeds 25-year environmental conditions. Environmental condition thresholds are subject to change based on lessons learned during operations. To change the post-storm event inspection environmental condition threshold, the Lessee must submit a revised plan to BSEE for review and concurrence. BSEE reserves the right to require post-storm mitigations and additional inspections to address conditions that could result in safety risks and/or impacts on the environment.	Benthic; Commercial and For-Hire Fishing; Finfish, Invertebrates, and EFH; Marine Mammals; Sea Turtles	BOEM and BSEE	Previously Applied
MUL-19	Post-installation cable monitoring	The Lessee must conduct an inspection of each interarray, interconnector, and export cable to determine cable location, burial depths, the state of the cable, and site conditions within 6 months following installation of a cable segment. Additional inspections must be conducted within 1 year following completion of the initial post-construction inspection, and every 3 years thereafter until decommissioning. These surveys must also be conducted within 180 days of a storm event (as defined by the post-storm event monitoring plan, described in MUL-16). The Lessee must provide BSEE and BOEM with a cable monitoring report within 90 days following each inspection. Inspections of the interarray and export cables must include HRG methods, involving, for example, multibeam bathymetric survey equipment, and identify seabed features, natural and human-made hazards, and site conditions along federal sections of the cable routing. • If BSEE determines that conditions along the cable corridor warrant adjusting the frequency of inspections (e.g., due to changes in cable burial or seabed conditions that may impact cable stability or other users of the seabed), then BSEE may require the Lessee to submit a revised inspection schedule for review and concurrence.	Benthic; Commercial and For-Hire Fishing; Finfish, Invertebrates, and EFH; Marine Mammals; Sea Turtles	BOEM, BSEE	Previously Applied

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		• If BSEE determines that burial conditions have deteriorated or changed significantly and remedial actions are warranted, BSEE will notify the Lessee that the Lessee must submit the following via TIMS Web within 90 days of being notified: a seabed stability analysis, a remedial action plan, and a schedule for completing remedial actions. All remedial actions must be consistent with the approved COP. BSEE will review the plan and schedule and provide any comments within 60 days of receiving the plan. The Lessee must resolve all comments to BSEE's satisfaction. • If the Lessee determines that burial conditions have deteriorated or changed significantly and remedial actions are warranted, the Lessee must submit the following to BSEE via TIMS Web within 90 days of making the determination: the data used to make the determination, a seabed stability analysis, a plan for remedial actions, and a schedule for the proposed work. All remedial actions must be consistent with those described in the approved COP. BSEE will review the plan and schedule and provide comments within 60 days, if applicable. The Lessee must resolve all comments to BSEE's satisfaction.			
MUL-20	Soft start for impact pile driving	The Lessee must use a soft start protocol for impact pile driving of monopiles. Soft start must be used at the beginning of each day's monopile installation, and at any time following a cessation of impact pile driving of 30 minutes or longer. If a marine mammal or sea turtle is detected within or about to enter the applicable clearance zones, prior to the beginning of soft-start procedures, impact pile driving must be delayed until the animal has been visually observed exiting the clearance zone or until a specific time period has elapsed with no further sightings (i.e., 15 minutes for small odontocetes and 30 minutes for all other marine mammal species and sea turtles).	Benthic; Finfish, Invertebrates, and EFH; Marine Mammals; Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied
MUL-29	Sound Field Verification (SFV) Process, Plan and Reporting	The purpose of the Sound Field Verification (SFV) process is to document sound propagation from foundation installation to verify that the modeled acoustic fields are within expected ranges. The Lessee must perform "Thorough SFV" (defined as recording along a minimum of two radials with at least one radial containing recorders at three or more distances) on the first installation represented by each modeling scenario used. The Lessee must also perform Thorough SFV on the first three foundation installations of the project. The Lessee must also perform "Abbreviated SFV," placing a single recorder approximately 2460 feet (750 meters) from the foundation, on the installation of any foundations not requiring "thorough." If levels measured in any SFV (Thorough or Abbreviated) imply the exceedance of agency-identified ranges to regulatory thresholds, the Lessee must take mitigative actions in consultation with the federal permitting agencies. The Lessee must submit an SFV plan for review by BOEM, BSEE, NMFS, and USACE (when applicable). The Lessee must obtain written concurrence of the SFV plan from BOEM and BSEE before the planned commencement of field activities for pile driving. The plan must include measurement procedures and results reporting that meet ISO standard 18406:2017 (Underwater acoustics – Measurement of radiated underwater sound from percussive pile driving). See Chapter three of *BOEM Nationwide Recommendations for Impact Pile Driving Sound Exposure Modeling and Sound Field Measurement for Offshore Wind Construction and Operations Plans* for more information. The submission of raw acoustic data or data products associated with SFV to BOEM may be required. The Lessee must follow the approved plan. The SFV plan should include approximations of the expected variation of key parameters (e.g., difficulty to drive, predicted number of necessary strikes, foundation type, pile size, installation method, hammer energy rating, water depth, seabed composition, and season) across the project and an estimate of how many thorough monitoring locations will be required to cover this variability. The plan must describe how the Lessee selected the Thorough SFV locations, identifying which modeled scenarios match to which foundation locations and therefore to what ranges the results of those SFVs will be compared. The SFV process must be sufficient to assess sound propagation from the foundation and the distances to regulatory acoustic thresholds. The measurements must be compared to the modeled Level A and Level B harassment zones for marine mammals and the injury and behavioral disturbance zones for sea turtles and Atlantic sturgeon. The plan must include a template of both Thorough and Abbreviated SFV interim reports. Thorough SFV interim reports must be submitted to BOEM, BSEE (TIMS), NMFS, and USACE (when applicable) within 48 hours of completion of foundation installation. Thorough SFV interim reports must include expected received level limits for future Abbreviated SFVs that are associated with the same modeled scenario and the Lessee must obtain BOEM and BSEE concurrence on these assumptions. Abbreviated SFV reports must also be submitted to BOEM, BSEE (TIMS), NMFS, and USACE (when applicable) but may be submitted in weekly batch reports as long as Abbreviated SFV measurements are at or below the received level limits defined in Thorough SFVs. The Lessee is referred to the BOEM *Nationwide Recommendations for Impact Pile-Driving Sound Exposure Modeling and Sound Field Measurement for Offshore Wind Construction and Operations Plans* (https://www.boem.gov/sites/default/files/documents/renewable-energy/state-activities/Nationwide%20Recommendations%20for%20Impact%20Pile%20Driving%20Sound%20Exposure%20Modeling%20and%20Sound%20Field%20Measurement.pdf) for other recommendations on what should be contained in the report. A final SFV Report must be submitted for review to agencies within 90 days of the cessation of foundation installation each calendar year. The Lessee must respond to requests for edits and updates in a timely manner.	Finfish, Invertebrates, and EFH; Marine Mammals; Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied
MUL-31	Fisheries Sampling gear removal between seasons	No wet storage of trap/pot gear is permitted. All trap/pot gear must be hauled at least once every 30 days, and all gear must be removed from the water and stored on land between survey seasons to minimize risk of entanglement.	Finfish, Invertebrates, and EFH; Marine Mammals; Sea Turtles	BOEM and BSEE	Previously Applied
MUL-32	Weekly, monthly, and final PSO reporting requirements (including foundation pile driving)	PSOs must collect data consistent with standard reporting forms, software tools, or electronic data forms authorized by BOEM for the particular activity. PSOs must fill out report forms for each vessel with PSOs aboard. Unfilled cells must be left empty and must not contain "NA." The reports must be submitted in Microsoft Word and Excel formats (not as a PDF). Enter all dates as YYYY-MM-DD. Enter all times in 24 Hour Coordinated Universal Time (UTC) as HH:MM. The PSO must create a new entry on the Effort form each time a pile segment changes, or weather conditions change, and at least once an hour as a minimum. The PSO must review and revise all forms for completeness and resolve incomplete data fields before submittal. The file name must follow this format: Lease#_ ProjectName_PSOData_YearMonthDay toYearMonthDay.xls. Data fields must be reported in Excel format. Data categories must include Project, Operations,	Finfish, Invertebrates, and EFH; Marine Mammals; Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		Monitoring Effort, and Detection, as further specified below. All PSO data must be generated through software applications or otherwise recorded electronically by PSOs and provided to BOEM and BSEE in electronic format (CSV files or similar format) and be checked for quality assurance and quality control. Applications developed to record PSO data are encouraged if the data fields listed below can be recorded and exported into Excel. Alternatively, BOEM has developed an Excel spreadsheet, with all the necessary data fields, that is available upon request. **Weekly Reports.** The Lessee must compile and submit weekly reports during construction that document pile driving, HRG survey, and detonation activities, including associated PSO, SFV, and noise abatement activities. These weekly reports must include any information required by a project's final NMFS BiOp and be submitted to NMFS GARFO-PRD, BOEM, and BSEE (protectedspecies@bsee.gov); they may be submitted directly from the PSO providers and may consist of raw data. Weekly reports must be submitted no later than Wednesday for the previous week (Sunday – Saturday). Weekly reports must include: • Summaries of pile-driving activities and piles installed, including pile ID, type of pile, pile diameter, start and finish time of each drilling and pile-driving event, hammer log (number of strikes, max hammer energy, duration of piling) per pile, any changes to noise attenuation systems and/or hammer schedule, details on the deployment of PSOs and PAM operators, including the start and stop time of associated observation periods by the PSOs and PAM Operators, and a record of all observations/detections of marine mammals and sea turtles as detailed below; • A summary of SFV and NAS implemented with pile driving. • Any UXO/MEC detonation activities, including a summary of SFV and NAS implemented during UXO/MEC detonation; • Which WTGs become operational and when (a map must be provided); • Summaries of HRG survey activities; • Vessel operations (including port departures and destinations, number of vessels, type of vessel(s), and route); • All protected species detections. This includes: species identification, number of animals, time at initial detection, time at final detection, distance to pile/vessel at initial detection, closest point of approach to pile/vessel, animal direction of travel relative to pile/vessel; description of animal behavior, features used to identify species, and for moving vessels: speed (knots), distance and bearing to animal at initial detection, closest point of approach and bearing to animal, distance and bearing to animal at final detection, and animal direction of travel relative to vessel. Sightings/detections during pile-driving activities (clearance, active pile driving, post-pile driving) and all other (transit, opportunistic, etc.) sightings/detection must be reported and identified as such; and • Vessel strike avoidance measures taken. **Monthly Reports**. Starting the first month that in-water activities occur on the OCS, the Lessee must compile and submit monthly reports that include a summary of all project activities carried out in the previous month, including dates and locations of any fisheries surveys, vessel transits (number of transits, name and type of vessel, ports used, and route inclusive of foreign and domestic ports), piles installed (number and ID), HRG surveys conducted, and UXO/MEC detonations, and all observations of ESA-listed whales, sea turtles, and sturgeon (i.e., MM-1, MUL-32, MUL-34, ST-2, MMST-1-2, STF-4 as applicable), inclusive of any mitigation measures taken as a result of those observations. Sightings/detections must include species ID, time, date, initial detection distance, vessel/platform name, vessel activity, vessel speed, bearing to animal, project activity, and if any, mitigation measures taken. These reports must include the information identified in the Project-specific NMFS BiOp, and the Lessee must submit the reports to BOEM, BSEE, and NMFS GARFO-PRD no later than the 15th of the month for the previous month. PSOs must collect data consistent with standard reporting forms, software tools, or electronic data forms authorized by BOEM for the particular activity. PSOs must fill out report forms for each vessel with PSOs aboard. Unfilled cells must be left empty and must not contain "NA." The reports must be submitted in Microsoft Word and Excel formats (not as a PDF). Enter all dates as YYYY-MM-DD. Enter all times in 24 Hour Coordinated Universal Time (UTC) as HH:MM. The PSO must create a new entry on the Effort form each time a pile segment changes, or weather conditions change, and at least once an hour as a minimum. The PSO must review and revise all forms for completeness and resolve incomplete data fields before submittal. The file name must follow this format: Lease#_ ProjectName_PSOData_YearMonthDay toYearMonthDay.xls. Data fields must be reported in Excel format. Data categories must include Project, Operations, Monitoring Effort, and Detection, as further specified below. All PSO data must be generated through software applications or otherwise recorded electronically by PSOs and provided to BOEM and BSEE in electronic format (CSV files or similar format) and be checked for quality assurance and quality control. Applications developed to record PSO data are encouraged if the data fields listed below can be recorded and exported into Excel. Alternatively, BOEM has developed an Excel spreadsheet, with all the necessary data fields, that is available upon request. Required data fields include: • Project Information: ○ Project name ○ Lease number ○ State coastal zones ○ PSO contractors ○ Vessel names ○ Reporting dates (YYYY-MM-DD) ○ Visual monitoring equipment used (e.g., bionics, magnification, IR cameras) ○ Distance finding method used ○ PSO names (Last, First) and training ○ Observation height above sea surface • Operations Information:			

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		○ Date (YYYY-MM-DD) ○ Hammer type used (make and model) ○ Greatest hammer power used for each pile ○ Pile identifier and pile number for the day (e.g., pile 2 of 3 for the day) ○ Pile diameters ○ Pile length ○ Pile locations (latitude and longitude) ○ Number of vessel transits ○ Types of vessels used ○ Vessel routes used • Monitoring Effort Information: ○ Date (YYYY-MM-DD) ○ Noise source (ON=Hammer On; OFF=Hammer Off) ○ PSO name(s) (Last, First) ○ If visual, how many PSOs on watch at one time? ○ Time pre-clearance visual monitoring began in UTC (HH:MM) ○ Time pre-clearance monitoring ended in UTC (HH:MM) ○ Time pre-clearance PAM monitoring began in UTC (HH:MM) ○ Time PAM monitoring ended in UTC (HH:MM) ○ Duration of pre-clearance PAM and visual monitoring ○ Time power-up or ramp-up began in UTC (HH:MM) ○ Time equipment full power was reached in UTC (HH:MM) ○ Duration of power-up or ramp-up ○ Time pile driving began (hammer on) in UTC (HH:MM) ○ Time pile driving activity ended (hammer off) in UTC (HH:MM) ○ Duration of activity ○ Duration of visual detection ○ Wind speed (kts), from direction • Swell height (m): ○ Water depth (m) ○ Visibility (kilometers) ○ Glare severity ○ Latitude (decimal degrees), longitude (decimal degrees) ○ Compass heading of vessel (degrees) ○ Beaufort scale ○ Precipitation ○ Cloud coverage (%) ○ Did a shutdown/power-down occur? ○ Time shutdown was called for (UTC) ○ Time equipment was shut down (UTC) ○ Habitat or prey observations ○ Marine debris sighted • Detection Information: ○ Date (YYYY-MM-DD) ○ Sighting ID (V01, V02, or sequential sighting number for that day; multiple sightings of the same animal or group must use the same ID) ○ Date and time at first detection in UTC (YY-MM- DDT HH:MM) ○ Time at last detection in UTC (YY-MM-DDT HH:MM) ○ PSO name(s) (Last, First) ○ Effort (ON=Hammer On; OFF=Hammer Off) ○ If visual, how many PSOs on watch at one time?			

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		○ Start time of observations ○ End time of observations ○ Duration of visual observation ○ Wind speed (kts), from direction ○ Swell height (m) ○ Water depth (m) ○ Visibility (kilometers) ○ Glare severity ○ Latitude (decimal degrees), longitude (decimal degrees) ○ Compass heading of vessel (degrees) ○ Beaufort scale ○ Precipitation ○ Cloud coverage (%) ○ Sightings including common name, scientific name, or family ○ Percent certainty of identification ○ Number of adults ○ Number of juveniles ○ Total number of animals ○ Bearing to animals when first detected (ship heading + clock face) ○ Bearing to animals at closest approach (ship heading+ clock face) ○ Bearing to animal at final detection (ship heading+ clock face) ○ Range from vessel and pile (reticle distance in meters) ○ Description (include features such as overall size; shape of head; color and pattern; size, shape, and position of dorsal fin; height, direction, and shape of blow, etc.) ○ Detection narrative (note behavior, especially changes in relation to activity and distance from service vessel) ○ Direction of animal travel in first approach relative to vessel and pile ○ Behaviors observed: indicate behaviors and behavioral changes observed in sequential order (use behavioral codes) ○ If any bow-riding behavior observed, record total duration during detection (UTC HH:MM) ○ Initial heading of animals (degrees) ○ Final heading of animals (degrees) ○ Shutdown zone size during detection (m) ○ Was the animal inside the shutdown zone? ○ Closest distance to vessel and pile (reticle distance in m) ○ Time at closest approach to vessel and pile (UTC HH:MM) ○ Time animal entered shutdown zone (UTC HH:MM) ○ Time animal left shutdown zone (UTC HH:MM) ○ If observed or detected during ramp-up or power-up: first distance (reticle distance in m), closest distance (reticle distance in m), last distance (reticle distance in m), behavior at final detection ○ Did a shutdown/power-down occur? ○ Time shutdown was called for (UTC HH:MM) ○ Time equipment was shut down (UTC HH:MM) ○ Detections with PAM **Annual Reports**. Beginning one calendar year after the completion of commissioning activities, the Lessee must compile and submit annual reports that include a summary of all project activities carried out in the previous year, including vessel transits (number, type of vessel, ports used, and route), repair and maintenance activities, survey activity, and all observations of ESA-listed species. The annual reports must be submitted to BOEM, BSEE, USACE, and NMFS GARFO. The Lessee must submit these reports by April 1 of each year for the previous calendar year (i.e., the 2026 report is due by April 1, 2027). Upon mutual agreement of NMFS GARFO, BOEM, and BSEE, the frequency of reports can be changed.			
MUL-33	Vessel communication of threatened and endangered species sightings and detections	The Lessee must ensure that whenever multiple project vessels are operating, any detections of ESA-listed species (marine mammals and sea turtles) are communicated in near real time to these personnel on the other project vessels: PSOs, vessel operators, or both. Year-round, all vessel operators must monitor the project's Situational Awareness System, WhaleAlert, USCG VHF Channel 16, and the Right Whale Sighting Advisory System (RWSAS) for the presence of NARWs once every 4-hour shift during project-related activities. The PSO and PAM operator monitoring teams for all activities must also monitor these systems no less frequently	Finfish, Invertebrates, and EFH; Marine	BOEM, BSEE, and NMFS	Previously Applied

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		than every 12 hours. If a vessel operator is alerted to a NARW detection within the project area, the operator must immediately convey this information to the PSO and PAM teams. For any UXO/MEC detonation, vessel operators must monitor these systems for 24 hours prior to detonating any UXO/MEC. Any observations of any large whale by any of the Lessee's staff or contractor, including vessel crew, must be communicated immediately to PSOs and all vessel operators to increase situational awareness.	Mammals; Sea Turtles		
MUL-34	Detected or impacted protected species reporting	The Lessee must report as soon as feasible but no later than 24 hours all observations of injured or dead whales, sea turtles, or sturgeon to BSEE and NMFS GARFO-PRD, including observations and interactions during the fisheries surveys (see STF-4 for additional details on take notification for sea turtles/Atlantic sturgeon during survey activities). The Lessee must ensure its reports reference the project and include the Take Report Form available on NMFS' webpage at: https://www.fisheries.noaa.gov/new-england-mid-atlantic/consultations/section-7-take-reporting-programmatics-greater-atlantic. The Lessee must ensure reports of Atlantic sturgeon take include a statement as to whether a fin clip sample for genetic sampling was taken. Fin clip samples are required in all cases with the only exception being when additional handling of the sturgeon may result in an imminent risk of injury to the fish or the PSO. Incidents falling within the exception are expected to be limited to capture and handling of sturgeon in extreme weather. Instructions for fin clips and associated metadata are available at https://www.fisheries.noaa.gov/new-england-midatlantic/consultations/section-7-take-reporting-programmatics-greater-atlantic under the "Sturgeon Genetics Sampling" heading. The Lessee must report any suspected or confirmed vessel strike of a sea turtle or sturgeon by any project vessel in any location, including observation of any injured sea turtle/sturgeon or sea turtle/sturgeon parts to BOEM, BSEE, NMFS GARFO-PRD, and to appropriate NOAA stranding hotline (for marine mammals between Maine-Virginia, report to 866-755-6622, and from North Carolina-Florida to 877-942-5343 and for sea turtles from Maine-Virginia, report to 866-755-6622, and from North Carolina-Florida to 844-732-8785) as soon as feasible. The Lessee must include in the report the following information: (a) time, date, and location (latitude/longitude) of the incident; (b) species identification (if known) or description of the animal(s) involved; (c) vessel's speed during and leading up to the incident; (d) vessel's course/heading and what operations were being conducted (if applicable); (e) status of all sound sources in use; (f) description of avoidance measures/requirements that were in place at the time of the strike and what additional measures were taken, if any, to avoid strike; (g) environmental conditions (e.g., wind speed and direction, Beaufort scale, cloud cover, visibility) immediately preceding the strike; (h) estimated size and length of animal that was struck; (i) description of the behavior of the animal immediately preceding and following the strike; (j) estimated fate of the animal (e.g., dead, injured but alive, injured and moving, blood or tissue observed in the water, status unknown, disappeared); and (k) to the extent practicable, photographs or video footage of the animal(s). In the event that an injured or dead marine mammal or sea turtle is sighted, the Lessee must report the incident to BOEM, BSEE, NMFS GARFO-PRD, and the appropriate hotline (options above), as soon as feasible, but no later than 24 hours from the sighting. The Lessee must include in the report the following information: (a) time, date, and location (latitude/longitude) of the first discovery (and updated location information if known and applicable); (b) species identification (if known) or description of the animal(s) involved; (c) condition of the animal(s) (including carcass condition if the animal is dead); (d) observed behaviors of the animal(s), if alive; (e) if available, photographs or video footage of the animal(s); and (f) general circumstances under which the animal was discovered. The Lessee must follow any instructions provided by staff responding to the hotline call for handling or disposing of any injured or dead animals, which may include coordination of transport to shore, particularly for injured sea turtles. **UXO Detonation Reports**. The Lessee must compile and submit reports following any UXO/MEC detonation that provide details on the UXO/MEC that was detonated (e.g., charge size), location of the detonation, the start and stop of associated observation periods by the PSOs and PAM operators, details on the deployment of PSOs and PAM operators, and a record of all observations of marine mammals and sea turtles including time (UTC) of sighting/detection, species ID, behavior, distance (m) from vessel to animal at time of sighting/detection, vessel activity, platform/vessel name, and mitigation measures taken (if any). These reports must include any observations of dead or injured fish or other marine life in the post detonation monitoring period. The Lessee must ensure that the PSO providers submit these reports directly to NMFS GARFO-PRD, BSEE, and BOEM within one week of the detonation. The reports may consist of raw data that has undergone initial QA/QC review, or the raw data must be made available upon request. The Lessee must also ensure that the PSO providers submit all reports of dead or injured ESA listed species directly to NMFS GARFO-PRD, BSEE, and BOEM immediately, but no later than 24 hours following the observation. **Detected or Impacted Dead Non-ESA-Listed Fish**. The Lessee must report any occurrence of at least 10 dead non-ESA-listed fish within established shutdown or monitoring zones to BOEM and to BSEE (via email to protectedspecies@bsee.gov) as soon as practicable (taking into account crew and vessel safety), but no later than 24 hours after the sighting. BOEM or BSEE will notify NMFS GARFO-HESD. The Lessee must confirm the relevant point of contact prior to reporting and confirm the reporting was received. **Protected Species Incident Reporting**. Regardless of activity/survey type or the need to provide a dedicated trained watch stander or PSO, any potential take, strikes, or dead/injured protected species caused by project activities must be reported to the NMFS GARFO Protected Resources Division nmfs.gar.incidental-take@noaa.gov), NOAA Fisheries 24-hour Stranding Hotline – for marine mammals from Maine-Virginia, report to (866) 755-6622, and from North Carolina-Florida to (877) 942-5343 and for sea turtles from Maine-Virginia, report to (866) 755-6622, and from North Carolina-Florida to (844)732-8785, BOEM (at mailto: renewable_reporting@boem.gov), and BSEE (at mailto: protectedspecies@bsee.gov) as soon as practicable, but no later than 24 hours from the time the incident took place (Protected Species Incident Report). The Protected Species Incident Report must include the following information: • Contact info for the person providing the report; • Time, date, and location (latitude/longitude) of the incident; • Species identification (if known) or description of the animal(s) involved; • Condition of the animal(s) (e.g., live, injured, dead); • Observed behaviors of the animal(s), if alive; • If available, photographs or video footage of the animal(s); and	Finfish, Invertebrates, and EFH; Marine Mammals; Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		• General circumstances (e.g. vessel speed/direction of travel, sound sources in use) under which the animal was impacted. **Dead or Injured Protected Species Reporting**. All dead or injured protected species must be reported, regardless of whether they were observed during operations or directly due to Lessee activities. In the event that an injured or dead marine mammal or sea turtle is sighted, regardless of the cause, the Lessee must report the incident to the NMFS Protected Resources Division (nmfs.gar.incidental-take@noaa.gov), NMFS 24-hour Stranding Hotline number (866-755-6622), BOEM (at renewable_reporting@boem.gov), and BSEE (at protectedspecies@bsee.gov) as soon as practicable (taking into account crew and vessel safety), but no later than 24 hours from the sighting (Dead or Injured Protected Species Report). Staff responding to the hotline call will provide any instructions for the handling or disposing of any injured or dead protected species by individuals authorized to collect, possess, and transport sea turtles. The Protected Species Incident Report must include the following information: • Time, date, and location (latitude/longitude) of the first discovery (and updated location information if known and applicable); • Species identification (if known) or description of the animal(s) involved; • Condition of the animal(s) (including carcass condition if the animal is dead); • Observed behaviors of the animal(s), if alive; • If available, photographs or video footage of the animal(s); and • General circumstances under which the animal was discovered.			
MUL-37	Aircraft Detection Lighting System (ADLS)	The Lessee must use an FAA-approved vendor for the ADLS, which will activate the FAA hazard lighting only when an aircraft is in the vicinity of the wind facility to reduce visual impacts at night. The Lessee must confirm the use of an FAA-approved vendor for ADLS on WTGs and OSSs in the FIR.	Birds; Cultural Resources; Marine Mammals; Recreation and Tourism; Sea Turtles; Scenic and Visual Resources	BOEM, BSEE, and FAA	Previously Applied
MUL-40 (Previously NAV-1)	Boulder relocation reporting	The Lessee must provide USCG and NOAA with a comprehensive list and shapefile of positions and areas to which boulders >6.6 feet (>2 meters) will be relocated (latitude, longitude) at least 60 days prior to boulder relocation activities.	Commercial and For-Hire Fishing; Navigation and Vessel Traffic	BOEM, BSEE, USCG, and NOAA	Previously Applied

OU-1	Mitigation for oceanographic high frequency radars	The Lessee must coordinate with the radar operators and the Surface Currents Program of NOAA Integrated Ocean Observing System (IOOS) Office to assess if the project causes radar interference to the degree that radar performance is no longer within the specified radar system's operation parameters or fails to meet mission objectives. If either is the case, the Lessee must notify BOEM and engage radar operators and NOAA IOOS on mitigation efforts. The following options to mitigate operational impacts on oceanographic high-frequency radars have been identified:
		• Data sharing from turbine operators to include the following:
		  ○ Sharing real-time telemetry of surface currents and other oceanographic data measured at locations in the project with radar operators and into the public domain.
		  ○ Sharing time-series of blade rotation rates, nacelle bearing angles, and other information about the operational state of each of the project's turbines with radar operators to aid interference mitigation.
		• Wind turbine curtailment/curtailment agreement between NOAA IOOS, Lessee and BOEM
		Additional modifications identified for oceanographic high-frequency radar systems to mitigate impacts:
		• Signal processing enhancements.
		• Antenna modifications
		If the Lessee's project causes radar interference to the degree that radar performance is no longer within the specific radar systems' operational parameters or fails to meet NOAA IOOS's mission objectives, at least 120 calendar days prior to commissioning the first WTG or the start of blades spinning, whichever is earlier, the Lessee must enter into a mitigation agreement with the Surface Currents Program of NOAA's Integrated Ocean Observing System (IOOS) Office. Within 15 calendar days of entering into the mitigation agreement, the Lessee must provide BOEM with a copy of the executed mitigation agreement. Within 45 calendar days of completing any requirements in the mitigation agreement, the Lessee must provide BOEM and BSEE with evidence of compliance with those requirements.
			Other Uses	BOEM and BSEE	Previously Applied

OU-3	Mitigation for ARSR-4 and ASR-8/9 radars	The Lessee must coordinate with ARSR-4 and ASR-8/9 radar operators, including the FAA and DoD Clearinghouse, to assess if the project causes radar interference to the degree that radar performance is no longer within the specified radar system's operation parameters or fails to meet mission objectives. If either is the case, the Lessee must notify BOEM and engage radar operators on mitigation efforts. Operational mitigations identified for impacts on airport surveillance radar (ASR)-8/9 include: • Passive aircraft tracking using ADS-B or signal/transponder • Increased aircraft altitude near radar • Sensitivity time control (range-dependent attenuation) • Range azimuth gating (ability to isolate/ignore signals from specific range-angle gates) • Track initiation inhibiting, velocity editing, plot amplitude thresholding (limiting the amplitude of certain signals) Modification mitigations for ARSR-4 and for ASR-8/9 systems include:	Other Uses	BOEM and BSEE	Previously Applied

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		• Utilizing the dual beams of the radar simultaneously • In-fill radars			
OU-7	Federal Survey Mitigation Program	There are NMFS scientific surveys that overlap with wind energy development in the northeast region. Consistent with NMFS and BOEM survey mitigation strategy actions 1.3.1, 1.3.2, 2.1.1, and 2.1.2 in the NOAA Fisheries and BOEM Federal Survey Mitigation Implementation Strategy – Northeast US Region (Hare et al. 2022),[3] within 120 days of COP approval, the Lessee must submit to BOEM a survey mitigation agreement between NMFS and the Lessee. The survey mitigation agreement must describe how the Lessee will mitigate the project impacts on the NMFS surveys. The Lessee must conduct activities in accordance with such agreement. If the Lessee and NMFS fail to reach a survey mitigation agreement, then the Lessee must submit a survey mitigation plan to BOEM and NMFS that is consistent with the procedures described below, within 180 days of COP approval. BOEM will review the survey mitigation plan in consultation with NMFS Northeast Fisheries Science Center (NEFSC), and the Lessee must resolve comments to BOEM's satisfaction and must conduct activities in accordance with the plan. • As soon as reasonably practicable, but no later than 30 days after the issuance of the project's COP approval, the Lessee must initiate coordination with NMFS NEFSC to develop the survey mitigation agreement. • Mitigation activities specified under the agreement must be designed to mitigate the project impacts on the NMFS NEFSC surveys that overlap with the project. At a minimum, the survey mitigation agreement must describe actions and the means to address impacts on the affected surveys due to the preclusion of sampling platforms and impacts on statistical designs. NMFS has determined that the project area is a discrete stratum for surveys that use a random stratified design. This agreement may also consider other anticipated project impacts on NMFS surveys, such as changes in habitat and increased operational costs due to loss of sampling efficiencies. • The survey mitigation agreement must identify activities that will result in the generation of data equivalent to data generated by NMFS' affected surveys for the duration of the project. The survey mitigation agreement must describe the implementation procedures by which the Lessee will work with NEFSC to generate, share, and manage the data required by NEFSC for each of the surveys impacted by the project, as mutually agreed upon between the Lessee and NMFS/NEFSC. The survey mitigation agreement must also describe the Lessee's participation in the NMFS NEFSC Northeast Survey Mitigation Program to support activities that address regional-level impacts for the surveys.	Other Uses	BOEM and NMFS	Previously Applied
ST-3	Sea turtle disentanglement	The Lessee must ensure all vessels deploying fixed gear (e.g., pots/traps) have adequate disentanglement equipment (i.e., knife and boathook) onboard. Any disentanglement will occur consistent with the Northeast Atlantic Coast STDN Disentanglement Guidelines (https://www.reginfo.gov/public/do/DownloadDocument?objectID=102486501) and the procedures described in Careful Release Protocols for Sea Turtle Release with Minimal Injury (NOAA Technical Memorandum 580; https://repository.library.noaa.gov/view/noaa/3773).	Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied
STF-2	Sea turtle/Atlantic sturgeon identification, handling, and resuscitation guidelines	The Lessee must ensure any live, uninjured animals are returned to the water as quickly as possible after completing the required handling and documentation. Live and responsive sea turtles or Atlantic sturgeon incidentally caught and retrieved in gear used in any fisheries survey must be released according to established protocols and whenever at-sea conditions are safe for those releasing the animal(s). Any unresponsive sea turtles or Atlantic sturgeon caught and retrieved in gear used in fisheries surveys must be handled and resuscitated according to established protocols and whenever at-sea conditions are safe for those handling and resuscitating the animal(s). a. To the extent allowed by sea conditions, the Lessee must give priority to the handling and resuscitation of any sea turtles or sturgeon that are captured in the gear being used, if conditions at sea are safe to do so. Handling times for these species must be minimized (i.e., kept to 15 minutes or less) to limit the amount of stress placed on the animals. b. All survey vessels must be equipped with copies of the sea turtle handling and resuscitation requirements found at 50 C.F.R. § 223.206(d)(1) prior to the commencement of any on-water activity (https://media.fisheries.noaa.gov/dam-migration/sea_turtle_handling_and_resuscitation_measures.pdf). These handling and resuscitation procedures (the latter, when necessary) must be executed any time a sea turtle is incidentally captured and brought onboard a survey vessel. c. For sea turtles that appear injured, sick, distressed, or dead (including stranded or entangled individuals), survey staff must immediately contact the Greater Atlantic Region Marine Animal Hotline at 866-755-6622 for further instructions and guidance on handling, retention, potential coordination of transfer to a rehabilitation facility, and/or disposal of the animal. If survey staff are unable to contact the hotline (e.g., due to distance from shore or lack of ability to communicate via phone), then survey staff must contact the USCG via very high frequency (VHF) marine radio on Channel 16. If required, hard-shelled sea turtles (i.e., non-leatherbacks) may be held on board for up to 24 hours, provided conditions during holding are authorized by the NMFS GARFO-PRD-PRD and safe handling practices are followed. If the hotline or an available veterinarian cannot be contacted and the injured animal cannot be taken to a rehabilitation center, activities that could further stress the animal must be stopped. When sea-to-shore contact with the hotline or an available veterinarian is not possible, the animal must be allowed to recover and be responsive before safely releasing it to the sea. d. The Lessee must make attempts to resuscitate any Atlantic sturgeon that are unresponsive or comatose by providing a running source of water over the gills as described in the Sturgeon Resuscitation Guidelines (https://media.fisheries.noaa.gov/dam-migration-miss/Resuscitation-Cards-120513.pdf). The Lessee shall comply with the version effective at the time of COP approval. e. Carcasses of incidentally caught sea turtles and sturgeon must be held in cold storage (frozen is preferred, although refrigerated is permitted if a freezer is not available) until retention or disposal procedures are authorized by the NMFS GARFO-PRD, which may include transfer to an appropriately permitted partner or	Finfish, Invertebrates, and EFH; Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied

[3] Hare, J.A., Blythe, B.J., Ford, K.H., Godfrey-McKee, S., Hooker, B.R., Jensen, B.M., Lipsky, A., Nachman, C., Pfeiffer, L., Rasser, M. and Renshaw, K., 2022. NOAA Fisheries and BOEM Federal Survey Mitigation Implementation Strategy - Northeast US Region. NOAA Technical Memorandum 292. Woods Hole, MA. 33 pp.

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		facility on shore. Following reporting of an incidental capture, NMFS may authorize that incidentally captured dead sea turtles or Atlantic sturgeon be retained on board the survey vessel, provided that appropriate cold storage facilities are available on the survey vessel.			
STF-4	Take notification for sea turtles/Atlantic sturgeon during survey activities	The Lessee must notify BOEM, BSEE, and NMFS GARFO-PRD via email within 24 hours of any interaction with a sea turtle or sturgeon and include the NMFS take reporting form (https://www.fisheries.noaa.gov/new-england-mid-atlantic/consultations/section-7-take-reporting-programmatics-greater-atlantic). The report must include, at a minimum, the following: (1) survey name and applicable information (e.g., vessel name, station number); (2) Global Positioning System (GPS) coordinates describing the location of the interaction (in decimal degrees); (3) gear type involved (e.g., bottom trawl, gillnet, longline); (4) soak time, gear configuration and any other pertinent gear information; (5) time and date of the interaction; (6) identification of the animal to the species level (if possible); and (7) a photograph or video of the animal (multiple photographs are suggested, including at least one photograph of the head scutes). If reporting within 24 hours is not possible (e.g., due to distance from shore or lack of ability to communicate via phone, fax, or email), the Lessee must submit reports as soon as possible and must submit late reports with an explanation for the delay. The Lessee must submit an annual report within 90 days of the completion of each survey season to BOEM, BSEE, and NMFS GARFO-PRD. The report must include all information on any observations of and interactions with ESA-listed species and contain information on all survey activities that took place during the season, including location of gear set, duration of soak, and total effort. The report on survey activities must be comprehensive of all activities, regardless of whether ESA-listed species were observed.	Finfish, Invertebrates, and EFH; Sea Turtles	BOEM, BSEE, and NMFS	Previously Applied
WQ-1	Avoid zinc anodes	To the extent it is technically and/or economically practicable or feasible, the Lessee must avoid using zinc sacrificial anodes on external components of WTG and OSS foundations to reduce the release of metal contaminants in the water column.	Water Quality	BOEM and BSEE	Previously Applied
WQ-2	Oil Spill Response Plan	In compliance with 33 U.S.C. 1321, and including information identified in 30 CFR part 254 that is applicable to Lessee activities, the Lessee must submit an Oil Spill Response Plan (OSRP) to the BSEE Oil Spill Preparedness Division (OSPD) at BSEEOSPD_ATL_OSRPs@bsee.gov for review and approval prior to the installation of any component that may handle or store oil on the OCS. The OSRP may be lease-specific, or it may be a regional OSRP covering multiple leases. Facilities and leases covered in a regional OSRP must have the same owner or operator (including affiliates) and must be located in the Atlantic OCS region. For a regional OSRP, subject to BSEE OSPD approval, the Lessee may group leases into sub-regions for the purposes of determining worst-case discharge (WCD) scenarios, conducting stochastic trajectory analyses, and identifying response resources. The Lessee's OSRP must be consistent with the National Contingency Plan, Regional Contingency Plan, and the appropriate Area Contingency Plan(s), as defined in 30 CFR 254.6. To continue operating, the Lessee must operate consistently with the OSRP approved by BSEE. The Lessee's OSRP, including any regional OSRP, must contain the following information: 1. Bookmarks. Appropriately labeled bookmarks that are linked to their corresponding sections of the OSRP. 2. Table of Contents. 3. Record of Change. A table identifying the changes made to the current version of the OSRP and, as applicable, a record of changes made to previously submitted versions of the OSRP. 4. Facility and Oil Information. "Facility," as defined in 30 CFR 585.113, means an installation that is permanently or temporarily attached to the seabed of the OCS. An OSS and WTG, as examples, each meet this definition of facility. "Oil," as defined in 33 U.S.C. 1321(a), means oils of any kind or in any form, including, but not limited to, petroleum, fuel oil, sludge, oil refuse, and oil mixed with wastes other than dredged spoil. Dielectric fluid, as an example, meets this definition of oil. The OSRP must: a. List the latitude and longitude, water depth, and distance to the nearest shoreline for each facility that may handle and/or store oil. b. List the oil(s) by product/brand name and corresponding volume(s) on each type of facility covered under the Lessee's OSRP. c. Include a map depicting the location of each facility that may handle and/or store oil within the boundaries of the covered lease area(s) and their proximity to the nearest shoreline. The map must also feature a compass rose, scale, and legend. 5. Safety Data Sheets. The OSRP must include a safety data sheet for every type of oil present on any OCS facility in quantities equal to or greater than 100 gallons. 6. Response Organization. The OSRP must identify a trained Qualified Individual (QI), and at least one alternate, with full authority to implement removal actions and ensure immediate notification of appropriate federal officials and response personnel. The Lessee must designate personnel to serve as trained members of an Incident Management Team (IMT) and identify them by name and Incident Command System (ICS) position in the OSRP. a. "Qualified Individual" (QI) means an English-speaking representative of the Lessee who is located in the United States, available on a 24-hour basis, and given full authority to obligate funds, carry out removal actions, and communicate with the appropriate federal officials and the persons providing personnel and equipment in removal operations. b. "Incident Management Team" (IMT) means the group of personnel identified within the Lessee's organizational structure who manage the overall response to an incident in accordance with the Lessee's OSRP. The IMT consists of the Incident Commander (IC), Command and General Staff, and other personnel assigned to key ICS positions designated in the Lessee's OSRP. With respect to the IMT, the Lessee must identify at least one alternate in the OSRP for the IC, Planning Section Chief (PSC), Operations Section Chief (OSC), Logistics Section Chief (LSC), and Finance Section Chief (FSC). If a contract has been established with a third-party IMT, the Lessee must provide evidence of such a contract in the Lessee's OSRP. 7. Notification Procedures. The OSRP must describe the procedures for spill notification. Notification procedures must include the 24-hour contact information for: a. The QI and an alternate, including phone numbers and email addresses. b. IMT members, including phone numbers and email addresses. c. Federal, state, and local regulatory agencies that must be notified when a spill occurs, including, but not limited to, the National Response Center.	Water Quality	BOEM and BSEE	Previously Applied

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		d. The Oil Spill Removal Organizations (OSRO) and Spill Response Operating Teams (SROT) that are available to respond. e. Other response organizations and subject matter experts that the Lessee will rely on for the Lessee's response. 8. Spill Mitigation Procedures. The OSRP must describe the different discharge scenarios that could occur from the Lessee's facilities and the mitigation procedures that the offshore facility operator and any listed/contracted OSROs would follow when responding to such discharges. The mitigation procedures must address responding to both smaller spills (with slow, low-volume leakage) and larger spills, to include the largest WCD scenario covered under the Lessee's OSRP. To achieve compliance with this section, the OSRP must include the following: a. Procedures for the early detection of a spill (i.e., monitoring procedures for detecting dielectric fluid and other oil-based substances handled or stored on the facility when spilled to the ocean). b. General procedures for ensuring that the source of a discharge is controlled as soon as possible after a spill occurs. c. Procedures to remove oil and oiled debris from shallow waters and along shorelines. d. Procedures to store, transfer, and dispose of recovered oil and oil-contaminated materials and to ensure that all disposal is consistent with federal, state, and local requirements. 9. Resources at Risk. The OSRP must include a concise list of the sensitive resources that could be impacted by a spill. In lieu of listing sensitive resources, the Lessee may identify the areas that could be impacted by a spill from the Lessee's facility and provide hyperlinks to corresponding Environmentally Sensitive Index Maps and Geographic Response Strategies/Plans for those areas from the appropriate Area Contingency Plan(s). 10. OSRO(s) and SROT(s). The OSRO is an entity contracted by the Lessee to provide spill response equipment and/or manpower in the event of an oil spill. The SROT is the trained persons who deploy and operate oil spill response equipment in the event of a spill, threat of a spill, or an exercise. The OSRP must include a list (with contact information) of the OSRO(s) and SROT(s) who are under contract and/or membership agreement to respond to the WCD of oil from the Lessee's offshore facilities. Evidence of such contracts or membership agreements must be provided in the OSRP. 11. Oil Spill Response Equipment. The OSRP must include a list, or a hyperlink to a list, of the oil spill response equipment that is available to the Lessee through a contract and/or membership agreement with the OSRO(s). The OSRP must include a map that shows the oil spill response equipment storage depot(s) and planned/potential staging area(s) for the oil spill response equipment that would be deployed by the facility operators or the OSRO(s) listed in the plan in the event of a discharge. a. The Lessee must ensure that the oil spill response equipment is maintained in proper operating condition. b. The Lessee must ensure that all oil spill response equipment maintenance, modification, and repair records are kept for a minimum of 3 years. c. The Lessee must provide oil spill response equipment maintenance, modification, and repair records to BSEE OSPD upon request. d. The Lessee or the OSRO must provide BSEE OSPD with physical access to the oil spill equipment storage depots and perform functional testing of the equipment upon request. e. BSEE OSPD may require maintenance, modifications, or repairs to oil spill response equipment or require the Lessee to remove response equipment from being listed in the OSRP if it does not operate as intended. 12. Training. The OSRP must include a description of the training necessary to ensure that the QI, IMT, OSRO(s) and SROT(s) are sufficiently trained to perform their respective duties. The Lessee must ensure that the IMT, OSRO(s), and SROT(s) receive annual training. The Lessee's OSRP must provide the most recent dates of applicable training(s) completed by the QI, IMT, OSRO(s) and SROT(s). The Lessee must maintain and retain training records for 3 years and must provide the training records to BSEE upon request. 13. Worst-Case Discharge (WCD) Scenario. The OSRP must describe the WCD scenario for the facility containing the highest cumulative volume of oil(s). For a regional OSRP covering multiple sub-regions, a WCD scenario must be described for each sub-region. a. If multiple candidate WCD facilities contain the same cumulative volume of oil(s), the WCD facility is the one closest to shore. b. The WCD facility must be identified on the facility map consistent with the "Facility and Oil Information" section. c. The OSRP must identify the subset of oil spill response equipment from the inventory listed in the OSRP that will be used to contain and recover the WCD volume. The OSRP must include timeframes for response resources to deploy to the WCD facility. Timeframes must include times for equipment procurement, loadout, travel, and deployment. 14. Stochastic Trajectory Analysis. The OSRP must include a stochastic spill trajectory analysis for the WCD facility. For a regional OSRP containing multiple WCD scenarios, a stochastic trajectory analysis must be included for each WCD scenario. The stochastic trajectory analysis must: a. Be based on the WCD volume. b. Be conducted for the longest period that the discharged oil would reasonably be expected to persist on the water's surface, or 14 days, whichever is shorter. c. Identify the probabilities for oiling on the water's surface and on shorelines, and minimum travel times for the transport of the oil over the duration of the model simulation. Oiling probabilities and minimum travel times must be calculated for exposure threshold concentrations reaching 10 grams per square meter. Stochastic analysis must incorporate a minimum of 100 different trajectory simulations using random start dates selected over a multi-year period. 15. Response Plan Exercise. The OSRP must include a triennial exercise plan for review and concurrence by BSEE to ensure that the Lessee is able to respond quickly and effectively whenever oil is discharged from the Lessee's facilities. Compliance with the National Preparedness for Response Exercise Program guidelines will satisfy the exercise requirements of this section. If the Lessee chooses to follow an alternative exercise program, the OSRP must provide a			

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		description of that program. For a regional OSRP covering multiple sub-regions, the IMT exercise scenarios must be rotated between each sub-region within the triennial exercise period. a. The Lessee must conduct an annual scenario-based notification exercise, an annual scenario-based IMT tabletop exercise (if applicable), and, during the triennial exercise period, at least one functional exercise. b. The Lessee must conduct an annual oil spill response equipment deployment exercise. c. The Lessee must notify BSEE OSPD at least 30 days in advance of any exercise it intends to conduct for compliance with this condition. d. BSEE will advise the Lessee about the options it has to satisfy these requirements and may require changes in the type, frequency, or location of the required exercises, exercise objectives, equipment to be deployed and operated, or deployment procedures or strategies. e. BSEE may evaluate the results of the exercises and advise the Lessee of any needed changes in response equipment, procedures, tactics, or strategies. f. BSEE may periodically initiate unannounced exercises to test the Lessee's spill preparedness and response capabilities. g. The Lessee must maintain and retain exercise records for at least 3 years and must provide the exercise records to BSEE upon request. 16. OSRP Review and Update. The Lessee must review and update the entire OSRP at least once every 3 years and more frequently as needed, starting from the date the OSRP was initially approved. The Lessee must send a written notification to BSEE OSPD upon completion of this review and submit any updates for concurrence. BSEE OSPD may require the Lessee to make changes to the OSRP at any time if it is determined to be outdated or to contain significant inadequacies as discovered through a review of the Lessee's OSRP, information obtained during exercises or actual spill responses, or other relevant information obtained by BSEE OSPD. 17. OSRP Maintenance. The Lessee must submit a revised OSRP to BSEE OSPD within 15 days if any of the following conditions occur: a. The Lessee experiences a change that would significantly reduce its oil spill response capability. b. The calculated WCD volume has significantly increased. c. The Lessee removes a contracted IMT, OSRO, or SROT from the Lessee's plan. d. There has been a significant change to the applicable area contingency plan(s).			
Not Previously Applied					
EJ-1a	Environmental Justice Communications Plan	The Lessee must create an Environmental Justice (EJ) Communications Plan in coordination with populations and communities with EJ concerns that identifies Lessee plans for communicating with these individuals and communities (defined for EJ-1a, and EJ-3 AMMM measures as "communities with environmental justice concerns" as related to Executive Order 14096 and 43 CFR 1508.1(f), referred to herein as "EJ populations"). BOEM will require a Final EJ Communications Plan created in coordination with EJ populations as a term and condition of COP approval, unless, during review of the COP NEPA document and based on COP-specific information on planned activities relative to EJ populations, BOEM determines an EJ Communications Plan is not warranted. The Final EJ Communications Plan shall be submitted to BOEM within 90 calendar days of the Record of Decision on the COP NEPA document. This term and condition would apply to any activity associated with the COP, including those performed by the Lessee's contractor(s). The Final EJ Communications Plan must propose a process for what, how, and to whom the Lessee plans to communicate during activities described in the COP that may affect EJ populations, including construction, operations and maintenance, and decommissioning. Because potential impacts on EJ populations are expected to be much lower during operations and maintenance than during construction or decommissioning, the EJ Communications Plan should reflect different levels of communications, as appropriate, during these different stages. The EJ Communications Plan must be specifically designed for EJ populations and be created in coordination with, at minimum, organizations that serve EJ populations, to inform the Lessee about the best ways to communicate information within EJ populations. The Lessee shall strive to include residents of EJ populations in the creation of the plan. The plan should be made available for review by EJ populations and should outline how the Lessee will advance meaningful engagement on a long-term and continuing basis accounting for each affected community's unique communication and information needs. The EJ Communications Plan must reflect the Lessee's efforts to coordinate with community organizations and leaders in the applicable communities to develop a communication plan that reflects community needs. This AMMM measure is not intended to duplicate communication plan requirements associated with state procurement or state or local permitting processes. The Lessee may utilize efforts or language developed for any state or local requirements to satisfy this Final EJ Communications Plan partially or wholly. The plan shall include EJ populations identified by applicable federal and state-level EJ and related screening tools, or other relevant local information. If states require an EJ Communications Plan with requirements described here, the Lessee may reference the state plan, as applicable. All information must be provided or referenced to fully meet this AMMM measure. In the EJ Communications Plan, the Lessee must: • Describe which EJ populations the EJ Communications Plan will target based on EJ populations identified by the COP NEPA document and any other supplementary information, including communities, organizations, and individual contacts learned about through ongoing engagement activities. The target reach of the EJ Communications Plans should be individuals within communities with environmental justice concerns that may be potentially affected by activities described in the COP. • Describe in detail which activities could impact which areas or populations and at what times; list which activities described in the COP must be included in the EJ Communications Plan and which activities are excluded. • Describe how the EJ Communications Plan was created in coordination with EJ populations and the actions EJ populations want the Lessee to take to demonstrate deep engagement on a long-term continuing basis. • Describe how each potentially affected EJ population desires to be communicated with during activities described in the COP (e.g., communication methods, language needs).	Environmental Justice; Land Use and Coastal Infrastructure	BOEM, BSEE, and USACE	Not Previously Applied

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		• Describe how coordination with other Lessees in the region will occur in advance of communication with EJ populations, especially in cases where onshore activities described in the COP may be in proximity to other projects. The intent of coordination is to reduce engagement redundancy and burden on EJ populations. • Describe how the Lessee will communicate when and where activities described in the COP will take place, who they may affect, and how they may affect EJ populations. • Identify a point of contact to receive reports of impacts throughout the life of the project, and provide notice through appropriate communication methods for the EJ populations potentially affected (e.g., postering, radio announcements) so that this point of contact is available to hear about impacts. • Identify the Lessee's approach to handling reports of impacts. • Describe how the Lessee will respond to any concerns or questions from EJ populations during activities described in the COP, and the process the Lessee will undertake to communicate with EJ populations to ensure these concerns or questions are addressed. Also include (1) how the Lessee will handle any questions or concerns that are not related to that Lessee's activities or applicable to regional offshore wind activities, and (2) how the Lessee will address reports of impacts to EJ populations from the Lessee's activities that are not otherwise addressed by existing AMMM measures or terms and conditions of the COP approval. • Describe when, how, and to whom employment opportunities are advertised and how the Lessee plans to maximize access to those opportunities for EJ populations, including but not limited to the communication and advertising for training programs and hiring processes. • Describe how the Lessee will communicate investment or supply chain opportunities to meet any Lessee commitments to diversity or equal access, including but not limited to those included in NY Bight lease stipulation 7.1. • Include a summary of feedback received from EJ populations on the above bullets (see EJ-3).			
EJ-3	Reporting and feedback requirements for EJ Communications Plan	The Lessee must report its activities under AMMM measure EJ-1a under the annual certification of compliance per 30 CFR 285.633, "How do I comply with my COP?". The Lessee shall provide a summary of any EJ Communications Plan activities that occurred. This report shall describe all actions taken and impacts reported that year through implementation of the EJ Communications Plan. The annual report of implementation of the EJ Communication Plan must provide enough details and description of activities for BSEE to determine if the Lessee is implementing the EJ Communications Plan during construction, operations, and decommissioning. The Lessee is expected to adaptively address communications, as well as address reported impacts, over the life of the project. The Lessee is expected to respond to any recommendations made by EJ populations. All written deliverables may be made publicly accessible on BOEM or BSEE's website; they must be submitted in a ready to publish format that also meets requirements of Section 508 of the Rehabilitation Act (29 U.S.C. 794d), as amended.	Environmental Justice	BOEM, BSEE, and USACE	Not Previously Applied
MUL-22	Received Sound Level Limit (RSLL)	Sound fields generated during impact pile driving of a single foundation in a 24-hour period may not exceed NOAA Fisheries' Level A permanent threshold shift (PTS) limits by the stated date and at the distances below. Current NOAA Fisheries PTS levels that are likely to occur at distances that exceed the proposed ranges are the LF SEL criteria, set at 183 dB (re 1 $\mu Pa^2 s$) weighted LF SEL, and the peak criteria for high-frequency cetaceans (HFC), set at 202 dB re 1 μPa^2 unweighted Lpk, but the Lessee must adhere to any updated thresholds produced by NOAA Fisheries as of the start of installation of piles. • May 1, 2026: After the first three foundations, no exceedance of RSLL beyond 4,921 feet (1,500 meters) from the foundation for 90% of remaining piles. • May 1, 2028: After the first three foundations, no exceedance of RSLL beyond 3,280 feet (1,000 meters) from the foundation for 90% of remaining piles.	Benthic; Finfish, Invertebrates, and EFH; Marine Mammals; Sea Turtles	BOEM, BSEE, and NMFS	Not Previously Applied
NAV-3	Cable placement for navigation and safety	The Lessee must seek to avoid unfavorable cable placement, including consideration of Federal Aids to Navigation (ATONs), Private Aids to Navigation (PATONs), anchorage areas (including Ambrose Anchorage), Traffic Separation Schemes, and Fairways.	Navigation and Vessel Traffic	BOEM, BSEE, and USCG	Not Previously Applied
OU-2	Mitigation for NEXRAD weather radar systems	The Lessee must coordinate with NEXRAD radar operators, through the Department of Commerce's National Information Telecommunications Administration (NTIA), to assess if the project causes radar interference to the degree that radar performance is no longer within the specified radar system's operation parameters or fails to meet mission objectives. If either is the case, the Lessee must notify BOEM and engage radar operators on mitigation efforts. Operational mitigations to NEXRAD weather radar systems may include the following: • Wind turbine curtailment/curtailment agreement • Phased array radars	Other Uses	BOEM and BSEE	Not Previously Applied
OU-4	Decommissioning in marine minerals resource areas	Infrastructure emplaced in marine minerals resource areas must be removed from the marine mineral resource area during decommissioning. In addition, any request to decommission in place in such areas through a departure request must demonstrate to BOEM's satisfaction that no significant impacts to marine minerals resources or their possible extraction or use will occur.	Other Uses	BOEM and BSEE	Not Previously Applied
STF-5	Trailing suction hopper dredge mitigation	If a trailing suction hopper dredge is used offshore, operators must disengage dredge pumps when the dragheads are not actively dredging and therefore working to keep the draghead firmly on the bottom in order to prevent impingement or entrainment of ESA-listed fish and sea turtle species. A state-of-the-art solid-faced deflector that is attached to the draghead must be used on all hopper dredges at all times. Pumps must be disengaged when lowering dragheads to the bottom to start dredging, turning, or lifting dragheads off the bottom at the completion of dredging.	Finfish, Invertebrates, and EFH; Sea Turtles	BOEM and BSEE	Not Previously Applied
VIS-7	Monitoring impacts on scenic and visual resources	In coordination with BOEM, the Lessee must prepare and implement a scenic and visual resource monitoring plan that monitors and compares the visual effects of the wind project during construction and operations/maintenance (daytime and nighttime) to the findings in the COP Visual Impact Assessment and verifies the accuracy of the visual simulations (photo and video). The monitoring plan must include monitoring and documenting the meteorological influences on actual wind turbine visibility over 3 years of operation, with the possibility of extension depending on consistency in data results, from selected onshore key observation points, as determined by BOEM and the Lessee.	Scenic and Visual Resources	BOEM and BSEE	Not Previously Applied

Measure ID[1]	Measure Name	Description	Resource Area Mitigated	Anticipated Enforcing Agency	Previously Applied or Not Previously Applied
		In addition, the Lessee shall include monitoring the operation of ADLS in the monitoring plan. The Lessee must monitor the frequency that the ADLS is operative, documenting when (dates and time) the aviation warning lights are in the on position and the duration of each event. Details for monitoring and reporting procedures must be included in the plan.			

[1] AMMM measure identification numbers start with a prefix corresponding to the resource or resources for which they were designed to mitigate and are defined as follows: AQ = air quality; BB = Birds and Bats; BEN = Benthic Resources; BIR = Birds; COMFIS = Commercial and For-Hire Recreational Fishing; CUL = Cultural Resources ; EJ = Environmental Justice; MM = Marine Mammal; MMST = Marine Mammals and Sea Turtles; MUL = Multiple; NAV = Navigation; OU = Other Uses; REC = Recreation and Tourism; ST = Sea Turtle; STF = Sea Turtle and ESA-listed Fish species; VIS = Scenic and Visual Resources; WQ = Water Quality

µPa = micro pascal; ADLS = aircraft detection lighting system; ADS-B = automatic dependent surveillance–broadcast; AMMM = avoidance, minimization, mitigation, and monitoring; AMP = alternative monitoring plan; ARSR-4 = air route surveillance radar; ASLF = ancient submerged landform features; ASR = airport surveillance radar; ASV = autonomous surface vehicles; ATONs = federal aids to navigation; AUV = autonomous underwater vehicle; BBPCMP = Bird and Bat Post-Construction Monitoring Plan; BiOp = biological opinion; BOEM = Bureau of Ocean Energy Management; BSEE = Bureau of Safety and Environmental Enforcement; CFR = code of federal regulation; COP = Construction and Operations Plan; CSV = comma-separated values; dB = decibel; DMA = dynamic management area; DoD = Department of Defense; DOI = Department of the Interior; EJ = environmental justice; ESA = Endangered Species Act; FAA = Federal Aviation Administration; FDR = facility design report; FIR = fabrication and installation report; FSC = Finance Section Chief; GARFO = Greater Atlantic Regional Fisheries Office; GHG = greenhouse gas; GPS = global positioning system; HD = high definition; HOV = human-occupied vehicles; HRG = high resolution geophysical; IC = Incident Commander; ICS = Incident Command System; IMPLAN = impact analysis for planning; IMR = injury and mortality reporting; IMT = Incident Management Team; IOOS = integrated ocean observing system; IR = inadvertent returns; ISO = independent system operator; IT = incidental take; JPEG = joint photographic experts group; kHz = kilohertz; km = kilometers; LOA = letter of authorization; LSC = Logistics Section Chief; MEC = munitions and explosives of concern; MMP = marine minerals program; MMPA = Marine Mammal Protection Act; NABat = North American Bat Monitoring Program database; NARW = North Atlantic right whale; NAS = noise attenuation system; NCEI = National Centers for Ecological Information; NEFOP = northeast fisheries observer program; NEFSC = Northeast Fisheries Science Center; NEPA = National Environmental Policy Act; NEXRAD = Next Generation Weather Radar; NJDEP = New Jersey Department of Environmental Protection; NMFS = National Marine Fisheries Service; NOAA = National Oceanic and Atmospheric Administration; NRHP = National Register of Historic Places; nT = nanotesla; NYSDEC = New York State Department of Environmental Conservation; NYSDOS = New York State Department of State; NYSERDA = New York State Energy Research and Development Authority; OCS = outer continental shelf; OPR = office of protected resources; OSC = Operations Section Chief; OSPD = Oil Spill Preparedness Division; OSRO = Oil Spill Removal Organizations; OSRP = Oil Spill Response Plan; OSS = offshore substation; PAM = passive acoustic monitoring; PATON = private aids to navigation; PDC = project design criteria; PDF = portable document format; POWERON = Partnership for an Offshore Wind Energy Regional Observation Network; PSC = Planning Section Chief; PSO = protected species observer; PTS = permanent threshold shift; QA/QC = quality assurance quality control; QI = Qualified Individual; RP = Recommended Practice; ROV = remotely operated vehicle; RSLL = received sound level limit; RVMP = Reduced Visibility Monitoring Plan; RWSC = Regional Wildlife Science Collaborative; SBP = sub-bottom profiler; SFV = sound field verification; SLR = single lens reflex; SLVIA = seascape, landscape, and visual impact assessment; SMA = seasonal management area; SMS = safety management system; SROT = Spill Response Operating Teams; STDN = sea turtle disentanglement network; T&C = terms and conditions; TIFF = tag image file format; TIMS = technical information management systems USACE = United States Army Corp of Engineers; U.S.C. = United States Code; USCG = United States Coast Guard; USFWS = United States Fish and Wildlife Service; UTC = universal time coordinated; UXO = unexploded ordnance; VFH = very high frequency; WCD = worst-case discharge; WTGs = wind turbine generators

Table G-2. Recommended Practices (RP) for Future Analysis

RP ID[1]	RP Name	Description	Applicable Resource Area
AQ-1	Using a substitute insulator gas in the switch gears and transmission systems to the maximum extent possible	The Lessee should evaluate the feasibility of using non-SF_6 switchgear and should provide the evaluation to BOEM for review as part of a brief memo following finalization of the FDR and FIR, totaling no more than 10 pages. To the maximum extent feasible, the Lessee should use a substitute insulator gas rather than SF6 in the switchgear and transmission systems. If the Lessee determines using non-SF6 switchgear is infeasible then the Lessee should provide written justification of this determination to BOEM. Any instances where the Lessee believes there is technical (and/or economic) infeasibility should be supported by a technical feasibility analysis, as appropriate.	Air Quality and GHG Emissions
AQ-2	Cleaner fuels for vessels, equipment, and vehicles engaged in activities on the OCS	The Lessee is encouraged to replace diesel fuel and marine fuel oil with alternative fuels such as natural gas, propane, or hydrogen, to the extent that use of such alternative fuels is feasible and provides emissions reductions. The Lessee should evaluate the feasibility of this mitigation measure and should provide the evaluation to BOEM for review as part of a brief memo following finalization of the FDR and FIR, totaling no more than 10 pages. Any instances where the Lessee believes there is technical (and/or economic) infeasibility should be supported by a technical feasibility analysis, as appropriate.	Air Quality and GHG Emissions
AQ-3	Electrification of vessels, equipment, and vehicles engaged in activities on the OCS	The Lessee is encouraged to replace combustion engines with zero-emissions technology (fuel cell-electric or battery-electric) if feasible. The Lessee should evaluate the feasibility of this mitigation measure and should provide the evaluation to BOEM for review as part of a brief memo following finalization of the FDR and FIR, totaling no more than 10 pages. Any instances where the Lessee believes there is technical (and/or economic) infeasibility should be supported by a technical feasibility analysis, as appropriate.	Air Quality and GHG Emissions
AQ-4	Exhaust aftertreatment for vessels engaged in activities on the OCS	The Lessee should evaluate, on a vessel-specific basis, the use of exhaust aftertreatments such as emission control technologies, for example, scrubbers for SO_2 and selective catalytic reduction for NO_X. The Lessee should evaluate the feasibility of this mitigation measure and should provide the evaluation to BOEM for review as part of a brief memo following finalization of the FDR and FIR, totaling no more than 10 pages. Any instances where the Lessee believes there is technical (and/or economic) infeasibility should be supported by a technical feasibility analysis, as appropriate.	Air Quality and GHG Emissions
AQ-5	Exhaust aftertreatment for older engines in vehicles and equipment engaged in activities on the OCS	The Lessee is encouraged to use diesel particulate filters and diesel oxidation catalysts to retrofit older (USEPA Tiers 1–3) diesel engines if feasible. The Lessee should evaluate the feasibility of this mitigation measure and should provide the evaluation to BOEM for review as part of a brief memo following finalization of the FDR and FIR, totaling no more than 10 pages. Any instances where the Lessee believes there is technical (and/or economic) infeasibility should be supported by a technical feasibility analysis, as appropriate.	Air Quality and GHG Emissions
AQ-6	Zero-emissions technologies	The Lessee is encouraged to require its contractors to use ports equipped with shore power and zero-emissions material-handling equipment, and construction firms that offer alternative-fueled or zero-emissions equipment and vehicles.	Air Quality and GHG Emissions
AQ-7	Diesel engine emissions standards	The Lessee is encouraged to require contractors using diesel engines that use a combination of combustion and post-combustion controls to meet or exceed applicable marine engine standards. These include the International Convention for the Prevention of Pollution from Ships (MARPOL) Annex VI for foreign vessels; 40 CFR Part 1039 for Tier 1 and 2 domestic marine diesel engines smaller than 37 kW- Control of Emissions from New and In-Use Nonroad Compression-Ignition Engines; 40 CFR Part 1042 for Tier 1 and 2 domestic marine diesel engines larger than 37 kW- Control of Emissions from New and In-Use Marine Compression-Ignition Engines and Vessels; and 40 CFR Part 1042 for Tier 3, Tier 4 Interim, and Tier 4 Final domestic marine diesel engines- Control of Emissions from New and In-Use Marine Compression-Ignition Engines and Vessels. On-road engines, non-road engines, and aircraft engines will meet or exceed similar standards, where practicable.	Air Quality and GHG Emissions

RP ID[1]	RP Name	Description	Applicable Resource Area
AQ-8	Technical feasibility analysis of air quality RPs	This measure encourages the Lessee to perform and present a technical feasibility analysis for air quality RPs 1 through 5 (AQ-1 – AQ-5), ensuring a comprehensive review of each measure's effectiveness, and readiness for implementation. The technical feasibility analysis should be submitted to BOEM/BSEE as part of a brief memo following finalization of the FDR and FIR, totaling no more than 10 pages.	Air Quality and GHG Emissions
BB-4	Bird and bat monitoring plan framework	The Lessee should develop a framework for a Bird and Bat Post-Construction Monitoring Plan (BB-3) in coordination with BOEM and USFWS. The Lessee is encouraged to include this framework with their initial COP submission or subsequent updated versions.	Bats, Birds
BEN-3	Benthic Survey Guidelines	The Lessee is encouraged to follow the BOEM Guidelines for Providing Benthic Habitat Survey Information for Renewable Energy Development on the Atlantic Outer Continental Shelf Pursuant to 30 CFR Part 585 (updated June 2019, at: https://www.boem.gov/sites/default/files/renewable-energy-program/Regulatory-Information/BOEM-Renewable-Benthic-Habitat-Guidelines.pdf) with regards to pre-, during- and post-construction benthic monitoring survey plan design.	Benthic
COMFIS-4	Fisheries mitigation	**Static cable design elements** are recommended: • All static cables should be buried to a minimum depth of 3 feet below stable seabed where technically feasible. Technical feasibility constraints include seabed conditions that preclude burial, such as telecommunication cable crossings. Deeper cable burial depths may be required dependent on risks identified in cable route design (see the Carbon Trust's Cable Burial Risk Assessment Methodology at: https://ctprodstorageaccountp.blob.core.windows.net/prod-drupal-files/documents/resource/public/cable-burial-risk-assessment-guidance.pdf). • The Lessee should avoid installation techniques that raise the profile of the seabed, such as the ejection of large, previously buried rocks or boulders onto the surface. The ejection of this material may damage fishing gear. If raising the profile of the seabed is unavoidable, the Lessee should propose measures in the COP to minimize the total area of impact through measures such as removing potential obstructions from areas where bottom-tending fishing gear is actively used or consolidating such obstructions in areas where bottom-tending fishing gear is not actively used. • If needed, cable protection measures should reflect the pre-existing conditions at the site. This mitigation measure ensures that seafloor cable protection does not introduce new obstructions for mobile fishing gear. Thus, the cable protection measures should be trawl-friendly with tapered or sloped edges. If cable protection is necessary in "non-trawlable" habitat, such as rocky habitat, then the Lessee should use materials that mirror the benthic environment. • Where technically and economically feasible, cables should share corridors and minimize the total area disturbed. **Project design** should be planned in coordination with fisheries: • The facility design should seek to maximize existing access to fisheries in balance with other siting constraints by considering: a. Transit within the project area and traditional fishing activities within the project area. b. Consolidation of infrastructure, where practicable, to reduce space-use conflicts. c. Technologies to reduce total project area and meet energy production commitments. • Turbine locations should be sited to avoid areas of commercial fishery production such as known sensitive benthic features and natural and artificial reefs. • Facility planning should use nature-inclusive designs (see Evaluating the Effectiveness of Nature Inclusive Design Materials at: https://www.boem.gov/sites/default/files/documents/environment/environmental-studies/SDP_2022-2023.pdf), where applicable, to maximize available habitat for fish. • Installation techniques and time windows should minimize disruption to fishing activities (e.g., simultaneous lay and burial, or conducting activity during the appropriate time of year). To improve **safety** at sea in and around offshore wind facilities, BOEM recommends that the Lessee consider the following measures in its plan submittals: • Charting all facilities and obstructions resulting from construction and operations of an offshore wind energy facility and providing that information to NOAA, USCG, and navigational software companies. • Employing liaisons with experience in the commercial fishing industry to provide safety and communication services during construction. • Monitoring cable burial in real-time and reporting all potential hazard events to USCG as soon as possible throughout the life of the project. • Using digital information technology platforms (e.g., smartphone applications) to bring together survey and construction schedules and locations in addition to standard local notices to mariners via the USCG. • Marking facilities and appurtenances with permanent identification of the project and company. • Providing training opportunities for the commercial fishing industry to simulate safe navigation through a wind facility in various weather conditions and at various speeds. • Monitoring safety threats (e.g., radar disruption, ice shedding, vessel allisions and collisions, security threats, unexploded ordnance/munitions of explosive concern, and impacts on search and rescue efforts) throughout the life of a project. • Consulting with the fishing industry and USCG to identify which structures would be most appropriate for Automatic Identification System (AIS) transponders consistent with BOEM's Lighting and Marking Guidelines (https://www.boem.gov/2021-lighting-and-marking-guidelines). • Considering Lessee-funded radar system upgrades for commercial and for-hire recreational fishing vessels (e.g., solid state Doppler-based marine vessel radar systems; see National Academies of Science Engineering and Medicine 2022).[4]	Commercial and For-Hire Fishing
COMFIS-5	Fisheries Survey Guidelines	The Lessee should follow the BOEM Fisheries Survey Guidelines (Fisheries Guidelines, updated March 27, 2023, at: https://www.boem.gov/sites/default/files/documents/about-boem/Fishery-Survey-Guidelines.pdf) with regards to pre-, during- and post-construction fisheries monitoring survey plan design.	Commercial and For-Hire Fishing; Marine Mammals
COMFIS-7	Fisheries Compensation Fund	The Lessee should consider contracting with a neutral third-party, such as a regional fund administrator, to process claims, manage, and disburse funds, and handle appeals.	Commercial and For-Hire Fishing
CUL-7	Section 106 mitigation fund	Through consultation, BOEM may request that the Lessee financially contributes to a third-party managed compensatory mitigation fund to address visual impacts on aboveground historic properties related to OCS offshore wind activities.	Cultural Resources
EJ-1b	Draft Environmental Justice Communication Plan	The Draft Environmental Justice (EJ) Communications Plan should be created in coordination with EJ populations and identify Lessee plans for communicating with EJ communities or populations (defined for EJ-1a and EJ-3 AMMM measures as "communities with environmental justice concerns" as related to Executive Order 14096 and the revised implementation	Environmental Justice

[4] National Academies of Science Engineering and Medicine. 2022. Wind Turbine Generator Impacts to Marine Vessel Radar. Washington, D.C.: The National Academies Press. https://doi.org/10.17226/26430.

RP ID[1]	RP Name	Description	Applicable Resource Area
		regulations for NEPA (National Environmental Policy Act Implementing Regulations Revisions Phase 2; 89 Federal Register 35554 – 35577 (May 1, 2024)), referred to herein as “EJ populations”). The Lessee should develop a Draft EJ Communications Plan early in the project planning process. The Lessee is encouraged to submit a Draft EJ Communications Plan to BOEM for BOEM’s feedback prior to publication of the Draft COP NEPA document. This will allow sufficient time for coordination with EJ populations during the development of an EJ Communications Plan in advance of activities. The Draft EJ Communications Plan should propose a process for how the Lessee plans to communicate during activities described in the COP, including construction, operations, and decommissioning. Because potential impacts on EJ populations are expected to be much lower during operations than during construction or decommissioning, the Draft EJ Communications Plan should reflect different levels of communications, as appropriate, during these different stages. The Lessee may utilize efforts or language developed for any state requirements (e.g., measures identified through state renewable energy procurement processes or as requirements of state permits) to satisfy this Draft EJ Communications Plan partially or wholly. In order to meet the intent of this RP to enhance ongoing Lessee communications with EJ populations, this Draft EJ Communications Plan should be developed in consultation with community leaders and community organizations who work with the identified EJ population(s). Plans should be specifically designed for EJ populations and advance meaningful engagement based on each affected community’s unique communication and information needs. EJ populations should be identified by any applicable federal and state-level EJ and related screening tools, or other relevant local information.	
EJ-2	Environmental Justice Impact Mitigation Plan	An EJ Impact Mitigation Plan (Plan) is recommended if EJ populations would potentially be impacted by onshore construction activities or any activity associated with the COP, including activities of the Lessee’s contractor(s). The Lessee is encouraged to submit a Draft Environmental Justice Impact Mitigation Plan during COP review, prior to publication of the Draft COP NEPA document. Submission of a Final Environmental Justice Impact Mitigation Plan is recommended before construction begins. The Environmental Justice Impact Mitigation Plan should be created in coordination with EJ populations, and should describe existing state or local requirements (e.g., noise ordinances; dust abatement requirements) that may reduce impacts in order to avoid any duplication. The plan should also describe scenarios of what actions, including distribution of mitigation resources or other mitigation strategies, the Lessee will take if the Lessee receives notice of an impact occurring. For engagement with EJ populations during development of the Impact Mitigation Plan, BOEM encourages the Lessee to coordinate with other Lessees, per the New York Bight Lease Sale lease stipulation (87 Federal Register 2446, VI, (a)), and to carry out engagement in coordination with the development of the communications plan (EJ-1a). The EJ Impact Mitigation Plan should provide sufficient detail on how impacts can be reported, how eligibility for action will be determined, and how EJ populations will have access to mitigation resources or how other mitigation strategies will be implemented. The Impact Mitigation Plan should include a description of all potential mitigation resources or strategies and the duration for which distribution of resources or strategy implementation will occur based on anticipated activity length and localized impacts. The plan should also outline roles and responsibilities of households and the Lessee, and there should be clear guidelines around principles of equity, transparency, and fairness. The EJ Impact Mitigation Plan should demonstrate that potentially affected EJ populations were coordinated with and had multiple and varied opportunities to provide information about the most effective and equitable strategies for all processes, including reporting of impacts, resource distribution, or implementation of mitigation strategies.	Environmental Justice
MM-2	Real-time PAM monitoring and alert system for baleen whales	A near real-time passive acoustic monitoring (PAM) system for the detection of baleen whales in the NY Bight during offshore wind development activities should be implemented, with an alert system/notice to mariners/construction operators. This could be achieved through the deployment of several ocean gliders or fixed PAM systems in the broader NY Bight area. The equipment could be deployed anywhere there is offshore wind development activities, including in the lease areas, but may be particularly useful between lease areas where the placement of other real-time PAM systems is not already directed, or near transit or cable-laying corridors, or other locations where real-time alerting of marine mammal presence would be beneficial to the offshore wind-related activities occurring in one or more lease areas. Every effort should be made to deploy equipment in advance of any on-water activity, including site characterization work, construction work, etc., to provide situational awareness toward vessel strike risk. Each system should be equipped with reliable PAM technology and marine mammal detection and classification software. Detections will be transmittable to a PAM analyst for verification. The systems will be capable of alerting offshore wind developers that a baleen whale has been detected in the general area of offshore wind development-related activity, through methods such as Whale Alert or an offshore wind-specific notification system. This could also be achieved through partnership with other industries, academia, NGOs, and federal agencies in a regional effort. A plan detailing any proposed localization system and analysis methods should be submitted and discussed with BOEM and other relevant permitting agencies in advance of deployment. This real-time PAM alert system will increase the opportunity to detect marine mammals in the greater NY Bight area, providing the opportunity for increased situational awareness (for vessel strike avoidance) to PSOs and others of marine mammal presence in the area. In addition, raw data or data products associated with real-time PAM should be submitted for archiving at the National Centers for Environmental Information or a similar entity determined by BOEM as soon as practicable after instrument retrieval. The archived data will be integrated into community PAM efforts in the broader region, such as through the Regional Wildlife Science Collaborative, to understand marine mammal distribution/occurrence in the area, which can then be used to inform future predictions of potential impacts to marine mammals.	Marine Mammals
MM-7	Additional vessel-related measures for the North Atlantic right whale	The Lessee should develop and implement the project's schedule to reduce vessel density during the times of year when North Atlantic right whales are most likely to occur in lease areas and along vessel routes. The Lessees should coordinate across different offshore wind development projects to reduce cumulative vessel density within the region to the extent practicable. Time periods of highest risk include but are not limited to during foraging and migration and times when mother-calf pairs, pregnant females, surface active groups (indicative of breeding or social behavior), or aggregations of three or more whales (indicative of feeding or social behavior) are, or are expected to be, present. Time periods should be defined based on the best available scientific information.	Marine Mammals
MM-8	Effectiveness criteria for vessel strike avoidance plans	The Lessee should include in its vessel strike avoidance plans the effectiveness criteria being applied. The joint Regional Wildlife Science Collaborative for Offshore Wind (RWSC) and Marine Technology Society Technology Workshop Series may be a good resource for such effectiveness criteria.	Marine Mammals
MUL-5	Low noise best practices	For onshore and offshore project activities and across all phases of construction and operations, operators should use equipment, technology, and best practices that produce the least amount of noise practicable to avoid and minimize noise impacts on the environment. See the following as examples: low noise foundations (MUL-6), vessel noise reduction guidelines (MUL-7), and the received sound level limit (MUL-22).	Bats; Benthic; Birds; Coastal Habitat and Fauna; Commercial and For-Hire Fishing; Finfish, Invertebrates, and EFH; Land Use and Coastal Infrastructure; Marine Mammals; Recreation and Tourism; Sea Turtles

<table>
<tr><th>RP ID[1]</th><th>RP Name</th><th>Description</th><th>Applicable Resource Area</th></tr>
<tr><td>MUL-6</td><td>Low noise foundations</td><td>BOEM encourages the use of low noise practices in foundation installation. The use of non-pile-driving foundation types (e.g., suction buckets, gravity-based foundations, etc.) should be considered first. If not practicable, then the use of the best available quieting technology should be applied to reach the received sound level limit (MUL-22). (See Appendix J for discussion on non-pile-driving foundations and noise abatement.) In addition, through the COP or a separate report, the Lessee should submit to BOEM (on behalf of BOEM, BSEE, NMFS and USACE) justification for why the use of non-pile-driving foundations is not possible.</td><td>Finfish, Invertebrates, and EFH; Marine Mammals; Sea Turtles</td></tr>
<tr><td>MUL-7</td><td>Vessel noise reduction guidelines</td><td>To the extent reasonable and practicable, BOEM encourages the Lessee to follow the most current International Maritime Organization's (IMO) Guidelines for the reduction of underwater radiated noise, including propulsion noise, machinery noise, and noise from dynamic positioning systems of any vessel associated with the project. BOEM encourages the Lessee to use quieter ships wherever possible, especially for new vessel builds, and contribute to the Experience Building Phase as outlined by the IMO endorsed Action Plan developed by the Sub-Committee on Ship Design and Construction for underwater noise reduction.</td><td>Finfish, Invertebrates, and EFH; Marine Mammals; Sea Turtles</td></tr>
<tr><td>MUL-10b</td><td>Avoid spawning and developmental habitat of sturgeon during data collection and site survey activities</td><td>No geotechnical or bottom-disturbing activities should take place during the spawning/rearing season within freshwater reaches of rivers where Atlantic or shortnose sturgeon spawning occurs. Any survey plan that includes geotechnical or other benthic sampling activities in freshwater reaches (salinity 0-0.5 ppt) of such rivers will identify a time of year restriction that will avoid such activities during the time of year when Atlantic sturgeon spawning and rearing of early life stages occurs in that river. Time of year restrictions include the following:
<table><tr><td>River</td><td>No Work Window</td><td>Area Affected</td></tr><tr><td>Hudson</td><td>April–July</td><td>Upstream of Newburgh, NY – Beacon Bridge/Rt 84</td></tr><tr><td>Delaware</td><td>April–July</td><td>Upstream of the Delaware Memorial Bridge</td></tr></table></td><td>Finfish, Invertebrates, and EFH; Benthic</td></tr>
<tr><td>MUL-10c</td><td>Minimize vessel interactions with listed species during use of a moon pool</td><td>During times of year when sea turtles are known to occur in the survey area and if there is an intention to utilize a moon pool for the required activities, the following RPs should be followed:
Closure of the Hull Door:
Should the moon pool have a hull door that can be closed, then prior to and following closure, the moon pool must be monitored continuously by a dedicated crew observer with no other tasks to ensure that no individual protected species is present in the moon pool area. If visibility is not clear to the hull door from above (e.g., turbidity or low light), 30 minutes of monitoring is required prior to hull door closure.
If a protected species is observed in the moon pool prior to closure of the hull door, the hull door must not be closed, to the extent practicable. If the observed animal leaves the moon pool, the operator may commence closure. If the observed animal remains in the moon pool, contact BSEE prior to closure of the hull doors according to reporting requirements (see Reporting of Observations of Protected Species within an Enclosed Moon Pool below).
Reporting of Observations of Protected Species within an Enclosed Moon Pool:
If a protected species is observed within an enclosed moon pool and does not demonstrate any signs of distress or injury or an inability to leave the moon pool of its own volition, RPs described in this section should be followed (only in cases where they do not jeopardize human safety). Although this particular situation may not require immediate assistance and reporting, a protected species could potentially become disoriented with their surroundings and may not be able to leave the enclosed moon pool of their own volition. In order for operations requiring use of a moon pool to continue, the following reporting RPs should be followed:
Within 24 hours of any observation, and daily after that for as long as an individual protected species remains within a moon pool (i.e., in cases where an ESA listed species has entered a moon pool but entrapment or injury has not been observed), the following information should be reported to BSEE (protectedspecies@bsee.gov). For an initial report, all information described above should be included.
For subsequent daily reports:
Describe the animal's status to include external body condition (e.g., note any injuries or noticeable features), behaviors (e.g., floating at surface, chasing fish, diving, lethargic, etc.), and movement (e.g., has the animal left the moon pool and returned on multiple occasions?);
Description of current moon pool activities, if the animal is in the moon pool (e.g., drilling, preparation for demobilization, etc.);
Description of planned activities in the immediate future related to vessel movement or deployment of equipment;
Any additional photographs or video footage of the animal, if possible;
Guidance received and followed from NMFS liaison or stranding hotline that was contacted for assistance;
Whether activities in the moon pool were halted or changed upon observation of the animal; and
Whether the animal remains in the moon pool at the time of the report, or if not, the time/date the animal was last observed.
BOEM does not advocate the lowering of crew members into the moon pool to free protected species and NMFS should be contacted if protected species are encountered in the moon pool.</td><td>Finfish, Invertebrates, and EFH; Marine Mammals; Sea Turtles</td></tr>
<tr><td>MUL-12</td><td>Ecological design elements</td><td>The Lessee is encouraged to incorporate ecological design elements into the project design where practicable. For example, nature-inclusive design products are an alternative to traditional concrete that enhance or encourage the growth of flora or fauna when placed in a marine environment and could result in reduced GHG emissions compared to conventional concrete. Other examples include artificial reefs or using nature-based scour protection such as oyster beds.</td><td>Air Quality and GHG Emissions; Benthic; Coastal Habitat and Fauna; Commercial and For-Hire Fishing; Finfish, Invertebrates, and EFH; Marine Mammals; Sea Turtles</td></tr>
<tr><td>MUL-14b</td><td>MEC Avoidance Best Practices</td><td>If MEC avoidance is not possible, submitted UXO/MEC avoidance plans should follow, when finalized, the US Committee on the Marine Transportation System general guidance addressing MEC at: https://www.cmts.gov/Portals/75/Documents/page_offshore_energy/DOT-OST-2023-0117-0001_attachment_1.pdf</td><td>Commercial and For-Hire Fishing; Finfish, Invertebrates, and EFH; Marine Mammals; Sea Turtles</td></tr>
<tr><td>MUL-18</td><td>Shared transmission corridor</td><td>Lessees should coordinate transmission infrastructure among projects. Where practicable, transmission infrastructure should use shared intra- and interregional connections, have requirements for meshed infrastructure, apply parallel routing with existing and proposed linear infrastructure (including export cables and other existing infrastructure such as power</td><td>Benthic; Coastal Habitat and Fauna; Commercial and For-Hire Fishing;</td></tr>
</table>

RP ID[1]	RP Name	Description	Applicable Resource Area
		and telecommunication cables, pipelines), and have a limited combined footprint to minimize impacts and maximize potential capacity. Where possible, Lessees should incorporate cable siting principles and routing measures for export cables and associated substations developed from the Atlantic Offshore Wind Transmission Study and the BOEM/DOE transmission planning effort, the NYSERDA's Offshore Wind Cable Corridor Constraints Assessment,[5] associated NYS Public Service Commission orders, and the results of other state and ISO/RTO transmission planning processes, to maximize the utility of Points of Interconnection (POIs). Lessees considering landfall in New Jersey should also comply with the results of the state agreement approach (SAA)[6] and any other future procurements resulting from similar initiatives.	Cultural Resources; Finfish, Invertebrates, and EFH; Marine Mammals; Navigation and Vessel Traffic; Sea Turtles; Wetlands
MUL-21	Use of new and emerging technology [7]	In addition to employing best available safest technology, the Lessee is encouraged to adopt new and emerging technologies to avoid or minimize potential impacts in both offshore and nearshore environments, where practicable. Examples include the use of jet plows, closed loop cooling systems, trenchless technology, gravity-based structures or foundation designs that do not rely on pile driving, and protected species detection technologies including MERLIN radar systems, thermal imaging cameras, acoustic devices, and the integrations of these data streams for real-time monitoring. In addition, the Lessee should explore opportunities to upgrade/retrofit equipment to the best available technology if it becomes available during project operations.	Bats; Benthic; Birds; Coastal Habitat and Fauna; Commercial and For-Hire Fishing; Finfish, Invertebrates, and EFH; Marine Mammals; Sea Turtles, Water Quality
MUL-23	Adjust project design to reduce impacts	The Lessee should review and refer to the Information Guidelines for Renewable Energy Construction and Operations Plan Best Management Practices (Attachment A, https://www.boem.gov/sites/default/files/documents/about-boem/COP%20Guidelines_Technical_Corrections.pdf) during project planning to avoid or reduce potential impacts on important environmental resources, including sensitive habitats. Additional, project design considerations include: • Using cable installation methods, such as horizontal directional drilling, that avoid and minimize adverse impacts on sensitive habitats and difficult-to-replace resources; • Avoiding routing export cables through estuaries and embayments to reduce impacts on numerous sensitive habitats and difficult-to-replace resources as well as many sensitive life stages of various species; • Ensuring all mooring systems and ancillary equipment are contained inside the approved lease area to reduce impacts on fishing, navigation, and other uses; • Using outputs from marine mammal vessel strike models to inform project design; • Considering all potential WTG positions to allow for flexibility in project design due to identification of sensitive habitats or cultural properties through the environmental review process; and • Using micrositing as a tool for identifying and avoiding sensitive habitats.	Bats; Benthic; Birds; Coastal Habitat and Fauna; Commercial and For-Hire Fishing; Finfish, Invertebrates, and EFH; Marine Mammals; Wetlands; Sea Turtles
MUL-25	Consistent turbine layout, markings, and lighting	The Lessee should employ consistent turbine grid layouts, spacing, markings, and lighting among lease areas to minimize navigational hazards and facilitate other ocean uses such as fishing and recreational activities. BOEM recommends the lessee have one of the two lines of orientation in the grided layout be spaced at least 1 nautical mile (1.9 kilometers) apart to support navigation safety and Search and Rescue (SAR). This recommended spacing is based on the USCG's 2020 Massachusetts and Rhode Island Port Access Route Study (https://www.navcen.uscg.gov/sites/default/files/pdf/PARS/FINAL_REPORT_PARS_May_14_2020.pdf). The spacing would also preserve structure-free areas to facilitate seabird passage and fishing operations. Also, per lease stipulations if applicable, adjacent lease areas that do not adopt the same layout must have an additional setback from shared borders. In accordance with BOEM lighting and marking guidelines, and USCG and FAA lighting and marking requirements, the Lessee must ensure that all structures are properly marked and lighted.	Bats; Birds; Commercial and For-Hire Fishing; Navigation and Vessel Traffic
MUL-26	Coordination for regional monitoring and surveys	Lessees are encouraged to: • Coordinate monitoring and survey efforts across lease areas in the NY Bight to standardize approaches, understand potential impacts to resources at a regional scale, and maximize efficiencies in monitoring and survey efforts; • Develop monitoring and survey plans that meet regional data requirements and standards, such as ROSA Offshore Wind Project Monitoring Framework and Guidelines (https://www.rosascience.org/wp-content/uploads/2022/09/ROSA-Offshore-Wind-Project-Montioring-Framework-and-Guidelines.pdf), the Regional Wildlife Science Collaborative's Science Plan (https://rwsc.org/science-plan/), and the NMFS/BOEM Federal Survey Mitigation Implementation Strategy; and • Make results from monitoring publicly available, for example through PNNL's offshore wind metadata tool (https://tethys.pnnl.gov/offshore-wind-metadata).	Benthic; Birds; Bats; Coastal Habitat and Fauna; Commercial and For-Hire Fishing; Finfish, Invertebrates, and EFH; Marine Mammals; Sea Turtles
MUL-27	Minimize sediment disturbance	The Lessee should employ methods to minimize sediment disturbance, including, but not limited to, the use of midline buoys to prevent cable sweep, not side casting materials, and removal and reuse of dredged material for backfill or other beneficial use where practicable.	Benthic; Finfish, Invertebrates, and EFH; Water Quality; Sea Turtles
MUL-28	Inadvertent Returns (IR) Plan and drilling fluids	The Lessee should coordinate with applicable agencies to develop an Inadvertent Returns (IR) Plan to address prevention, control, and clean-up of potential IR, which is the unintended release of drilling fluids to the surface during drilling operations. To the extent practicable, use biodegradable drilling solution, and recirculate and recycle drilling fluids used during HDD construction to minimize required water use. Avoid discharging drilling fluids onto the seabed.	Benthic; Finfish, Invertebrates, and EFH; Water Quality
MUL-39	Electrical shielding on underwater cables	The Lessee should use standard underwater cable design that mitigates the intensity of electromagnetic fields (EMF) at the seafloor. EMF will be further refined as part of the design or cable burial risk assessment.	Benthic; Finfish, Invertebrates, and EFH; Marine Mammals; Sea Turtles
NAV-4	Marine Vessel Radar	Where possible, the Lessee should adhere to the recommendations for mitigation to marine radar interference from the National Academy of Science: *Wind Turbine Generator Impacts to Marine Vessel Radar* (2022).	Navigation and Vessel Traffic
OU-8	Marine minerals resource area avoidance	The Lessee should ensure that bottom-disturbing activities avoid, to the maximum extent practicable, nearshore borrow areas and OCS sediment resources. Any activity that lasts more than 180 days and is located within 500 lateral meters of any marine minerals resource areas or limits the long-term use of the resource is considered bottom disturbing. The Lessee should use its geophysical and geological information collected in/along proposed corridors to demonstrate and verify the existence of sand resource or dearth of sand resource and estimate (via range) the possible implication of cable crossing on volume access. The Lessee is responsible for responding to any request from BOEM Marine Minerals Program (MMP),	Other Uses

[5] For a list of specific cable siting principles, refer to Section 4.1 in the Offshore Wind Cable Corridor Constraints Assessment at: https://www.nyserda.ny.gov/-/media/Project/Nyserda/Files/Programs/Offshore-Wind/2306-Offshore-Wind-Cable-Corridor-Constraints-Assessment--completeacc.pdf.
[6] https://www.nj.gov/bpu/pdf/boardorders/2022/20221026/8A%20ORDER%20State%20Agreement%20Approach.pdf.
[7] Appendix B, *Supplemental Information and Additional Figures and Tables*, Section B.9 describes examples of new and emerging technologies that the Lessee could research and consider for adoption as part of MUL-21.

RP ID[1]	RP Name	Description	Applicable Resource Area
		USACE, and state resource agencies (e.g., NJDEP, NYSDEC, NYSDOS) in writing and to show good faith efforts to avoid sand resources to the maximum extent practicable or explain why another alternative is not technically or economically feasible.	
STF-1	Monitoring on strategically placed WTGs	The Lessee is encouraged to incorporate technologies for detecting tagged sea turtles and highly migratory fish in its project to monitor the effect of increases in habitat use and residency around WTG foundations. The Lessee is encouraged to share monitoring results and propose new or additional mitigation measures and/or monitoring methods if appropriate.	Finfish, Invertebrates, and EFH; Sea Turtles
VIS-1	Onshore transmission tower visual contrast mitigation	The Lessee should select a transmission tower type that has the least amount of visual contrast within the surrounding setting and the extended landscape within view of which the transmission line is routed in order to avoid undue and unnecessary visual impact. Monopoles typically have less visual contrast within built environments, whereas lattice towers typically have less visual contrast in more natural settings. The Lessee should color-treat the transmission tower darker grays (chemically treated galvanized finishes) to reduce visual contrast or powder-coat the tower with Bureau of Land Management Environmental Color Covert Green or Shadow Gray, or a BOEM-approved equivalent submitted by the Lessee for settings where Covert Green or Shadow Gray does not minimize the visual contrast. The Lessee should prepare photo simulations of proposed onshore facilities with and without onshore transmission tower visual contrast mitigation. Bureau of Land Management color samples may be acquired by email to blm_oc_pmds@blm.gov.	Scenic and Visual Resources
VIS-2	Onshore substation visual contrast mitigation	The Lessee should color treat all substation facilities the same color, and color-treat them to minimize visual contrast with the surrounding setting, and the extended landscape within view. The default color choice for substations should be Bureau of Land Management Environmental Color Covert Green or Shadow Gray, or a BOEM-approved equivalent submitted by the Lessee for settings where Covert Green or Shadow Gray does not minimize the visual contrast in order to avoid undue and unnecessary visual impact. The Lessee should prepare photo simulations of proposed onshore facilities with and without onshore substation visual contrast mitigation. Bureau of Land Management color samples may be acquired by email to blm_oc_pmds@blm.gov.	Scenic and Visual Resources
VIS-3	Onshore overhead transmission conductors visual contrast mitigation	The Lessee should use non-specular conductors for overhead transmission powerlines to avoid glare commonly associated with untreated conductors to avoid undue and unnecessary visual impact. The Lessee should prepare photo simulations of proposed onshore facilities with and without onshore overhead transmission conductors visual contrast mitigation.	Scenic and Visual Resources
VIS-4	Onshore overhead transmission line insulator visual contrast mitigation	The Lessee should use polymer insulators to minimize glare commonly associated with glass insulators. The Lessee should use polymer insulators that are a color that minimizes visual contrast with the surrounding setting and the extended landscape that is within view to avoid undue and unnecessary visual impact. The default color choice for polymer insulators substations should be Bureau of Land Management Environmental Color Covert Green or Shadow Gray, or Sudan Brown, or a BOEM-approved equivalent submitted by the Lessee for settings where Covert Green or Shadow Gray or Sudan Brown do not minimize the visual contrast. Bureau of Land Management color samples may be acquired by email to blm_oc_pmds@blm.gov. The Lessee should prepare photo simulations of proposed onshore facilities with and without onshore overhead transmission line insulator visual contrast mitigation.	Scenic and Visual Resources
VIS-5	Onshore facility security fencing visual contrast mitigation	The Lessee should ensure galvanized and other types of security fencing are treated to eliminate glare and color-treated to minimize visual contrast with the surrounding setting and the extended landscape that is within view to avoid undue and unnecessary visual impact. Methods include vinyl-coating, powder-coating, and oxidizing treatments. Colors should be dark brown, dark grays, or dark brown (oxidizing treatments only). The Lessee should prepare photo simulations of proposed onshore facilities with and without onshore facility security fencing visual contrast mitigation.	Scenic and Visual Resources
VIS-6	Offshore and Onshore facility lighting	In order to avoid undue and unnecessary visual impact, the Lessee should ensure artificial light at night needed for nighttime operations and security at offshore and onshore facilities such as wind turbine generators, operational and maintenance facilities, offshore and onshore substations and booster stations, and others follows the night lighting principles to avoid light pollution and the artificial lighting BMPs outlined in National Park Service Sustainable Lighting Best Principles (https://www.nps.gov/subjects/nightskies/sustainable-outdoor-lighting.htm) and the Bureau of Land Management Technical Note 457 available at https://www.blm.gov/sites/default/files/docs/2023-05/IB2023-038_att1.pdf. The Lessee should prepare photo simulations of proposed facilities with and without offshore and onshore facility lighting mitigation.	Scenic and Visual Resources; Birds
VIS-8	Scenic and Visual Resources Mitigation Analysis	The Lessee should prepare a methodology for using and integrating BOEM's 2021 SLVIA guidance into the COP SLVIA, and submit to BOEM for review and comment before initiating the impact assessment. The COP SLVIA should also include onshore facilities associated with the offshore wind energy project. Onshore facilities should incorporate visual RPs 1 through 6 (VIS-1 – VIS-6). The SLVIA should include photo simulations, time-lapse video simulations, and/or other forms of visualization technology showing the existing condition, proposed changes to the offshore and onshore visual environment, and effectiveness of mitigation measures, if not included as a part of the proposed action.	Scenic and Visual Resources
REC-1	Nearshore construction timing restriction	The Lessee should prioritize scheduling of nearshore construction activities for outside the summer tourist season, which is generally between Memorial Day and Labor Day.	Land Use and Coastal Infrastructure, Recreation and Tourism

[1] RP measure identification numbers start with a prefix corresponding to the resource or resources for which they were designed to mitigate and are defined as follows: AQ = air quality; BB = Birds and Bats; BEN = Benthic Resources; BIR = Birds; COMFIS = Commercial and For-Hire Recreational Fishing; CUL = Cultural Resources ; EJ = Environmental Justice; MM = Marine Mammal; MMST = Marine Mammals and Sea Turtles; MUL = Multiple; NAV = Navigation; OU = Other Uses; REC = Recreation and Tourism; ST = Sea Turtle; STF = Sea Turtle and ESA-listed Fish species; VIS = Scenic and Visual Resources; WQ = Water Quality

AIS = automatic identification system; AMMM = avoidance, minimization, mitigation, and monitoring; BMPs = best management practices; BOEM = Bureau of Ocean Energy Management; BSEE = Bureau of Safety and Environmental Enforcement; CFR = code of federal regulation;
COP = Construction and Operations Plan; DOE = Department of Energy; EMF = electromagnetic field; ESA = Endangered Species Act; FAA = Federal Aviation Administration; FDR = facility design report; FIR = fabrication and installation report; GHG = greenhouse gas; HDD = horizontal directional drilling; IMO = international maritime organization; IMPLAN = impact analysis for planning; IR = inadvertent returns; ISO = independent system operator; kW= kilowatt; MARPOL = The International Convention on the Prevention of Pollution from Ships; MEC = munitions and explosives of concern; NEPA = National Environmental Policy Act; NGOs = non-governmental organization; NMFS = National Marine Fisheries Service; NOAA = National Oceanic and Atmospheric Administration; NO_X = nitrogen oxides; NRHP = National Register of Historic Places; nT = nanotesla; NYS = New York State;

Appendix H: Seascape, Landscape, and Visual Impact Assessment

H.1 Introduction

This appendix describes the seascape, landscape, and visual impact assessment (SLVIA) methodology and key findings that the Bureau of Ocean Energy Management (BOEM) used to identify the potential impacts of offshore wind structures (wind turbine generators [WTGs] and offshore substations [OSSs]) on scenic and visual resources in the geographic analysis area. The SLVIA methodology applies to any offshore wind energy development proposed for the Outer Continental Shelf (OCS) and incorporates by reference the detailed description of the methodology described in the *Assessment of Seascape, Landscape, and Visual Impacts of Offshore Wind Energy Developments on the Outer Continental Shelf of the United States* (BOEM 2021). The analysis in this appendix relies on and incorporates by reference the assessment of the six New York Bight (NY Bight) lease areas conducted by Argonne National Laboratory (Argonne) and BOEM in accordance with the SLVIA methodology, *Ocean, Seascape, Landscape, and Visual Impact Assessment of the New York Bight Offshore Wind Lease Areas* (Argonne 2024). These documents are available on the BOEM website.

Section H.2, *Method of Analysis*, of this appendix describes the specific methodology used to apply the SLVIA methodology to the NY Bight projects, and Section H.3, *SLVIA Results,* summarizes the wind farm distances, fields of view (FOVs), noticeable elements, visual contrasts, scale of change, and prominence that contributed to the determination of impact levels for ocean, seascape, and landscape and each key observation point (KOP) for the NY Bight projects. Section H.4, *Cumulative Impacts of NY Bight Projects*, describes the cumulative impacts from the NY Bight projects in combination with other ongoing and planned offshore wind projects. Detailed maps of character areas, KOPs, and other scenic resources within view of each lease area and of the six NY Bight lease areas collectively are contained in Argonne (2024). Visual simulations of the NY Bight projects alone, other ongoing and planned offshore wind projects without the NY Bight projects, and other offshore wind projects in combination with the NY Bight projects are provided on BOEM's NY Bight website: https://www.boem.gov/renewable-energy/state-activities/new-york-bight.

The demarcation line between seascape and open ocean is the U.S. states jurisdictional boundary, 3 nautical miles (nm) (3.45 statute miles [5.5 kilometers]) seaward from the coastline (U.S. Congress Submerged Lands Act, 1953). This line coincides with the area of sea visible from the shoreline. The line defining the separation of seascape and landscape is based on the juxtaposition of apparent seacoast and landward landscape elements, including topography, water (bays and estuaries), vegetation, and structures.

H.2 Method of Analysis

The SLVIA has two separate but linked parts: the open ocean, seascape, and landscape impact assessment (SLIA) and the visual impact analysis (VIA). The SLIA analyzes and evaluates the *sensitivity* of the receptor and the *magnitude of change* in consideration of impacts on both the physical elements and features that make up a landscape, seascape, or open ocean. The VIA analyzes and evaluates the impacts on people from adding the proposed development to views from selected viewpoints.

The inclusion of both the SLIA and VIA in the BOEM SLVIA methodology is consistent with the National Environmental Policy Act's (NEPA) objective of providing Americans with aesthetically and culturally pleasing surroundings and its requirement to consider all potentially significant impacts of development.

H.2.1 SLIA Methodology

The SLIA inventories and describes the visual character of the ocean and the coastal landscape and seascape. It analyzes and evaluates the magnitude of change and the sensitivity of the receptor in consideration of impacts on both the physical elements and features that make up the open ocean, seascape, or landscape. The magnitude of change depends on a project's scale or degree of change, geographic extent, and duration and reversibility.

Sensitivity is measured by the impact receptor's susceptibility to change, its ability to accommodate the impacts of a proposed project without changing its basic character, and its perceived value to society. These impacts affect the "feel," "character," or "sense of place" of an area of open ocean, seascape, or landscape, rather than the composition of a view from a particular place. Social value is based on the aesthetic, perceptual, and experiential aspects of the landscape, seascape, or open ocean that make it distinctive. In the SLIA, the impact receptors (the entities that are potentially affected by the proposed project) are the open ocean/seascape/landscape itself and its components, both its physical features and its distinctive character.

H.2.2 VIA Methodology

The VIA analyzes and evaluates the impacts on people of adding the proposed development to views from selected viewpoints. It also evaluates the change to the composition of the view itself and assesses how the people who are likely to be at that viewpoint may be affected by the change to the view. Enjoyment of a particular view is dependent on the viewer, and, in the VIA, the impact receptors are people.

The VIA for an offshore wind project assesses the impacts of adding the proposed development to views from selected viewpoints (referred to as key observation points or KOPs). The VIA assesses how the change to the view itself caused by the addition of the wind energy project components, such as seeing wind turbines instead of an open ocean horizon, affects people who are likely to be at the viewpoint. The change to the view as a result of adding the proposed project may affect viewers' experience of that particular view. How the addition of the project to the view affects the viewers' experiences and their responses depends in part on who they are, what they are doing when viewing the facility, and how much they value the view. The experience of a particular view is dependent on the viewers, and, as noted, in the VIA, the impact receptors are people, rather than the seascape or landscape itself.

H.2.3 Project Visibility Factors

WTG visibility would be variable throughout the day depending on many factors. View angle, sun angle, and atmospheric conditions would affect the WTG visibility. Visual contrast of WTGs would vary throughout the day depending on the visual character of the horizon's backdrop and whether the WTGs are backlit, side-lit, or front-lit. If less visual contrast is apparent in the morning hours, then it is likely that the visual contrast may be more pronounced in the afternoon. The inverse is possible as well. These effects are also influenced by varying atmospheric conditions, direction of view, distance between the viewer and the WTGs, and elevation of the viewer.

At closer distances, approximately 16 miles (26 kilometers) or closer, the form of the 1,312-foot (400-meter) WTG may be the dominant visual element creating the visual contrast regardless of color. At approximately 12 miles (19 kilometers) or closer the form of the 853-foot (260-meter) WTG may be the dominant visual element creating contrast regardless of color. At greater distances, color may become the dominant visual element creating visual contrast under certain visual conditions that gives visual definition to the WTG's form and line. As the elevation of the viewer increases, earth curvature (EC) has a decreasing effect on the visible height of individual WTGs, allowing a greater proportion of the turbine infrastructure to be seen.

The noticeable daytime and nighttime elements of the project's WTGs and OSSs and their viewshed distances are listed in Table H-1 for 1,312-foot (400-meter) WTGs and in for 853-foot (260-meter) WTGs. Each WTG would have two L-864 flashing red obstruction lights at the top of the nacelle, one of which is required to be lit (BOEM 2021). WTGs would have additional intermediate lighting on the tower utilizing low-intensity red flashing (L-810) obstruction lighting. Line-of-sight calculations for onshore viewers (5.9-foot [1.8-meter] eye level) are based on intervening EC screening (7.98-inch [20.3-centimeter] height per mile). Heights of WTG and OSS components are stated relative to mean lower low water and highest astronomical tide.

Table H-2 and Table H-3 for 1,312-foot (400-meter) WTGs and Table H-5 and Table H-6 for 853-foot (260-meter) WTGs indicate the NY Bight projects' effects based on horizontal and vertical FOV, respectively, defined as the extent of the observable landscape seen at any given moment, usually measured in degrees (BOEM 2021). The horizontal FOV for each KOP is listed in Argonne (2024). FOVs are valid and reliable indicators of the magnitude of view occupation by NY Bight project facilities.

Table H-1. Heights of noticeable[1] 1,312-foot WTG elements and OSS, and visible distances[2]

Noticeable Element[1]	Height in Feet (Meters)	Visible Distance[2] in Miles (Kilometers)
Rotor Blade Tip	1,312 (400) MLLW	0–47.4 (76.3)
Upper Aviation Light	728 (221.9) MLLW	0-36.1 (58.1)
Nacelle	718 (218.8) MLLW	0-35.8 (57.6)
Hub	706 (215.2) MLLW	0-35.6 (57.3)
Mid-tower Navigation Light	353 (107.6) MLLW	0-26.0 (41.8)
OSS	295.3 (90.0) HAT	0–24.1 (38.9)
Yellow Tower Base Color	50 (15.2) HAT	0–11.5 (18.5)

[1] Perception of project elements, from 5.9 feet (1.8 meters) human eye-level while standing at mean sea level, involves static distance-related sizes, forms, lines, colors, and textures; variable daytime lighting conditions; variable nighttime light conditions; and variable meteorological conditions.
[2] Based on intervening EC and clear-day conditions.
HAT = highest astronomical tide; MLLW = mean lower low water

Table H-2. Horizontal FOV occupied by the 1,312-foot WTGs

State	Noticeable Element	Width[1] Miles (Kilometers)	Distance[2] Miles (Kilometers)	Horizontal FOV	Human FOV	Percent of FOV
New York	Wind turbine array	28.9 (46.5)	23.6 (38.0)	50°	124°	40%
New Jersey	Wind turbine array	46.7 (75.1)	30.7 (49.4)	57°	124°	46%

[1] Maximum extent of the visible wind turbine array.
[2] Nearest onshore distance to the wind turbine array: Atlantique Beach, New York, and Long Island Beach, New Jersey.

Table H-3. Vertical FOV occupied by the 1,312-foot WTGs

State	Noticeable Element	Height Feet (meters)	Distance Miles (Kilometers)	Height Above Horizon[1] Feet (Meters)	Vertical FOV	Human FOV	Percent of FOV
New York	Rotor Blade Tip	1,312 (400.0) MLLW	23.6 (38.0)	1,036.5 (311.5)	0.48°	55°	0.8 %
New Jersey	Rotor Blade Tip	1,312 (400.0) MLLW	30.7 (49.4)	799.4 (311.5)	0.28°	55°	0.5 %

[1] Based on intervening EC, clear-day, and clear-night conditions.
MLLW = mean lower low water

Table H-4. Heights of noticeable[1] 853-foot WTG elements and OSS, and visible distances[2]

Noticeable Element[1]	Height in Feet (Meters)	Visible Distance[2] in Miles (Kilometers)
Rotor Blade Tip	853 (260.0) MLLW	0–38.7 (62.3)
Aviation Light	513 (156.4) MLLW	0–30.8 (49.6)
Nacelle	503 (153.3) MLLW	0–30.5 (49.1)
Hub	492 (150.0) MLLW	0–30.2 (48.6)
OSS	295.3 (90.0) HAT	0–24.1 (38.7)
Mid-tower Navigation Light	246 (75.0) MLLW	0–22.2 (35.7)
Yellow Tower Base Color	50 (15.2) HAT	0–11.5 (18.5)

[1] Perception of project elements, from 5.9 feet (1.8 meters) human eye-level while standing at mean sea level, involves static distance-related sizes, forms, lines, colors, and textures; variable daytime lighting conditions; variable nighttime light conditions; and variable meteorological conditions.

HAT = highest astronomical tide; MLLW = mean lower low water

Table H-5. Horizontal FOV occupied by the 853-foot WTGs

State	Noticeable Element	Width[1] Miles (Kilometers)	Distance[2] Miles (Kilometers)	Horizontal FOV	Human FOV	Percent of FOV
New York	Wind turbine array	19.0 (30.6)	23.6 (38.0)	39°	124°	31%
New Jersey	Wind turbine array	23.9 (38.5)	30.7 (49.4)	38°	124°	31%

[1] Maximum extent of the visible wind turbine array.
[2] Nearest onshore distance to the wind turbine array: Atlantique Beach, New York, and Long Island Beach, New Jersey.

Table H-6. Vertical FOV occupied by the 853-foot WTGs

State	Noticeable Element	Height Feet (meters)	Distance Miles (Kilometers)	Height Above Horizon[1] Feet (Meters)	Vertical FOV	Human FOV	Percent of FOV
New York	Rotor Blade Tip	853 (260.0) MLLW	23.6 (38.0)	577.5 (176.0)	0.27°	55°	0.4%
New Jersey	Rotor Blade Tip	853 (260.0) MLLW	30.7 (49.4)	340.4 (103.7)	0.12°	55°	0.2%

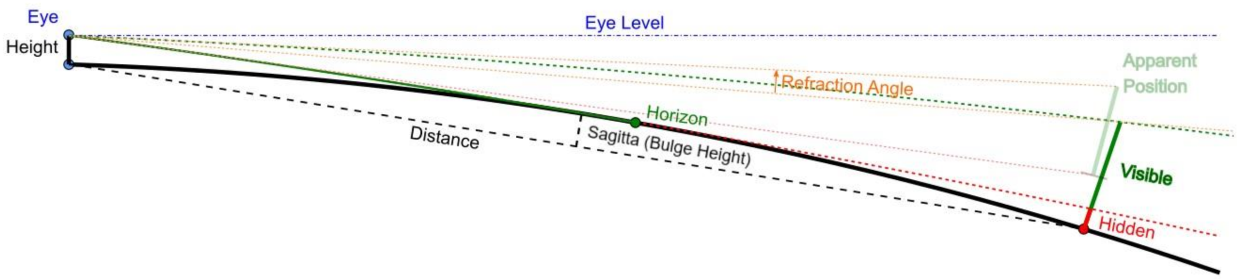
[1] Based on intervening EC, clear-day, and clear-night conditions.
MLLW = mean lower low water

While the coastal shoreline has a prevailing eastward viewing direction, localized views may vary from southeast to northeast. All cardinal directions are conceivable when viewing from a lighthouse or a water vessel at sea. When viewing from onshore toward a southerly direction and scanning to the east and west, the color of the horizon backdrop often will vary. Variation will continue as the sun arcs across the sky from sunrise to sunset. Depending on sun angle, the backdrop sky color may have various intensities of white to gray and sky blue to pale blue to dark blue-gray. Partly cloudy to overcast conditions will also influence the color make-up of the horizon's backdrop. The sunrise and sunset have varying degrees of light blue to dark blue, light and dark purples intermixed with oranges, yellows, and reds. Partly cloudy skies may increase the remarkable color effects during the sunset and sunrise periods of the day.

When placing WTGs offshore, the visual interplay and contrasting elements in form, line, color, and texture may vary with the ever-changing character of the backdrop. Front-lit WTGs may have strong color contrast against a darker gray sky, giving definition to the WTG's vertical form and line contrast to the ocean's horizontal character and the line where the sea meets sky, or visually dissipates against a whiter backdrop created by high levels of evaporative atmospheric moisture during clear sunny days. Partly cloudy skies may create varying degrees of sunlight reflecting off the white wind turbines, placing some WTGs in the shadow and making them appear a darker gray and less conspicuous while highlighting others with a bright white color contrast. The level of noticeability would be directly proportional to the degree of visual contrast and scale of change between the WTGs and the corresponding backdrop. Visual simulations prepared of the NY Bight projects depict both maximum visibility, illustrating no atmospheric haze, and predicted visibility, depicting visibility with the atmospheric conditions on the day the photograph was taken. These variations through the course of the day may result in periods of moderate to major visual effects while at other times of day would have minor or negligible effects.

WTG blade motion also affects visibility. Empirical studies of offshore wind turbine visibility have shown that WTG blade movement is routinely visible at distances of 21 miles (34 kilometers) or less and as far as 26 miles (42 kilometers) (Sullivan et al. 2013). In a visually empty seascape, the rotational movement of the turbines can dominate the scene during the day. Contrary to static turbine noticeability, blade motion is visible regardless of lighting conditions, sun angle, and sky contrast levels. Blade motion contributes substantially to visual contrast and may contribute relatively more at shorter viewing distances (Sullivan 2013). Blade movement noticeability would be dependent on meteorological conditions. It is critical to note that the studies cited above were conducted on smaller WTGs than those considered for the NY Bight projects in the NY Bight Programmatic Environmental Impact Statement [PEIS] or other offshore wind projects along the U.S. eastern seaboard; therefore, noticeability distances would increase with larger wind turbines.

Atmospheric refraction of light rays causes fluctuations in the extents and appearances of offshore and onshore facilities. It results from the bending of light rays between viewers and objects due to current air temperature, water vapor, and barometric pressure (Bislins 2022). Atmospheric refraction can increase the visibility of objects, making them look larger or taller, depending on conditions, as depicted in Figure H-1. Table H-7 provides a summary of increased visibility ranges for the nearest beach viewers for each lease area and both turbine sizes based on the average sea level refraction calculation coefficient of 0.17 (Bislins 2022) applied to the turbine blade tip viewshed distances. Daytime and nighttime atmospheric refraction-based visibility varies with sea level's continuous increases and decreases in temperature, water vapor, and barometric pressure.



Source: Bislins 2022

Figure H-1. Effects of atmospheric refraction and earth curvature on WTG visibility

Table H-7. Atmospheric refraction summary for all lease areas for 1,312-foot and 853-foot WTGs

Lease Area	1,312-Foot WTG		853-Foot WTG	
	Rotor Blade Tip Increased Visibility Feet (Meters)	Nearest Beach Increased Visibility Feet (Meters)	Rotor Blade Tip Increased Visibility Feet (Meters)	Nearest Beach Increased Visibility Feet (Meters)

Visibility thresholds have been described and rated through research by Robert Sullivan at Argonne based on WTGs in England. Table H-8 describes visibility threshold levels and ratings based on this work. This research, along with distance and observer elevation considerations, informed by the visual simulations, EC calculations, horizontal FOV, and vertical FOV in undeveloped open ocean provide the basis for evaluating visibility.

Table H-8. Visibility threshold levels

Visibility Rating	Description
Visibility level 1. Visible only after extended, close viewing; otherwise, invisible.	An object/phenomenon that is near the extreme limit of visibility. It could not be seen by a person who was unaware of it in advance and looking for it. Even under those circumstances, the object can be seen only after looking at it closely for an extended period.
Visibility level 2. Visible when scanning in the general direction of the subject; otherwise, likely to be missed by casual observers.	An object/phenomenon that is very small and/or faint, but when the observer is scanning the horizon or looking more closely at an area, can be detected without extended viewing. It could sometimes be noticed by casual observers; however, most people would not notice it without some active looking.
Visibility level 3. Visible after a brief glance in the general direction of the study subject and unlikely to be missed by casual observers.	An object/phenomenon that can be easily detected after a brief look and would be visible to most casual observers, but without sufficient size or contrast to compete with major landscape/seascape elements.
Visibility level 4. Plainly visible, so could not be missed by casual observers, but does not strongly attract visual attention or dominate the view because of its apparent size, for views in the general direction of the study subject.	An object/phenomenon that is obvious and with sufficient size or contrast to compete with other landscape/seascape elements, but with insufficient visual contrast to strongly attract visual attention and insufficient size to occupy most of an observer's visual field.
Visibility level 5. Strongly attracts the visual attention of views in the general direction of the study subject. Attention may be drawn to the strong contrast in form, line, color, or texture, luminance, or motion.	An object/phenomenon that is not large but contrasts with the surrounding landscape elements so strongly that it is a major focus of visual attention, drawing viewer attention immediately and tending to hold attention. Has strong contrasts in form, line, color, and texture. In addition, bright light sources and moving objects contribute substantially to drawing viewer attention. The study subject's visual prominence noticeably interferes with views of nearby landscape/seascape elements.
Visibility level 6. Dominates the view because the study subject fills most of the visual field of views in its general direction. Strong contrasts in form, line, color, texture, luminance, or motions may contribute to view dominance.	An object/phenomenon with strong visual contrasts that is so large it occupies most of the visual field, and views cannot be avoided except by turning one's head more than 45 degrees from a direct view of the object. The phenomenon is the major focus of visual attention, and its large apparent size is a major factor in its view dominance. The study subject's visual prominence noticeably detracts from views of other landscape/seascape elements.

Source: Sullivan et. al 2013.

H.2.4 Geographic Scope

As described in Section 3.6.9, *Scenic and Visual Resources,* of the PEIS, the scenic and visual resources geographic analysis area extends approximately 47.4 miles (76.3 kilometers) offshore and 50 miles (80.5 kilometers) onshore to capture potential views of the NY Bight projects, and includes the coastlines from Atlantic City, New Jersey, to the Shinnecock Indian Nation in Long Island, New York, as well as elevated viewpoints of national significance (e.g., Empire State Building) (Argonne 2024).

H.2.5 Defining Potential Impacts

Project activities for all stages of the project life cycle (construction and installation, operations and maintenance [O&M], and decommissioning) are assessed against the environmental baseline to identify the potential interactions between a project and the seascape, landscape, and viewers. Analysis of visual impacts for the onshore geographic analysis area should include an assessment of landfalls, buried onshore export cables, onshore substation/converter station, and transmission connections to the electric grid. Because the locations of onshore infrastructure for the NY Bight projects are currently unknown, this assessment only analyzes impacts from offshore structures. Visual impacts from onshore infrastructure will be analyzed during the project-specific NEPA review for each Construction and Operations Plan (COP). Potential impacts from offshore infrastructure are assessed to determine an impact level consistent with the definitions in Table H-9.

Table H-9. Definitions of potential adverse impact levels for SLIA and VIA

Impact Level	Impact Type	Definition
Negligible	Adverse	**SLIA**: Very little or no effect on seascape/landscape unit character, features, elements, or key qualities either because unit lacks distinctive character, features, elements, or key qualities; values for these are low; or project visibility would be minimal. **VIA**: Very little or no effect on viewers' visual experience because view value is low, viewers are relatively insensitive to view changes, or project visibility would be minimal.
Minor	Adverse	**SLIA**: The project would introduce features that may have low to medium levels of visual prominence within the geographic area of an ocean/seascape/landscape character unit. The project features may introduce a visual character that is slightly inconsistent with the character of the unit, which may have minor to medium negative effects on the unit's features, elements, or key qualities, but the unit's features, elements, or key qualities have low susceptibility or value. **VIA**: The visibility of the project would introduce a small but noticeable to medium level of change to the view's character; have a low to medium level of visual prominence that attracts but may or may not hold the viewer's attention; and have a small to medium effect on the viewer's experience. The viewer receptor sensitivity/susceptibility/value is low. If the value, susceptibility, and viewer concern for change is medium or high, then evaluate the nature of the sensitivity to determine if elevating the impact to the next level is justified. For instance, a KOP with a low magnitude of change, but that has a high level of viewer concern (combination of susceptibility/value), may justify adjusting to a moderate level of impact.
Moderate	Adverse	**SLIA**: The project would introduce features that would have medium to large levels of visual prominence within the geographic area of an ocean/seascape/landscape character unit. The project would introduce a visual character that is inconsistent with the character of the unit, which may have a moderate negative effect on the unit's features, elements, or the key qualities. In areas affected by large magnitudes of change, the unit's features, elements or key qualities have low susceptibility and/or value. **VIA:** The visibility of the project would introduce a moderate to large level of change to the view's character, may have a moderate to large level of visual prominence that attracts and holds but may or may not dominate the viewer's attention, and has a moderate effect on the viewer's visual experience. The viewer receptor sensitivity/susceptibility/value is medium to low. Moderate impacts are typically

Impact Level	Impact Type	Definition
		associated with medium viewer receptor sensitivity (combination of susceptibility/value) in areas where the view's character has medium levels of change, or low viewer receptor sensitivity (combination of susceptibility/value) in areas where the view's character has large changes to the character. If the value, susceptibility, and viewer concern for change is high, then evaluate the nature of the sensitivity to determine if elevating the impact to the next level is justified.
Major	Adverse	**SLIA:** The project would introduce features that would have dominant levels of visual prominence within the geographic area of an ocean/seascape/landscape character unit. The project would introduce a visual character that is inconsistent with the character of the unit, which may have a major negative effect on the unit's features, elements, or key qualities. The concern for change (combination of susceptibility/value) to the character unit is high. **VIA:** The visibility of the project would introduce a major level of character change to the view; will attract, hold, and dominate the viewer's attention; and have a moderate to major effect on the viewer's visual experience. The viewer receptor sensitivity/susceptibility/value is medium to high. If the magnitude of change to the view's character is medium, but the susceptibility or value at the KOP is high, then evaluate the nature of the sensitivity to determine if elevating the impact to major is justified. If the sensitivity (combination of susceptibility/value) at the KOP is low in an area where the magnitude of change is large, then evaluate the nature of the sensitivity to determine if lowering the impact to moderate is justified.

H.2.6 Laws, Ordinances, and Regulations

Open ocean, seascape, landscape, and visual resource protection and management laws, ordinances, and regulations are identified in Table H-10.

Table H-10. Laws, Ordinances, and Regulations

Jurisdiction	Authority	Objectives
Federal		
BOEM	Code of Federal Regulations (CFR) Title 30 of the CFR Part 585, Subpart F, Plans and Information Requirements	This title provides guidance on survey requirements, project-specific information, and information to meet the requirements of the Outer Continental Shelf Lands Act, NEPA, and other applicable laws and regulations. It also specifies that to comply with NEPA and other relevant laws, the COP must include a detailed description of visual resources and various social and economic resources that could be affected by the proposed project, that would be addressed in an SLVIA.
BOEM	Outer Continental Shelf Lands Act (OCSLA), Title 43, Chapter 29, Subchapter I, Section 1301 (1953)	The primary purpose of the OCSLA is to facilitate the federal government's leasing of its offshore mineral resources and energy resources. As set forth in the Energy Policy Act of 2005, OCSLA was amended to authorize the Department of the Interior (DOI) to issue submerged land leases for alternate uses and alternative energy development on the OCS. Through this amendment and subsequent delegation by the Secretary of the Interior, BOEM has the authority to issue these leases and regulate activities that occur within them, including the authorization of a COP.

Jurisdiction	Authority	Objectives
BOEM	Submerged Lands Act (SLA) of 1953	The SLA grants coastal states title to natural resources located within their coastal submerged lands out to 3 miles (4.8 kilometers) from their coastline.
BOEM	National Environmental Policy Act (NEPA)	NEPA was signed into law in 1970 and set forth a national environmental policy in the United States meant to ensure federal agencies consider the significant environmental consequences of their proposed actions and inform the public about their decision making. NEPA established the Council on Environmental Quality (CEQ) to advise agencies on the NEPA process and to oversee and coordinate the development of federal environmental policy. The CEQ issued revised NEPA regulations (40 CFR 1500-1508) in 2021. The regulations include procedures to be used by federal agencies for the NEPA review process.
BOEM	Clean Air Act (CAA) of 1970	The CAA authorized the U.S. Environmental Protection Agency (USEPA) to establish National Ambient Air Quality Standards (NAAQS) to protect public health and the environment. The states were directed to develop State Implementation Plans (SIPs), which consist of emission reduction strategies, with the goal of achieving the NAAQS by the legislated date. BOEM has jurisdiction over OCS air emissions in the Gulf of Mexico west of 87.5 degrees west longitude (off the coasts of Texas, Louisiana, Mississippi, and Alabama). BOEM also has jurisdiction over OCS air emissions within the Chukchi and Beaufort Seas in Alaska according to the Consolidated Appropriations Act of 2012. In all other OCS areas, the USEPA has jurisdiction, as mandated by Section 328 of the CAA.
BOEM	Coastal Zone Management Act (CZMA) (1972)	The U.S. Congress recognized the growth in the coastal zone by passing the CZMA, which is administered by the National Oceanic and Atmospheric Administration (NOAA). The goal is to "preserve, protect, develop, and where possible, to restore or enhance the resources of the nation's coastal zone." Authorized by the CZMA in 1972, the Coastal Zone Management Program (CZMP) was established as a voluntary partnership between the federal government and U.S. coastal and Great Lakes states and territories (BOEM 2009).
BOEM	National Historic Preservation Act 1966	This act establishes a preservation program and a system of protections, which encourages both the identification and protection of historic resources. As part of this program, historic districts and individual properties are either listed or eligible for listing on the National Register of Historic Places (NRHP) or National Historic Landmarks (NHL).
BOEM	Inflation Reduction Act of 2022	This act offers funding, programs, and incentives to accelerate the transition to a clean energy economy and will likely drive significant deployment of new clean electricity resources. The act's incentives reduce renewable energy costs for organizations, businesses, nonprofits, educational institutions, and state, local, and tribal organizations. Taking advantage of Inflation Reduction Act incentives, such as tax credits, is key to lowering greenhouse gas emission footprints and accelerating the clean energy transition.

Jurisdiction	Authority	Objectives
BOEM	Information Guidelines for a Renewable Energy Construction and Operations Plan (COP). Version 4.0. (BOEM 2020)	BOEM's guidelines indicate that the visual resource assessment should apply appropriate viewshed mapping, photo simulations, and field inventory techniques to determine the visibility of the proposed project at scenic viewpoints.
BOEM	Assessment of Seascape, Landscape, and Visual Impacts of Offshore Wind Energy Developments on the Outer Continental Shelf of the United States (2021)	This OCS Study provides the methodology for assessing the seascape, landscape, and visual impacts of offshore wind within a particular study area. Developers are to use this guidance in preparation as part of a COP for their lease development. This assessment is to be reviewed by BOEM.
State of New York		
New York State Department of State (NYSDOS)	New York State Coastal Management Program and Final Environmental Impact Statement (NYSDOC 2017)	Policy 24: Prevent impairment of scenic resources of statewide significance. Policy 25: Protect, restore, or enhance natural and man-made resources which are not identified as being of statewide significance, but which contribute to the overall scenic quality of the coastal area.
New York State Department of Environmental Conservation (NYSDEC)	NYSDEC Policy DEP-00-2: Assessing and Mitigating Visual and Aesthetic Impacts	The purpose of this policy is to guide the evaluation of visual impacts for proposed projects as they relate to scenic and aesthetic resources of statewide significance.
New York State Department of State (NYSDOS)	Long Island Sound Coastal Management Program (LIS CMP) (1999) (NYSDOS 1999)	Policy 3: Enhance visual quality and protect scenic resources throughout Long Island Sound. The LIS CMP provides a recommendation to protect scenic resources within the Long Island Sound coastal region by having the NYSDOS and local government undertake a comprehensive scenic resources evaluation of the Long Island Sound Coastal Area and prepare appropriate area designations. This would include scenic areas of statewide significance (SASS). Another recommendation is to identify, preserve, and provide access to regionally important vistas. The NYSDOS proposed to evaluate scenic land and water vistas as part of the SASS Program (Executive Law, Article 42 and 19 NYCRR Part 602.5c). The NYSDOS will also work with Local Waterfront Revitalization Programs to identify locations for protection and enhancement of visual access.
South Shore Estuary Reserve	Long Island South Shore Estuary Reserve Comprehensive Management Plan (CMP) 2022	Originally implemented in 2001, The Long Island South Shore Estuary Reserve CMP is the result of The Long Island South Shore Estuary Reserve Act passed in 1993 creating the Long Island South Shore Estuary Reserve (Reserve). The act also implemented the Long Island South Shore Estuary Reserve Act Council (Council) whose task was to design a CMP to protect the reserve and its inhabitants. This CMP emphasizes the importance of the Long

Jurisdiction	Authority	Objectives
		Island South Shore Estuary Ecosystem and outlines actions necessary to preserve, protect, and enhance the natural, recreational, economic, aesthetic, and educational resources that the reserve provides. The CMP discusses various components, such as: • Action 2.3.8: Reduce negative environmental consequences of duck sludge and other legacy pollutants through removal and/or restoration. The restoration of former duck farms represents an important opportunity to improve aesthetic and environmental conditions for nearby neighborhoods and provide County residents with the opportunity to access these waterways for recreational and educational purposes. • Action 4.3.4: Increase end-of-street parks and parking access to the shoreline. Implement projects that create parks at the end of streets and in vacant lots, provide public parking access, and provide benefits such as improved aesthetics and public access. Parks that utilize green infrastructure best management practices can also contribute to water quality improvement.
New York City, New York		
New York City Planning (NYCP)	New York City Waterfront Revitalization Program (WRP) (2016)	The WRP establishes New York City's policies for waterfront planning, preservation, and development projects to ensure consistency over the long term. The goal of the WRP is to maximize the benefits derived from economic development, environmental conservation, and public use of the waterfront, while minimizing any potential conflicts among these objectives (NYCP 2016). The WRP includes policies that are intended to protect and enhance scenic resources: • Policy 9: Protect scenic resources that contribute to the visual quality of the New York City coastal area. • Policy 9.1: Protect and improve visual quality associated with New York City's urban context and the historic and working waterfront. • Policy 9.2: Protect and enhance scenic values associated with natural resources.
New York City Department of City Planning	New York City Comprehensive Waterfront Plan (2021)	This plan, updated every 10 years, puts forth new strategies for an equitable, resilient and healthy waterfront in the face of climate change. Goal 1: Expand public access to the waterfront with an emphasis on equity by bridging access gaps in historically underserved areas and supporting growing waterfront communities. An important part of this goal is visual access. Clear, unobstructed sightlines down to the waterfront expand connectivity. Visual corridors typically overlap with streets and other upland connections to guide people safely to the water. Where physical access to the water cannot be achieved immediately, visual connectivity can provide communities with an opportunity to see and engage with their waterfronts and form a meaningful connection.

Jurisdiction	Authority	Objectives
Suffolk County, New York		
Suffolk County	Suffolk County Comprehensive Master Plan 2035 (Suffolk County Department of Economic Development and Planning 2023)	The vision of the 2035 Plan is captured by three themes: Revitalize, Rebuild, and Reclaim, i.e., revitalize the economy; rebuild the downtowns and infrastructure; and reclaim the quality of the groundwater, surface water and terrestrial resources. The Master Plan discusses the importance of the rural water setting of Suffolk County that attracts visitors who enjoy bathing beaches, fishing, boating, and other water sports as well as hiking, bicycling, adventure tourism, and other outdoor recreation or simply viewing the scenery and historic hamlets.
Babylon, Town of	2020-2024 Consolidated Plan & 2020 Annual Action Plan (2020)	No specific objectives are included within the plan for protecting or improving scenic views, nor beach/waterfront views.
Brookhaven, Town of	Local Waterfront Revitalization Program (Anticipated Completion Date of August 2023) (Town of Brookhaven 2023)	The Local Waterfront Revitalization Program will provide strategies and identify projects that improve public access, establish connections between downtown and the waterfront, modify local codes and ordinances to remove barriers to sustainable development, and incorporate sea level rise projections and resiliency measures into community planning.
Islip, Town of	None identified	The Town of Islip is in the process of creating a Comprehensive Plan.
Southampton, Town of	Town of Southampton Coastal Resources & Water Protection Plan (2016)	The plan describes the community's scenic resources as follows: "Southampton's unique scenic quality and sense of place is derived from the interplay of rural farmland, areas of undeveloped open space, water frontage (bay, ocean) and the hamlet centers. This rural character graces the Town with significant natural and historic resources. It is this quality that maintains the Town's vitality as a resort, second home and visitor attraction, as well as an attractive place to live and work." The Plan presents the different visual resources found within the town, including natural environments, built environments, historic vistas, and recognized areas of high scenic quality.
Nassau County, New York		
Nassau County	Nassau County Master Plan (2010)	The Nassau County Master Plan's goals are centered around a framework that helps shape the county's jobs, places, and infrastructure. Economic development is to be enhanced by strengthening downtowns, revitalizing underutilized commercial properties, and redeveloping brownfields to preserve the quality of life for residents by protecting environmental, scenic, and historic resources. Within the Master Plan, sections are dedicated to the importance of historic and cultural assets, along with the sustainable land use development and waterfront and coastal zones. The plan addresses the county's variety of historic, cultural, and scenic resources in addition to the environmental resources Nassau County has to offer.

Jurisdiction	Authority	Objectives
Long Beach City	Comprehensive Plan 2022–2023 (draft)	The 2023 Comprehensive Plan outlines the city's values, visions, and goals for the next 15 years. One of the city's goals is to enhance the physical attributes of all commercial districts and areas. This includes improving aesthetics in streetscapes and commercial areas. Increasing public access to the waterfront is an important aspect to the Comprehensive Plan, along with the ability for beaches and dunes for the southern waterfront to provide resiliency, environmental, social, and economic benefits. However, no specific objectives are included in the plan for protecting or improving scenic views, or beach/waterfront views.
Hempstead, Town of	Energy and Sustainability Master Plan (Town of Hempstead 2012)	The implementation of a "green grounds" policy would promote greener and more cost-effective maintenance and operations strategies. This is important as the demand for high quality public-use landscapes has increased. The "green grounds" policy would not compromise the visual landscape quality. There is no town master plan or specifics discussed in the plan referenced about the preservation of scenic views.
Oyster Bay, Town of	Town of Oyster Bay: Open Space Preservation Plan (South Shore Estuary Reserve Workplan Implementation) (2010)	Scenic value is identified in the Open Space Preservation Plan as an important factor in identifying open space and resource protection.
State of New Jersey		
New Jersey Coastal Management Program	Section 309 Assessment and Strategy (2021-2025)	Section 309 Enhancement Objective: Attain increased opportunities for public access, considering current and future public access needs, to coastal areas of recreational, historical, aesthetic, ecological, or cultural value.
New Jersey Department of Environmental Protection	Green Acres Program (2023)	The mission of this program is "to achieve, in partnership with others, a system of interconnected open spaces, the protection of which will preserve and enhance New Jersey's natural environment and its historic, scenic, and recreational resources for public use and enjoyment."
State Historic Preservation Office	New Jersey State Register of Historic Places	The geographic analysis area contains additional historic resources that the state has determined are worthy of preservation, but which have either not been determined eligible for inclusion or have not been evaluated for listing in the NRHP.
Atlantic County, New Jersey		
Atlantic County	Atlantic County, New Jersey Master Plan (2018); Atlantic County, New Jersey Open Space and Recreation Plan (2018)	The Master Plan includes a goal to preserve and protect resources, environmentally sensitive areas, particularly watersheds, recharge areas, threatened and endangered species habitat, scenic view sheds, and other valuable features. The Pine Barrens Byway is located partially within the county and includes a variety of historic and scenic sites. There are no specific objectives to preserve and protect scenic views from within the community or the ocean/beach areas. The Open Space and Recreation Plan defines open space as consisting of "diverse environments such as forests, fields, meadows, lakes, ponds, beaches, rivers, streams, historic sites and structures, scenic views and corridors, athletic

Jurisdiction	Authority	Objectives
		fields, gardens, orchards, farmland, and vacant lots." No specific objectives are included within the plan for protecting or improving scenic views, or beach/waterfront views.
Absecon, City of	2016 Reexamination Report (2017)	The need to develop and implement programs and regulatory controls to protect scenic resources is identified in the reexamination report, specifically pertaining to residential structures along the Shore Road Corridor and adjacent streets. The report introduces recommendations for historic preservation. No specific objectives are included within the report for protecting or improving scenic views, or beach/waterfront views.
Atlantic City	Atlantic City Master Plan (2008); Master Plan Reexamination Report (2016)	An objective under the Open Space and Recreation section of the Master Plan is to preserve and protect open space areas that have scenic views and/or important historical, cultural significance and exceptional ecological value. Gardner's Basin Maritime Park is identified as being the most scenic park in the city as it sits by the water's edge. The Conservation Element section describes tidal marshes to provide grand scenic views of the city's urban skyline due to the flat landscape character. Although areas are identified as being scenic, no specific objectives are included within the Master Plan for protecting or improving scenic views, or beach/waterfront views. The reexamination report does provide specifications.
Brigantine, City of	2016 Master Plan Re-examination Report (2016)	An objective identified from the previous planning documents includes an intent to "implement programs and regulatory controls designed to protect the scenic resources of the community." Zoning controls such as building height restrictions and setbacks have previously been implemented. There is public concern for access to scenic resources due to the development of the waterfront. There is a need to promote and preserve access to the Bay and Atlantic Ocean. A general goal to promote a desirable visual environment through creative development techniques and good civic design and arrangements is in the 2016 General Goals and Objectives Statement section. Provisions are made in subsequent sections to respond to this objective and improve the visual environment through changes to building setbacks, height restrictions, and similar measures. However, no additional measures are proposed to protect or enhance visual access and protect scenic corridors.
Egg Harbor Township	Egg Harbor Township Master Plan (2002); Master Plan Reexamination Report (2017)	The Master Plan wants to provide resource protection by enhancing the natural, cultural and scenic resources of the Great Egg Harbor River (GEHR) and its watershed. The GEHR and its tributaries are described as a scenic resource with many scenic landscapes including lakes, streams, pristine forest areas, and cedar/hardwood swamps. The Pinelands Comprehensive Management Plan designates the lower and middle portions of the river and its tributaries as scenic corridors of "special significance" within the Pinelands. It identifies the need to incorporate resource protection measures and proposes the creation of a River Conservation (RC) overlay zoning district and the establishment of a land use plan that protects river resources. Recommendations for this zoning district include minimizing the

Jurisdiction	Authority	Objectives
		visual impacts of development as seen from the river. The 2017 Reexamination Report has shown no progress in implementing the proposed RC zone overlay and is still a recommendation.
Galloway Township	Master Plan Reexamination Report (2020)	An objective identified from the previous planning documents is to preserve and protect open space areas having scenic views or important historical, cultural, or agricultural significance. Another identified objective is to maintain continuous networks of open spaces along streams, scenic areas, and critical environmental areas. However, no specific objectives are included within the Master Plan for protecting or improving scenic views, or beach/waterfront views.
Linwood City	City of Linwood Master Plan (2002); Master Plan Reexamination Report (2018)	The City of Linwood's goals include preserving the city's historic, scenic, and recreational assets. However, there is no specific mention of the preservation of outward views from within the community, or ocean/beach views. No specific objectives are included within the Master Plan for protecting or improving scenic views, or beach/waterfront views.
Longport, Borough	Municipal Public Access Plan (2020) (Borough of Longport 2020)	This plan lays out the visions for providing access to tidal waters and shorelines. There is no mention of visual or scenic resources; however, the importance for public water access is important in this Borough.
Margate City	2016 Comprehensive Master Plan Update (2017)	This Master Plan is in place to address the city's increased seasonal population by developing plans and strategies for the city to adapt and thrive in the future. One goal is to promote a desirable visual environment through creative development techniques and good civic design and arrangement. A second objective is to establish within the Land Use Plan and Land Development Ordinance, as appropriate, specific architectural design standards to promote a desirable visual environment and ensure the continued visual integrity of both the commercial and residential sections of the city. A goal set forth around waters includes minimizing pollutants in stormwater runoff from new and existing development to restore, enhance, and maintain the chemical, physical, and biological integrity of the waters of the state; protect public health; safeguard fish and aquatic life and scenic and ecological values; and enhance the domestic, municipal, recreational, industrial, and other uses of water.
Pleasantville City	Pleasantville Master Plan Reexamination (2015)	An objective of this plan is to create a conservation zone along the city's eastern boundary where the bay and marine tidal marsh exist so that development is not permittable. However, no specific objectives are included within the plan for protecting or improving scenic views, or beach/waterfront views.
Port Republic City	None identified	
Ventnor City	2016 Master Plan Reexamination (2016) (Ventnor City 2016)	No specific objectives are included within the plan for protecting or improving scenic views, or beach/waterfront views.

Jurisdiction	Authority	Objectives
Burlington County, New Jersey		
Burlington County	Parks and Open Space Master Plan (2002)	An objective of this plan is to identify and preserve areas of significant scenic beauty. This includes roads that provide visual or physical access to extraordinary scenic, cultural, recreational, or natural features. These areas will be submitted to the New Jersey Department of Transportation for designation in accordance with the New Jersey Scenic Byways Program. The plan recommends that the county should work with appropriate staff and outside agencies to identify, map, and develop viewsheds and areas of significant beauty. As a part of the county's goal to advance the county's culture, character, and heritage through development of the county park system, the county plans to erect interpretative signs to promote historic viewsheds. No specific objectives are included for protecting or improving beach/waterfront views.
Bass River Township	None identified	
Cape May County, New Jersey		
Cape May County	Cape May County Open Space and Recreation Plan (2007); Comprehensive Plan (2022)	One goal of the Cape May County Open Space and Recreation Plan is to protect and preserve natural and scenic resources. However, there are no specific objectives for protecting or improving scenic views, or beach/waterfront views. The Comprehensive Plan also does not include objectives for protecting or improving scenic views, or beach/waterfront views.
Ocean City	City of Ocean City Master Plan (1988); Ocean City Open Space & Recreation Plan (2014); Master Plan Reexamination Report (2019); Conservation Plan Element, Environmental Resources and Recreation Inventory (2009)	An objective of the Ocean City Master Plan is to promote a desirable visual environment through creative development techniques with respect to environmental assets and constraints of the overall city and of individual development sites. Another objective is to encourage the preservation and restoration of historically significant buildings and sites within the city. There are development provisions for structures in the waterfront neighborhoods of the city to preserve waterfront views. The Ocean City Open Space and Recreation Plan includes a conservation goal to preserve and maintain the ecological, historical, visual, recreational, and scenic resources of the city. The plan includes guidelines to acquire sites of special scenic value that should be protected to preserve or enhance the character of the community. The goal of the Conservation Plan Element, Environmental Resources and Recreation Inventory is to preserve and maintain the ecological, historic, visual, recreational, and scenic resources of the city. However, there are no objectives for protecting or improving scenic views, or beach/waterfront views. There are also no additional objectives in terms of scenic resources in the Master Plan Reexamination Report.
Monmouth County, New Jersey		
Monmouth County	The Monmouth County Master Plan (2016); 2018 Master Plan Reexamination (2018)	This plan's objectives are to help guide efforts and actions that contribute to a strong, stable, and sustainable prosperity through redevelopment, revitalization, and rediscovery. Relevant objectives of the plan include:

Jurisdiction	Authority	Objectives
		• Protect, conserve, and enhance the county's significant, diverse, natural, and scenic resources utilizing sound ecological protection and restoration measures. • Support investment in the preservation of cultural, historic, and scenic resources located in priority growth areas and locations. • Support retention, preservation, restoration, and improvement of our cultural, historic, and scenic resources that define a community's distinct character. The Reexamination Plan does not mention any changes to the goals pertaining to scenic resources.
Allenhurst Borough	Master Plan Reexamination Report (2018)	The Master Plan references the Coastal Metropolitan Planning Area, within which the Borough falls. One of the objectives of this reference is to encourage the reclamation of environmentally damaged sites and mitigate future negative impacts, particularly for waterfronts, beaches, scenic vistas, and habitats. It also references the State Development and Redevelopment Plan (SDRP) goals, one of which is to preserve and enhance areas with historic, cultural, scenic, open space, and recreation value.
Asbury Park City	Master Plan & Master Plan Reexamination Report (2017)	The Master Plan provides improvement to the lakes in the city that would enhance the public's enjoyment through aesthetic and environmentally healthy improvements of the water and surrounding areas. However, no specific provisions are included for protecting or enhancing the outward views from within the community, or beach/ocean views.
Avon-by-the-Sea Borough	Municipal Public Access Plan (2017)	This plan identifies the boardwalk as an important public access point that provides visual and physical access to the oceanfront. There are five locations along Shark River that are limited to visual access only due to safety concerns.
Belmar Borough	Master Plan Reexamination Report & Update (2016)	One of the four goals of this Master Plan is Preservation and Enhancement of Critical State Resources – Ensure that strategies for growth include preservation of the State's critical natural, agricultural, scenic, recreation, and historic resources, recognizing the roles they play in sustaining and improving the quality of life for New Jersey residents and attracting economic growth.
Bradley Beach Borough	Master Plan Reexamination Report (2018); Recreation, Open Space, and Conservation Element of the Bradley Beach Borough Master Plan; Municipal Public Access Plan (2019)	The Master Plan Reexamination Report addresses land development issues and provides recommendations where necessary. The Recreation, Open Space, and Conservation Plan objective is to provide an inventory of the Borough's existing recreation, open space, and observation facilities and establish goals and objectives to guide enhancement, preservation, and development of these facilities. The Municipal Public Access Plan includes the enhancement of public access to tidal waters and shorelines for recreation, navigation, commerce, and fishing. Recreation activities in this Borough include swimming, sunbathing, fishing, surfing, sport diving, bird watching, walking, and boating along the tidal shores. No specific objectives are included within the three plans for protecting or improving scenic views, or beach/waterfront views.

Jurisdiction	Authority	Objectives
Deal Borough	Municipal Public Access Plan (2017)	This plan not only identifies physical beach access areas in the Borough, but visual access of the beach and ocean for those who choose not to physically access the beaches. Three points of visual access are identified.
Highlands Borough	2016 Master Plan Reexamination Report and Master Plan Amendments (2016)	This plan recognizes the importance of aesthetics in terms of new buildings, and landscape design, streetscapes, and neighborhoods. The land use plan elements include open space preservation and living shorelines. No specific objectives are included within the plan for protecting or improving scenic views, or beach/waterfront views.
Loch Arbour Village	Municipal Public Access Plan (2017)	The Village is responsible for providing public access to the tidal waters. No specific objectives are included within the Access Plan for protecting or improving scenic views, or beach/waterfront views.
Long Branch City	2020 Master Plan Reexamination (2020) Municipal Public Access Plan (2017)	Some goals in the Master Plan include promoting aesthetically pleasing development that recognizes the character of the traditional New Jersey shore towns, preserving the city's natural resources and historically and architecturally significant districts and structures. In the Municipal Public Access Plan, the city supports the reconstruction of the historic Long Branch Pier as a multi-purpose facility. This pier will be open for public use and includes a fishing area, a garden, a children's play area, visual access, and proximity to beach and boardwalk access points. There are 27 public access locations identified as having visual access. Between these two plans, no specific objectives are included for protecting or improving scenic views, or beach/waterfront views.
Manasquan Borough	Master Plan Re-examination (2017)	This plan encourages the development of both active and passive recreation for residents and visitors while maintaining the sensitivity to environmental and cultural resources. No specific objectives are included within the plan for protecting or improving scenic views, or beach/waterfront views.
Middletown Township	Master Plan Reexamination Report & Amended Housing Master Plan Element and Open Space, Recreation and Conservation Master Plan Element	This report discusses the approach to site design that promotes preservation of significant resources, including scenic corridors, historic roadways, architecturally and historically significant structures, and open space. No specific objectives are included within the plan for protecting or improving scenic views, or beach/waterfront views.
Monmouth Beach Borough	Municipal Public Access Plan (2017); Master Plan Reexamination Report and Plan Amendment (2017)	The plan identifies 13 publicly accessible areas that are for visual purposes only of the water. The plan is consistent with Goal #2 of the Monmouth County Comprehensive Master Plan, including to protect, conserve, and enhance the county's significant, diverse, natural, and scenic resources utilizing sound ecological protection and restoration measures. One of the report's goals is to promote aesthetically pleasing human scale development that recognizes the character of traditional New Jersey shore towns. No specific objectives are included within the plan or the report for protecting or improving scenic views, or beach/waterfront views.

Jurisdiction	Authority	Objectives
Neptune Township	The Township of Neptune Comprehensive Master Plan (2011)	The Master Plan provides a framework for development and preservation of the township throughout its scenic, historic, and natural areas. The plan provides goals and recommendations for future development while preserving natural and historic resources. This includes promoting aesthetics in terms of commercial and industrial areas, future utility installations, and the visual quality of scenic corridors. The Fletcher Lake and Wesley Lake corridors will be evaluated for potential designation as scenic corridors and to consider adopting appropriate design standards and guidelines for development along designated corridors. However, no specific objectives are included for protecting or improving beach/waterfront views.
Sea Bright Borough	2017 Sea Bright Borough Master Plan (2017)	This plan notes the importance of conserving the beach and river waterfronts for the value of providing both scenic vistas and recreational opportunities. A policy of the Borough includes promoting visual environment through creative development techniques and good civic design and arrangement.
Sea Girt Borough	Master Plan Reexamination Report (2018)	The Master Plan states the Coastal Area Facilities Review Act policies, including the reclamation of environmentally damaged sites and mitigation of future negative impacts, particularly for waterfronts, beaches, scenic vistas, and habitats. The plan discusses the need for a historic preservation plan. No specific objectives are included for protecting or improving scenic views, or beach/waterfront views.
Spring Lake Borough	Master Plan (2010)	Some of the goals presented in the Master Plan include maintaining historic resources and the natural beauty of the Borough, enhancing conservation, recreational, and open spaces. No specific objectives are included for protecting or improving scenic views, or beach/waterfront views.
Ocean County, New Jersey		
Ocean County	Conservation Plan Element, Environmental Resources and Recreation Inventory (2009); 2011 Comprehensive Master Plan (2011); Open Space, Parks & Recreation Plan (2020)	The Conservation Plan Element's overall goal is to preserve and maintain the ecological, historic, visual, recreational, and scenic resources of the city. However, there are no objectives for protecting or improving scenic views, or beach/waterfront views. The Comprehensive Master Plan and the Open Space, Parks, and Recreation Plan include no objectives for protecting or improving scenic views, or beach/waterfront views.
Barnegat Light Borough	Barnegat Light Borough Master Plan Reexamination (2018)	One goal of the Municipal Public Access Plan (attached to the Master Plan) is to maintain and continue to promote a visually pleasing aesthetic along the waterfront areas. The plan identifies four public access points that are used for visual access only.
Barnegat Township	2011 Barnegat Township Master Plan (2011)	Historic preservation is a valuable asset to the community. By protecting aesthetically attractive architectural elements and utilizing existing infrastructure, historic preservation is essential. Significant sites are often those that already provide the town with open space, recreation, and scenic vistas. Referencing the

Jurisdiction	Authority	Objectives
		State Development and Redevelopment Plan, the Borough will preserve and enhance historic, cultural, scenic, open space, and recreational value. However, no specific objectives are included within the plan for protecting or improving scenic views, or beach/waterfront views.
Bay Head Borough	Municipal Public Access Plan (2020); Master Plan Reexamination Report and Update (2021)	There are 22 public access points identified as having visual access to the water in the Municipal Public Access Plan. There are no specific objectives in the plan for protecting or improving scenic views, or beach/waterfront views.
Beach Haven Borough	Beach Haven Borough Comprehensive Master Plan (2018)	A goal of the Comprehensive Master Plan is to maintain and continue to promote a visually pleasing aesthetic along the waterfront areas. However, there are no specific objectives included for protecting or improving scenic views, or beach/waterfront views.
Berkeley Township	Berkeley Township Comprehensive Master Plan (1997) General Reexamination of the Master Plan (2019) Environmental Resources Inventory (2012)	The Township Master Plan, the Reexamination Report, and the Township Environmental Resources Inventory include no specific objectives for protecting or improving scenic views, or beach/waterfront views.
Brick Township	Master Plan Reexamination Report (2018) Master Plan: Part 2 – Land Use Element	In the Land Use Element of the Master Plan, there is recognition of the special attraction and scenic value placed on the residential uses of a barrier island location and the over-water views it provides. However, no specific provisions for protecting or enhancing the outward views from within the community, or beach/ocean views are included. The Master Plan Reexamination Report includes no specific objectives for protecting or improving scenic views, or beach/waterfront views.
Eagleswood Township	None Identified	
Harvey Cedars Borough	Municipal Public Access Plan (2017)	A goal of the Municipal Public Access Plan is to maintain and continue to promote a visually pleasing aesthetic along waterfront areas. There are 21 publicly accessible areas listed as having visual access to the waterfront.
Lacey Township	Master Plan (1991) Lacey Township Master Plan Update – Revised Land Use Element (2016); Master Plan Reexamination Report (2018)	The Township Master Plan includes a townscape objective that states that all elements that could be obtrusive to the boating public should be reviewed and specifically addressed through view studies or simulations prior to receiving approvals. The Township Reexamination Report and Revised Land Use Element include no specific objectives for protecting or improving scenic views, or beach/waterfront views.
Lavallette Borough	Master Plan Reexamination (2006);	The Reexamination of the Master Plan encourages the preservation and maintenance of Lavallette’s historic sites. The original Master Plan encourages the importance of aesthetic

Jurisdiction	Authority	Objectives
	Master Plan for the New Millennium (1999)	streetscapes, commercial land uses, and historical and cultural qualities. However, neither plan includes specific objectives for protecting or improving scenic views, or beach/waterfront views.
Little Egg Harbor Township	Reexamination Report and Master Plan Amendment (2015)	The Township Master Plan includes a goal to promote a desirable visual environment through conservation and preservation of valuable natural features. However, the plan does not include specific objectives for protecting or improving scenic views, or beach/waterfront views.
Long Beach Township	Comprehensive Master Plan Update (2017)	The Comprehensive Master Plan does not include specific objectives for protecting or improving scenic views, or beach/waterfront views.
Mantoloking Borough	2017 Master Plan Re-Examination Report (2017)	The Master Plan does not include specific objectives for protecting or improving scenic views, or beach/waterfront views.
Ocean Township	Ocean Township Master Plan (1990); 2019 Master Plan Reexamination Report (2019)	The Ocean Township Master Plan includes a conservation goal to identify scenic areas within the Township and provide for their preservation. The Reexamination Report includes no specific objectives for protecting or improving scenic views, or beach/waterfront views.
Point Pleasant Beach Borough	2021 Reexamination & Master Plan Amendment	One plan objective is to strive to foster an aesthetically pleasing downtown commercial district for the ease and safety of pedestrians. This includes protecting and enhancing the historic maritime character of the Borough by maintaining appropriate scales of development, intensity of use, and architectural style. However, it does not include specific objectives for protecting or improving scenic views, or beach/waterfront views.
Seaside Heights Borough	Master Plan Reexamination Report (2022); Vision Plan (2009)	The Vision Plan recognized the need for increased access to the bay front. However, neither plan includes objectives for protecting or improving scenic views, or beach/waterfront views.
Seaside Park Borough	2008 Seaside Park Master Plan (2008)	Although a goal of the Master Plan is to encourage desirable visual design of new and upgraded businesses, it does not include specific provisions for protecting or enhancing the outward views from within the community, or beach/ocean views. Standards for preservation of historic structures are included.
Ship Bottom Borough	2021 Master Plan Reexamination Report (2021)	This report prioritizes the value of public access to the waterfront and the importance of a sustainable shoreline void of erosion. However, it does not include specific objectives for protecting or improving scenic views, or beach/waterfront views.
Stafford Township	2017 Master Plan: Land Use Element (2017)	The Land Use Element of the Master Plan does not include specific objectives for protecting or improving scenic views, or beach/waterfront views.
Surf City Borough	Comprehensive Master Plan Re-examination (2019)	This Master Plan Re-examination highlights the need to prioritize the value of public access to the waterfront and the importance of a sustainable shoreline void of erosion, especially being a barrier island community. The municipal Public Access Plan, attached to the Re-examination, works to maintain and promote visually pleasing aesthetic waterfront areas. However, neither plan includes specific objectives for protecting or improving scenic views, or beach/waterfront views.

Jurisdiction	Authority	Objectives
Toms River Township	Natural Resources Inventory (2016) Township of Toms River Master Plan (2017)	No specific objectives are included within the Natural Resources Inventory or the Master Plan for protecting or improving scenic views, or beach/waterfront views.
Tuckerton Borough	Master Plan (2002)	An objective in the Master Plan is to preserve and protect the distinctive physical and historic character of the Borough and preserve maritime heritage by recognizing the ties to Tuckerton Creek, Little Egg Harbor, and the Atlantic Ocean. The Conservation Plan Element states that the protection of scenic visual corridors is valued as an important contribution to the quality of life for residents and should be protected from inappropriate development. These visual corridors are the view of Lake Pohatcong from Route 9, the view of Long Beach Island and Little Egg Harbor from the Tuckerton Cover area, and views of Tuckerton Creek.

H.3 SLVIA Results

This section presents the results of the SLVIA analysis, organized by SLIA (Section H.3.1) and VIA (Section H.3.2) results. The results are applicable to both action alternatives analyzed in the Final PEIS, Alternative B and Alternative C, unless otherwise specified.

Visual simulations from representative viewpoints (available on BOEM's NY Bight website: https://www.boem.gov/renewable-energy/state-activities/new-york-bight) indicate that daytime and nighttime visibility of wind turbines and offshore substations would be noticeable to the casual observer from the open ocean character area, seascape character areas, landscape character areas, and viewer viewpoints. Figure H-2 through Figure H-7 show character areas with KOPs, sensitive resource areas (e.g., overburdened communities, protected natural landscapes, and historic areas), and visibility buffers for the 1,312-foot (400-meter) and 853-foot (260-meter) wind turbines. The visibility buffers for the two turbine heights are based on the rotor blade tip height and the parameters for the digital elevation model (DEM) and the digital surface model (DSM) using best practices recommended by ESRI (refer to Argonne 2024 for more information regarding viewshed modeling). Figure H-8 through Figure H-13 show the extent of onshore visibility for each lease area and both turbine heights based on viewshed modeling along with KOPs and sensitive resources. Sensitive resources are defined as overburdened communities, protected lands, and publicly accessible cultural and historic sites (refer to Argonne 2024 for more information on these resources).

H.3.1 Open Ocean, Seascape, and Landscape Impact Assessment (SLIA)

H.3.1.1 Offshore Open Ocean, Seascape, and Landscape Character

Open ocean, seascape, and landscape character in the geographic analysis area is organized in a three-level hierarchy (Argonne 2024):

- **Level 1:** Defines the broad character of ocean, seascape, and landscape.
- **Level 2:** Character types are relatively homogeneous in character. They are generic in nature and share similar combinations of geology, topography, drainage patterns, vegetation, historical land use and settlement patterns, and perceptual and aesthetic attributes. Level 2 is specific to the seascape character, which is split into two discrete character types: those that maintain visibility to the ocean (oceanside seascape) and those that maintain visibility to the bay (bayside seascape). If both elements are visible, the discrete area is considered part of the oceanside seascape character area. Level 2 is not represented in ocean or landscape character, only in seascape.
- **Level 3:** Level 3 focuses on the aesthetic, perceptual, and experiential aspects of a character area (or type) with unique qualities that contribute to a sense of place. Within Level 3, character areas (or types) are further broken down into specific areas with common character and perceptual attributes. For example, these areas may have similar architectural styles, scale, development patterns, or other similarities that are identified and described for their unique qualities.

Table H-11 identifies the characters, character types, and character areas delineated in the geographic analysis area.

Table H-11. Summary of character (level 1), character types (level 2), and character areas (level 3)

Level 1: Characters	Level 2: Character Types	Level 3: Character Areas
Ocean Character	N/A	Open Ocean
Seascape Character	Bayside	Bayside Commercial Park
		Bayside Industrial
		Bayside Industrial Resource
		Bayside Military Site
		Bayside Natural Area Upland
		Bayside Natural Area Wetland
		Bayside Recreation
		Bayside Residential
		Bayside Urban
		Bayside Waterbodies
		Seascape Residential
		Seascape Urban
	Oceanside	Nearshore Ocean
		Oceanside Beach

Level 1: Characters	Level 2: Character Types	Level 3: Character Areas
		Oceanside Recreation
		Oceanside Residential/Commercial
		Oceanside Urban
Landscape Character	N/A	Inland Agriculture
		Inland Commercial Park
		Inland Industrial
		Inland Industrial Resource
		Inland Military Site
		Inland Natural Area
		Inland Recreation
		Inland Rural
		Inland Suburban/Exurban Residential
		Inland Urban

The following subsections include a description of each character, character type, and character area. Detailed descriptions and photographs of the character areas can be found in Argonne (2024).

H.3.1.1.1 Open Ocean Character

The Open Ocean zone includes the open water of the Atlantic Ocean off the coast of New Jersey and New York and portions of Delaware Bay. This character area's defining characteristic is the presence of open water as a dominant element and unobstructed views in all directions. This primarily includes open waters of the Atlantic Ocean that are 3 nm (5.5 kilometers) beyond the Atlantic shoreline and unbounded by landforms. Human elements, such as ships of various sizes, lighthouses, buoys, and other infrastructure, can be seen at various distances throughout the study area, but the emphasis of the view is consistently on the overall flatness and variable colors of the water.

H.3.1.1.2 Seascape Character Descriptions

The regions that comprise the seascape character type are unified by a view of and relationship to the ocean and other saltwater bodies such as bays, inlets, and sounds, extending 3 nm (5.5 kilometers) from the edge of the ocean's coastline into the ocean. These unified areas include bayside and oceanside features, as they are deeply connected visually, ecologically, and recreationally to each other. The land uses in seascape areas may vary significantly, but the emphasis on the connectivity between the land and ocean remains an important visual and experiential element across all areas with seascape character.

Bayside Seascape Types maintain a view and direct connection to bays and other related saltwater bodies and associated features such as marinas and other developments along the bay and related waterbodies. These areas, however, do not maintain a direct connection to the coastline or ocean itself.

Bayside Commercial Park

These areas reflect business districts and commercial areas composed of office complexes, big box stores, strip malls, and parking lots. Relatively few residential spaces exist within these landscapes. Buildings are nondescript, often single-story, but may also contain office complexes several stories tall. Major roads and highways may have such office parks and strip malls running alongside them, but these character areas are specifically delineated when the density of such development is significant. While non-ocean waterbodies may be visible from the premises, little to no infrastructure or general design of the space and the buildings themselves emphasize the view of the waterbodies.

Bayside Commercial Parks have low sensitivity. Their blocky, nondescript built features cause low susceptibility to changes in their character, and the low scenic quality of commercial parks contributes to the low value associated with the character of these areas. This character area occurs along the coast of Brooklyn, within Gravesend Bay.

Bayside Industrial

Bayside Industrial areas are adjacent to the bay or other bayside waterbody and are industrial in nature, with features such as smokestacks, large blocky buildings, docks, large freight ships, bare earth, concrete, waste pilings, metal silos, warehouses, cranes, vehicles, and industrial materials. The scale of the industrial infrastructure is typically large, with angular, geometric cranes lining the waterfront. Freighters and other large coastal ships move within this environment, adding an additional visual weight and blocky pattern. While they are sometimes connected to residential and urban areas, they typically lack public access and do not provide views of the ocean and horizon.

Bayside Industrial areas have low sensitivity because they are not susceptible to changes to their character from the NY Bight projects due to having similar industrial characteristics, including tall, vertical elements and blocky infrastructure, and the low scenic quality of industrial areas and oftentimes poor condition contribute to the low value associated with the character of these areas. Bayside Industrial areas occur sporadically, mostly along the mainland coastal edge of both New York and New Jersey. There is a higher density of industrial areas within the mainland edge of Brooklyn and western Long Island.

Bayside Industrial Resource

The Bayside Industrial Resource areas consist of industrial zones such as wastewater treatment plants, landfills, and quarries. These industrial resource areas are generally smaller in scale than other industrial facilities, less dependent on large facilities for manufacturing, and are frequently visually obscured by vegetation. These facilities are often more secluded and obscured behind forested areas. The industrial elements within this category generally have low-lying, horizontal flat features, such as retention ponds and mining pits, that may not be visible from public rights-of-way.

Bayside Industrial Resource areas have low sensitivity because they are not susceptible to changes to their character from the NY Bight projects due to having similar industrial characteristics, including tall, vertical elements and blocky infrastructure. Also, the low scenic quality of industrial resource areas and their oftentimes poor condition contribute to the low value associated with the character of these areas. Industrial resource areas occur sporadically, mostly along the mainland coastal edge of both New York and New Jersey. There is a higher density of Bayside Industrial Resource areas within the mainland edge of Brooklyn and western Long Island.

Bayside Military Site

These sites may have docks, piers, or other waterfront resources. When not obscured by vegetation, such as dense trees, military sites generally consist of light industrial and office buildings, gravel roads, chain-link fence, and railways. Buildings are generally small, square, and nondescript in the traditional industrial style of the early 20th century.

Bayside Military Sites are low in sensitivity. They are not susceptible to changes to their character from the NY Bight projects due to their existing light industrial character, including their blocky infrastructure, and they are moderately valued for having some forested areas that contribute to the areas' scenic qualities and having bayside elements like docks and piers. The only Bayside Military Site is near Leonardo, New Jersey, within Sandy Hook Bay.

Bayside Natural Area Upland

Upland forests, shrubland, and grasses within natural or natural-appearing spaces occur within islands of the non-ocean waterbodies, as well as on adjacent bayside upland areas on the mainland and barrier islands. These upland natural areas maintain visual connection to the bay, estuaries, inlets, etc., and often have trails or other forms of access from the natural areas to the non-ocean waterbodies.

Bayside Natural Area Uplands are highly sensitive due to their natural sense of place, and lack of human development or industrial features, making these areas highly susceptible to change from the NY Bight projects. They are also highly valued due to their high scenic quality, wildness, and tranquility. This character area is common along the coastal edges of the mainland in both New York and New Jersey, typically occurring directly behind, and slightly elevated from, tidal wetlands. They are more common in the mainland of southern New Jersey. They can also occur on sufficiently elevated islands and within the non-ocean waterbodies and the barrier islands themselves, which is more common within Long Island.

Bayside Natural Area Wetland

Large swaths of wetlands, marshes, estuaries, mudflats, and islands exist within the interior inlets or sounds, and on the mainland side of coastal islands. Due to the changing nature of the boundaries of marshes, borders of these areas are less defined compared to more stable habitats such as forests. These areas are dominated by emergent grasses, reeds, and rushes.

Bayside Natural Area Wetlands are highly sensitive due to their natural sense of place, and lack of human development or industrial features, making these areas highly susceptible to change from the NY Bight projects. They are also highly valued due to their high scenic quality, wildness, and tranquility. From Ocean City north to Barnegat Lighthouse, a significant portion of the area between the mainland

and the barrier islands is Bayside Natural Area Wetland. The character area also extends from Jamaica Bay to Fire Island.

Bayside Recreation

Bayside Recreation consists of developed green space along the edge of a bay, which has amenities adjacent to a beach. These recreational areas are differentiated from other greenspaces, such as natural areas, by their scale of human development and recreational focus. These non-natural appearing areas often have seascape-related amenities such as marinas, fishing piers, boat launches, and water parks, as well as parks with significant sports and recreational resources such as tennis courts, baseball diamonds, walking trails in non-natural landscapes, and public and private golf courses.

Bayside Recreation areas are highly sensitive. The infrastructure is often limited in these areas, making their character highly susceptible to change. They are highly valued due to their high scenic qualities and locally held values and are often historic designated parks.

Bayside Residential

Bayside Residential consists of developed land that contains mostly residential units of low to high density; with views of bayside saltwater waterbodies from any vantage point, including marinas, docks, and piers; or that are located directly on the shoreline itself. These homes often have direct access to the waterfront and are generally designed in a way to provide significant views of the inlets, marshes, rivers, or other areas on the landward side of the barrier islands. The shoreline can be hardened and highly developed with houses built directly on piers or adjacent to hard-edged shorelines, or soft, naturalized, gradual slopes. The scale of development can be variable.

The Bayside Residential character area is highly sensitive. The composition of low to high density structures—some of which may have architectural historic interest—and lack of industrial elements makes for a character that is highly susceptible to change from the NY Bight projects. Bayside Residential areas are highly valued due to their scenic quality, houses' architectural and/or historic interest, and locally held values based on the bayside orientation.

Bayside Urban

Bayside Urban includes highly developed land with a view of bayside waterbodies from any vantage point—including marinas, docks, and piers—or that are located directly on the bayside shoreline. These areas are multiuse, with a mix of commercial, residential, and public lands. There can be restaurants, commercial districts, or public/private parks with significant infrastructure for waterfront access, such as large marinas or piers.

The sensitivity for Bayside Urban areas is medium. They are typically characterized by dense built structures with significant waterfront access infrastructure. This highly developed area has low susceptibility to character change from the NY Bight projects. Bayside Urban areas are highly valued for their tourism value and connection to the bayside waterbodies, and sometimes for having historically significant features. In Atlantic City, much of the Bayside Urban area consists of large hotels and entertainment complexes situated along the water's edge. In addition, houses, condominiums, and apartment buildings are densely situated along the canals and marinas.

Bayside Waterbodies

Bayside Waterbodies are partially enclosed marine waterbodies with direct access to the ocean and the associated docks, marinas, and other infrastructure. Although not essential to the viewing experience, these areas may have full, partial, or no views of the ocean and extend to the edge of river deltas and other waterbodies.

Bayside Waterbodies are highly sensitive and highly valued for their scenic qualities. These calm waterbodies are highly susceptible to change. The inlets between Ocean City and Seaside Park, with their extensive natural areas, are an example of Bayside Waterbodies.

Seascape Residential

Seascape Residential areas are neighborhoods directly tied to the seascape character but that do not maintain direct views of the ocean, non-ocean waterbodies, beaches, or other marine infrastructure. They are intrinsically connected to the seaside character due to proximity, character of the built environment, or overall experience, but they do not directly connect to the ocean features. For example, a barrier island may be large enough that the interior residential streets maintain cohesive cultural and/or architectural cues to seaside elements but are too far from beach access points or are disconnected due to distance and large roads that act as a visual and physical barrier to the ocean and non-ocean waterbodies.

These areas are highly sensitive, highly susceptible to change from industrial infrastructure, and highly valued for their aesthetic and perceptual elements. Ocean City, Mantoloking, and Navesink are all examples of Seascape Residential areas.

Seascape Urban

Seascape Urban areas include developed urban land that is directly tied to seascape character but does not maintain direct views of the ocean, dunes, beaches, or other marine infrastructure. They have medium sensitivity and are typically characterized by densely built structures and are highly locally valued for their integration into the seascape character elements and tourism. Atlantic City, New Jersey, and Island Park, New York, are examples of Seascape Urban areas.

Oceanside Seascape Types maintain clear visibility and connectivity to the ocean. The shared inter-visibility between natural lands and developed areas and the sea is such that the land, coastline, and sea maintain visibility of the ocean.

Nearshore Ocean

The nearshore ocean stretches 3 nm (5.5 kilometers) from the coastline in which the ocean relates to the seascape. Here, long horizontal waves typically roll towards the coast, with regular whitecaps and breaking waves occurring, except in calm weather. Colors and textures vary consistently, and change constantly, throughout this stretch of water.

Nearshore Ocean is highly sensitive due to its pristine, flat, vast, and minimal character and lack of infrastructure and industrial elements. It is highly valued for scenic qualities, wildness, and tranquility. Nearshore ocean extends all along the New York and New Jersey.

Oceanside Beach

Oceanside Beach areas maintain features, such as dunes and vegetation, in a way that makes the beach appear to be natural or have a minimal human impact. Here, human development is either not present, mostly obscured, or is built in a way that enhances rustic and/or natural features. Activities are passive and active, from swimming, surfing, and beachcombing, to relaxation and viewing nature. The emphasis of the view is the uninterrupted, wide horizon of the beach and ocean. Examples include Brigantine Beach, Island Beach State Park, and Highland Beach of Sandy Hook National Park in New Jersey. New York examples include Breezy Point and the majority of Fire Island's coastline.

Oceanside Beach is highly susceptible to changes due to its flat nature and natural appearance, is highly valued due to scenic quality and locally held values, and is therefore a highly sensitive environment.

Oceanside Recreation

Oceanside Recreation areas are characterized by developed recreational park land with a view of the beach and/or ocean from any vantage point. These include walking trails and seaside promenades, seaside recreational resources, public marinas, and piers. The infrastructure is often limited within Oceanside Recreation areas, but when it is present, it is human-scale and not industrial. Jones Beach and Robert Moses State Park are examples of Oceanside Recreation areas.

The Oceanside Recreation character is highly susceptible to change. These areas are highly valued due to their high scenic qualities with oceanside characteristics and their locally held values, and they are often natural or historic designated parks.

Oceanside Residential/Commercial

This zone consists of developed residential land, with a view of the beach and/or ocean from any vantage point. Architectural styles vary, but seaside residential units may reflect cottage, Victorian, and modern styles with an emphasis on decks, balconies, and windows that encourage views of the surrounding seascape. Access to the beach and ocean is often delineated through fenced walkways or boardwalks, often at the end of streets that abut dunes, guiding individuals up the dunes to the beach and ocean. In other instances, commercial areas such as cafes, gift shops, hotels, and other small-scale businesses are intermixed with residential units and maintain architectural vernacular that connects them to the seascape. Vegetation can include dune grasses and shrubs along the more natural beach and dune edge, and conventional landscaping elements within the properties themselves.

These areas are highly sensitive. The medium density structures with historic buildings and architectural significance are highly susceptible to change. The scenic quality, historic interest, and local value towards oceanside orientation make this character area highly sensitive. Oceanside Residential/Commercial areas occur between Ocean City and Ventnor City.

Oceanside Urban

Oceanside Urban areas consist of dense residential, commercial, and public lands, while still emphasizing the view of the beach and/or ocean. Certain elements that regularly occur, such as boardwalks or other paths along the beach edge, provide additional means for recreation, including food, drink, and other entertainment. Although the oceanside urban structures are often dense they have scenic quality and historic interest. Brighton Beach and Long Beach are examples of Oceanside Urban areas, with a variety of dense multi-use buildings, hotels, and beach recreation.

The scenic quality, historic interest, and local value towards oceanside and historically significant features make these areas highly valued environments.

H.3.1.1.3 Landscape Character

Land uses and landcover types vary significantly across the Landscape Character type. The common thread amongst the landscape character areas is that they have minimal visibility and opportunities for interaction with the ocean and/or seascape in general. Typologies in the study range from the highly urban, dense built environment of Manhattan, suburban New Jersey, and the agricultural landscapes of eastern Long Island, to the extensive natural areas of central New Jersey. While changes in elevation may allow for rare instances of ocean views from certain vantage points, such as skyscrapers in Midtown Manhattan, the landscape and seascape boundary is on the mainland wherever direct, ground-level connectivity to the seascape has ended.

Inland Agriculture

This character area consists of managed fields for agricultural purposes, and the adjacent housing and related agricultural structures such as barns, silos, and other elements of the farmstead. Fields are typically large, rectangular, and consist of pasture, row crops, or large raised beds and/or greenhouse structures for a variety of crops and agricultural products.

Inland Agriculture areas are highly sensitive. Agricultural areas consist of open fields with flat to rolling hills containing farm-related light industrial infrastructure such as silos that lend significant vertical elements to the character, making Inland Agriculture areas moderately susceptible to change due to the NY Bight projects. Agricultural fields provide tranquil scenic quality and open landscape views, making for high locally held values associated with them and overall high value in their character. This character area is found inland and to the far south in New Jersey, and inland to the far east of Long Island.

Inland Commercial Park

Inland Commercial Park areas are composed of office complexes, big box stores, strip malls, and parking lots. Relatively few residential units exist within these landscapes. Buildings are nondescript, often single-story buildings, but may contain office complexes several stories tall. Major roads and highways may have such office parks and strip malls along them, but these character areas are specifically delineated when the density of such development is significant. These typically occur near highway ramps and have no proximity to or view of the ocean.

Inland Commercial Park areas have low sensitivity. Their blocky, nondescript built features and varying human development create low susceptibility to changes in character from the NY Bight projects, and the low scenic quality of commercial parks contributes to the low value associated with their character. Inland Commercial Park occurs frequently adjacent to urban and residential areas along stretches of highway.

Inland Industrial

These are significant areas of developed land that are industrial in nature, with features such as smokestacks, large blocky buildings, and limited access to the shoreline for the public. While they are connected to residential and urban areas, these large areas typically lack public access and do not particularly provide views of the ocean and horizon. Bare earth, concrete, waste pilings, metal silos, warehouses, vehicles, and industrial materials are typical in this environment.

Inland Industrial areas have low sensitivity because they have a low susceptibility to changes to their character from the NY Bight projects due to their similar industrial characteristics, including tall, vertical elements and blocky infrastructure; the low scenic quality of industrial areas and their oftentimes poor condition contribute to the low value associated with the character of these areas. Inland Industrial areas are sporadic throughout the geographic analysis area, with increasing frequency in areas surrounding New York City and Jersey City.

Inland Industrial Resource

Inland Industrial Resource areas consist of industrial zones related to natural resources, such as wastewater treatment plants, landfills, and quarries. They are generally smaller in scale than other industrial facilities, less dependent on large facilities for manufacturing, and are frequently visually obscured by vegetation. These facilities are often more secluded and obscured behind forested areas. The industrial elements within this category are smaller in scale and generally consist of low-lying, horizontal flat features, such as retention ponds and mining pits, that may not be visible from public rights-of-way.

Inland Industrial Resource areas have low sensitivity. They are moderately susceptible to changes to their character from the NY Bight projects. Although there is an industrial character, infrastructure is at a smaller scale with often low-lying horizontal flat features. However, the low scenic quality of Inland Industrial Resource areas contributes to the low value associated with their character. Inland Industrial Resource areas are infrequent but dispersed evenly throughout the geographic analysis area. They often exist along the edge of large population centers, adjacent to forests and/or wetlands.

Inland Military Site

When not obscured by vegetation such as dense trees, Inland Military Sites generally consist of light industrial infrastructure, office buildings, gravel roads, chain-link fence, and railways making them moderately valued. Buildings are generally small, square, and nondescript in the traditional industrial style of the early 20th century.

Inland Military Sites consist of extensive forested areas of moderate to high scenic quality, along with varying industrial elements, making them moderately susceptible to changes to their character from the NY Bight projects and moderately valued due to their scenic qualities. Sections of central and southern New Jersey have large military complexes, mostly set far from developed areas.

Inland Natural Area

Inland Natural Areas predominantly include greenspace that is natural or natural appearing. Inland, this typically comprises forests, savannahs, and grasslands. Pine barrens are a representative habitat of such natural area. These spaces lack significant development, or at least appear to lack development, using smaller trails and paths enclosed in these natural spaces, rather than wide trails with high visibility.

Inland Natural areas are highly sensitive due to their sense of place and lack of human development/ built environment, making these areas highly susceptible to change from the NY Bight projects. They are also highly valued due to their high scenic quality, wildness, and tranquility. Much of inland central and southern New Jersey is composed of natural areas. In contrast, far eastern Long Island has significant natural areas; western and central Long Island has natural areas along inland waterbodies.

Inland Recreation

These areas include developed recreational park lands with no view of the beach and/or ocean and that are clearly part of the inland landscape. These include parks with significant sports and recreational resources such as tennis courts, baseball diamonds, walking trails in non-natural landscapes, as well as public and private golf courses.

Inland Recreation areas are highly sensitive. They are mainly composed of developed parks and sports infrastructure, which is not similar in character to WTG infrastructure, making the character of the area highly susceptible to change. Recreation areas have high locally held value, often have significant or historic designation, and have high scenic qualities, making them highly valued in character. In Long Island, many of these areas are highly developed parks with baseball fields, tracks, open fields for recreation, and clearly designed walking paths, all identifying areas for specific active recreation.

Inland Rural

Inland Rural areas have a low population density. Architecturally there may be similar vernacular elements related to agricultural areas, but significant architectural and structural elements persist between Inland Rural and the Inland Suburban/Exurban Residential character areas.

Sensitivity is high for Inland Rural character areas. These areas are typically open with flat to rolling hills with sparse residential structures, making the character of the area highly susceptible to change due to the NY Bight projects. They may have valued conservation and open space areas around the sparse residential homes, but the homes themselves typically lack architectural interest, making them moderately valued. Southern inland New Jersey and far eastern Long Island have instances of low-density housing often set within natural areas such as forest land, or adjacent to agricultural fields. These do not include farmsteads, but rather the low-density development far from the urban/suburban core.

Inland Suburban/Exurban Residential

Inland Suburban/Exurban Residential character areas reflect developed land, mostly residential units, that do not have a view of the beach and/or ocean from any vantage point. These neighborhoods are clearly part of the inland landscape, and lack connection or reference to the seascape. They vary in architectural styles and densities, but most importantly do not bear architectural or cultural elements associated with seaside communities. There is significant variation in architectural and structural styles of Inland Suburban/Exurban Residential areas, ranging from conventional suburban design at various densities, to exurban and rural styles.

The Inland Suburban/Exurban Residential character areas are highly sensitive. They lack industrial elements similar to that of a WTG and are composed of mostly residential structures, which are minimal when compared to the project infrastructure, making the area highly susceptible to change to its character due to the NY Bight projects. These areas may have valued conservation and open space areas around the residential neighborhoods, but the homes themselves lack significant architectural elements and there are no particular locally held values tied to this character, making it moderately valued. In Long Island, the Inland Suburban/Exurban Residential area is defined by a dense, gridded network of streets and homes, of varying styles typical of suburban conventions of the 20th century. In New Jersey, there is a similar density closer to the coast. Further inland, the housing density and size of homes increases, and the structure of neighborhoods is less gridded.

Inland Urban

Inland Urban areas consist of developed land without a view of the beach or ocean from any vantage point. Dense commercial areas, dense residential areas with apartment buildings, and other areas with significant development are considered in this landscape.

Inland Urban character areas are overall low in sensitivity. They typically have lower scenic qualities, but have locally held value, tourism value, and sometimes historically significant features, making their character moderately valued. Long Island, New York, includes several examples of Inland Urban.

H.3.1.2 Sensitivity

The sensitivity of an open ocean, seascape, or landscape impact receptor is dependent on its susceptibility to change and its perceived value to society. Sensitivity is based on the value placed on a character area by residents and visitors and the susceptibility of the character area, which is the ability to accept or not accept additions of elements or features that affect the scenic character of that area. Receptor sensitivity is recorded on an ordinal scale of high, medium, or low based on information from the baseline data collected; therefore, sensitivity of each character area is determined and described in the character area classification part of the methodology. Section 3.6.9, Table 3.6.9-5, Table 3.6.9-6, and Table 3.6.9-7 contain detailed definitions of the criteria ratings (high, medium, low) for susceptibility, value, and sensitivity. *Ocean, Seascape, Landscape, and Visual Impact Assessment of the New York Bight Offshore Wind Lease Areas* (Argonne 2024) has detailed baseline data and descriptive rationale for the rating determinations.

Table H-12 summarizes the susceptibility, value, and sensitivity ratings for the open ocean, seascape, and landscape character as described in the preceding character area descriptions.

Table H-12. Open ocean, seascape, and landscape sensitivity

Open Ocean, Seascape, and Landscape Character Area	Susceptibility	Value	Sensitivity
Open Ocean	High	High	**High**
Seascape – Bayside Seascape			
Bayside Commercial Park	Low	Low	**Low**
Bayside Industrial	Low	Low	**Low**
Bayside Industrial Resource	Low	Low	**Low**
Bayside Military Site	Low	Medium	**Low**
Bayside Natural Area Upland	High	High	**High**
Bayside Natural Area Wetland	High	High	**High**
Bayside Recreation	High	High	**High**
Bayside Residential	High	High	**High**
Bayside Urban	Low	High	**Medium**
Bayside Waterbodies	High	High	**High**
Seascape Residential	High	High	**High**
Seascape Urban	Low	High	**Medium**
Seascape – Oceanside Seascape			
Nearshore Ocean	High	High	**High**
Oceanside Beach	High	High	**High**
Oceanside Recreation	High	High	**High**
Oceanside Residential/Commercial	High	High	**High**
Oceanside Urban	Medium	High	**High**
Landscape			
Inland Agriculture	Medium	High	**High**
Inland Commercial Park	Low	Low	**Low**
Inland Industrial	Low	Low	**Low**
Inland Industrial Resource	Medium	Low	**Low**
Inland Military Site	Medium	Medium	**Medium**
Inland Natural Area	High	High	**High**
Inland Recreation	High	High	**High**
Inland Rural	High	Medium	**High**
Inland Suburban/Exurban Residential	High	Medium	**High**
Inland Urban	Low	Medium	**Low**

H.3.1.3 Magnitude

The magnitude of effect in an open ocean, seascape, or landscape depends on the size or scale of the change associated with the proposed project, the geographic extent of the change based on the viewshed, and the duration and reversibility of a NY Bight project. Acreages of character areas in the offshore geographic analysis area overall and within the viewshed (i.e., the amount of character area from which the WTG array would be visible) are listed in Table H-13 for the 1,312-foot (400-meter) wind turbines and Table H-14 for the 853-foot (260-meter) wind turbines. Each lease area is measured/calculated as a fraction of the entire six lease area. The acreages for each individual lease are greater than the total area for the combined six-project geographic analysis area because the individual lease viewsheds overlap.

Note that character areas that are not a part of the geographic extent that is visually exposed to the offshore projects but that are adjacent to it may not be physically affected but may be perceptually affected. For instance, the Oceanside Residential character areas on Long Beach Island that have views to the offshore project may be the only character areas on the island that are directly affected. However, the other character areas of Long Beach Island adjacent to or one removed from the Oceanside Residential character areas (e.g., Seascape Residential, Bayside Recreation, Bayside Commercial Park, Bayside Urban) may be perceptually affected because they are all a cohesive part of the Long Beach Island community, and the offshore wind energy development becomes a part of the identity of the whole community.

Size and scale of change considers changes to the physical elements of the open ocean, seascape, and landscape, and their aesthetic, experiential, and perceptual aspects. Although size and scale does not refer to the size and scale of the project per se, understanding the degree of visibility provides measurable context for analyzing the perceptual aspects of scale, prominence, and impacts on open ocean, seascape, and landscape. Table H-15 and Table H-16 list specific locations in New York and New Jersey where the NY Bight projects' noticeable features, based on their heights, distances, and EC for the 1,312-foot (400-meter) WTGs and 853-foot (260-meter) WTGs, respectively, have a perceptual effect on the open ocean, seascape, or landscape. Higher impact levels would stem from unique, extensive, and long-term appearance of strongly contrasting, large, and prominent vertical structures in the otherwise horizontal open ocean and seascape environments where wind turbine structures are an unexpected element. Table H-17 and Table H-18 break out the geographic extent of each character area based on project noticeability and provide additional detail to describe the degree of change from existing conditions for each lease area. Within Table H-17 and Table H-18, the project analysis area corresponds to the area within a 50-mile (80.5-kilometer) buffer of each individual lease area and is equivalent to the geographic analysis area for all six NY Bight lease areas. The impact area is the portion of the project analysis area that is visible and is associated with each individual lease area, not all six lease areas combined.

Operational effects would be similar to those of end-stage construction and installation and would be long term and fully reversible. The duration and reversibility of each character area is documented in the summary tables, Table H-19 through Table H-32.

This page was intentionally left blank.

Table H-13. Area of open ocean, seascape, and landscape character areas within the project area viewsheds for 1,312-foot WTGs

Character Area	Total Area in the Geographic Analysis Area		Area Within the 1,312-Foot WTG GAA Viewshed [1]

Note: areas <0.00 square miles (0.00 square kilometers) = 0.64 acres or less.
Source: Argonne 2024.
[1] Areas are not additive across leases due to overlap in lease area viewsheds. The area affected is a percentage of the total area GAA, not the individual lease area.
km^2 = square kilometers

Table H-15. Noticeable elements and impacts by open ocean, seascape, and landscape character area for the 1,312-foot WTGs

Noticeable Elements Impacts	Open Ocean, Seascape, and Landscape Character Areas
R, AL, N, H, O, M, Y Prominence 6	**Open Ocean Character Area**: Ocean
R, AL, N, H, O, M Prominence 5	**Open Ocean Character Area:** Ocean **Seascape Character Areas:** Bayside Natural Wetland, Bayside Residential, Bayside Waterbodies, Nearshore Ocean, Oceanside Beach, Oceanside Recreation, Oceanside Residential (NY: Ocean Beach, Fire Island, Saltaire)
R, AL, N, H Prominence 3–4	**Open Ocean Character Area:** Ocean **Seascape Character Areas:** Bayside Commercial Park, Bayside Industrial, Bayside Industrial Resource, Bayside Natural Upland, Bayside Natural Wetland, Bayside Recreation, Bayside Residential, Bayside Urban, Bayside Waterbodies, Seascape Residential, Seascape Urban, Nearshore Ocean, Oceanside Beach, Oceanside Recreation, Oceanside Residential/Commercial, Oceanside Urban (NY: Brookhaven, Islip, Massapequa Park, Long Beach, Jones Beach. NJ: Beach Haven, Long Beach, Barnegat) **Landscape Character Areas:** Inland Commercial Park, Inland Industrial, Inland Industrial Resource, Inland Natural Area, Inland Recreation, Inland Suburban/Exurban Residential, Inland Urban (NY: Islandia, Islip, Brookhaven, Babylon. NJ: Barnegat Township)
R Prominence 1–2	**Open Ocean Character Area:** Ocean **Seascape Character Areas:** Bayside Commercial Park, Bayside Industrial, Bayside Industrial Resource, Bayside Natural Upland, Bayside Natural Wetland, Bayside Recreation, Bayside Residential, Bayside Urban, Bayside Waterbodies, Seascape Residential, Seascape Urban, Nearshore Ocean, Oceanside Beach, Oceanside Recreation, Oceanside Residential/Commercial, Oceanside Urban (NY: Lawrence, Westhampton Beach, Atlantic Beach, Rockaway Beach, Quogue. NJ: Brigantine, Atlantic City, Monmouth Beach, Highlands, Belmar, Bay Head, Mantoloking, Point Pleasant Beach Borough) **Landscape Character Areas:** Inland Agriculture, Inland Commercial Park, Inland Industrial, Inland Industrial Resource, Inland Military Site, Inland Natural Area, Inland Recreation, Inland Rural, Inland Suburban/Exurban Residential, Inland Urban (NY: Huntington, Southampton. NJ: Barnegat Township, Egg Harbor Township, Berkeley Township, Brick Township, Point Pleasant Beach Borough)

R = rotor, AL = aviation light, N = nacelle, H = hub, M = mid-tower light, O = OSS, Y = yellow tower base color.
Prominence: 0 = Not visible. 1 = Visible only after extended study; otherwise not visible. 2 = Visible when viewing in general direction of the wind farm; otherwise likely to be missed by casual observer. 3 = Visible after brief glance in general direction of the wind farm; unlikely to be missed by casual observer. 4 = Plainly visible; could not be missed by casual observer, but does not strongly attract visual attention or dominate view. 5 = Strongly attracts viewers' attention to the wind farm; moderate to strong contrasts in form, line, color, or texture, luminance, or motion. 6 = Dominates view; strong contrasts in form, line, color, texture, luminance, or motion fill most of the horizontal FOV or vertical FOV

Table H-16. Noticeable elements and impacts by open ocean, seascape, and landscape character area for the 853-foot WTGs

Noticeable Elements Impacts	Open Ocean, Seascape, and Landscape Character Areas
R, AL, N, H, O, M, Y Prominence 6	**Open Ocean Character Area:** Ocean
R, AL, N, H, O Prominence 5	**Open Ocean Character Area:** Ocean **Seascape Character Areas:** Bayside Natural Wetland, Bayside Residential, Bayside Waterbodies, Nearshore Ocean, Oceanside Beach, Oceanside Recreation, Oceanside Residential/Commercial (NY: Fire Island, Saltaire, Davis Park.)
R, AL, N, H Prominence 3–4	**Open Ocean Character Area:** Ocean **Seascape Character Areas:** Bayside Natural Wetland, Bayside Residential, Bayside Waterbodies, Nearshore Ocean, Oceanside Beach, Oceanside Recreation, Oceanside Residential/Commercial (NY: Fire Island, Saltaire, Davis Park.)
R Prominence 1–2	**Open Ocean Character Area**: Ocean **Seascape Character Areas:** Bayside Commercial Park, Bayside Industrial, Bayside Industrial Resource, Bayside Natural Wetland, Bayside Natural Upland, Bayside Recreation, Bayside Residential, Bayside Urban, Bayside Waterbodies, Seascape Residential, Seascape Urban, Nearshore Ocean, Oceanside Beach, Oceanside Recreation, Oceanside Residential/Commercial, Oceanside Urban (NY: Long Beach, Jones Beach, Islip, Mastic Beach, Babylon, Brookhaven. NJ: Beach Haven, Long Beach Island, Surf City) **Landscape Character Areas:** Inland Agriculture, Inland Commercial Park, Inland Industrial, Inland, Industrial Resource, Inland Natural Area, Inland Recreation, Inland Rural Inland Suburban/Exurban Residential, Inland Urban (NY: Massapequa, Patchogue, Islip, Babylon, Brookhaven. NJ: Barnegat Township Tuckerton Borough)

R = rotor, AL = aviation light, N = nacelle, H = hub, O = OSS, M = mid-tower light, Y = yellow tower base color.
Prominence: 0 = Not visible. 1 = Visible only after extended study; otherwise not visible. 2 = Visible when viewing in general direction of the wind farm; otherwise likely to be missed by casual observer. 3 = Visible after brief glance in general direction of the wind farm; unlikely to be missed by casual observer. 4 = Plainly visible; could not be missed by casual observer, but does not strongly attract visual attention or dominate view. 5 = Strongly attracts viewers' attention to the wind farm; moderate to strong contrasts in form, line, color, or texture, luminance, or motion. 6 = Dominates view; strong contrasts in form, line, color, texture, luminance, or motion fill most of the horizontal FOV or vertical FOV

[1] Area measures represent totals by noticeable elements in the viewshed. Areas that are <0.00 sq miles (0.00 sq KM) are 0.64 acres or less.
km² = square kilometers

H.3.1.4 Open Ocean, Seascape, and Landscape Impact Assessment Summary and Impact Levels

Table H-19 through Table H-32 summarize the effects from the offshore components of each lease area and all six NY Bight lease areas on sensitivity, magnitude, and visibility thresholds (Table H-8). The tables also present the impact levels for each character area based on the impact level definitions in Table H-8.

Lease areas farther from shore (i.e., OCS-A 0537 and OCS-A 0538) have less effect on seascape and landscape character areas because of their smaller perceptive scale, whereas lease areas nearer to shore (i.e., OCS-A 0544) have a greater perceptive scale and therefore a greater effect on oceanside seascape character type sense of place in limited areas of New York.

High to moderate magnitudes of visual impact would occur in the ocean-facing and bay-facing seascape character areas and diminish to moderate and minor as distance increases and screening effects increase from topography, structures, and vegetation. Nearshore Ocean is the largest and most vulnerable character area to change, outside of the Open Ocean. Medium to minor size or scale changes to character type sense of place would occur in all other seascape and landscape character areas. Impacts of the NY Bight projects on open ocean character, seascape character, and landscape character range from **negligible** to **major**.

H.3.2 Visual Impact Assessment (VIA)

H.3.2.1 Sensitivity

Impacts on people are considered in evaluating KOPs. The susceptibility of viewers to changes in views is a function of the activities in which the viewers are engaged and their attention or interest on the view. Visual receptors most susceptible to change generally include residents with views of the proposed project from their homes, people engaged in outdoor recreation whose attention is focused on the views, visitors to historic or culturally important sites where views are an important contributor to the experience, people who regard the visual environment as an asset to their community, and people traveling scenic highways, railroads, or other transport specifically for enjoyment of the views.

KOPs are generally selected to represent high value, highly susceptible viewpoints to evaluate impacts at these special places; therefore, it is not surprising that all the KOPs are highly sensitive. Table H-33 documents the susceptibility, value, and sensitivity of viewers at each KOP. Overall, residents, tourists, and visitors engaging in recreation at these viewpoints are highly susceptible to changes from the NY Bight projects due to their interest in ocean-facing views and the visual environment being an important asset to their community. It is noted that susceptibility may be variable for visitors based on the activities people are engaged in and the nuances of each location. For example, visitors at Lucy the Elephant have a higher susceptibility while in the howdah and viewing the open ocean, and a lower susceptibility while on the ground or inside the structure. Many of the KOPs have special local, state, or national designations that demonstrate their value. For all the KOPs, their expansive ocean-facing views define their experiential character, which contributes to their overall view value.

Table H-33. View value, susceptibility, and viewer sensitivity for each KOP

KOP[1]	Viewer Experience								
	View Value			Receptor Susceptibility			Viewer Sensitivity

[1] Elevated viewpoint
[2] Simulation

H.3.2.2 Magnitude

The measure of magnitude of visual impacts is similar to that used for SLIA and is based on the size or scale of change, the geographic extent of its effects, and its duration and reversibility. Large-scale changes that introduce new, non-characteristic, discordant, or intrusive elements are more important than small changes or changes involving similar features already present within the view.

Size and scale of change and geographic extent is measured by a project's distances, horizontal FOVs, noticeable features based on their heights and EC, and visual contrasts. The analysis considers the introduction of WTGs and OSSs to an open ocean baseline. The scale, size, contrast, and prominence of change focuses on the:

- Arrangement of WTGs and OSSs in the view.
- Horizontal and vertical FOV scale of the wind turbine array, based on WTG and OSS size and number.
- Position of the array in the open ocean.
- Position of the array in the view.
- Wind turbine array's distance from the viewer.

Geographic extent is a measure of visibility, character-changing effects, scale, prominence, and visual contrasts reduce steadily with distance from the observation point and increase with elevated observer positions in comparison with the wind turbine array. Distance and observer elevation considerations are informed by the visual simulations (BOEM's NY Bight website: https://www.boem.gov/renewable-energy/state-activities/new-york-bight), EC calculations, horizontal FOV, and vertical FOV in undeveloped open ocean. The wind turbine array and nearest WTGs would be:

- Unavoidably dominant features in the boat and ship ocean view between 0 and 5 miles (0 and 8.0 kilometers) distance.
- Strongly pervasive features in the onshore to offshore view between 5 and 16 miles (8 and 25.75 kilometers) distance.
- Clearly visible features in the onshore to offshore view between 16 and 20 miles (25.75 and 45.1 kilometers) distance.
- Low on the horizon, but persistent features in the onshore to offshore view between 20 and 36.1 miles (45.1 and 58.1 kilometers) distance.
- Intermittently noticed features in the onshore to offshore view between 36.1 and 47.4 miles (58.1 and 76.3 kilometers) distance.
- Below the horizon beyond 47.4 miles (76.3 kilometers) distance.

Like duration and reversibility in the SLIA, this is a measure of the length of time over which the impact is likely to occur and the degree to which the pre-project conditions can be restored after decommissioning. Duration is recorded on an ordinal scale of short term (less than 5 years), long term (5–30 years), or considered permanent (more than 30 years). Reversibility is recorded on a scale of nonreversible, partially reversible, or fully reversible. In the assessment of impact level, duration and reversibility are considered together and recorded on a scale of good, fair, and poor, with good combining short duration with full reversibility, and poor combining permanent with nonreversible. A combination matrix can be found in Argonne 2024. Impact levels are recorded in the visual summary tables found in Section H.3.2.3.

Construction and installation involving moving and stationary visual feature contrasts to forms, lines, colors, and textures, scale, and prominence in formerly open seascape may have more effect on viewers than operational and decommissioning impacts, where the viewing context is existing WTGs and OSSs. Construction impacts would be temporary and include:

- Daytime and nighttime movement of installation vessels, cranes, and other equipment visible in the seascape in and around the lease area.
- Dawn, dusk, and nighttime construction and installation lighting on WTGs and OSSs.
- Beach, other sensitive land-based, and boat and cruise ship views of WTGs and OSSs under construction and installation.

Foreground influence assessments, involving the presence of intervening or framing elements and their influence on effects of project characteristics, are based on each KOP's locale photography and visual simulations and summarized in Table H-34.

Table H-34. Foreground view framing and intervening elements between the KOPs and the lease areas

Foreground Element(s) Influence[1]	Offshore Key Observation Points
Open Ocean **Negligible Influence**	KOP-A Recreational Fishing, Pleasure, and Tour Boat Area KOP-B Commercial and Cruise Ship Shipping Lanes
Beach and Ocean **Minor Influence**	KOP-28 Jones Beach State Park KOP-31 Westhampton Beach KOP-36 Asbury Convention Hall Balcony KOP-11 US Life Saving Station #14 KOP-12 Seaside Beach Park KOP-17 Asbury Park Beach KOP-37 Point O' Woods
Dunes, Beach, and Ocean **Minor Influence**	KOP-3 Stafford Hall Boardwalk KOP-4 Stafford Hall Beach Entrance KOP-10 Barnegat Lighthouse KOP-18 Allenhurst KOP-30 Shinnecock Inlet KOP-14 Bayhead KOP-15 Point Pleasant KOP-16 Ocean Grove
Structures, Dunes, and Beach **Moderate Influence**	KOP-8A Beach Haven (daytime) KOP-8B Beach Haven (night) KOP-6 Atlantic City Boardwalk – Ocean Casino KOP-7 Ocean Casino – Top KOP-9 Barnegat Jetty KOP-27 Magnolia Beach KOP-33 Fire Island Lighthouse – Base

Foreground Element(s) Influence[1]	Offshore Key Observation Points
	KOP-38 Robert Moses Field 5 KOP-40 Robert Moses Field – Nighttime
Bay, Vegetation, Roadway, and Structures **Minor Influence**	KOP-32 Fire Island Lighthouse – Top
Landscape Structures, Vegetation, and Topography **Minor to Moderate Influence**	KOP-13 Mantoloking KOP-35 Navesink Twin Lights – Top
Bay, Landscape Structures, and Topography **Dominant/Major Influence**	KOP-29 Rudolph Oyster House (Long Island Maritime Museum)
Bay, Structures, and Roadways **Dominant/Major Influence**	KOP-39 Empire State Building
Vegetation, Roadway, and Topography **Dominant/Major Influence**	KOP-19 Navesink Twin Lights
Structures, Landscape Structures, Vegetation, and Topography **Minor to Moderate Influence**	KOP-26 Fort Tilden/Jacob Riis (night)
Structures, Dunes, Beach Structures, and Ocean **Dominant/Major Influence**	KOP-2 Lucy the Margate Elephant KOP-5 Jim Whelan KOP-35 Navesink Twin Lights Lighthouse – Top

[1] Based on conditions portrayed by representative photography contained in Argonne (2024). Nearby view receptor locations may vary from screened to open views of the lease area.

Visual contrast determinations on viewer experience are based on visual simulations for 17 representative KOPs (Argonne 2024). Potential viewpoints' evaluations range from faint to dominant. Visual contrast determinations involve comparisons of characteristics of the KOPs before and after implementation of the NY Bight projects. The range of potential contrasts includes strong, moderate, weak, and none. The strongest daytime contrasts would result from tranquil and flat seas combined with sunlit WTG towers, nacelles, flickering rotors, and the yellow tower 50-foot (15.2-meter) base color against a dark background sky and an undifferentiated foreground. The weakest daytime contrasts would result from turbulent seas combined with overcast daylight conditions on WTG towers, nacelles, and rotors against an overcast background sky and a foreground modulated by varied landscape elements. The strongest nighttime contrasts would result from dark skies (absent moonlight) combined with aviation lights, lighting on the OSS, mid-tower lights, and project lighting reflections on low clouds and active (non-reflective) surf, and the dark-sky light dome. The weakest nighttime contrasts would result from moonlit, cloudless skies; tranquil (reflective) seas; and aircraft detection lighting system (ADLS) activation (Sub-alternative C1 [Preferred Alternative]).

There would be daily variation in WTG color contrast as sun angles change from backlit to front-lit (sunrise to sunset), and the backdrop would vary under different lighting and atmospheric conditions. Two sets of photo simulations were produced for selected KOPs. One set approximates the predictable visibility based on the atmospheric visual clarity at the time the photograph was taken. The other set approximates the maximum visibility potential with no visual interference from atmospheric conditions.

Table H-35 identifies which KOPs are simulated and additional KOPs that use this simulation as a reference.

Visual contrast, scale of change, and prominence determinations for KOPs with simulations are listed in Table H-36 through Table H-41 for each lease area and the 1,312-foot (400-meter) and 853-foot (260-meter) WTGs, followed by Table H-42 and Table H-43 for the six projects and 1,312-foot (400-meter) and 853-foot (260-meter) WTGs, respectively.

Photo-simulations are instrumental when assessing visual impacts from KOPs. Table H-35 lists the KOPs with photo-simulations, as well as the KOPs without simulations that are similar in distance to the lease area WTGs as the KOPs with simulations and would represent similar level of visual impact. This table also lists KOPs initially identified for impact evaluation, but were found to be outside of the view of WTGs within any of the six NY Bight lease areas.

Table H-35. KOPs with simulations, KOPs represented by KOPs with simulations, and KOPs outside of view of the lease areas

KOPs with Simulations		KOPs Represented by the KOPs with Simulations

KOPs with Simulations		KOPs Represented by the KOPs with Simulations	
KOP #[1]	KOP Name	KOP #	KOP Name
KOPs without Simulation Representation (analysis based solely on GIS)			
KOP-09	Barnegat Jetty		
KOP-11	US Life Saving Station #14		
KOP-12	Seaside Park Beach		

[1] Eight KOPs were identified but following the analysis appeared outside of the affected viewshed and have been removed from the impact analysis. These are: KOP-01 Ocean City Music Hall, KOP-20 Sandy Hook Beach, KOP-21 Great Kills, KOP-22 Roosevelt Pier, KOP-23 Statue of Liberty – Upper Deck, KOP-24 Statue of Liberty – Base, KOP-25 Coney Island Boardwalk, and KOP-34 Sandy Hook Observatory.
[2] KOP 40 provides a representative example of nighttime effects for KOP-33 and KOP-37.

The following tables list the analytical results for the two different sets of simulations when the results are different at the respective KOPs. KOPs noted with results based on maximum visibility conditions are labeled with **MAXIMUM VISIBILITY** in the tables, and results on the predicted visibility based on the visual clarity at the time of the photo are labeled with **PREDICTED VISIBILITY**.

[2] Noticeable elements: R = rotor, AL = aviation light, N = nacelle, H = hub, M = mid-tower light, O = OSS, and Y = yellow tower base color.

[3] WTGs and OSS visibility: 0 – Not visible. 1 – Visible only after extended study; otherwise not visible. 2 – Visible when viewing in general direction of the lease areas; otherwise likely to be missed by casual observer. 3 – Visible after brief glance in general direction of the lease areas; unlikely to be missed by casual observer. 4 – Plainly visible; could not be missed by casual observer, but does not strongly attract visual attention or dominate view. 5 – Strongly attracts viewers' attention to the lease areas; moderate to strong contrasts in form, line, color, or texture, luminance, or motion. 6 – Dominates view; strong contrasts in form, line, color, texture, luminance, or motion fill most of the horizontal FOV or vertical FOV (Sullivan et al. 2013).

H.3.2.3 Visual Impact Assessment Summary

The VIA considers the characteristics of the view receptor, characteristics of the view toward the NY Bight project facilities, and the experiential impacts of the NY Bight project. The viewer experiences would be affected by the NY Bight projects' noticeable features; applicable distances and FOV extents; open views versus view framing and intervening foregrounds, and form, line, color, and texture contrasts; scale of change; and prominence in the characteristic seascape and landscape. Higher impact levels would stem from unique, extensive, and long-term appearance of strongly contrasting, large, and prominent vertical structures in the otherwise horizontal seascape environment; where structures are an unexpected element and viewer experience is of formerly open views of high-sensitivity seascape and landscape; and from high sensitivity view receptors. Based on these VIA impact range factors and the geographic analysis area viewer experience analyses, Table H-44 through Table H-50 summarize impacts from the NY Bight projects on the viewer experience (KOP locations) for each lease area and the six NY Bight projects combined. Impacts of the NY Bight projects on viewer experiences range from **negligible** to **major**.

H.4 Cumulative Impacts of NY Bight Projects

NEPA requires consideration of other reasonably foreseeable activities in the project's viewshed and the project's additive effects on open ocean character, seascape character, landscape character, and viewer experience. These effects include direct physical effects on the open ocean, seascape, and landscape or changes to the distinct character of the open ocean, seascape, and landscape.

Effects on open ocean character, seascape character, and landscape character can occur in the following conditions (SLVIA Chapter 8; BOEM 2021).

- Multi-project WTGs and OSSs visible within or from the open ocean character unit as overlapping or adjacent features and elements.
- Multi-project WTGs and OSSs visible from seascape character units as overlapping or adjacent features and elements.
- Multi-project WTGs and OSSs visible from landscape character units as overlapping or adjacent features and elements.

Effects on viewer experience can occur in the following conditions (SLVIA Chapter 8; BOEM 2021).

- Multi-project WTGs and OSSs visible as overlapping features and elements.
- Multi-project WTGs and OSSs visible as adjacent features and elements.
- Multi-project WTGs and OSSs visible as viewers move through the open ocean, seascape, and landscape.

Simulations of the additive effects of the project in the context of other offshore wind projects are available on the BOEM website (https://www.boem.gov/renewable-energy/state-activities/new-york-bight). The KOP-based visual simulations portray 1,312-foot (400-meter) and 853-foot (260-meter) WTG predicted and maximum visibility for three construction and installation scenarios:

- The project construction (six NY Bight lease areas) without other foreseeable planned activities.
- The project construction with other foreseeable planned activities. 2024–2030 Project Construction includes Ocean Wind 1 OCS-A-0498, Empire Wind OCS-A 0512, Empire Wind II OCS-A 0512, Atlantic Shores Offshore Wind South OCS-A 0499, Atlantic Shores Offshore Wind North OCS-A 0539, and Ocean Wind 2 OCS-A532.[1]
- Other foreseeable planned activities without the six NY Bight leases.

[1] Refer to footnotes 9 and 10 in PEIS Chapter 1 for additional information on the status of Ocean Wind 1, Empire Wind 1, and Empire Wind 2.

The number of offshore wind structures illustrated in the simulations differs from the number of structures assumed in Appendix D, *Planned Activities Scenario*. This is due to the timing of when Appendix D and simulations documents were developed, and the assumptions used in developing the layouts for the simulations. The number of offshore structures identified in both documents are estimates of reasonably foreseeable offshore wind development and are subject to change as lessees submit COPs and refine their development plans. BOEM believes the simulations presented on their website provide a reasonable approximation of the scale, contrast, and prominence of visual impacts that would occur from development of the NY Bight projects in combination with other ongoing and planned offshore wind projects.

The effects of other lease areas on open ocean character, seascape character, and landscape character are described in Table H-51. Increased impacts on the open ocean character area, seascape character areas, and landscape character areas stem from the effects of additional WTGs in view of the character areas. Effects include additive expansions to the perceived geographic extents of lease areas' FOVs, greater magnitudes of character-changing turbines and substations, and increased daytime and nighttime vessel traffic. Simulations show that lease area proximities to character areas increase and decrease the character-changing interactions of key features and key elements. Those simulations showing beach views toward lease areas with visible WTGs' yellow bases and platforms, mid-tower lights, substations, hubs, nacelles, aviation lights, and rotors change seascape character more than views with more distant and fewer visible WTG elements.

The effects on open ocean character, seascape character, and landscape character of other lease areas in combination with the NY Bight projects are described in Table H-52.

The effects on viewer experience from non-NY Bight projects are described in Table H-53.

The effects on viewer experience of other lease areas in combination with the NY Bight projects are described in Table H-54.

Table H-51. Non-NY Bight projects' open ocean, seascape, and landscape areas cumulative lease area distances, FOVs, noticeable elements, visual contrasts, scale of change, and prominence

Lease Area and Additive Date	Distance in Miles (Kilometers)[1] and Impacts			FOV Degrees (% of 124°)			Noticeable Elements[2] and Impact Level	Visual Contrast, Scale of Change, and Prominence					
	Seascape[4]	Open Ocean	Landscape[4]	Seascape	Open Ocean	Landscape		Form	Line	Color	Texture	Scale	Prominence[3]
Atlantic Shores Offshore Wind South OCS-A 0499 2026	8.7 (14.0) **Major**	0 (0)–42.5 (68.4) **Major**	9.0 (14.5) **Major**	136° (110%)	82° to 360° (66 to 290%)	136° (110%)	R, AL, N, H, O, M, Y Major	Strong	Strong	Strong	Strong	Large	6
Atlantic Shores Offshore Wind North OCS-A 0549 2030	9.0 (14.5) **Major**	0 (0)–42.5 (68.4) **Major**	9.2 (14.8) **Major**				R, AL, N, H, O, M, Y Major	Strong	Strong	Strong	Strong	Large	6
Empire Wind I and II OCS-A 0512 2030	14.1 (22.7) **Moderate**	0 (0)–40.7 (65.5) **Major**	34.9 (56.1) **Minor**				R, AL, N, H, O, M, Y Major	Strong	Strong	Strong	Strong	Large	6
Ocean Wind 1 OCS-A-0498 2025	15.3 (24.6) **Major**	0 (0)–39.6 (63.7) **Major**	15.5 (24.9) **Major**				R, AL, N, H, O, M, Y Major	Strong	Strong	Strong	Strong	Large	6
Ocean Wind 2 OCS-A532 2030	9.2 (14.7) **Major**	0 (0)–39.6 (63.7) **Major**	15.5 (24.9) **Major**				R, AL, N, H, O, M, Y Major	Strong	Strong	Strong	Strong	Large	6

[1] The most conservative onshore case involves the seaward edge of the beach nearest the projects. The seascape unit edge is 3.45 miles (5.6 kilometers) offshore (New Jersey jurisdictional boundary).
[2] Noticeable elements: R = rotor, AL = aviation light, N = nacelle, H = hub, O = OSS, M = mid-tower light, Y = yellow tower base color.
[3] WTGs and OSS Prominence (visibility): 0 = Not visible. 1 = Visible only after extended study; otherwise not visible. 2 = Visible when viewing in general direction of the lease areas; otherwise likely to be missed by casual observer. 3 = Visible after brief glance in general direction of the lease areas; unlikely to be missed by casual observer. 4 = Plainly visible; could not be missed by casual observer but does not strongly attract visual attention or dominate view. 5 = Strongly attracts viewers' attention to the lease areas; moderate to strong contrasts in form, line, color, or texture, luminance, or motion. 6 = Dominates view; strong contrasts in form, line, color, texture, luminance, or motion fill most of the horizontal FOV or vertical FOV (Sullivan et al. 2013).
[4] The seaward edge between landscape and seascape varies. The most conservative case is 0.2-mile (0.3-kilometer) landward distance from seaward beach edge.

Table H-52. NY Bight and other WTGs' cumulative open ocean, seascape, and landscape areas lease area distances, FOVs, noticeable elements, visual contrasts, scale of change, and prominence

Lease Area and Incremental Date	Distance in Miles (Kilometers)[1] and Impacts			FOV Degrees (% of 124°)			Noticeable Elements[2] and Impact Level	Visual Contrast, Scale of Change, and Prominence					
	Seascape[1]	Open Ocean	Landscape[4]	Seascape	Open Ocean	Landscape		Form	Line	Color	Texture	Scale	Prominence[3]
NY Bight (2030)	20.2 (32.6) **Moderate**	0 (0)–47.2 (68.4) **Major**	27.3 (44.0) **Minor**	136° (110%)	82° to 360° (66 to 290%)	136° (110%)	R, AL, N, H, O, M, Y Major	Strong	Strong	Strong	Strong	Large	6
Atlantic Shores Offshore Wind South OCS-A 0499 (2026)	8.7 (14.0) **Major**	0 (0)–42.5 (68.4) **Major**	9.0 (14.5) **Major**				R, AL, N, H, O, M, Y Major	Strong	Strong	Strong	Strong	Large	6

Empire Wind I and II OCS-A 0512 (2030)	14.1 (22.7) **Moderate**	0 (0)–40.7 (65.5) **Major**	34.9 (56.1) **Minor**				R, AL, N, H, O, M, Y Major	Strong	Strong	Strong	Strong	Large	6
Ocean Wind 1 OCS-A-0498 (2025)	15.3 (24.6) **Major**	0 (0)–39.6 (63.7) **Major**	15.5 (24.9) **Major**				R, AL, N, H, O, M, Y Major	Strong	Strong	Strong	Strong	Large	6
Ocean Wind 2 OCS-A532 (2030)	9.2 (14.7) **Major**	0 (0)–39.6 (63.7) **Major**	15.5 (24.9) **Major**				R, AL, N, H, O, M, Y Major	Strong	Strong	Strong	Strong	Large	6

[1] The most conservative onshore case involves the seaward edge of the beach nearest the projects. The seascape unit edge is 3.45 miles (5.6 kilometers) offshore (New Jersey jurisdictional boundary).
[2] Noticeable elements: R = rotor, AL = aviation light, N = nacelle, H = hub, O = OSS, M = mid-tower light, Y = yellow tower base color.
[3] WTGs and OSS Prominence (visibility): 0 = Not visible. 1 = Visible only after extended study; otherwise not visible. 2 = Visible when viewing in general direction of the lease areas; otherwise likely to be missed by casual observer. 3 = Visible after brief glance in general direction of the lease areas; unlikely to be missed by casual observer. 4 = Plainly visible; could not be missed by casual observer but does not strongly attract visual attention or dominate view. 5 = Strongly attracts viewers' attention to the lease areas; moderate to strong contrasts in form, line, color, or texture, luminance, or motion. 6 = Dominates view; strong contrasts in form, line, color, texture, luminance, or motion fill most of the horizontal FOV or vertical FOV (Sullivan et al. 2013).
[4] The seaward edge between landscape and seascape varies. The most conservative case is 0.2-mile (0.3-kilometer) landward distance from seaward beach edge.

Table H-53. Non-NY Bight projects' cumulative viewer experience WTG distances, FOVs, noticeable elements, visual contrasts, scale of change, and prominence
