Abstract:

The *South Fork Wind Farm and South Fork Export Cable Project Final Environmental Impact Statement* (final EIS) assesses the reasonably foreseeable impacts to physical, biological, socioeconomic, and cultural resources that could result from the construction and installation, operations and maintenance, and conceptual decommissioning of a commercial-scale wind energy project, the South Fork Wind Farm and South Fork Export Cable Project (the Project), located in the area covered by BOEM Renewable Energy Lease Number OCS-A 0517, approximately 19 miles southeast of Block Island, Rhode Island, and 35 miles east of Montauk Point, New York.

South Fork Wind, LLC, is proposing the Project, which is designed to contribute to New York's renewable energy requirements, particularly, the state's goal of generating 9,000 megawatts of offshore wind energy by 2030. BOEM has prepared the EIS following the requirements of the National Environmental Policy Act (42 USC 4321–4370f) and implementing regulations. This final EIS will inform BOEM in deciding whether to approve, approve with modifications, or disapprove the Project. Cooperating agencies will rely on the final EIS to support their decision making and to determine if the analysis is sufficient to support their decision. BOEM's action furthers United States policy to make the Outer Continental Shelf energy resources available for development in an expeditious and orderly manner, subject to environmental safeguards (43 USC 1332(3)), including consideration of natural resources and existing ocean uses.

EXECUTIVE SUMMARY

The *South Fork Wind Farm and South Fork Export Cable Project Final Environmental Impact Statement* (final EIS) assesses the reasonably foreseeable impacts to physical, biological, socioeconomic, and cultural resources that could result from the construction and installation, operations and maintenance (O&M), and conceptual decommissioning of a commercial-scale offshore wind energy facility and transmission cable to shore known as the South Fork Wind Farm (SFWF) and South Fork Export Cable (SFEC) Project (Project). The Bureau of Ocean Energy Management (BOEM) has prepared the final EIS under the National Environmental Policy Act (NEPA) (42 USC 4321–4370f).

Council on Environmental Quality (CEQ) NEPA regulations from 1978 were revised on July 26, 2020, and took effect on September 14, 2020. Because work on the EIS began before September 14, 2020, BOEM has followed the 1978 CEQ NEPA regulations. All following citations to CEQ NEPA regulations refer to the regulations before they were revised on July 26, 2020 (see 40 CFR 1506.13 of the revised regulations). The final EIS will inform BOEM's decision on whether to approve, approve with modifications, or disapprove the Project's construction and operations plan (COP).

Cooperating agencies may rely on this final EIS to support their decision-making. In conjunction with submitting its COP, SFW applied to the National Marine Fisheries Service (NMFS) for an incidental take authorization (ITA) under the Marine Mammal Protection Act (MMPA) of 1972, as amended (16 USC 1361 et seq.), for incidental take of marine mammals during Project construction. NMFS is required to review applications and, if appropriate, issue an ITA under the MMPA. In addition, NMFS has an independent responsibility to comply with NEPA and will rely on the information and analyses in BOEM's final EIS after independent review to fulfill its NEPA obligations. NMFS intends to adopt the final EIS and sign the record of decision (ROD), if appropriate. The U.S. Army Corps of Engineers (USACE) similarly intends to adopt the final EIS and sign the joint ROD in respect to its responsibilities under Section 404 of the Clean Water Act and Section 10 of the Rivers and Harbors Act of 1899.

Purpose of and Need for the Proposed Action

Through a competitive leasing process under 30 CFR 585.211, Deepwater Wind New England, LLC was awarded Commercial Lease OCS-A 0486 covering an area offshore Rhode Island. This lease was later assigned to South Fork Wind, LLC (SFW) and segregated to Commercial Lease OCS-A 0517 (the Lease). SFW has the exclusive right to submit a COP for activities within the area of the Lease (the Lease Area), and it has submitted a COP to BOEM proposing the construction and installation, O&M, and conceptual decommissioning of the Project.

The purpose of the Project is to develop a commercial-scale offshore wind energy facility in the Lease Area with wind turbine generators (WTGs), an offshore substation, and one transmission cable making landfall in Suffolk County, New York. The Project would contribute to New York's renewable energy requirements, particularly the state's goal of 9,000 MW of offshore wind energy generation by 2030. In addition, SFW's goal is to fulfill its contractual commitments to Long Island Power Authority (LIPA) pursuant to a power purchase agreement executed in 2017 resulting from LIPA's technology-neutral competitive bidding process.

The purpose of BOEM's action is to respond to and determine whether to approve, approve with modifications, or disapprove the COP to construct and install, operate and maintain, and decommission a commercial-scale offshore wind energy facility within the Lease Area. BOEM's action is needed to further the United States' policy to make Outer Continental Shelf (OCS) energy resources available for expeditious and orderly development, subject to environmental safeguards (43 USC 1332(3)), including consideration of natural resources and existing ocean uses. In addition, other federal agencies may consider requests for authorizations related to the Project under applicable laws and regulations not administered by BOEM. These considerations differ from BOEM's consideration of the Proposed Action but they are related and constitute connected actions under 40 CFR 1508.25, with discrete purposes and needs based on their respective statutory and regulatory obligations. The purpose and need of other federal agencies' action is to evaluate the applicant's request pursuant to specific requirements of the statutes and implementing regulations administered by those agencies, considering impacts of the applicant's activities on relevant resources, and if appropriate, issue the permit or authorization.

Public Involvement

Before the preparation of the EIS, BOEM conducted a 30-day public comment period and held three public scoping meetings near the Lease Area to solicit feedback and identify issues and potential alternatives for consideration. BOEM considered all scoping comments while preparing the EIS; the topics most referenced in the comments include commercial fisheries and for-hire recreational fishing; finfish, invertebrates, and essential fish habitat; the NEPA process; socioeconomics; and alternatives. Additional public input occurred during the Project's planning and leasing phases between 2010 and 2018. Publication of the draft EIS initiated a 45-day comment period open to all, after which BOEM assessed and considered all the comments received in preparation of the final EIS. See Appendix A for additional information on public involvement.

Alternatives

The final EIS analyzes in detail a No Action alternative and three action alternatives, as briefly described below. Chapter 2 provides detailed descriptions of the analyzed alternatives.

- <u>No Action alternative</u>: Under this alternative, BOEM would not approve the COP, and Project construction and installation, O&M, and conceptual decommissioning activities would not occur. Any potential environmental and socioeconomic impacts, including benefits, associated with the Project as described under the Proposed Action would not occur.
- <u>Proposed Action</u>: Under this alternative, the construction and installation, O&M, and conceptual decommissioning of up to 15 wind turbine generators (WTGs) in the 6- to 12-MW range and an offshore substation (OSS) within the Lease Area (including the expanded area) and associated export cables would occur within the range of design parameters outlined in the COP, subject to applicable mitigation measures. SFW would space WTGs in a uniform east–west and north–south grid with 1 × 1–nautical-mile (nm) spacing between WTGs and diagonal transit lanes at least 0.6 nm wide. This configuration would still allow micrositing of WTGs to avoid sensitive cultural resources and marine habitats.
- <u>Vessel Transit Lane alternative (Transit alternative)</u>: Under this alternative, BOEM evaluated a 4-nm-wide vessel transit lane[1] through the Lease Area where no surface occupancy would occur. BOEM developed this alternative in response to the January 3, 2020, Responsible Offshore Development Association (RODA) layout proposal (RODA 2020). The RODA proposal includes designated transit lanes, each at least 4 nm wide. Although the proposal includes six total transit lanes, only one lane intersects the Lease Area. The vessel transit lane is unique to this alternative and could facilitate transit of vessels through the Lease Area from southern New England and eastern Long Island ports to fishing areas in the region. WTGs located within the transit lane would be eliminated under this alternative. SFW would develop the remaining WTGs with a 12-

[1] BOEM also evaluated a 2-nm and 3-nm transit lane alternative. However, these smaller lanes would result in the same impacts as the Proposed Action because the lane would not overlap any proposed WTGs or the OSS. Therefore, a smaller lane width was dismissed from further evaluation.

MW turbine capacity and would move the offshore substation north of the currently proposed location and install it in one of the remaining WTG locations. The Transit alternative is within the proposed design envelope of up to 15 turbines in the 6- to 12-MW range. This alternative would disclose the effect a transit lane could have on the expected effects from the other action alternatives analyzed in the final EIS.

- Fisheries Habitat Impact Minimization alternative (Habitat alternative): Under this alternative, the construction and installation, O&M, and conceptual decommissioning of WTGs and an OSS within the Lease Area and associated inter-array and export cables would occur within the range of design parameters outlined in the COP, subject to applicable mitigation measures. However, to reduce impacts to complex fisheries habitats as compared to the Proposed Action, BOEM would require SFW to exclude certain WTGs and associated cable locations, if micrositing is not possible to maintain a uniform east–west and north–south grid of 1 × 1–nm spacing between WTGs with diagonal transit lanes of at least 0.6 nm wide. Under the Habitat alternative, BOEM may approve fewer WTG locations than proposed by SFW. Two options for layout of this alternative are considered in this EIS: Habitat alternative layout (a) Conservation Recommendations from the National Oceanic and Atmospheric Administration (NOAA) (June 7, 2021) and Habitat alternative layout (b) SFW Technical Memorandum (June 14, 2021). These options are described in Section 2.1.3. BOEM considers Habitat alternative layout (a) to be the preferred alternative.

Environmental Impacts

The final EIS uses four levels of classification to characterize the potential adverse or beneficial impacts as negligible, minor, moderate, or major. Chapter 2, Section 2.3 provides a detailed comparison of impacts by alternative, whereas Table ES-1 provides a summary of key findings for the Proposed Action. Impacts include both Project-specific impacts and incremental impacts of the Project when combined with other current and reasonably foreseeable projects (i.e., cumulative impacts). Where directionality (e.g., adverse or beneficial) is not specifically noted, the reader should assume the impact is adverse.

Impacts associated with the other action alternatives are generally similar to those described for the Proposed Action. See Section 3.1 for additional information on impact levels, and Sections 3.3 through 3.5 for detailed descriptions of the impacts for each resource under each alternative. CEQ NEPA implementing regulations (40 CFR 1502.16) require that an EIS evaluate the potential for unavoidable adverse impacts associated with a proposed action. The same regulations also require that an EIS review the potential impacts on irreversible or irretrievable commitments of resources resulting from implementation of a proposed action. Chapter 4 of the final EIS provides these disclosures.

Table ES-1. Key Environmental Impact Statement Findings for the Proposed Action

Resource	Proposed Action
Air quality	Minor to moderate temporary adverse impacts to air quality in the region due to construction and installation, O&M, and conceptual decommissioning, as well as minor beneficial, long-term air quality and reduced health event impacts. The overall cumulative impacts to air quality would be minor adverse and minor beneficial.
Water quality	Negligible to moderate temporary impacts to onshore surface water and groundwater quality and offshore water quality from erosion, sediment resuspension and deposition and scouring, discharges, and inadvertent spills. Onshore and offshore, overall cumulative impacts to water quality would be minor.
Bats	Negligible to minor adverse temporary to long-term impacts on bats and suitable habitat from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative adverse impacts would be minor.

Resource	Proposed Action
Benthic habitat, essential fish habitat (EFH), invertebrates, and finfish	Negligible to moderate impacts on benthic habitat, EFH, invertebrates, and finfish from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative impacts to benthic habitat, EFH, invertebrates, and finfish would be moderate.
Birds	Negligible to minor impacts on birds and suitable habitat from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative impacts would be minor.
Marine mammals	Negligible to moderate impacts, as well as minor beneficial impacts from construction and installation, O&M, and conceptual decommissioning activities, varying by species. Overall cumulative adverse impacts would be moderate adverse and minor to moderate beneficial.
Terrestrial and coastal habitats and fauna	Negligible to minor impacts to terrestrial and coastal habitats and fauna from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative adverse impacts would be minor.
Sea turtles	Negligible to minor impacts from elevated underwater noise from construction, vessel traffic, and accidental discharges of spills or trash. Overall cumulative impacts would be minor adverse and minor beneficial.
Wetlands and other waters of the United States (WOTUS)	Short- to long-term negligible to minor adverse impacts to wetlands and WOTUS from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative adverse impacts would be minor.
Commercial fisheries and for-hire recreation fishing	Negligible to major adverse construction and installation, O&M, and conceptual decommissioning impacts to commercial fisheries and for-hire recreational fishing due to increased port congestion; changes to fishing access, primarily through reduced fishing opportunity when construction activities are occurring; damage to or loss of fishing gear; and impacts on the catch due to changes in target species abundance or availability during construction activities. The “reef effect” of WTG foundations and associated scour protection would have minor beneficial impacts to for-hire recreational fisheries, depending on the extent to which the foundations enhance fishing opportunities. Overall cumulative adverse impacts would be major.
Cultural resources	Negligible to major adverse impacts to marine and terrestrial archaeological resources and to historic visual resources from Project construction and installation, O&M, and conceptual decommissioning activities. Overall cumulative adverse impacts would be negligible to major across marine, terrestrial and viewshed resources.
Demographics, employment, and economics	Negligible to minor adverse and minor to moderate beneficial impacts to the socioeconomic analysis area in terms of employment, federal revenue, and income. Overall cumulative impacts would be minor adverse and minor beneficial.
Environmental justice	Negligible to moderate adverse impacts to minority or low-income populations and tribes from the Project construction and installation, O&M, and conceptual decommissioning activities. Overall cumulative adverse impacts would be minor to moderate adverse and minor beneficial.
Land use and coastal infrastructure	Minor beneficial impacts to land use due to increased compatible uses at ports, whereas construction or conceptual decommissioning of onshore components would have negligible to moderate, temporary adverse impacts due to disturbance associated with onshore construction, including traffic delays and re-routing. Overall cumulative impacts would be minor adverse and minor beneficial.
Navigation and vessel traffic	Negligible to minor impacts on navigation and vessel traffic in the region from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative adverse impacts would be moderate.
Other marine uses	Negligible to major impacts to mineral extraction, military use, air traffic, land-based radar services, cables and pipelines, and scientific surveys. Overall cumulative adverse impacts would be minor for most uses. However, the overall impact would be moderate adverse for some military uses and radar and major adverse for scientific research and protected species surveys.
Recreation and tourism	Negligible to minor impacts to recreation and tourism due to Project construction and conceptual decommissioning activities. O&M and conceptual decommissioning of offshore Project activities could elicit both beneficial and adverse impacts to recreational use of resources within the viewshed of the WTGs. Overall cumulative impacts would be minor adverse and minor beneficial.
Visual resources	Negligible to major, adverse impacts on non-historic visual resources from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative adverse impacts would be minor to moderate, as the viewshed would return to previous condition after conceptual decommissioning.

CHAPTER 1. INTRODUCTION

1.1 BACKGROUND

This chapter introduces a proposed offshore wind energy project, the South Fork Wind Farm and South Fork Export Cable Project (the Project). On June 29, 2018, South Fork Wind, LLC (SFW)[2] submitted a Project construction and operations plan (COP) to BOEM. After addressing BOEM's comments on this initial COP, SFW resubmitted an updated COP on May 24, 2019. SFW submitted a second updated COP for the Project in February 2020, a third updated COP in July 2020, and a fourth updated COP in May 2021 (Jacobs 2021)[3]. Information regarding the planning and leasing process that occurred before the development of the initial COP is available on BOEM's website and in Section 2 of the COP.

The Project would be located in the area of BOEM's Renewable Energy Lease Number OCS-A 0517 (Lease Area) approximately 19 miles southeast of Block Island, Rhode Island, and 35 miles east of Montauk Point, New York (Figure 1.2-1) in the Atlantic Ocean. In this document, distances in miles are in statute miles (miles used in the traditional sense) or nautical miles (miles used specifically for marine navigation). Statute miles are more commonly used and are referred to simply as *miles*, whereas nautical miles are referred to by name or by their abbreviation *nm*.

The COP describes the construction and installation, operations and maintenance (O&M), and conceptual decommissioning of the Project, which consists of the following components (see Project Operational Concept [Figure 1.1-1] in the COP):

- SFWF: This would include up to 15 wind turbine generators (WTGs or turbines), submarine cables between the WTGs (inter-array cables), and an offshore substation (OSS). The SFWF would also include an onshore O&M facility.
- SFEC: This would include an alternating current (AC) electric cable and an interconnection facility that connects the SFWF to the existing mainland electric grid in East Hampton, New York, and delivers power to the South Fork of Suffolk County, Long Island.

BOEM has prepared this final environmental impact statement (final EIS) in accordance with the National Environmental Policy Act (NEPA) to consider and disclose potential environmental impacts associated with the construction and installation, O&M, and conceptual decommissioning of the Project. This final EIS will inform BOEM in deciding whether to approve, approve with modifications, or disapprove the COP. Publication of the draft EIS initiated a 45-day comment period. BOEM assessed and considered the comments received during the comment period in the preparation of this final EIS. The final EIS has 10 appendices. Appendix A describes required environmental permits and consultations; Appendix B provides a list of preparers and reviewers, references cited, and glossary; Appendix C provides additional figures; Appendix D describes the Project design envelope (PDE) and maximum-case scenario; Appendix E describes the cumulative activities scenario; Appendix F provides supplemental information to the final EIS; Appendix G describes environmental protection measures, mitigation, and monitoring; Appendix H provides an assessment of resources with negligible to minor impacts from implementation of the Proposed Action and other considered alternatives; Appendix I provides BOEM's response to all comments received during the draft EIS 45-day comment period; and Appendix J provides a summary of any incomplete or unavailable information identified during preparation of the final EIS.

---

[2] On November 7, 2018, Orsted completed an acquisition of all of the equity of Deepwater Wind. A new company, Orsted US Offshore Wind, combines the personnel and assets of the two North American offshore wind developers. Orsted also subsequently renamed the subsidiary as SFW. However, Deepwater Wind New England, LLC submitted their COP prior to this ownership and name change. Therefore, the EIS refers to SFW throughout.

[3] The most recent COP—*South Fork Wind Farm and South Fork Export Cable Construction and Operations Plan*—is referred to frequently throughout the EIS, and therefore the author-date citation is provided here at first mention only.

1.2 PURPOSE OF AND NEED FOR THE PROPOSED ACTION

Through a competitive leasing process under 30 CFR 585.211, Deepwater Wind New England, LLC was awarded Commercial Lease OCS-A 0486 covering an area offshore Rhode Island. This lease area was later assigned to SFW and segregated to Commercial Lease OCS-A 0517 (Lease). SFW has the exclusive right to submit a COP for activities within the area of the Lease (Lease Area), and it has submitted a COP to BOEM proposing the construction and installation, O&M, and conceptual decommissioning of the Project.

The purpose of the Project is to develop a commercial-scale offshore wind energy facility in the Lease Area with WTGs, an offshore substation, and one transmission cable making landfall in Suffolk County, New York. The Project would contribute to New York's renewable energy requirements, particularly the state's goal of developing 9,000 MW of offshore wind energy generation by 2030. In addition, SFW's goal is to fulfill its contractual commitments to Long Island Power Authority (LIPA) pursuant to a power purchase agreement executed in 2017 resulting from LIPA's technology-neutral competitive bidding process.

The purpose of BOEM's action is to respond to and determine whether to approve, approve with modifications, or disapprove the COP to construct and install, operate and maintain, and decommission a commercial-scale offshore wind energy facility within the Lease Area. BOEM's action is needed to further the United States' policy to make Outer Continental Shelf (OCS) energy resources available for expeditious and orderly development, subject to environmental safeguards (43 USC 1332(3)), including consideration of natural resources and existing ocean uses. In addition, other federal agencies may consider requests for authorizations related to the Project under applicable laws and regulations not administered by BOEM. These considerations differ from BOEM's consideration of the Proposed Action but they are related and constitute connected actions under 40 CFR 1508.25, with discrete purposes and needs based on their respective statutory and regulatory obligations. The purpose and need of other federal agencies' action is to evaluate the applicant's request pursuant to specific requirements of the statutes and implementing regulations administered by those agencies, considering impacts of the applicant's activities on relevant resources, and if appropriate, issue the permit or authorization.

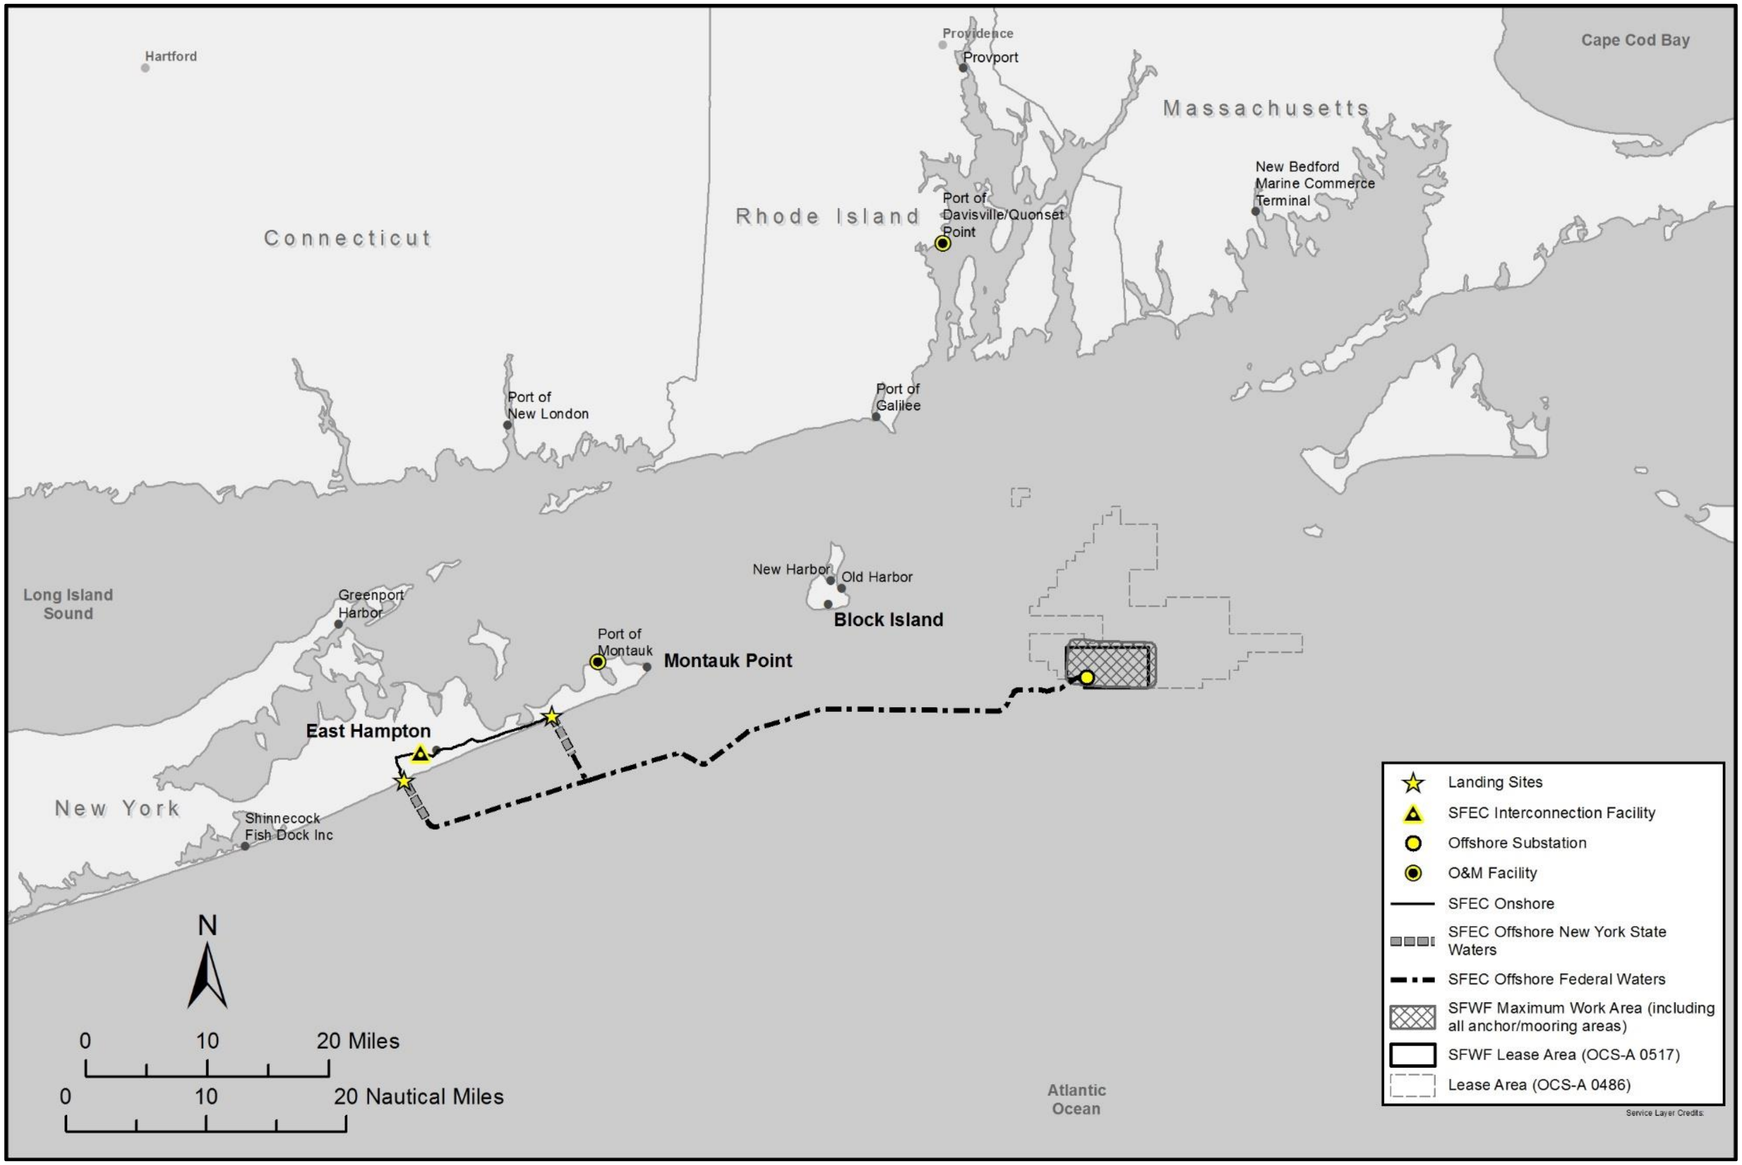

Figure 1.2-1. Project location

1.3 REGULATORY FRAMEWORK

The Energy Policy Act of 2005 (Public Law No. 109-58) added Section 8(p)(1)(C) to the Outer Continental Shelf Lands Act (OCSLA; 43 USC 1331 et seq.), which authorized the Secretary of the Interior to issue leases, easements, or rights-of-way (ROWs) on the OCS for wind energy development (see 43 USC 1337(p)(1)(C)). The Secretary of the Interior delegated this authority to the former Minerals Management Service (MMS), now BOEM. Final regulations implementing this authority at 30 CFR part 585 were promulgated on April 22, 2009.

Under the renewable energy regulations, BOEM's issuance of leases and subsequent approval of wind energy development on the OCS are part of a staged decision-making process (BOEM 2017). In that process, the action here is the fourth phase: evaluation of a COP. BOEM may approve, approve with modifications, or disapprove a lessee's COP (see 30 CFR 585.620–585.638). If BOEM approves—or approves with modifications—a COP, the lessee must submit a facility design report and a fabrication and installation report. If BOEM does not object to the facility design report and/or fabrication and installation report, or once any objections are resolved, the lessee may construct and operate the Project for 25 years from the date of COP approval (plus up to an additional 2 years for conceptual decommissioning). BOEM will periodically review the activities conducted under an approved COP. The frequency and extent of the review will be based on the significance of any changes in available information and on onshore or offshore conditions affecting, or affected by, the activities conducted under the COP. If the review indicates that the COP should be revised to meet the requirement of BOEM's renewable energy regulations, the lessee will be required to submit the needed revisions (30 CFR 585.634(b)).

Cooperating agencies may rely on this final EIS to support their decision-making. In conjunction with submitting its COP, SFW applied to the National Marine Fisheries Service (NMFS) for an incidental take authorization (ITA) under the Marine Mammal Protection Act (MMPA) of 1972, as amended (16 USC 1361 et seq.), for incidental take of marine mammals during Project construction. NMFS is required to review applications and, if appropriate, issue an ITA under the MMPA. In addition, NMFS has an independent responsibility to comply with NEPA and intends, after independent review, to rely on the information and analyses in BOEM's final EIS to fulfill its NEPA obligations. NMFS intends to adopt the final EIS and sign the record of decision (ROD), if appropriate. The U.S. Army Corps of Engineers (USACE) similarly intends to adopt the final EIS and sign the joint ROD in respect to its responsibilities under Section 404 of the Clean Water Act and Section 10 of the Rivers and Harbors Act of 1899. Appendix A provides a description of BOEM's consultation efforts in the development of the final EIS. SFW would be required to construct and install, operate and maintain, and decommission the Project in compliance with the terms and conditions of all required permits and approvals.

On July 16, 2020, the Council on Environmental Quality (CEQ), which is responsible for federal agency implementation of NEPA, revised the regulations for implementing the procedural provisions of NEPA (85 CFR 43304–43376). The revised regulations went in effect on September 14, 2020. Because BOEM's NEPA review of the Project and publication of the Project's notice of intent began prior to this effective date, the EIS was prepared under the previous version of the regulations (1978, as amended in 1986 and 2005).

The final EIS evaluates various alternatives to meet the need to execute BOEM's duty to approve, approve with modifications, or disapprove the COP. This was done in furtherance of BOEM's responsibility to make OCS energy resources available for development in an expeditious and orderly manner, subject to environmental safeguards (43 USC 1332(3)), including consideration of natural resources and existing ocean uses. This responsibility balances different goals and does not hold one as controlling all others, which is consistent with the opinion recently issued by the Solicitor, M-37067, "Secretary's Duties under Subsection 8(p)(4) of the Outer Continental Shelf Lands Act When Authorizing Activities on the Outer Continental Shelf" (U.S. Department of the Interior Office of the Solicitor 2021). M-37067 provides that "subsection 8(p)(4) of OCSLA and similar statutes require only that the Secretary strike a rational balance between Congress's enumerated goals, i.e., a variety of uses. In making this determination, the Secretary retains wide discretion to weigh those goals as an application of her technical expertise and policy judgment" (U.S. Department of the Interior Office of the Solicitor 2021:2).

1.4 RELEVANT EXISTING NATIONAL ENVIRONMENTAL POLICY ACT AND CONSULTING DOCUMENTS

BOEM has conducted several other environmental analyses that were used to inform the EIS. Consistent with the CEQ directive "Incorporation by reference" (40 CFR 1502.21), the incorporated material is cited and briefly described in the final EIS.

1.5 INCOMPLETE AND UNAVAILABLE INFORMATION

Under 40 CFR 1502.22, BOEM is required to identify any incomplete or unavailable information that is relevant to the evaluation of potential Project impacts. Appendix J identifies incomplete or unavailable information that is essential to a reasoned choice among alternatives.

1.6 METHODOLOGY FOR ASSESSING THE DESIGN ENVELOPE

The Project is being developed based on an envelope approach, consistent with BOEM's *Draft Guidance Regarding the Use of a Project Design Envelope in a Construction and Operations Plan* (BOEM 2018). This approach is intended to provide flexibility for lessees and minimize the need for subsequent NEPA reviews as the Project design is refined.

The final EIS assesses the impacts of a range of characteristics and locations for components that would be considered as part of the Proposed Action and other action alternatives using a "maximum-case scenario" process. Through the maximum-case scenario process, BOEM analyzes the aspects of each design parameter or combination of parameters that would result in the greatest impact for each physical, biological, socioeconomic, and cultural resource (see Appendix D for list of parameter specifications). Through consultation with its own engineers and outside industry experts, BOEM verified that the maximum-case scenario analyzed in the final EIS could reasonably occur.

1.7 METHODOLOGY FOR ASSESSING CUMULATIVE IMPACTS

Cumulative impacts are the incremental effects of the Proposed Action on the environment when added to other past, present, and reasonably foreseeable future actions, regardless of which agency or person undertakes the actions (see 40 CFR 1508.7). Appendix E provides a description of the resource-specific geographic analysis areas and analyzes the impacts of the types of actions (including the future action of approving wind farm development activities other than the Project) that BOEM has identified as potentially contributing to cumulative impacts when combined with impacts from the Proposed Action and other alternatives over the geography and time scale identified.

In 2019, BOEM released a study of impact-producing factors (IPFs) from renewable energy projects on the North Atlantic OCS (BOEM 2019). As noted, in addition to the general cumulative analysis associated with onshore and offshore non-wind activities, the EIS specifically discloses the cumulative impacts of relevant IPFs from offshore wind by resource. Where possible, BOEM provides a quantitative estimate of these offshore wind impacts. However, readers of the final EIS should not consider these results as absolute values or predictions of actual future conditions. Although BOEM estimates represent the best tool currently available to inform the impact analysis in the final EIS, it is not possible to precisely predict future conditions. Correspondingly, estimates are based on past experience and trends and represent reasonable assumptions about future behaviors.

This page intentionally left blank.

CHAPTER 2. ALTERNATIVES INCLUDING THE PROPOSED ACTION

2.1 ALTERNATIVES

This chapter describes in detail three action alternatives and a No Action alternative for the Project. Chapter 2, Section 2.1.5 provides a discussion of the alternative development process and alternatives not carried forward for analysis, whereas Chapter 2, Section 2.3 provides a summary and comparison of impacts by alternative.

2.1.1 Proposed Action Alternative

The SFWF and SFEC are the two primary components of the Project (see Figure 1.2-1). The Project uses a design envelope approach, consistent with BOEM's *Draft Guidance Regarding the Use of a Project Design Envelope in a Construction and Operations Plan* (BOEM 2018). This approach results in a range of characteristics and locations for some components of the Proposed Action. Chapter 1, Section 1.6 and Appendix D provide additional information on the PDE approach. The SFWF maximum work area (MWA) used during construction and installation would encompass the Lease Area as well as a buffer of approximately 2,070 feet around the outer edge of the proposed WTG layout (for increased temporary workspace, as described in Section 3.1.1 of the COP). However, only a small portion of the Lease Area would be permanently developed and occupied by Project components (see Table 2.1.1-1).

2.1.1.1 South Fork Wind Farm Component

SFWF would be located within federal waters (Atlantic Ocean) on the OCS, specifically in the Lease Area, approximately 16.6 nm (19 miles) southeast of Block Island, Rhode Island, and 30.4 nm (35 miles) east of Montauk Point, New York. Table 2.1.1-1 summarizes the SFWF components. The sections that follow Table 2.1.1-1, Section 3.1 of the COP, and Appendix D provide additional details. A detailed map showing the location of all proposed WTGs, inter-array cables, and the offshore substation is provided in Figure 3.1-1 in the COP

Table 2.1.1-1. South Fork Wind Farm Components and Footprint

Project Component	Location	Project Envelope Characteristic	Construction and Installation Footprint (temporary)	Operation Footprint (permanent)
WTGs	Offshore	Up to 15 WTGs; 6 to 12 MW each; sited in a grid with a spacing of approximately 1.0 nm (1.9 km, 1.15 miles) × 1.0 nm (1.9 km, 1.15 miles) that aligns with other proposed adjacent offshore wind projects in the Rhode Island/Massachusetts Wind Energy Area	17,202 acres (MWA)	840 feet, measured from mean lower water level to the tip of the blade
Foundations	Offshore	Monopile with piles up to 11 meters in diameter	14.8 acres	14.6 acres
		Foundation cable protection	Not applicable (N/A)	7.5 acres

Project Component	Location	Project Envelope Characteristic	Construction and Installation Footprint (temporary)	Operation Footprint (permanent)
Inter-array cable	Offshore	34.5-kilovolt (kV) or 66-kV cable	340 acres	2.5 acres
		Cable protection	N/A	10.2 acres
OSS	Offshore	Mounted on a dedicated framework or co-located with a WTG	Same as foundations (see above)	If on dedicated framework: 150 to 200 feet, measured from mean sea level to the top of the substation. If collocated with a WTG: total maximum height of the OSS plus WTG would not exceed the height of other WTGs.
Vessel anchoring / mooring	Offshore	Six vessels used during anchoring/mooring	821 acres	N/A
O&M facility	Onshore	Located in Montauk, New York, or Quonset Point, Rhode Island	Montauk: dredge footprint of up to 37,350 square feet	7,600 to 12,000 square feet of office and storage space (all locations) 37.250 square feet of annual maintenance dredging
Port facilities	Onshore	Located in New York, Rhode Island, Massachusetts, Connecticut, New Jersey, Maryland, or Virginia	N/A (the SFWF would use existing facilities only.)	N/A (the SFWF would use existing facilities only.)

Source: Jacobs (2021).

Note: Table 3.1-1 in the COP provides a detailed description of assumptions used to develop the footprint estimates.

2.1.1.1.1 WIND TURBINE GENERATORS

The SFWF would consist of up to 15 WTGs. SFW has committed to an indicative layout with WTGs sited in a grid with a spacing of approximately 1.0 nm (1.9 kilometers [km], 1.15 miles) × 1.0 nm (1.9 km, 1.15 miles) that aligns with other proposed adjacent offshore wind projects in the Rhode Island/Massachusetts Wind Energy Areas (RI-MA WEAs). Each WTG would comprise the following major components: a tower, nacelle (a cover housing the generator, gear box, drive train, and brake assembly), and rotor that includes the blades. Figure 3.1-3 in the COP provides typical dimensions for different WTG size classes that could be used for the Project. Control, lighting, marking, and safety systems would be installed on each WTG. Each WTG would also contain small amounts of lubrication, grease, oil and cooling fluids, as well as heating, ventilation, and air conditioning for climate control. If needed, a small, temporary diesel generator could also be placed at each WTG on the work deck of the foundation, with a maximum power of 200 horsepower (hp) and up to a 50-gallon diesel tank with secondary containment. Each WTG would also have helicopter access by means of winching personnel onto and/or from a landing area. Fugro (2018), SFWF (2017, 2016a, 2016b), and Jacobs (2021) provide additional design details.

2.1.1.1.2 FOUNDATIONS

Each WTG would be supported by one steel monopile foundation installed into the seabed, as shown in COP Figure 3.1-2. Fugro (2018), SFWF (2017, 2016a, 2016b), and Jacobs (2021) provide additional design details.

2.1.1.1.3 INTER-ARRAY CABLES

Inter-array cables would connect individual WTGs and transfer power between the WTGs and the OSS. The inter-array cables would either be a 34.5-kilovolt (kV) or a 66-kV three-phase, AC, 6- to 12-inch-diameter cables. The cables would contain three conductors, screens, insulators, fillers, sheathing, armor, and fiber optic cables; they would not contain lubricants, liquids, oils, or insulating fluids. The cables would be buried in a seabed trench to a target depth of 4 to 6 feet, for a total estimated maximum distance of 21.4 miles long. Where the inter-array cable emerges from the trench and is attached to the foundation, cable protection (rock or engineered concrete mattresses) would be used. Similarly, additional cable protection would be used to protect portions of the inter-array cable that did not achieve the target burial depth (see Table 3.1-4 in the COP and Fugro [2021] for details).

Fugro (2018), SFWF (2017, 2019a, 2019b), and Jacobs (2021) provide additional inter-array cable design details.

2.1.1.1.4 OFFSHORE SUBSTATION

The OSS would collect electric energy generated by the WTGs through the inter-array cables. The OSS would also house the supervisory control and data acquisition system that serves as the means for wind farm monitoring and control between the WTGs, substation, and onshore O&M facility. The OSS would consist of a high and secondary medium-voltage power transformer, a reactor, and switchgears along with utility equipment and a small permanent diesel generator. The OSS could also include boat landing and helicopter access (i.e., helideck) for emergency transport and limited maintenance activities, including transport of crew and supplies. The OSS would be either 1) located above water on a platform supported by a foundation similar to those used for the WTGs and would be in line with the WTG's east–west and north–south grid of 1 × 1–nm spacing, or 2) collocated on a foundation with a WTG (see Figure 3.1-4 in the COP).

2.1.1.1.5 OPERATIONS AND MAINTENANCE FACILITY

The O&M facility would include the potential construction of a building, installation of a stationary land-based crane, and installation of one floating pontoon dock (floating dock) for crew transfer vessels so that O&M staff could prepare and mobilize for offshore maintenance activities. The O&M facility would be located in Montauk, New York, or Quonset Point, Rhode Island. The O&M facility would also include office and storage space for spare parts and other equipment.

In-water work would not be required at the Quonset Point location. If the Lake Montauk location is selected, modifications would be required for the in-water portions of the site, which currently functions as a marina (BOEM 2021). To allow for suitable depths for navigation and berthing of crew transfer vessels, dredging would be required; approximately 2,500 cubic yards of sediment would be dredged within a dredge footprint of up to 1,500 square feet to a depth of 12.4 feet below the plane of mean low water, including a 1-foot overdredge. Maintenance dredging of up to 40,500 cubic feet of sediment would be required annually over a 10-year period. Dredged materials would be loaded into scows that, once full, would be transported to the adjacent beach west of the Montauk Harbor entrance, where sediment would be pumped to shore and used as nourishment material. This beach was identified by the Town of East Hampton as requiring beach nourishment. The total volume of dredged material proposed to be placed below the plane of spring high water is 1,070 cubic yards and the total area of beach to be occupied by the dredged material is 51,000 square feet. The total area of beach below the plane of spring high water to be occupied by the dredged material is 21,900 square feet. Dredging would require one dredge barge, three disposal scows, tugboats to aid in the positioning of equipment, and small vessels for transporting crews and materials to and from the shore.

Other potential in-water work at the Lake Montauk location would include maintenance repairs to the existing bulkhead (i.e., new water and tie rods). One 100 × 16–foot floating dock would also be installed to support berthing a single crew transfer vessel that would be used to move staff and equipment between the O&M facility and offshore portions of the Project. To accommodate the pontoon dock, the piles and docks associated with the existing marina would be removed, and five 2-foot-diameter steel pipe piles would be installed to anchor the pontoon floating dock. One additional 2-foot-diameter steel pipe pile would be installed at the eastern end of the pontoon dock to provide safe berthing conditions (i.e., mooring dolphin). Piles would be driven to the engineered penetration depth and cut at a +15 foot North American Vertical Datum top of pipe elevation. One 4 × 28–foot aluminum gangway would be installed to provide access to the floating dock. Installation of the floating dock would require the use of a deck barge with a crane, small work boats, and a tugboat.

2.1.1.1.6 PORT FACILITIES

The Project would use existing port facilities located in New York, Rhode Island, Massachusetts, Connecticut, New Jersey, Maryland, Virginia, or Nova Scotia for offshore construction, staging and fabrication, crew transfer, and logistics support. Modifications of these ports specifically for the Project are not anticipated. Final port selection has not been determined at this time; Table 3.1-5 in the COP provides a summary of potential ports that could be used to support the Project.

2.1.1.2 South Fork Export Cable Component

The SFEC is an AC electric cable and interconnection facility that would connect the SFWF to the existing mainland electric grid in East Hampton, New York, and deliver power to the South Fork of Suffolk County, Long Island. The SFEC would be located offshore, in both federal waters and New York state waters, and onshore in East Hampton, New York (see COP Figure 1.1-2). Table 2.1.1-2 summarizes the distances for each segment of the SFEC by landing site. Additional details on these segments and the SFEC components follow the table.

Table 2.1.1-2. Distances for Each Segment of the South Fork Export Cable by Landing Site

SFEC Segment	Landing Site	
	Beach Lane (miles)	Hither Hills (miles)
Offshore federal waters	58.3	46.0
Offshore New York State waters	3.5	3.5
Onshore	4.1	11.5

2.1.1.2.1 OFFSHORE SEGMENTS

The SFEC would extend westward through federal waters from the OSS, pass south of Block Island, and cross into state waters 3 nm offshore New York State. The SFEC would consist of a buried 138-kV submarine power cable, with one segment of single three-core conductor and fiber optic cable for communication and control. The SFEC would be approximately 8 to 12 inches in diameter and installed to a target burial depth of 4 to 6 feet. Additional cable protection or armoring would be installed in locations where the target burial depth is not achieved (see Tables 3.2-2 and 3.2-3 in the COP for details).

2.1.1.2.2 ONSHORE SEGMENT

The onshore SFEC would begin at the transition vault located at the landing site and end at the interconnection facility. The onshore SFEC would consist of a 138-kV underground power cable installed within a new underground electrical duct bank. The duct bank would comprise a conduit surrounded by concrete through which the SFEC would be run, and it would be located underground within public

ROWs and alongside the tracks within the Long Island Railroad (LIRR) ROW. No overhead lines would be constructed. The specific configuration of the duct bank is not yet determined; however, the ducts would be placed within a 4 × 8–foot trench along the onshore route.

SFW initially considered five landing sites for the SFEC (see Section 2.2.2 in the COP for details). Of these five initial sites, BOEM carried two potential cable landing sites forward for analysis (see COP Figure 3.2-3): Beach Lane and Hither Hills.[4] The Beach Lane onshore SFEC route would primarily follow the Town of East Hampton Road and LIRR ROWs. The route would travel northwest along Beach Lane to Wainscott Main Street, then northeast on Wainscott Main Street, and then northwest onto Sayre's Path. The route would continue north onto Wainscott Stone Road and then northwest on Wainscott Northwest Road, crossing Montauk Highway/State Route 27 (state-owned), to get to the LIRR where it would route along the LIRR to the interconnection facility. The Hither Hills onshore SFEC route would transition from the Hither Hills State Park parking lot to the Old Montauk Highway, which it would follow southwesterly to its intersection with the Montauk Highway. The SFEC would then follow the Montauk Highway westward to Main Street and then Buell Lane, which it would follow until its intersection with the LIRR. The route would follow the LIRR westward to the interconnection facility.

2.1.1.2.3 SEA-TO-SHORE TRANSITION

The sea-to-shore transition is the point at which the offshore and onshore cables are spliced together. Using horizontal directional drilling (HDD), the offshore cable would be installed at least 30 feet below the current beach profile. The cable would connect to a new onshore underground transition vault, constructed approximately 650 to 800 feet from the mean high-water level (MHWL). Pedestrian and vehicle access would be maintained throughout installation. If a temporary offshore cofferdam is required, it would be installed using a sheet pile or gravity cell. Once construction is complete the cofferdam would be removed; excavated sediments would be placed on a barge for potential reuse as backfill during the same construction season. Alternatively, to support HDD activities, temporary casing pipes could be installed at the currently proposed exit pit location. The casing pipe would be driven into the seafloor at the approach angle of the HDD. The casing pipe would extend from the seafloor up through the water column to the sea surface, where a work vessel would be able to access the open end of the pipe. The casing pipe may require that temporary support piles be installed to ensure pipe stability. These support piles are anticipated to consist of steel sheet piles temporarily driven into the seafloor. It is anticipated that up to 8 sheet piles would need to be driven to support the casing pipe. Once the HDD operation has been completed, the casing pipe and support would be removed using a similar methodology to those used for installation.

It is anticipated that the casing pipe would consists of a steel pipe pile, approximately 48 to 60 inches in diameter, and approximately 300 feet in length. Casing pipe installation is anticipated to be accomplished using a small pneumatic impact hammer (e.g., Grundoram Taurus or similar) to drive the pipe in the seafloor. It is estimated that the hammer operates at up to 18.6 kilojoules, and the pile driving would take approximately 2 hours to complete.[5] See COP Figure 3.2-2 and COP Section 3.2.2.2 for additional details.

[4] Although SFW's COP proposes both these alternative landing sites, in the period since the draft EIS was published, SFW has secured approvals from the state and local agencies for the Beach Lane site and not the Hither Hills site. In part, because both routes are part of the envelope in the COP and partly because the offshore cable routes are largely overlapping, this final EIS still considers the impacts associated with both routes.

[5] Use of casing and pipes would result in a smaller disturbance footprint and reduced sound levels as compared to the cofferdam. Since BOEM analyzes the aspects of each design parameter or combination of parameters that would result in the greatest impact for each physical, biological, socioeconomic, and cultural resource, this alternative construction approach is not carried forward for analysis in the EIS. All impacts associated with this alternative would be captured by the cofferdam.

2.1.1.2.4 INTERCONNECTION FACILITY

SFW would construct the interconnection facility to connect the SFEC with the existing 69-kV LIPA substation, located off Cove Hollow Road in East Hampton, New York. SFW would locate the facility adjacent to the existing LIPA substation (see COP Figure 3.2-4) and would include all equipment necessary to safely connect to the New York Independent System Operator (NYISO) transmission system.

Table 2.1.1-3 provides a summary of SFEC components and the Project footprint. Additional information is provided in Appendix D.

Table 2.1.1-3. South Fork Export Cable Components and Footprint

Project Component	Location	Project Envelope Characteristic	Construction and Installation Footprint (temporary)	Operation Footprint (permanent)
SFEC	Offshore	138 kV; target burial depth of 4 to 6 feet	573.3 acres	7.4 acres
		Cable protection	Not applicable (N/A)	7.9 acres
SFEC	Onshore	Onshore duct bank within existing paved road and railroad ROWs, target burial of 8 feet	2.6 to 6.3 acres (depending on route)	2.4 acres
Sea-to-shore transition	Offshore–onshore	Landing site at either Beach Lane or Hither Hills Installed using HDD between onshore underground cable transition vault and the offshore HDD exit location Offshore sheet pile cofferdam*, gravity cell cofferdam, or no cofferdam at the HDD exit location	850 square yards (cofferdam)	N/A
Interconnection facility	Onshore	Newly constructed, air-insulated facility adjacent to the East Hampton substation	2.7-acre parcel	Approximately 71,000 square feet with maximum equipment height of approximately 43 feet
Port facilities	Onshore	Located in New York, Rhode Island, Massachusetts, Connecticut, New Jersey, Maryland, or Virginia	N/A (the SFWF would use existing facilities only.)	N/A (the SFWF would use existing facilities only.)

Source: Jacobs (2021).

Note: For a detailed description of assumptions used to develop the footprint estimates, see Tables 3.2-2 and 3.2-3 in the COP.

* A cofferdam is a watertight enclosure pumped dry to permit construction work below the waterline.

2.1.1.3 Construction and Installation

Construction and installation of the SFWF and SFEC are scheduled to take place over 2 years within applicable seasonal work windows and within a uniform east–west and north–south grid with 1 × 1–nm spacing between WTGs. Construction and installation would include transportation and installation of foundations, installation of cable systems, installation of WTGs, and installation of the OSS. Table 1.5-1 in the COP provides a construction and installation schedule for all Project components.

2.1.1.3.1 TRANSPORTATION AND INSTALLATION OF FOUNDATIONS

SFW would transport WTGs and other components to area ports for staging prior to installation. During installation, transportation barges and material barges would transport components and equipment to the Lease Area (as described in Section 3.1.3.1 of the COP). Foundation installation steps would include preparing the seafloor (if necessary); installing foundations and commissioning the platform, which includes installation of marking and lighting for Private Aids to Navigation required by the U.S. Coast Guard (USCG); and conducting inspection and quality control checks. Section 3.1.3.2 of the COP provides details on foundation installation.

To allow for site-specific micrositing, SFW would install each foundation within a 1,000-foot radius of the proposed locations (in accordance with 30 CFR 585.634) shown on COP Figures 3.1-1 and 3.1-2 (Jacobs 2021) while maintaining the 0.6-nm-wide northwest–southeast transit lanes as recommended by the USCG. The COP assumes that each monopile foundation would require a total of 2 to 4 days for construction but would be driven into the seabed in a single day. Board and lodging for the construction crew and other personnel would be provided on large vessels; crew transfers would be provided via crew transport vessels (CTVs) or during port visits for provisioning and material transport.

2.1.1.3.2 INSTALLATION OF CABLE SYSTEMS

South Fork Wind Farm: Inter-Array Cables

Prior to installation, SFW would ensure all possible obstructions and debris are removed from the cable route. Inter-array cables would then be installed using a mechanical cutter, mechanical plow, or jet-plow to a target burial depth of 4 to 6 feet (see Section 3.1.3.3 of the COP for construction details). Cable installation would occur out to approximately 300 feet from each WTG foundation, at which point the cable would be laid out and cut. At that point, a pulling head would be put on the cable end to allow the cable to be pulled into the foundation. After cable installation, scour protection would be installed, as applicable.

If seabed conditions do not permit cable burial, SFW would employ other methods of cable protection (fronded mattresses, rock bags, rock, or engineered concrete mattresses) (see Table 3.1-1 in the COP for details). A cable inspection program would be developed to confirm the cable burial depth along the route and to identify any further remedial burial activities or secondary cable protection.

South Fork Export Cable: Offshore

Construction staging and installation for the offshore SFEC would generally be as described for the inter-array cables. Cable lay and burial would be conducted for the entire SFEC route, up to approximately 300 feet from the OSS. At that point, the cable would be attached to the OSS in the same process as described for connecting inter-array cables to WTGs. If seabed conditions do not permit cable burial, remedial burial could occur using a controlled flow excavator or other methods of cable protection (e.g., rock or engineered concrete mattresses) would be employed. SFW would cross other existing telecommunication cables using industry standards, including cable protection and clearing of inactive cables from the burial route, where applicable (see Tables 3.2-2 and 3.2-3 in the COP for details regarding cable protection at crossings).

South Fork Export Cable: Sea-to-Shore Transition

SFW would locate the work area and drill entry point for installation of the sea-to-shore transition onshore at least 650 feet from the MHWL and would end offshore at least 1,750 feet from the MHWL. If necessary, a temporary 75 × 25–foot cofferdam would be installed at the offshore end of the HDD to contain drilling returns. The cofferdam would be constructed using either sheet pile or gravity cell construction (see Section 3.2.3.4 of the COP for details) and would be clearly marked to indicate presence to vessels. A drill and drilling fluid would be used to construct a 32-inch-diameter borehole under the beach and intertidal zone. A 24-inch-diameter conduit (high-density polyethylene pipe) would be inserted through the entire length of the borehole, through which the cable would be installed. After installation, a transition vault would be installed onshore around the drill pit; the offshore and onshore cables would be spliced together; and the transition vault would then be sealed, covered, and repaved with manhole covers at the surface. The cofferdam would be removed; excavated sediments would be placed on a barge for potential reuse as backfill during the same construction season.

HDD installation is estimated to take 10 to 16 weeks, including equipment mobilization and breakdown. Work would typically be completed outside the summer season using 12-hour work windows in residential areas, barring any extenuating circumstances.

South Fork Export Cable: Onshore

SFW would install the onshore SFEC cable in an underground duct bank consisting of concrete-encased conduits within the ROW of existing roads or within the LIRR ROW. Existing pavement, gravel, or dirt would be removed, along with vegetation clearing as needed, and a trench of up to 4 feet wide and 8 feet deep would be excavated. As needed, SFW could also use HDD to cross under existing infrastructure. The conduits would be assembled and then lowered. The area around the conduits would be filled with concrete. Once the conduit is installed, the trench would be backfilled with compacted soil. Temporary pavement would be applied followed by full pavement of the affected lane or the road, as appropriate. After duct bank installation is complete, the onshore SFEC would be installed by pulling the cable from manhole to manhole, with cables spliced at each manhole.

Construction of the interconnection facility would include site preparation, excavation, and grading; construction of foundations for control building, transformer, reactors, and switchgear; construction of electrical grounding, duct banks, and underground conduits; installation of drainage systems and station service; and installation of aboveground structures. Any temporary staging areas required during construction would be located within, or adjacent to, the proposed facility. Onshore construction is estimated to take 9 to 12 months; however, the construction schedule would be designed to minimize impacts during the summer tourist season (see Section 4.6.1.3 of the COP).

2.1.1.3.3 INSTALLATION OF WIND TURBINE GENERATORS

After installation of the foundation and the inter-array cables, SFW would transport WTGs from onshore staging facilities by barge or other vessel to the offshore installation site. A jack-up vessel would be located next to each foundation and would individually lift and set the tower, either in sections or as a single piece (see COP Figure 3.1-6). The nacelle would then be lifted and connected to the tower, followed by installation of each blade to the hub. Once the components are installed, workers would finalize securing each WTG component. Installation of each WTG would require up to 3 days, assuming a 24-hour work window and no delays due to weather, sea conditions, or other circumstances.

2.1.1.3.4 INSTALLATION OF OFFSHORE SUBSTATION

The installation process for the OSS would be similar to that described for WTGs. The substation would be brought to a foundation on a transportation barge and lifted into place by a jack-up lift barge or a derrick barge.

2.1.1.4 Operations and Maintenance

SFW would provide O&M for the duration of the Project. The SFWF would operate at maximum capacity while complying with all electric grid requirements from LIPA and NYISO. The SFWF and SFEC would be monitored 24 hours a day and 365 days a year from a remote facility. The anticipated vessels and support vehicles to be used during operations are described in Section 3.1.3.1 and Table 3.1-6 in the COP. WTGs and the OSS would be maintained and equipped with safety devices and Federal Aviation Administration (FAA) and USCG-recommended marking and lighting. The OSS and interconnection facility would also contain a utility generator in the case of emergency events. For planned maintenance activities, personnel access would be provided using crew transfer vessels during low wind periods. SFW would also conduct routine foundation inspections. Unscheduled maintenance, including major repairs, could require the use of jack-up or crane barges if repairs to equipment such as power transformers, reactors, or switchgear are necessary.

Inter-array cables and the SFEC are not expected to require planned maintenance; however, SFW would develop a cable inspection program prior to Project commissioning; regular monitoring and inspections would be based on manufacturer-suggested methods. Cable monitoring would include assessment of cable location, burial depths, state of the cable, and site conditions. Inspection methods would include conducting high resolution geophysical (HRG) surveys (using equipment such as a multi-beam bathymetric survey equipment) and identifying seabed features, natural and human-made hazards, and site conditions along federal sections of the cable routing.

2.1.1.5 Conceptual Decommissioning

Pursuant to 30 CFR 585 and other BOEM requirements, SFW would be required to remove or decommission all installations and clear the seabed of all obstructions created by the Project. In accordance with applicable regulations and a BOEM-approved conceptual decommissioning plan, SFW would have up to 2 years to decommission the Project after the 25-year lease ends (approximately 2052), unless the lease is extended, which would return the area to pre-construction conditions, as feasible. WTG components and the OSS would be disconnected and would be removed using a jack-up lift vessel or a derrick barge. Cables would be removed, in accordance with BOEM regulations (30 CFR 585, subpart I). A material barge would transport components to a recycling yard where the components would be disassembled and prepared for re-use and/or recycling for scrap metal and other materials. The foundations would be cut by an internal abrasive water jet cutting tool at 15 feet below the seabed and returned to shore for recycling in the same manner described for the WTG components and the OSS. SFW would clear the area after all components have been decommissioned to ensure that no unauthorized debris remains on the seabed. Onshore conceptual decommissioning requirements would be subject to state and local authorizations and permits. SFW would be required to complete conceptual decommissioning within 2 years of the termination of its lease.

SFW would need to obtain separate and subsequent approval from BOEM to retire any portion of the Project in place. SFW would submit a conceptual decommissioning application prior to any conceptual decommissioning activities. BOEM would conduct a NEPA review at that time, which could result in the preparation of a NEPA document. If the COP is approved or approved with modifications, SFW would have to submit a bond that would be held by the United States government to cover the cost of conceptually decommissioning the entire facility.

Conceptual decommissioning may not occur for all Project components. However, for the purposes of the final EIS, all analyses assume that conceptual decommissioning would occur as described in this section.

2.1.1.6 Environmental Protection Measures and Additional Authorizations

SFW has committed to environmental protection measures (EPMs) as part of its Project to avoid or minimize impacts to physical, biological, socioeconomic, and cultural resources. These measures are described in Table G-1 in Appendix G and are incorporated as part of the Proposed Action in the final EIS. During the development of the final EIS, BOEM considered potential additional mitigation measures that could further avoid, minimize, or mitigate impacts on the physical, biological, socioeconomic, and cultural resources assessed in this final EIS. Table G-2 in Appendix G describes these potential additional mitigation measures, and the subsequent Chapter 3 sections analyze them separately by resource. As noted in Section 1.3, SFW would also obtain all other necessary state and federal permits and authorizations under applicable statutes prior to Project construction. These other permits and authorizations could include additional measures.

2.1.1.7 Monitoring Surveys

As part of the Proposed Action, SFW has committed to conducting pre-, during, and post- construction surveys and monitoring (Table 2.1.1-4). SFW is voluntarily conducting the surveys under existing permits, prior to approval of the COP. These surveys are included in Table G-2 in Appendix G and may be required by BOEM in the ROD.

Table 2.1.1-4. South Fork Wind Monitoring and Surveys

Survey Gear	Location	Status/Time Frame	Duration	General Notes
Beam Trawl Survey	SFWF and control areas	Started October 2020	2 years of pre-construction monitoring, monitoring will continue during construction, and at least 2 years of post-construction monitoring will occur.	Small beam trawl towed on bottom behind vessel.
Ventless Trap Survey	SFWF and control areas	Started May 3, 2021	2 years of pre-construction monitoring, monitoring will continue during construction, and at least 2 years of post-construction monitoring will occur.	Using weak-link buoy lines (< 1,700-pound breaking strength) that are recommended by NMFS with sinking groundline between pots. Other mitigating measures associated with protected resources are detailed in the SFW fisheries monitoring plan.
Gillnet Survey	SFWF and control areas	Pre-construction: Started in May 2021	2 years of pre-construction monitoring, monitoring will continue during construction, and at least 2 years of post-construction monitoring will occur.	Using weak-link buoy lines (< 1,700-pound breaking strength) that are recommended by NMFS. The survey will not result in more gear in the water than what is already permitted to the fishery. Other mitigating measures associated with protected resources are detailed in the SFW fisheries monitoring plan.
Fish Pot Survey	SFWF	Pre-construction: Started in June 2021	2 years of pre-construction monitoring, monitoring will continue during construction, and at least 2 years of post-construction monitoring will occur.	Survey is using sinking groundline between pots and using weak-link end lines (< 1,700-pound breaking strength) that are recommended by NMFS. Other mitigating measures associated with protected resources are detailed in the SFW fisheries monitoring plan.
Acoustic Telemetry - NYS waters	SFEC-NYS	Pre-construction: Started in May 2021	June 2021 through December 2025	Researchers will use VR2AR acoustic release receivers; no vertical lines in the water for the acoustic receivers to mitigate entanglement risk. Receivers will have a low vertical profile (< 6 feet) off the bottom.
Trawl Survey - NYS waters	SFEC-NYS	Pre-construction: Started in June 2021	July 2021 through November 2025	Northeast Area Monitoring and Assessment Program bottom otter trawl survey protocols. Magnuson-Stevens Act Letter of Acknowledgment received from NOAA May 2021.
Moored archival recorders, or mobile platforms, or moored surface buoys; no line	SFWF/SFEC-OCS	Pre-construction, during construction, post-construction	Tentative: start Q1–Q3 2022, possible 2–3 year deployment (2025?)	Requirement of the COP for all projects.
PAM – Sound field verification: temporary moorings with surface buoy and line	All piles; 1–7 locations. Lease area and HDD cofferdam installation (if sheet pile cofferdam is used)	Construction	Offshore: May–December 2023 (maximum deployment) Nearshore: Short duration–only days, winter–spring months 2022–2023	Required of COP and Incidental Harassment Authorization (IHA) Mitigation: Could be moored with acoustic release.
PAM – Temporary mooring with line; single hydrophones or hydrophone arrays	SFWF	Construction	Offshore: May–December 2023 (maximum deployment)	Required of COP and IHA. Mitigation: Equipment not determined; will have surface component.

2.1.2 Vessel Transit Lane Alternative

Under the Vessel Transit Lane alternative (hereafter the Transit alternative), BOEM evaluated a 4-nm-wide vessel transit lane[6] through the Lease Area where no surface occupancy would occur. BOEM developed this alternative in response to the January 3, 2020, Responsible Offshore Development Association (RODA) layout proposal (RODA 2020). The RODA proposal includes designated transit lanes, each at least 4 nm wide. Although the proposal includes six total transit lanes, only one lane intersects the Lease Area. The vessel transit lane is unique to this alternative and could facilitate transit of vessels through the Lease Area from southern New England and eastern Long Island ports to fishing areas in the region (Figure 2.1.3-1).

WTGs located within the transit lane would be eliminated under this alternative. SFW would develop the remaining WTGs with a 12-MW turbine capacity and would move the offshore substation north of the currently proposed location and install it in one of the remaining WTG locations. The Transit alternative is within the proposed design envelope of up to 15 turbines in the 6- to 12-MW range.

All other Project components and construction and installation, O&M, and conceptual decommissioning would be identical to the Proposed Action. The Transit alternative discloses the effect a vessel transit lane could have on resources analyzed in the final EIS. The final EIS also considers the five other transit lanes that could intersect the other reasonably foreseeable projects to the extent that the impacts of those additional lanes would contribute to cumulative impacts in the analysis area considered for each resource area (see Figure 2.1.3-1).

2.1.3 Fisheries Habitat Impact Minimization Alternative (Preferred Alternative)

Under the Fisheries Habitat Impact Minimization alternative (hereafter the Habitat alternative), the construction and installation, O&M, and conceptual decommissioning of WTGs and an OSS within the Lease Area and associated inter-array and export cables would occur within the range of design parameters outlined in the COP, subject to applicable mitigation measures. However, to reduce impacts to complex fisheries habitats as compared to the Proposed Action, BOEM would require SFW to exclude certain WTGs and associated cable locations within complex fisheries habitats if micrositing to avoid complex habitat is not possible while maintaining a uniform east–west and north–south grid of 1 × 1–nm spacing between WTGs with diagonal transit lanes of at least 0.6 nm wide.

Under this alternative, BOEM may approve up to four fewer WTG locations than proposed by SFW to reduce impacts to complex habitat (Figure 2.1.3-2). Additionally, other WTGs would be microsited, subject to engineering and spacing constraints, to further reduce impacts. However, this alternative is still within the proposed design envelope of up to 15 turbines and the 6- to 12-MW range. All other Project components and construction and installation, O&M, and conceptual decommissioning would be identical to the Proposed Action.

Two options for layout of the Habitat alternative are considered in this EIS.

On June 7, 2021, NOAA provided their conservation recommendations to BOEM for which specific turbine locations BOEM should eliminate and microsite under this alternative. NOAA recommended that proposed wind turbine locations WTG 1, WTG 5, WTG 15, WTG 16A, and WTG 17A (Figure 2.1.3-2a)

[6] BOEM also evaluated a 2-nm and 3-nm-wide transit lane alternative. However, these smaller lanes would result in the same impacts as the Proposed Action because the lane would not overlap any proposed WTGs or the OSS. Therefore, a smaller lane width was dismissed from further evaluation.

be removed from consideration because they would result in substantial adverse impacts to complex habitats. NOAA also recommended that turbine locations WTG 2, WTG 4, WTG 6, WTG 8, WTG 9, WTG 10, WTG 12, WTG 13, and WTG 14, the OSS, and the associated inter-array cables be microsited into low multibeam backscatter return areas and that restrictions on seafloor disturbance (e.g., anchoring) during construction be required to avoid impacts to higher multibeam backscatter return areas. BOEM considers this layout to be the preferred alternative.

However, SFW has expressed concerns about the particular locations NOAA suggested for removal. On June 14, 2021, SFW provided BOEM with a proposed layout in response to the consistency determination of Rhode Island Coastal Resources Management Council (CRMC), which requires a reduction in the number of wind turbines by three. The proposed layout removes wind turbine locations WTG 5, WTG 6, WTG 9, WTG 16A, and WTG 17A (Figure 2.1.3-2b). Other wind turbine locations would be microsited, including WTG1 and WTG15, to reduce impacts to complex habitat. The proposed layout takes into consideration the optimization of the cable length, which reduces transmission loss. WTG 15 is located within proximity to the OSS to limit electrical losses. If WTG 15 was not utilized, as NOAA recommends, SFW has expressed that it would require redesign of the inter-array cable layout and cable specifications. In contrast, WTG 06 is the farthest location from the OSS, which means that using that location would increase electrical losses, require an increase in inter-array cable length and a re-assessment and potential redesign of the cable specifications. In addition, installation feasibility is challenging at WTG 06 as load pressure assessments indicate an increased risk of punch-through of jack-up vessel legs due to soft soil conditions. These soft soil conditions result in an elevated risk for installation feasibility and safety. SFW also proposed to eliminate WTG 09 because it is surrounded by a dense boulder field which would yield increased installation risk and environmental impacts from boulder relocation. There is also a potential munition and explosive of concern target at WTG 03 which would make connecting WTG 03 to WTG 09 technically challenging. Therefore, WTG 09 would require an increase in inter-array cable length, resulting in increased electrical losses.

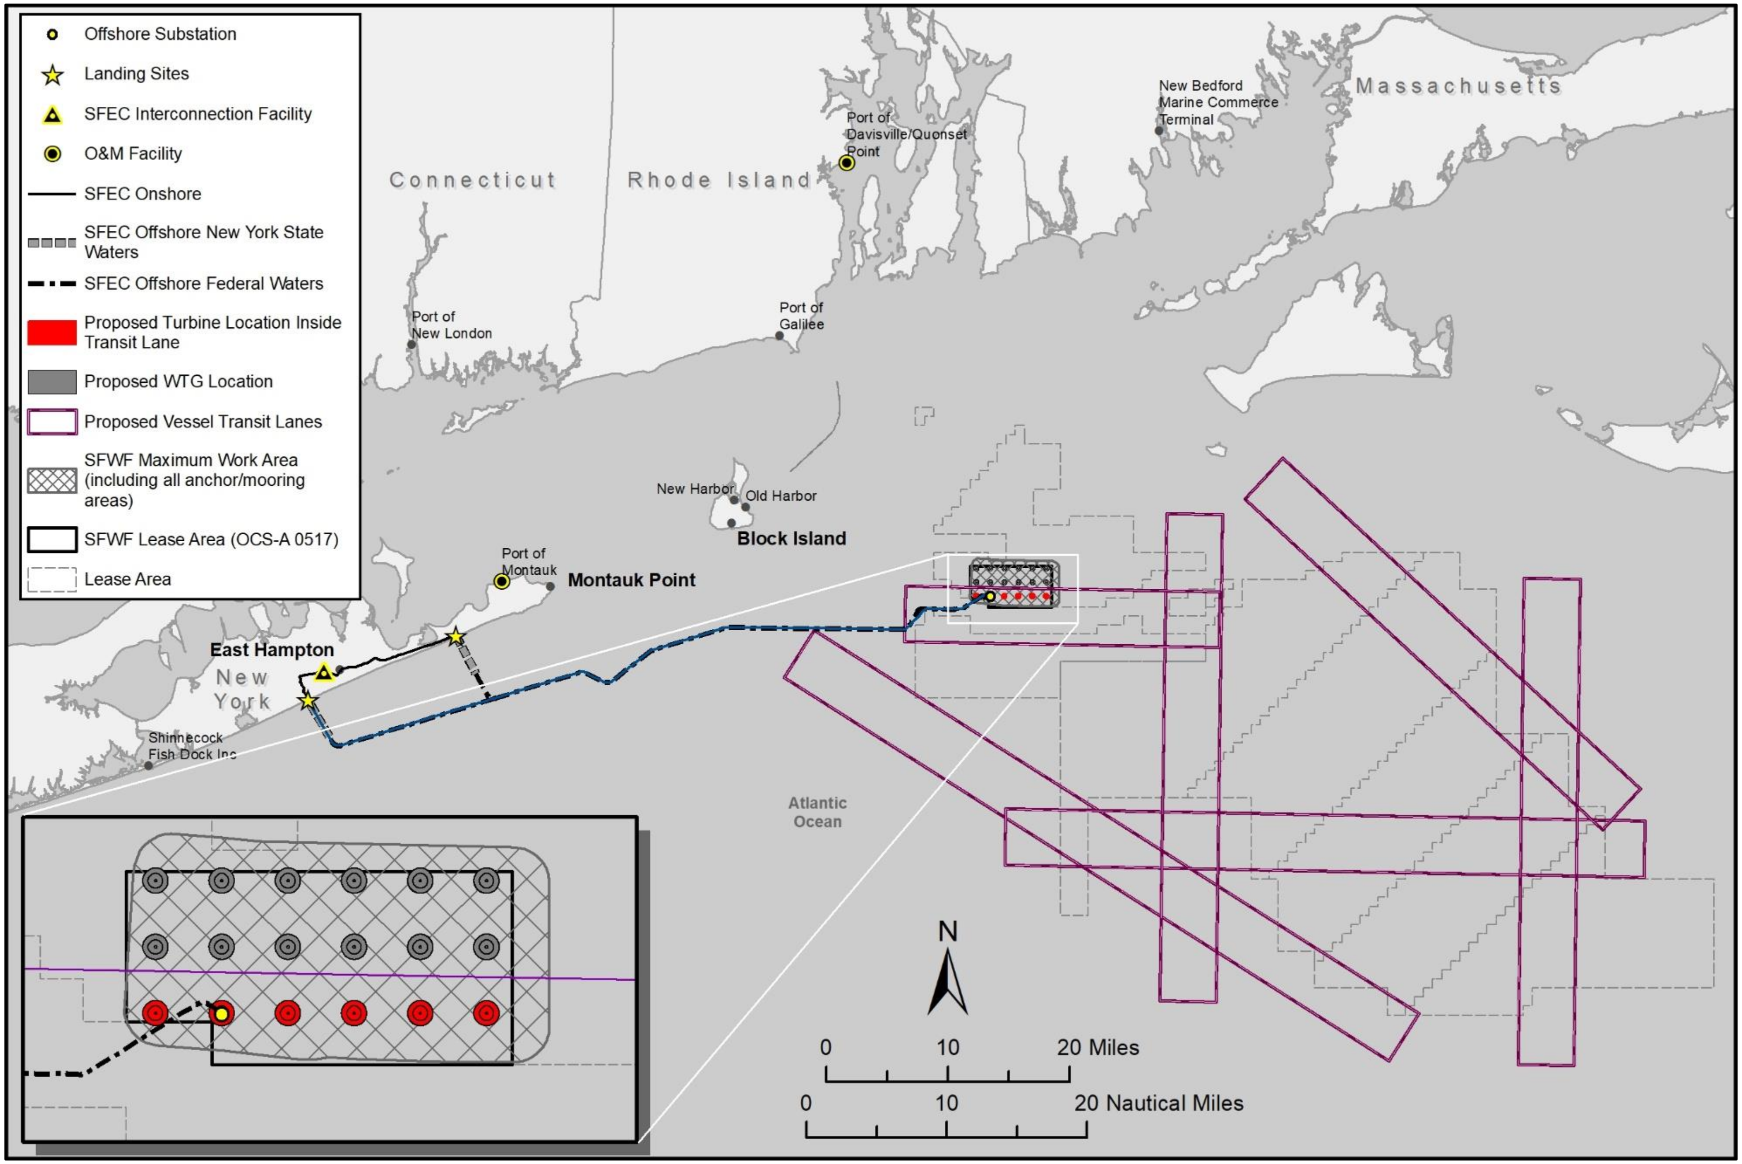

Figure 2.1.3-1. Transit alternative layout.

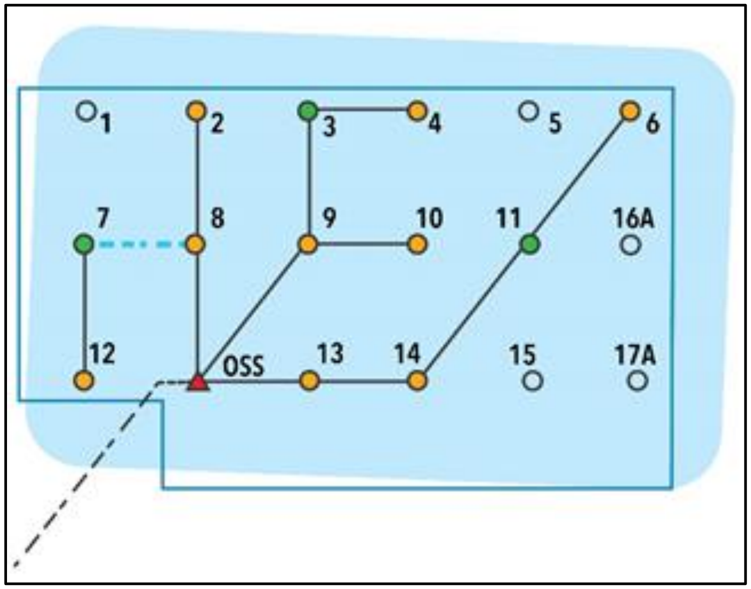

Figure 2.1.3-2a. Habitat alternative layout (a) Conservation Recommendations from NOAA (June 7, 2021)). Orange avoids complex fisheries habitat with micrositing. Green avoids complex fisheries habitat without micrositing.

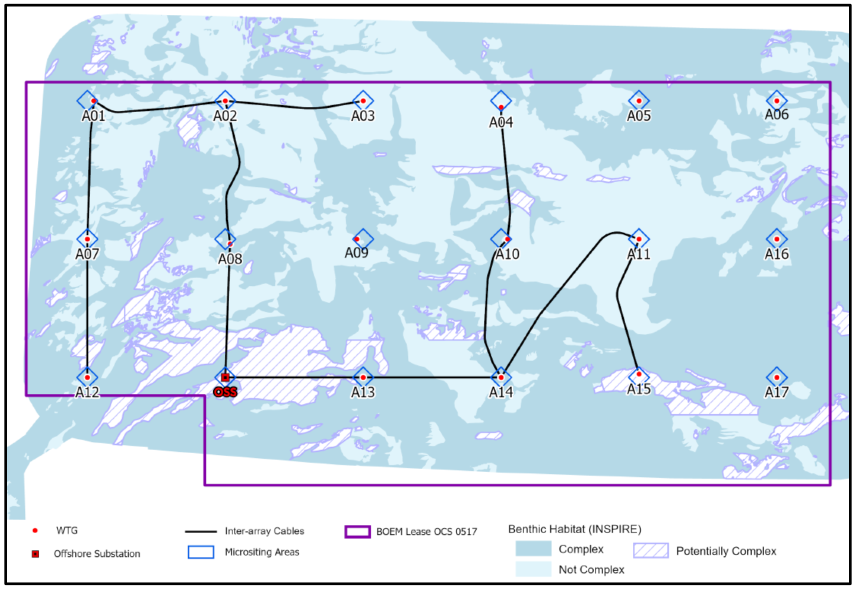

Figure 2.1.3-2b. Habitat alternative layout (b) SFW Technical Memorandum (June 14, 2021).

2.1.4 No Action Alternative

Under the No Action alternative, BOEM would not approve the COP, and the Project construction and installation, O&M, and conceptual decommissioning activities would not occur.[7] Likewise, no additional permits or authorizations would be required. Any potential environmental and socioeconomic impacts, including benefits, associated with the Project as described under the Proposed Action would not occur. However, all other existing or other reasonably foreseeable future impact-producing activities would persist in the Lease Area. Table 2.3.1-1 includes an impact assessment of the No Action alternative for each resource, including an assessment for cumulative effects. The No Action alternative cumulative effects assessment provides an assessment for impacts with and without approval of additional wind farms in BOEM lease areas. Through these assessments, the No Action alternative provides a baseline against which all action alternatives are evaluated.

2.1.5 Alternatives Considered but Dismissed from Detailed Analysis

BOEM considered a range of alternatives during the EIS development process that emerged from scoping, interagency coordination, and internal BOEM deliberations. To be carried forward for analysis, all considered alternatives were required to meet the following screening criteria: 1) meet the purpose of and need for the Proposed Action; 2) be operationally, technically, and economically feasible and implementable; 3) be consistent with other local, state, or federal plans, permits, and regulations; 4) further reduce or avoid impacts as compared to the Proposed Action; and 5) not be substantially the same as another alternative. Table 2.1.5-1 summarizes the alternatives considered but dismissed from detailed analysis along with detailed rationale for elimination.

[7] Under the No Action alternative, NMFS would not issue the requested authorization under the MMPA to the applicant. NMFS's action alternative is to issue the requested Incidental Harassment Authorization to the applicant to authorize incidental take for the activities specified in its application and which are being analyzed by BOEM in the reasonable range of alternatives described here.

Table 2.1.5-1. Alternatives Considered but Dismissed from Detailed Analysis

Alternative	Objective	Rationale for Dismissal
Minimizing the number of turbines/maximizing power output of individual turbines	Reduce impacts to benthic and marine species	The design envelope considered under the other action alternatives includes a range of turbine and WTG power outputs, including options to reduce the number of turbines and increase power outage. The Proposed Action considers one of the highest potential WTG power outputs currently available in the market. Therefore, this alternative was not carried forward for separate analysis but is addressed within the final EIS analysis of the Proposed Action and other action alternatives.
Alternative location in the Lease Area 0486	Reduce impacts to Cox Ledge resources	On January 16, 2020, Deepwater Wind New England, LLC requested that a portion of Lease OCS-A 0486, which corresponds to the defined geographic area identified in the COP, be assigned to a different entity, SFW. Under BOEM's regulations, an assignment request can only be denied if the applicants fail to comply with the regulatory requirements applicable to assignments. Essentially, those requirements are limited to the technical, financial, and legal qualifications and capabilities of the assignee to comply with the obligations under the lease being assigned. Absent any deficiency in the technical, financial, and legal qualifications and capabilities of the assignee, BOEM is required to approve the assignment because denial or delay in approving the assignment for reasons other than those contemplated in the regulations cannot be legally justified. BOEM reviewed the assignment application submitted by SFW and determined that it complied with the technical, financial, and legal requirements for approval under BOEM's regulations. The assignment was approved by BOEM on March 23, 2020, and had the effect of segregating the area assigned from Lease OCS-A 0486 and created a new lease (i.e., OCS-A 0517). The assignment also had the effect of rendering the "Alternate Location within the Lease Area Alternative" no longer viable because its selection would mean that BOEM would be requiring the lessee to develop the Project in a lease held by a different legal entity and for which another proposal is currently under evaluation by BOEM (i.e., the Revolution Wind Project proposed by DWW Rev I, LLC). The Revolution Wind Project is intended to satisfy energy demands agreed to under power purchase agreements executed with the States of Connecticut and Rhode Island. BOEM selecting an alternative that would approve the Project in a lease held by another legal entity, and for which there is a project proposal intended to satisfy contractual commitments different than those intended to be satisfied by the SFWF, is the equivalent of choosing the No Action alternative because it is not a viable alternative that can be implemented by SFW. Analysis and selection of the "Alternate Location within the Lease Area Alternative" would not result in developing the Project in that other location. Instead, it would result in deciding not to develop the Project in the defined geographic area where it was proposed because developing the Project in another location would have been preferable. The No Action alternative and the action alternatives currently being analyzed in detail allow the Secretary to understand the impacts that would be avoided or caused if the Project is developed or not in the defined geographic area where it is proposed. The alternatives being analyzed in detail would also allow the Secretary to determine whether the activities proposed in Lease OCS-A-0517 would, among others, cause "undue harm or damage to natural resources; life (including human and wildlife); property; the marine, coastal, or human environment; or sites, structures, or objects of historical or archaeological significance" 30 CFR 585.621(d). Based on the above, BOEM finds that the selection and implementation of the "Alternate Location within the Lease Area Alternative" is no longer viable and analyzing such alternative in detail would not contribute to the Secretary's determination on whether the Project should be denied in the location where it is currently proposed. Said differently, the Secretary does not need to analyze the impacts the Project would have in other locations to determine whether the activities proposed in the defined geographic area would, among others, cause "undue harm or damage to natural resources; life (including human and wildlife); property; the marine, coastal, or human environment; or sites, structures, or objects of historical or archaeological significance." 30 CFR 585.621(d). This alternative emerged because of concerns related to Cox Ledge; these concerns are addressed through the Habitat alternative, which avoids sensitive habitat in that area.

Alternative	Objective	Rationale for Dismissal
Using a 1 × 1–nm wind turbine layout	Reduce impacts to fisheries and navigation	SFW has committed to an indicative layout with WTGs sited in a grid with a spacing of approximately 1.0 nm (1.9 km, 1.15 miles) × 1.0 nm (1.9 km, 1.15 miles) that aligns with other proposed adjacent offshore wind projects in the RI-MA WEAs. Therefore, this alternative is already considered under the Proposed Action and was dismissed from further consideration.
Reducing the permitted operating life of the facility	Reduce impacts to all resources	The lease allows for 25 years of operations (plus up to an additional 2 years for conceptual decommissioning). Reducing the permitted operating life would violate the lease.
Using the LIPA 138-kV land-based transmission cable project or the East End – Battery large-scale facility to meet energy demand.	Reduce impacts to all marine resources	Not responsive to the purpose and need. May be considered as the No Action alternative, where power generation would come from alternate sources.
Alternatives for cable construction methods and protection (e.g., natural materials vs. artificial materials), including using smaller cable, burying the cable deeper, alternatives to side-casting spoils, route alternatives that allow for full cable burial, and using better shielding materials	Reduce impacts to benthic and marine resources	No cable construction alternatives were identified during Project development that would further reduce or avoid marine impacts (see New York Article VII submitted by SFW and Section 2.3.2 of the COP). Project impacts associated with cable construction methods and protection are disclosed in Chapter 3 of the final EIS for relevant affected resources. As applicable, BOEM could also choose to implement additional mitigation measures to further reduce or avoid impacts. The Habitat alternative evaluated in the final EIS also considers ways to minimize certain habitat impacts. Therefore, this alternative was not carried forward for separate analysis because it would not provide a substantially different analysis than that provided with the analysis of the Proposed Action and other action alternatives, and because of the mitigation measures identified and considered in the final EIS.
Alternatives to cable routes that minimized impacts to sensitive biotic/benthic habitats	Reduce impacts to benthic resources	SFW identified an alternative SFEC cable route that ran southwest from the SFWF, passing north of Montauk Point and into Napeague Bay on the north shore of the South Fork in the town of Easthampton, New York. However, this route was rejected because of commercial fishing concerns expressed by stakeholders. No other feasible route alternatives were identified during Project development or scoping that would allow SFW to meet its power purchase agreement. Therefore, this alternative was not carried forward for analysis.
Alternatives to cofferdam excavation	Reduce impacts to water quality and marine resources	The final EIS considers scenarios where cofferdam excavation may or may not be needed as part of the PDE. A cofferdam would only be used if needed to contain HDD drilling returns. Alternatives to cofferdam excavation, such as inflatable dams, would not provide a substantially different analysis than that provided with the analysis of the Proposed Action. As applicable, BOEM could also choose to implement additional mitigation measures to further reduce or avoid impacts. Therefore, this alternative was not carried forward as a separate alternative.
Alternatives to cable decommissioning that remove all cables, etc. rather than burying cables in place	Reduce impacts to benthic and marine resources	BOEM regulations (30 CFR 585, Subpart I) currently require the removal of the cables, and the Proposed Action addresses the removal of cables.

Alternative	**Objective**	**Rationale for Dismissal**
Alternative renewable energy technology such as solar or wave devices rather than wind	Reduce impacts to all resources	Alternative technologies such as offshore solar facilities and wave devices that would meet renewable energy goals, including time frames, are not technologically and commercially feasible at this time. Additionally, this alternative is not responsive to the purpose and need to respond to the Project COP and determine whether to approve, approve with modifications, or disapprove the COP to construct, operate, and conceptually decommission a commercial-scale wind energy facility within Lease Area OCS-A 0517.
Alternate locations for turbines including an upland site near East Hampton that would involve no discharge of dredged or fill material in wetlands and other waters of the United States	Reduce impacts to all resources	Evaluating an alternate location outside of Lease Area OCS-A 486 would constitute a new Proposed Action and would not meet BOEM's purpose and need to respond to the Project COP and determine whether to approve, approve with modifications, or disapprove the COP to construct, operate, and conceptually decommission a commercial-scale wind energy facility within Lease Area OCS-A 0517. BOEM's regulations require BOEM to analyze SFW's proposal to build a commercial wind energy facility on Lease OCS-A 0517. BOEM would consider proposals on other existing leases through a separate regulatory process. Other potential lease areas may be considered at a later date, either through a competitive lease sale process if multiple companies wish to bid, or through a non-competitive process if no competitive interest exists. This alternative would therefore not meet the purpose and need of the Project, and would effectively be the same as selecting the No Action alternative.
Alternate location closer to shore or within state waters		
Alternate location for the wind energy facility outside of Lease Area OCS-A 0486		
Alternative wind turbine foundations	Reduce impacts to benthic and marine resources	BOEM received comments suggesting the use of alternative foundation types, including suction bucket foundations and floating wind turbine foundation types to reduce impacts on marine mammals, sea turtles, and fish from pile driving associated with monopile and jacket foundations. These foundation types are not feasible within the Lease Area because of the following: The dense soils beneath an upper loose surficial layer of sand may prevent the full penetration required for stability of suction bucket foundations. The loose upper layer of sandy sediment also presents a settlement risk for gravity-based foundations. The water depths are too shallow in portions of the Lease Area for floating foundations, which is a technology that is unproven for a project the size of what is proposed by SFW. Although these foundation types would not require pile driving, the larger footprint of suction bucket foundations would increase seabed disturbance; additionally, all alternate foundation types would create less room for fishing activities between turbines when compared to monopile foundations. The cables associated with floating wind turbines would also increase the risk of entanglement for marine mammals. Overall, these alternative foundation types are not feasible in the Lease Area and may increase long-term environmental impacts to some resources over those from monopile foundations within the Lease Area.
Alternatives to cable landing site options	Reduce socioeconomic and human health impacts	SFW evaluated a total of five landing sites. Two of these sites were located in Napeague Bay, which required a cable route that was eliminated because of commercial fishing concerns. Of the three remaining sites, only Beach Lane and Hither Hills were considered feasible from an engineering and environmental perspective, as discussed in the COP, Section 2.2.2. No other cable landing site alternatives were identified during Project development or scoping that would further reduce or avoid social or environmental impacts (see New York Article VII submitted by SFW). For these reasons, and because the final EIS already considers an alternative cable landing location as part of the PDE, there is no need to consider it as a separate alternative.

Alternative	Objective	Rationale for Dismissal
Eliminating Beach Lane landing site	Reduce socioeconomic impacts	The final EIS evaluates and discloses the impacts of both the Beach Lane and Hither Hills landing site as part of the PDE. Therefore, this alternative was not carried forward. BOEM would use the information disclosed in the final EIS to evaluate landing sites and may choose to identify a specific landing site as part of their preferred alternative.
Transit lane alternative with widths greater than 4 nm	Reduce navigation impacts	BOEM's subject matter experts believe that an analysis of additional transit lane widths would not provide the U.S. Secretary of the Interior significantly different information regarding impacts on affected resources when compared to the 4-nm alternative analyzed in the final EIS. Although BOEM is aware of a desire for vessel transit lanes with widths in excess of 4 nm, BOEM is unaware of any studies justifying that width. The closest metric that BOEM has seen (from U.K. Maritime Guidance MGN 543) is that routes should be wide enough to allow for a 20 degree course variation in rough conditions. For the 15-nm-long diagonal transit lane through the RI and MA Lease Areas, a 20-degree course variation would require a lane of 5.5 nm. However, MGN 543 indicates that this metric is intended for larger commercial vessels with less responsive steering and that are more heavily impacted by wind, such as the vessels moving through New York Harbor that are in excess of 800 feet. Conversely, the fishing vessels transiting the RI and MA Lease Areas are much smaller, with the largest licensed fishing vessel in the area being 138 feet (42.1 meters). Nearby lanes intended for deep-draft traffic include the Traffic Separation Schemes for Narragansett Bay (11.5 nm long and 4 nm wide) and Boston (127.5 nm long and 4 nm wide). These Traffic Separation Schemes see both a larger traffic volume and larger individual vessel size than the entirety of the RI and MA Lease Areas, and include a separation zone of 1 to 2 nm in the middle of the lane. Additionally, BOEM expects that transit lanes greater than 4 nm wide would be equivalent to the No Action alternative because additional WTGs would be removed, and remaining WTGs would be insufficient to meet SFW's power purchase agreement and therefore this would not meet the purpose and need.
Atlantic Avenue landing site	Reduce socioeconomic and human health impacts	SFW considered the Atlantic Avenue landing site during initial screening but did not include the site in permitting documents because it was determined, based on discussions with local government, that securing property rights for routing of the cable was not possible.

2.2 NON-ROUTINE ACTIVITIES AND LOW-PROBABILITY EVENTS

Non-routine activities and low-probability events associated with the Project could occur during construction and installation, O&M, or conceptual decommissioning. Although these activities or events are impossible to predict with certainty, examples of such activities and events and potential for Project impacts are briefly summarized below.

- Corrective maintenance activities: These activities could be required as a result of other low-probability events, or as a result of unanticipated equipment wear or malfunctions. SFW would stock spare parts and have sufficient workforce available to conduct corrective maintenance activities, if required.
- Collisions and allisions: These activities could result in spills (described below) or injuries or fatalities to humans or wildlife (addressed in Chapter 3). Collisions and allisions would be minimized through USCG's requirement for lighting on vessels, temporary safety zones anticipated to be implemented by SFW during construction, the implementation of National Oceanic and Atmospheric Administration (NOAA) vessel-strike guidance, proposed spacing between WTGs and other facility components, and inclusion of Project components on nautical charts.
- Cable displacement or damage by vessel anchors or fishing gear: This could result in safety concerns and economic damages to vessel operators. However, such incidents would be minimized by inclusion of Project components on nautical charts and the cable burial or other protection measures.
- Chemical spills or releases: For offshore activities, these would include inadvertent releases from refueling vessels, spills from routine maintenance activities, and any more significant spills as a result of a catastrophic event. SFW would comply with USCG and Bureau of Safety and Environmental Enforcement regulations relating to prevention and control of oil spills. Onshore, releases could occur from construction equipment or HDD activities. SFW would prepare a construction spill prevention, control, and countermeasure plan in accordance with applicable requirements, and would outline spill prevention plans and measures to take to contain and clean up spills that may occur.
- Severe weather (e.g., hurricanes) and natural events: The design parameters for the WTGs are sufficient based upon historical data, site-specific measurements, and engineering design practices. There have been three Category 3 hurricanes (tropical cyclones) in the historical record in the area, and no Category 4 or 5 hurricanes. The South Fork Wind project will be designed in accordance with the International Electrotechnical Commission (IEC) 61400-1 and 61400-3 standards. These standards require designs to withstand forces based on site-specific conditions for a 50-year return interval (2% chance occurrence in a single year) for the WTGs, which corresponds to a Category 3 hurricane in this area. This means that the WTGs are designed not merely for average conditions but for the higher end event that is reasonably likely to occur. The newly revised IEC standard now also recommends a robustness load case for extreme metocean conditions, where the WTG support structures are checked for a 500-year event (0.2% chance occurrence in a single year), which corresponds to wind gusts at the strength of a Category 5 hurricane, to ensure that the appropriate level of safety is maintained in case of a less likely event. The Project will be constructed using a certified verification agent to ensure that all design specifications are met. It is possible that severe weather could cause blades to fail, but because of the construction design, it is highly unlikely that the towers would topple. However, severe flooding or coastal erosion could require repairs during construction and installation activities of onshore project components. Although highly unlikely, structural failure of a WTG (i.e., loss of a blade or tower collapse) would result in temporary hazards to navigation for all vessels.

- Terrorist attacks: Impacts from terrorist attacks could greatly vary in magnitude and extent and, therefore, their analysis would be highly speculative. BOEM also considers terrorist attacks unlikely and therefore does not analyze them further in the final EIS.

2.3 SUMMARY AND COMPARISON OF IMPACTS BY ALTERNATIVE

2.3.1 Comparison of Impacts by Alternative

Table 2.3.1-1 summarizes and compares the impacts from Chapter 3 by environmental resource and alternative. Where directionality (e.g., adverse or beneficial) is not specifically noted, the reader should assume the impact is adverse.

Table 2.3.1-1. Comparison of Impacts by Alternative

Resource	No Action	Proposed Action	Vessel Transit Lane Alternative	Fisheries Habitat Impact Minimization Alternative (both layout options)
Air quality	Continuation of existing air quality trends and sources of air pollution. Minor to moderate adverse effects if no other wind farms are authorized and negligible to moderate adverse and moderate beneficial effects if they are authorized.	Minor to moderate temporary adverse impacts to air quality in the region due to vessel activity during construction and installation, O&M, and conceptual decommissioning, as well as minor beneficial long-term air quality and reduced health event impacts. The overall cumulative impacts to air quality would be minor adverse and minor beneficial long-term air quality and reduced health event impacts.	Minor to moderate temporary adverse impacts to air quality in the region due to construction and installation, O&M, and conceptual decommissioning, as well as minor beneficial long-term air quality and reduced health event impacts. The overall cumulative impacts to air quality would be minor adverse and minor beneficial. When compared to the Proposed Action, air quality impacts could slightly decrease depending on final design.	Minor to moderate temporary adverse impacts to air quality in the region due to construction and installation, O&M, and conceptual decommissioning, as well as minor beneficial, long-term air quality and reduced health event impacts. The overall cumulative impacts to air quality would be minor adverse and minor beneficial. When compared to the Proposed Action, air quality impacts could slightly decrease depending on final design.
Water quality	Continuation of existing water quality trends. Minor to moderate adverse effects if no other wind farms are authorized and minor to moderate adverse effects and minor beneficial effects if they are authorized.	Negligible to moderate impacts on onshore surface water and offshore water quality from erosion, sediment resuspension and deposition and scouring, discharges, and inadvertent spills or releases. Onshore and offshore, overall cumulative impacts to water quality would be minor.	Negligible to moderate impacts on onshore surface water and offshore water quality from erosion, sediment resuspension and deposition and scouring, discharges, and inadvertent spills or releases. Onshore and offshore, overall cumulative impacts to water quality would be minor. When compared to the Proposed Action, offshore water quality impacts could slightly decrease depending on final design.	Negligible to moderate impacts on onshore surface water and offshore water quality from erosion, sediment resuspension and deposition and scouring, discharges, and inadvertent spills or releases. Onshore and offshore, overall cumulative impacts to water quality would be minor. When compared to the Proposed Action, offshore water quality impacts could slightly decrease depending on final design.
Bats	Continuation of population trends and continuation of effects to species from natural and human-caused stressors. Minor adverse effects if no other wind farms are authorized and minor adverse effects if they are authorized.	Negligible to minor adverse impacts on bats and suitable habitat from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative adverse impacts would be minor.	Negligible to minor adverse impacts on bats and suitable habitat from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative adverse impacts would be minor. When compared to the Proposed Action, collision risk could slightly decrease depending on final design.	Negligible to minor adverse impacts on bats and suitable habitat from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative adverse impacts would be minor. When compared to the Proposed Action, collision risk could slightly decrease depending on final design.
Benthic habitat, essential fish habitat (EFH), invertebrates, and finfish	Continuation of population trends. Continuation of effects to species from natural and human-caused stressors. Minor to moderate adverse effects if no other wind farms are authorized and minor to moderate adverse effects if they are authorized. Moderate beneficial from artificial reef effects.	Negligible to moderate impacts on benthic habitat, EFH, invertebrates, and finfish from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative impacts to benthic habitat, EFH, invertebrates, and finfish would be moderate.	Negligible to moderate impacts on benthic habitat, EFH, invertebrates, and finfish from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative impacts to benthic habitat, EFH, invertebrates, and finfish would be moderate. When compared to the Proposed Action, reduced WTG and cable installation could slightly decrease impacts depending on final design.	Negligible to moderate impacts on benthic habitat, EFH, invertebrates, and finfish from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative impacts to benthic habitat, EFH, invertebrates, and finfish would be moderate. When compared to the Proposed Action, impacts to complex habitat would be reduced. Reduced WTG and cable installation, as well as micrositing of these components, could slightly decrease other Project-related impacts depending on final design.
Birds	Continuation of population trends. Continuation of effects to species from natural and human-caused stressors. Minor adverse effects if no other wind farms are authorized and negligible to moderate adverse and moderate beneficial effects if they are authorized.	Negligible to minor temporary adverse impacts on birds and suitable habitat from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative impacts would be minor.	Negligible to minor impacts on birds and suitable habitat from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative impacts would be minor. When compared to the Proposed Action, collision risk could slightly decrease depending on final design.	Negligible to minor impacts on birds and suitable habitat from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative impacts would be minor. When compared to the Proposed Action, collision risk could slightly decrease depending on final design.
Marine mammals	Continuation of population trends and continuation of effects to species from natural and human-caused stressors. Moderate adverse effects if no other wind farms are authorized and Moderate effects if they are authorized.	Negligible to moderate impacts from construction and installation, O&M, and conceptual decommissioning activities, varying by species. Overall cumulative adverse impacts would be moderate adverse and minor to moderate beneficial.	Negligible to moderate impacts from construction and installation, O&M, and conceptual decommissioning activities, varying by species. Overall cumulative adverse impacts would be moderate adverse and minor to moderate beneficial. When compared to the Proposed Action, reduced WTG and cable installation could slightly decrease noise, turbidity, and collision impacts depending on final design.	Negligible to moderate impacts from construction and installation, O&M, and conceptual decommissioning activities, varying by species. Overall cumulative adverse impacts would be moderate adverse and minor to moderate beneficial. When compared to the Proposed Action, reduced WTG and cable installation could slightly decrease noise, turbidity, and collision impacts depending on final design.
Other terrestrial and coastal habitats and fauna	Continuation of population trends and continuation of effects to species from natural and human-caused stressors. Minor adverse effects if no other wind farms are authorized and negligible to minor adverse effects if they are authorized.	Negligible to minor impacts to terrestrial and coastal habitats and fauna from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative adverse impacts would be minor.	Negligible to minor impacts to terrestrial and coastal habitats and fauna from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative adverse impacts would be minor.	Negligible to minor impacts to terrestrial and coastal habitats and fauna from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative adverse impacts would be minor.
Sea turtles	Continuation of population trends and continuation of effects to species from natural and human-caused stressors. Minor adverse effects if no other wind farms are authorized and minor adverse effects if they are authorized.	Negligible to minor impacts from elevated underwater noise from construction, vessel traffic, and accidental discharges of spills or trash. Overall cumulative impacts would be minor adverse and minor beneficial.	Negligible to minor impacts from elevated underwater noise from construction, vessel traffic, and accidental discharges of spills or trash. Overall cumulative impacts would be minor adverse and minor beneficial. When compared to the Proposed Action, reduced WTG and cable installation could slightly decrease noise, turbidity, and collision impacts depending on final design.	Negligible to minor impacts from elevated underwater noise from construction, vessel traffic, and accidental discharges of spills or trash. Overall cumulative impacts would be minor adverse and minor beneficial. When compared to the Proposed Action, reduced WTG and cable installation could slightly decrease noise, turbidity, and collision impacts depending on final design.

Resource	No Action	Proposed Action	Vessel Transit Lane Alternative	Fisheries Habitat Impact Minimization Alternative (both layout options)
Wetlands and WOTUS	Continuation of existing trends/issues for wetland resources. Minor adverse effects if no other wind farms are authorized and minor adverse effects if they are authorized.	Short- to long-term, negligible to minor adverse impacts to wetlands and WOTUS from Project construction and installation, and conceptual decommissioning. No O&M impacts are anticipated. Overall cumulative adverse impacts would be minor.	Short- to long-term, negligible to minor adverse impacts to wetlands and WOTUS from Project construction and installation, and conceptual decommissioning. No O&M impacts are anticipated. Overall cumulative adverse impacts would be minor.	Short- to long-term, negligible to minor adverse impacts to wetlands and WOTUS from Project construction and installation, and conceptual decommissioning. No O&M impacts are anticipated. Overall cumulative adverse impacts would be minor.
Commercial fisheries and for-hire recreation fishing	Continuation of current trends. Negligible to moderate adverse effects if no other wind farms are authorized and negligible to moderate effects if they are authorized.	Negligible to major adverse construction and installation, O&M, and conceptual decommissioning impacts to commercial fisheries and for-hire recreational fishing due to increased port congestion; changes to fishing access, primarily through reduced fishing opportunity when construction activities are occurring; damage to or loss of fishing gear; and impacts on the catch due to changes in target species abundance or availability during construction activities. The reef effect of WTG foundations and associated scour protection is expected to have negligible to minor beneficial impacts to for-hire recreational fisheries, depending on the extent to which the foundations enhance fishing opportunities. Overall cumulative adverse impacts would be major.	Negligible to major adverse construction and installation, O&M, and conceptual decommissioning impacts to commercial fisheries and for-hire recreational fishing due to increased port congestion; changes to fishing access, primarily through reduced fishing opportunity when construction activities are occurring; damage to or loss of fishing gear; and impacts on the catch due to changes in target species abundance or availability during construction activities. The reef effect of WTG foundations and associated scour protection is expected to have negligible to minor beneficial impacts to for-hire recreational fisheries, depending on the extent to which the foundations enhance fishing opportunities. Overall cumulative adverse impacts would be major. When compared to the Proposed Action, the transit corridor could facilitate or hinder vessel transit, depending on the type of vessel. The transit corridor could increase the potential for allision, collision, and other navigation conflicts as compared to the Proposed Action.	Negligible to major adverse construction and installation, O&M, and conceptual decommissioning impacts to commercial fisheries and for-hire recreational fishing due to increased port congestion; changes to fishing access, primarily through reduced fishing opportunity when construction activities are occurring; damage to or loss of fishing gear; and impacts on the catch due to changes in target species abundance or availability during construction activities. The reef effect of WTG foundations and associated scour protection is expected to have negligible to minor beneficial impacts to for-hire recreational fisheries, depending on the extent to which the foundations enhance fishing opportunities. Overall cumulative adverse impacts would be major.
Cultural resources	Continuation of existing trends/issues. Negligible to major adverse effects if no other wind farms are authorized and negligible to major effects if they are authorized.	Negligible to major adverse impacts to marine and terrestrial archaeological resources and to historic visual resources from Project construction and installation, O&M, and conceptual decommissioning activities. Overall cumulative adverse impacts would be negligible to major across marine, terrestrial, and viewshed resources.	Negligible to major adverse impacts to marine and terrestrial archaeological resources and to historic visual resources from Project construction and installation, O&M, and conceptual decommissioning activities. Overall cumulative adverse impacts would be negligible to major across marine, terrestrial, and viewshed resources. When compared to the Proposed Action, could decrease viewshed impacts and the risk of marine resource damage or destruction to unknown submerged cultural resources based on final design.	Negligible to major adverse impacts to marine and terrestrial archaeological resources and to historic visual resources from Project construction and installation, O&M, and conceptual decommissioning activities. Overall cumulative adverse impacts would be negligible to major across marine, terrestrial, and viewshed resources. When compared to the Proposed Action, could decrease viewshed impacts and the risk of marine resource damage or destruction to unknown submerged cultural resources based on final design.
Demographics, employment, and economics	Continuation of existing trends for population and employment. Minor adverse to minor beneficial effects if no other wind farms are authorized and negligible to minor adverse and minor beneficial effects if they are authorized.	Negligible to minor adverse and minor to moderate beneficial impacts to the socioeconomic analysis area in terms of employment, federal revenue, and income from construction and installation, O&M, and conceptual decommissioning. Overall cumulative impacts would be minor adverse and minor beneficial.	Negligible to minor adverse and minor to moderate beneficial impacts to the socioeconomic analysis area in terms of employment, federal revenue, and income from construction and installation, O&M, and conceptual decommissioning. Overall cumulative impacts would be minor adverse and minor beneficial. When compared to the Proposed Action, slightly reduced, beneficial and adverse economic impact.	Negligible to minor adverse and minor to moderate beneficial impacts to the socioeconomic analysis area in terms of employment, federal revenue, and income from construction and installation, O&M, and conceptual decommissioning. Overall cumulative impacts would be minor adverse and minor beneficial. When compared to the Proposed Action, slightly reduced, beneficial and adverse economic impact.
Environmental justice	Continuation of current demographic trends. Minor to moderate adverse effects if other wind farms are not authorized and negligible to moderate effects if they are authorized.	Negligible to moderate adverse impacts to minority or low-income populations and tribes from Project construction and installation, O&M, and conceptual decommissioning activities. Overall cumulative adverse impacts would be minor to moderate adverse and minor beneficial.	Negligible to moderate adverse impacts to minority or low-income populations and tribes from the Project construction and installation, O&M, and conceptual decommissioning activities. Overall cumulative adverse impacts would be minor to moderate adverse and minor beneficial. When compared to the Proposed Action, air, water quality, and commercial fishing impacts could slightly decrease depending on final design.	Negligible to moderate adverse impacts to minority or low-income populations and tribes from the Project construction and installation, O&M, and conceptual decommissioning activities. Overall cumulative adverse impacts would be minor to moderate adverse and minor beneficial. When compared to the Proposed Action, air, water quality, and commercial fishing impacts could slightly decrease depending on final design.
Land use and coastal infrastructure	Continued activity in accordance with established land use patterns and regulations. Minor adverse effects if other wind farms are not authorized and negligible to minor effects if they are authorized.	Minor, beneficial impacts to land use due to increased compatible uses at ports, whereas construction or conceptual decommissioning of onshore components would have negligible to moderate, temporary adverse impacts due to disturbance associated with onshore construction, including traffic delays and re-routing. Overall cumulative impacts would be minor adverse and minor beneficial.	Minor, beneficial impacts to land use due to increased compatible uses at ports, whereas construction or conceptual decommissioning of onshore components would have negligible to moderate, temporary adverse impacts due to disturbance associated with onshore construction, including traffic delays and re-routing. Overall cumulative impacts would be minor adverse and minor beneficial.	Minor, beneficial impacts to land use due to increased compatible uses at ports, whereas construction or conceptual decommissioning of onshore components would have negligible to moderate, temporary adverse impacts due to disturbance associated with onshore construction, including traffic delays and re-routing. Overall cumulative impacts would be minor adverse and minor beneficial.
Navigation and vessel traffic	Current navigation trends would continue. Minor to moderate adverse effects if other wind farms are not authorized and minor to moderate adverse effects if they are authorized.	Negligible to minor impacts on navigation and vessel traffic in the region from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative adverse impacts would be moderate.	Negligible to minor impacts on navigation and vessel traffic in the region from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative adverse impacts would be moderate. When compared to the Proposed Action, navigation impacts could slightly increase or decrease depending on final design.	Negligible to minor impacts on navigation and vessel traffic in the region from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative adverse impacts would be moderate. When compared to the Proposed Action, navigation impacts could slightly decrease depending on final design.

Resource	No Action	Proposed Action	Vessel Transit Lane Alternative	Fisheries Habitat Impact Minimization Alternative (both layout options)
Other marine uses	No new impacts to marine uses and continuation of existing uses. Negligible to minor adverse effects if no other wind farms are authorized and negligible to minor (most uses) to moderate (military uses) to major (scientific research surveys) effects if they are authorized.	Negligible to major impacts to mineral extraction, military use, air traffic, land-based radar services, cables and pipelines, and scientific surveys. Overall cumulative adverse impacts would be minor for most uses. However, the overall impact would be moderate adverse for some military uses and radar and major adverse for scientific research and protected species surveys.	Negligible to major impacts to mineral extraction, military use, air traffic, land-based radar services, cables and pipelines, and scientific surveys. Overall cumulative adverse impacts would be minor for most uses. However, the overall impact would be moderate adverse for some military uses and radar and major adverse for scientific research and protected species surveys.	Negligible to major impacts to mineral extraction, military use, air traffic, land-based radar services, cables and pipelines, and scientific surveys from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative adverse impacts would be minor for most uses. However, the overall effect would be moderate adverse for military uses and major adverse for scientific research and protected species surveys.
Recreation and tourism	Continuation of existing trends and no beneficial impacts from Proposed Action. Minor to moderate adverse effects if no other wind farms are authorized and minor to moderate adverse and minor beneficial effects if they are authorized.	Negligible to minor short- to long-term impacts to recreation and tourism due to Project construction and conceptual decommissioning activities. O&M of offshore Project activities could elicit both beneficial and adverse impacts to recreational use of resources within the viewshed of the WTGs. Overall cumulative adverse impacts would be minor adverse and minor beneficial.	Negligible to minor short- to long-term impacts to recreation and tourism due to Project construction and conceptual decommissioning activities. O&M of offshore Project activities could elicit both beneficial and adverse impacts to recreational use of resources within the viewshed of the WTGs. Overall cumulative adverse impacts would be minor adverse and minor beneficial. When compared to the Proposed Action, recreation impacts could slightly increase or decrease depending on final design.	Negligible to minor short- to long-term impacts to recreation and tourism due to Project construction and conceptual decommissioning activities. O&M of offshore Project activities could elicit both beneficial and adverse impacts to recreational use of resources within the viewshed of the WTGs. Overall cumulative adverse impacts would be minor adverse and minor beneficial. When compared to the Proposed Action, recreation impacts could slightly increase or decrease depending on final design.
Visual resources	Continuation of impacts to viewshed from past and current activities. Minor to major adverse effects if no other wind farms are authorized and negligible to major adverse effects if they are authorized.	Negligible to major short- to long-term impacts on non-historic visual resources from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative adverse impacts would be minor to moderate, as the viewshed would return to previous condition after conceptual decommissioning.	Negligible to major short- to long-term impacts on non-historic visual resources from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative adverse impacts would be minor to moderate, as the viewshed would return to previous condition after conceptual decommissioning. When compared to the Proposed Action, visual impacts from nighttime lighting and structures could slightly decrease depending on final design.	Negligible to major short- to long-term impacts on non-historic visual resources from Project construction and installation, O&M, and conceptual decommissioning. Overall cumulative adverse impacts would be minor to moderate, as the viewshed would return to previous condition after conceptual decommissioning. When compared to the Proposed Action, visual impacts from nighttime lighting and structures could slightly decrease depending on final design.

CHAPTER 3. AFFECTED ENVIRONMENT AND ENVIRONMENTAL CONSEQUENCES

3.1 ANALYSIS APPROACH

Based on previous environmental reviews, subject-matter expert input, consultation efforts, and public involvement to date, BOEM identified the resources addressed in Section 3.3 Physical Resources, 3.4 Biological Resources, and 3.5 Socioeconomic and Cultural Resources as potentially affected by the Project. Each resource section identifies a unique geographic analysis area. Geographic analysis area descriptions and maps are provided in Appendix E.

With regard to temporal extent, the final EIS assumes that potential construction effects generally diminish once construction ends; however, ongoing O&M activities could result in additional impacts for the 25-year life of the Project. Additionally, SFW would have up to an additional 2 years to complete conceptual decommissioning activities. Therefore, the final EIS considers the time frame beginning with construction and ending when the Project's conceptual decommissioning is complete, unless otherwise noted. Final EIS figures called out in Chapter 3 are available in Appendix C (Figures C-1 through C-33), Appendix E (Figures E-1 through E-17), and Appendix F (Figures F-1 through F-7) unless otherwise noted.

The final EIS uses the following duration terms:

- Long-term effects: Effects that last for a long period of time (e.g., decades or longer). An example would be the loss of habitat where a foundation has been installed.
- Short-term effects: Effects that extend beyond construction, potentially lasting for several months, but not for several years or longer. An example would be clearing of onshore shrubland vegetation during construction; the area would be revegetated when construction is complete, and once revegetation is successful, this effect would end.
- Temporary effects: Effects that end as soon as the activity ceases. An example would be road closures or traffic delays during onshore cable installation. Once construction is complete, the effect would end.

In accordance with previous 1978 NEPA regulations (40 CFR 1508.27), the EIS evaluates Project impacts based on the criteria of context and intensity. Impact levels described in BOEM's 2007 *Programmatic Environmental Impact Statement for Alternative Energy Development and Production and Alternate Use of Facilities on the Outer Continental Shelf* (MMS 2007) were used as the initial basis for establishing adverse impacts specific to each resource. These resource-specific adverse impact levels were then further refined based on scientific literature and best professional judgment and are presented by resource in Sections 3.3 to 3.5.

When evaluating beneficial impacts and assigning an overall impact level to each resource, BOEM used a more general impact definition. Table 3.1.1-1 and Table 3.1.1-2 provide the definitions of potential adverse impact levels and potential beneficial impact levels, respectively, that are used for overall determinations across all resources in the final EIS. Where directionality (e.g., adverse or beneficial) is not specifically noted, the reader should assume the impact is adverse. These overall determinations consider the combined effects of the individual impact level for each IPF for each resource. Furthermore, BOEM has focused the main body of the final EIS on the impacts for resources of most concern and moved the analysis of other resources, including all resources consisting of only negligible to minor Proposed Action impacts, to Appendix H.

3.1.1 Definitions of Potential Adverse and Beneficial Impact Levels

Table 3.1.1-1. Definitions of Potential Adverse Impact Levels

Impact Level	Physical, Biological, and Cultural Resources	Socioeconomic Resources
Negligible	Either no effect or no measurable impacts	Either no effect or no measurable impacts
Minor	Most adverse impacts on the following affected resource(s) could be avoided; OR impacts that could occur would be small and the affected resource would recover completely without remedial or mitigating action, including the following: Local ecosystem health The extent and quality of local habitat for both special-status species and species common to the Lease Area The richness or abundance of local species common to the Lease Area Air or water quality Cultural resources	Most adverse impacts on the affected activity or community could be avoided; impacts would not disrupt the normal or routine functions of the affected activity or community; or the affected activity or community would return to a condition with no measurable effects without remedial or mitigating action.
Moderate	A notable and measurable adverse impact on the following affected resource(s) could occur, some of which may be irreversible; OR the affected resource would recover completely when remedial or mitigating action is taken, including the following: Local ecosystem health The extent and quality of local habitat for both special-status species and species common to the Lease Area The richness or abundance of local species common to the Lease Area Air or water quality Cultural resources	Mitigation would reduce adverse impacts substantially during the life of the Project, including conceptual decommissioning; the affected activity or community would have to adjust somewhat to account for disruptions due to notable and measurable adverse impacts of the Project; or once the impacting agent is gone, the affected activity or community would return to a condition with no measurable effects, when remedial or mitigating action is taken.
Major	A regional or population-level impact on the affected following resource(s) could occur; AND the affected resource would not fully recover, even after the impacting agent is gone and remedial or mitigating action is taken, including the following: Ecosystem health The extent and quality of habitat for both special-status species and species common to the Lease Area Species common to the Lease Area Air or water quality Cultural resources	Mitigation would reduce adverse impacts somewhat during the life of the Project, including conceptual decommissioning; the affected activity or community would have to adjust to significant disruptions due to large local or notable regional adverse impacts of the Project; and the affected activity or community may retain measurable effects indefinitely, even after the impacting agent is gone and remedial action is taken.

Table 3.1.1-2. Definitions of Potential Beneficial Impact Levels

Impact Level	Biological, Cultural, and other Physical Resources	Socioeconomic Resources
Negligible	Either no effect or no measurable impacts	Either no effect or no measurable impacts
Minor	Small and measurable effects that would comprise one of the following: Improvement in ecosystem health Increase in the extent and quality of habitat for both special-status species and species common to the Lease Area Increase in populations of species common to the Lease Area Improvement in air or water quality Limited aerial extent or short-term temporal duration of improved protection of cultural resources	Small and measurable effects that would comprise one of the following: Improvement in human health Benefits for employment Improvement to infrastructure/facilities and community services Economic improvement Benefit for tourism or cultural resources
Moderate	Notable and measurable effects comprising one of the following: Improvement in local ecosystem health Increase in the extent and quality of local habitat for both special-status species and species common to the Lease Area Increase in individuals or populations of species common to the Lease Area Improvement in air or water quality Extensive/complete aerial extent, or long-term temporal duration of, improved protection of cultural resources	Notable and measurable effects comprising one of the following: Improvement in human health Benefits for employment Improvements to facilities/infrastructure and community services Economic improvement Benefit for tourism or cultural resources
Major	Regional or population-level effects comprising one of the following: Improvement in the health of ecosystems Increase in the extent and quality of habitat for both special status and commonly occurring species Improvement in air or water quality Permanent protection of cultural resources	Large local, or notable regional effects comprising one of the following: Improvement in human health Benefits for employment Improvements to facilities and community services Economic improvement Benefit to tourism or cultural resources

3.2 MITIGATION IDENTIFIED FOR ANALYSIS IN THE ENVIRONMENTAL IMPACT STATEMENT

During the development of the EIS, BOEM considered potential additional mitigation measures that could further avoid, minimize, or mitigate impacts on the physical, biological, socioeconomic, and cultural resources assessed in this document. Table G-2 in Appendix G describes these potential additional mitigation measures and the subsequent Chapter 3 sections analyze them separately by resource. BOEM may choose to incorporate one or more additional mitigation measures in the ROD. As discussed previously, all SFW-committed measures are part of the Proposed Action (see Section 2.1.1.6 for details).

3.3 PHYSICAL RESOURCES

3.3.1 Air Quality

The reader is referred to Table 2.3.1-1 and Appendix H for a discussion of current conditions and potential impacts to air quality from implementation of the Proposed Action and other considered alternatives.

3.3.2 Water Quality

The reader is referred to Table 2.3.1-1 and Appendix H for a discussion of current conditions and potential impacts to water quality from implementation of the Proposed Action and other considered alternatives.

3.4 BIOLOGICAL RESOURCES

3.4.1 Bats

The reader is referred to Table 2.3.1-1 and Appendix H for a discussion of current conditions and potential impacts to bats from implementation of the Proposed Action and other considered alternatives.

3.4.2 Benthic Habitat, Essential Fish Habitat, Invertebrates, and Finfish

3.4.2.1 Affected Environment

The SFWF and SFEC would be developed in regional waters off the coasts of Rhode Island, Massachusetts, and Long Island, New York. The affected environment is a transitional zone separating Narragansett Bay and Long Island Sound from the OCS (BOEM 2013) and forms the approximate boundary between the Mid-Atlantic and New England oceanic ecoregions. These waters support a diverse and abundant assemblage of fishes and invertebrates, including many commercially and recreationally important species.

Two geographic analysis areas (see Table E-4 in Appendix E for descriptions) are used in the analysis of impacts for this resource group: one for benthic resources (Figure E-4a in Appendix E) and the other for EFH, invertebrates, and finfish (Figure E-4b in Appendix E). The benthic analysis area includes a 10-mile radius around the Lease Area and a 330-foot buffer on either side of the SFEC. The EFH, invertebrates, and finfish analysis area encompasses the Scotian Shelf, Northeast Shelf, and Southeast Shelf Large Marine Ecosystems, which captures most of the movement range within U.S. waters for most species in this group. Since the EFH, invertebrates, and finfish geographic analysis area encompasses the Gulf of Maine down to Cape Hatteras, North Carolina, for the purposes of Project-specific analysis in this final EIS, the focus is on EFH, invertebrates, and finfish that would be likely to have regular or common occurrences in the SFWF and SFEC and could be impacted by Project activities (Figure C-3 in Appendix C).

All of the evaluated analysis areas overlap Cox Ledge, an area of concern for fishery managers because it provides important habitat for several commercially and recreationally important species—notably, spawning habitat for Atlantic cod (*Gadus morhua*). A portion of Cox Ledge was designated by the New England Fishery Management Council (NEFMC) as a habitat management area to protect EFH for a number of managed fish species. NOAA acknowledged the importance of Cox Ledge but disapproved the designation because they concluded the proposed gear restrictions approved by the NEFMC would likely be ineffective at minimizing impacts on habitat function (NEFMC 2018; NOAA 2017a). BOEM is currently funding a 3-year study (AT-19-08) examining movement patterns of Atlantic cod, black sea bass, and other species in the southern New England region, including the SFWF Lease Area. The study is being conducted by NMFS and a team comprising a state resource agency, a university, and a nonprofit organization (BOEM 2019). Given the level of concern raised about potential impacts on Cox Ledge and Atlantic cod, the discussion of potential effects presented in the following sections places emphasis on this and other species of particular concern.

The affected environment for benthic habitat, EFH, invertebrates, and finfish is described below. Additional details on baseline conditions are provided in technical reports developed by SFW (Inspire Environmental 2020; Stantec 2020), which are available on BOEM's public Project website. The information presented here summarizes a refined characterization of benthic habitat conditions developed by BOEM and SFW working in collaboration with NMFS to support the EFH consultation (BOEM 2021a).

3.4.2.1.1 BENTHIC HABITAT

The Mid-Atlantic Regional Council on the Ocean (MARCO 2019), BOEM (Guida et al. 2017), NYSDEC (Nelson, Pope & Voorhis, LLC 2014), and SFW (Fugro 2019, 2021; Stantec 2020) have conducted large-scale general benthic habitat mapping within the SFWF and along the SFEC corridor. Inspire Environmental (2020) characterized site-specific benthic habitat conditions by combining photographic surveys with extensive side-scan sonar and backscatter data collected by Fugro (2018, 2019) to support the EFH analysis. Inspire Environmental (2020) identified four substrate classes: 1) glacial moraine, 2) coarse sediment, 3) sand and muddy sand, and 4) mud and sandy mud. Inspire Environmental (2019a, 2019b, 2020) provides photographic examples of these substrate classes.

For the purposes of analysis, these four substrate classes are consolidated into three habitat groups: 1) complex habitat, 2) potentially complex habitat, and 3) soft-bottom habitat (Figure 3.4.21 and Figure 3.4.2-2). Groups were based on substrate sizes and composition and by their use by marine organisms. Complex habitat includes glacial moraine and coarse sediment because boulders, cobbles, and pebbles dominate the sea floor in these areas, along with finer material (e.g., pebbles in a sand matrix), thus providing a heterogeneous variety of hard surfaces and fine material that provide habitat for many different species. Potentially complex habitat includes areas with mixed backscatter returns that may contain a substantial portion of boulders, cobbles, and pebbles but are lacking sufficient ground truthing images. Inspire Environmental (2019a, 2019b, 2020) provides photographic examples of these habitat types.

Soft-bottom benthic habitat is composed of sand and muddy sand and mud and sandy mud areas and does not include a substantial portion of coarse-grained sediment, although there may be scattered patches of gravels and small cobbles that constitute complex habitat. The mobile sediments that comprise soft-bottom habitat, such as sand and silt, are continually reshaped by bottom currents (Butman and Moody 1983; Daylander et al. 2012) and biological activity, forming features like sand waves and depressions that are used by many different fish species (Langton et al. 1995). Natural depressions and associated biological structures like amphipod tubes are components of designated EFH for some species, such as red and silver hake.

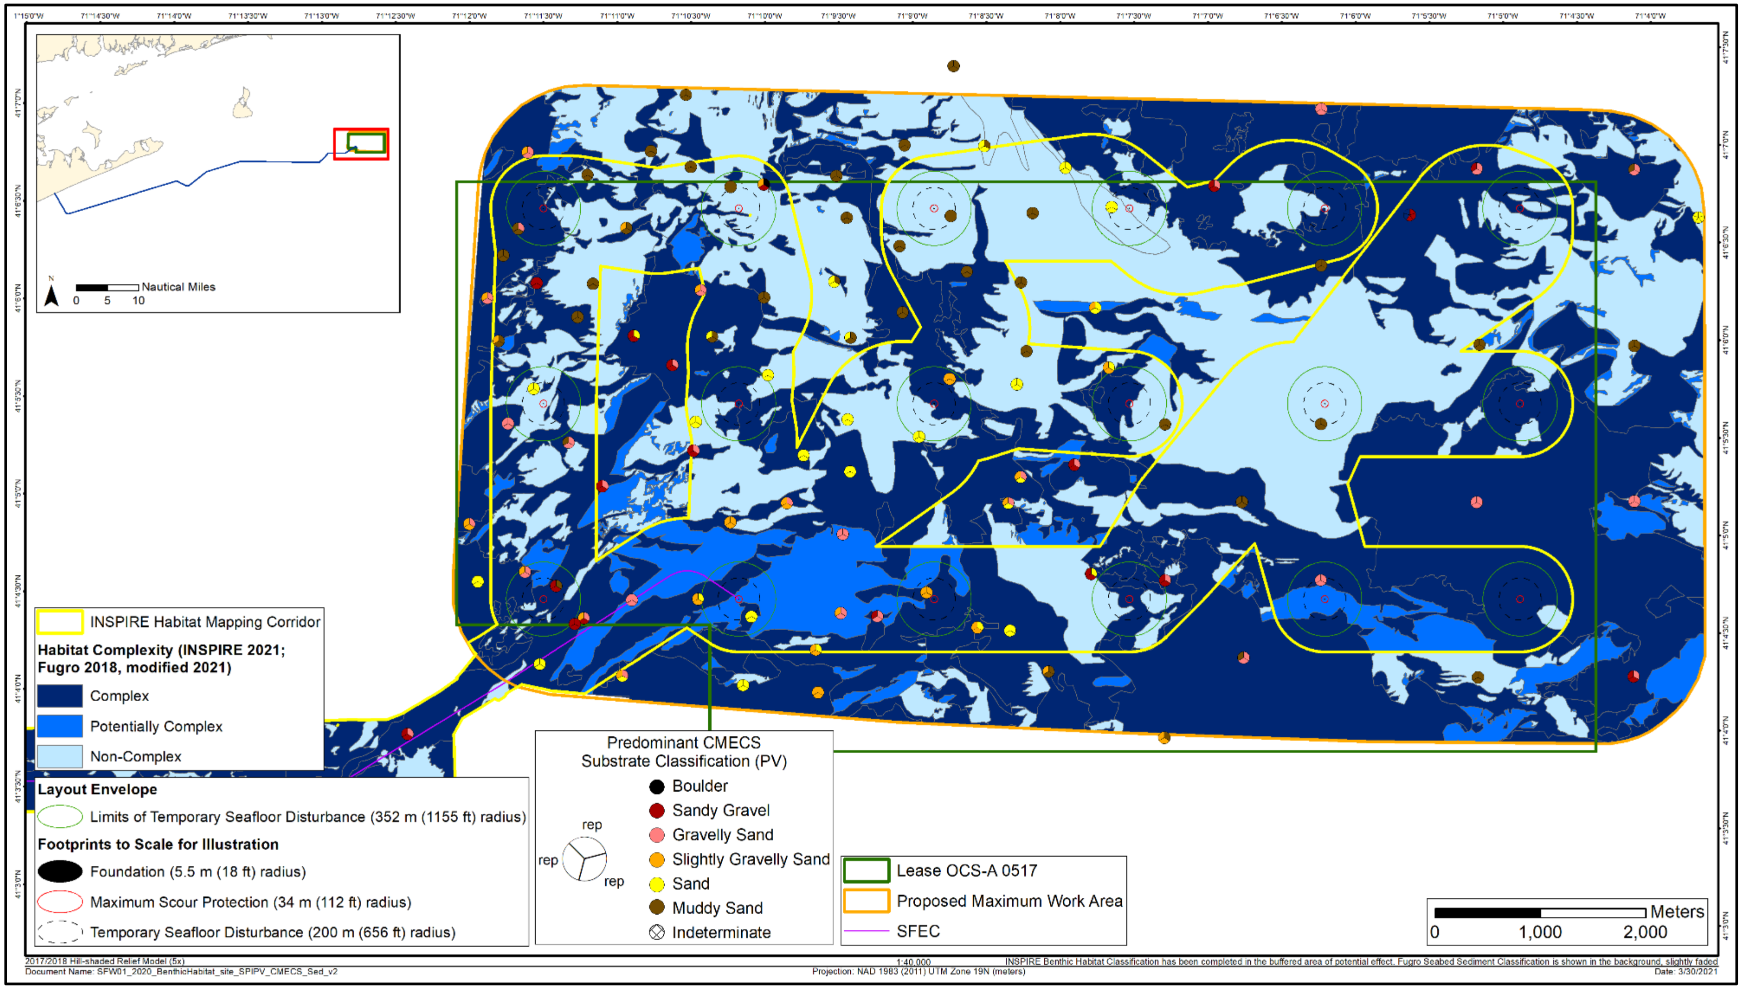

Figure 3.4.2-1. Distribution of complex, potentially complex, and soft-bottom benthic habitats and CMECS substrate classifications within the proposed MWA for SFWF construction, including alternate foundation locations.

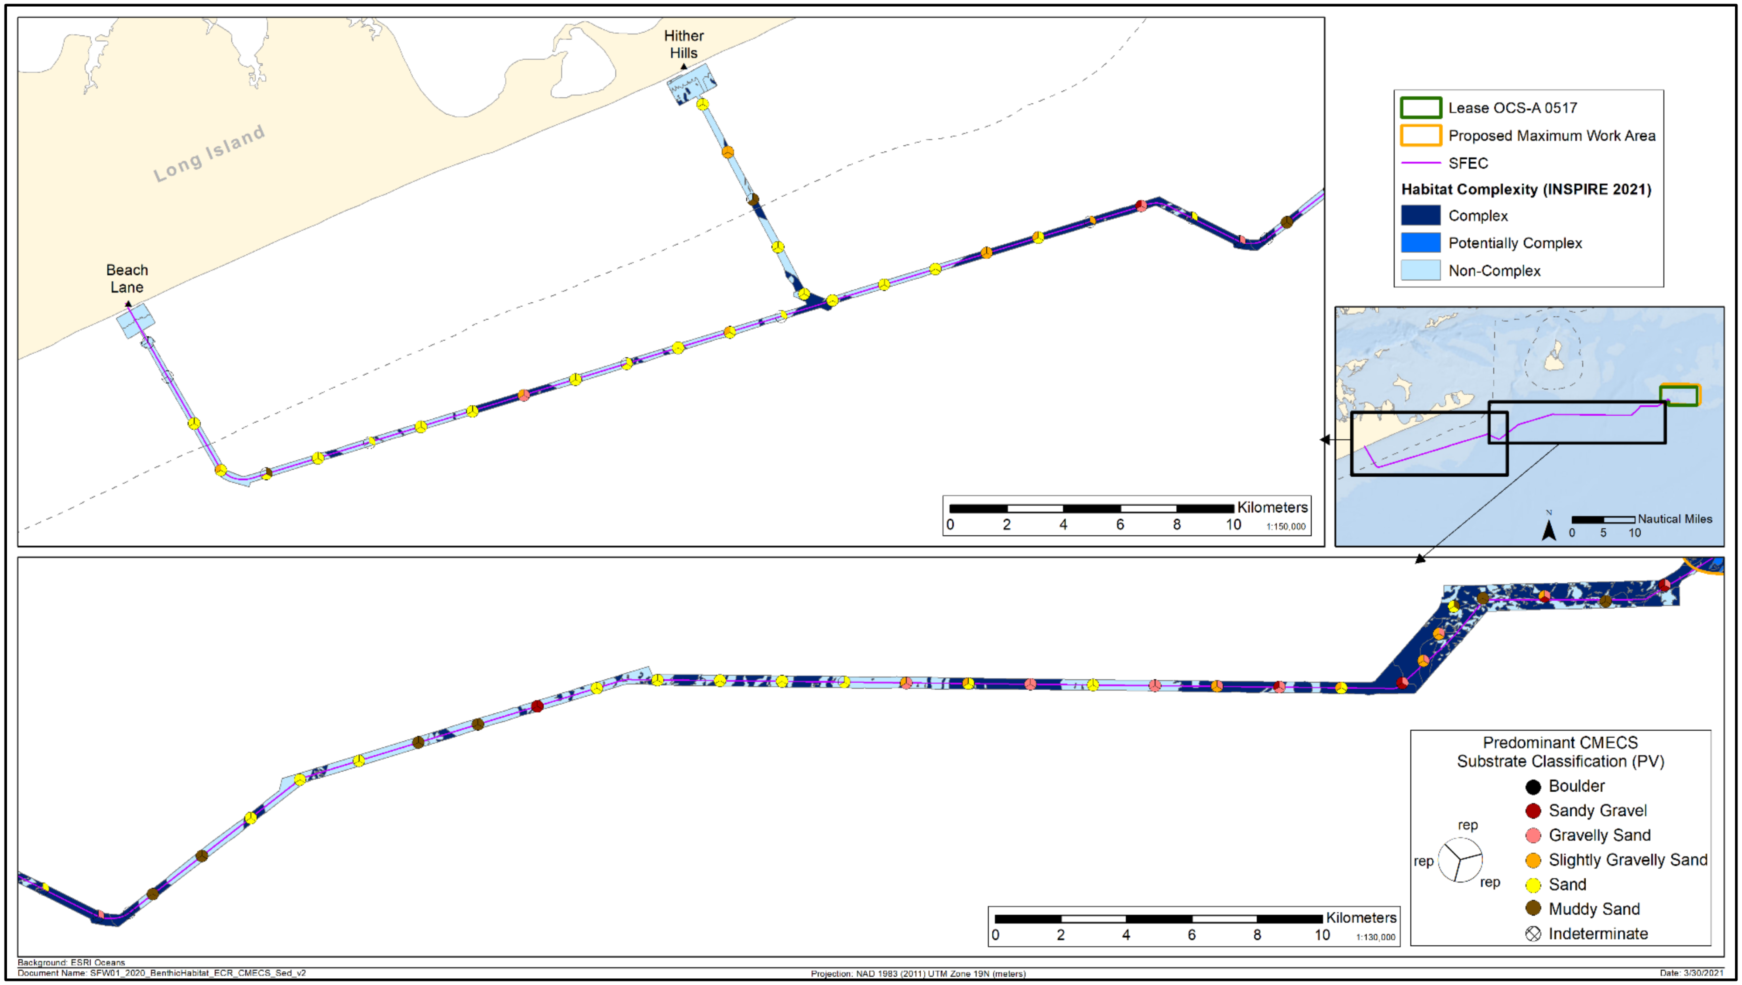

Figure 3.4.2-2. Distribution of complex, potentially complex, and soft-bottom benthic habitats and CMECS substrate classifications within the proposed MWA for SFEC construction, including the Hither Hills route alternative.

3.4.2.1.2 ESSENTIAL FISH HABITAT

The Magnuson-Stevens Fishery Conservation and Management Act requires federal agencies to consult with NMFS on activities that could adversely affect EFH. NOAA defines EFH as "those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity" (NOAA 2004, 2018). The majority of the EFH-listed species occurring in the waters of the mid-Atlantic and southern New England OCS are managed under federal fishery management plans (FMPs) developed by the NEFMC and the Mid-Atlantic Fishery Management Council (MAFMC) (2018; NEFMC 2018). In addition to these species, several other protected and/or highly migratory species that are managed through an FMP developed by NMFS (NOAA 2019) are known or likely to occur in the geographic area.

BOEM has prepared an EFH assessment for the Project (BOEM 2021a). The EFH assessment provides detailed species descriptions and life history information. In summary, EFH has been designated for the following species or management groups that occur on the southern New England and mid-Atlantic OCS (MARCO 2019):

- Northeast multispecies (e.g., Atlantic cod, haddock [*Melanogrammus aeglefinus*], Atlantic pollock [*Pollachius virens*], and summer flounder [*Paralichthys dentatus*])
- Shellfish, Atlantic sea scallop (*Placopecten magellanicus*), Atlantic surfclam (*Spisula solidissima*), and ocean quahog (*Arctica islandica*)
- Monkfish (*Lophius americanus*)
- Atlantic herring (*Clupea harengus*)
- Skates (Rajidae)
- Small-mesh species (e.g., silver hake [*Merluccius bilinearis*] and red hake [*Urophycis chuss*])
- Bluefish (*Pomatomus saltatrix*)
- Mackerel (*Scomber scombrus*), squids (Decapodiformes), and butterfish (*Peprilus triacanthus*)
- Highly migratory species (e.g., tunas [Thunnini], swordfish [*Xiphias gladius*], sharks [Selachimorpha], and billfish [Istiophoridae]
- Atlantic salmon (*Salmo salar*)
- Tilefish (Malacanthidae)
- Red crab (*Chaceon quinquedens*)
- Scup (*Stenotomus chrysops*) and black sea bass (*Centropristis striata*)
- Spiny dogfish (*Squalus acanthias*)

Some, but not all, of the EFH species covered by the respective FMPs occur within the geographic area. The Project EFH assessment (BOEM 2021a) identifies the EFH species and designated habitats by life stage that are known or likely to occur in the geographic area and provides a detailed assessment of the potential effects of the Proposed Action on EFH. The EFH assessment is available to the public on BOEM's SFW Project website (https://www.boem.gov/renewable-energy/state-activities/south-fork).

NOAA and fishery management councils also identify habitat areas of particular concern (HAPCs) as a component of EFH. HAPCs are high-priority areas for conservation, additional management focus, or research because they are rare, sensitive, stressed by development, or important to ecosystem function. The only HAPCs that could be impacted by Project activities are specific habitats for summer flounder. The summer flounder HAPC includes all native species of macroalgae, seagrasses, and freshwater and tidal macrophytes (i.e., submerged aquatic vegetation [SAV]) in any size bed, as well as loose aggregations, found within currently designated adult and juvenile summer flounder EFH. In locations where native SAV species have been eliminated from an area, then exotic species are included (MAFMC et al. 1998). The HAPC for juvenile Atlantic cod is defined as rocky habitats, in SAV or in sandy habitats adjacent to rocky and SAV habitats, from the mean high-water line to a depth of 66 feet (20 meters) in designated juvenile EFH in coastal areas extending from Maine through and including portions of Rhode Island. The juvenile inshore cod HAPC does not occur within the area impacted by Project activities and is therefore not considered further. No eelgrass, macroalgae, or other SAV is present within the dredging footprint, but eelgrass beds and other SAV are present approximately 375 feet (114 meters) to the northwest and 900 feet (275 meters) to the south and southeast of the O&M facility footprint.

3.4.2.1.3 INVERTEBRATES

For the purposes of the final EIS, marine invertebrates are grouped into three categories: 1) pelagic invertebrates, specifically squid, and pelagic invertebrate eggs and larvae; 2) benthic invertebrates associated with soft sediments (i.e., soft-bottom benthic habitat); and 3) benthic invertebrates associated with hard surfaces, such as boulders, cobble, and coarse gravel (i.e., complex benthic habitat).

Squid, specifically longfin and shortfin squid, are the pelagic invertebrate species likely to occur in the geographic area during their juvenile and adult life stages. However, numerous benthic invertebrate species have pelagic eggs and larvae and rely on currents to disperse their offspring to new habitats. These dispersed eggs and larvae are also a component of EFH, as they form part of the prey base for a variety of species during one or more life stages.

Soft-sediment invertebrates create a permanent or semipermanent home in the bed sediments. Most of these invertebrates possess specialized organs for burrowing, digging, embedding, tube building, anchoring, or locomotion in soft substrates. Some species are capable of moving slowly over the bed surface on soft substrates, but these species are generally not able to travel across hard substrates for long periods. Soft-sediment invertebrates include various types of annelid worms (oligochaetes and polychaetes), flatworms (Platyhelminthes), and nematodes (Nematoda); crustaceans, such as burrowing amphipods (Amphipoda), mysids (Mysida), copepods (Copepoda), and crabs (Brachyura); echinoderms, including sand dollars (Clypeasteroida), starfish (Asteroidea), and sea urchins (Echinoidea); and bivalve mollusks (Pelecypoda) (Federal Geographic Data Committee 2012; Inspire Environmental 2019a; Stantec 2020). Economically important species, including Atlantic sea scallop, bay scallop (*Argopecten irradians*), horseshoe crab (*Limulus polyphemus*), Atlantic surfclam, squid, and ocean quahog, are associated with soft sediments on the mid-Atlantic OCS.

Hard-surface invertebrates prefer harder substrate (such as boulders) and cobbles (defined in Section 3.4.2.1.1) as complex habitat. This group includes a diversity of species, such as members that firmly attach to hard surfaces or that crawl, rest, and/or cling to the surface of and/or shelter in the interstitial spaces between hard substrates. Attached invertebrates use structures like pedal discs, cement, and byssal threads to attach to the surface. Non-attached organisms use feet, claws, appendages, spines, suction, negative buoyancy, or other means to stay in contact with the hard substrate and may or may not be capable of slow movement over the surface. Examples of attached invertebrates include sea anemones, barnacles, corals, sponges, hydroids, bryozoans, mussels, and oysters. Examples of non-attached organisms include crabs, small shrimp, amphipods, starfish, and sea urchins (Federal Geographic Data Committee 2012; Inspire Environmental 2019a). Some economically important invertebrate species—notably, American lobster (*Homarus americanus*; also referred to as lobster)—are associated with hard substrates. Both soft-sediment and hard-surface invertebrate species are likely to be present within complex benthic habitat, with the former using patches of soft substrate commonly found in this habitat type. Soft-sediment invertebrates would be largely dominant in soft-bottom habitats, although some hard-surface species may occur on scattered hard surfaces where they are available.

Several commercially important invertebrate species, such as lobster, Atlantic sea scallop, longfin and shortfin squid, and ocean quahog, occur within the SFWF and SFEC portions of the geographic area (Inspire Environmental 2019a), and bay scallop, lobster, and channeled whelk (*Busycotypus canaliculatus*) occur in Lake Montauk and could occur within the O&M facility footprint (Stantec 2020). Squid eggs, most likely longfin inshore squid (*Doryteuthis pealeii*), were observed in two locations within the SFWF footprint, indicating that this species spawns in the vicinity. Longfin inshore squid also occur within Lake Montauk as foraging juveniles and adults (Inspire Environmental 2019a; Stantec 2020). Squid attach their eggs to bottom substrates and use both complex and soft-bottom benthic habitats for spawning.

The affected environment for invertebrates is influenced by commercial and recreational harvest of certain invertebrate species (e.g., squid, lobster), habitat modification, benthic habitat disturbance by activities like vessel anchoring and bottom-disturbing fishing methods, and regional shifts in biological community structure caused by climate change. Some commercial fishing methods, specifically scallop and clam dredges and bottom trawling, are a source of chronic disturbance of seabed habitats. Depending on the frequency of disturbance, this type of fishing activity can impact community structure and diversity and limit recovery (Nilsson and Rosenberg 2003; Rosenberg et al. 2003). The severity and rate of recovery from fishing-related disturbance is variable and dependent on the type of gear used and the nature of the affected habitat.

3.4.2.1.4 FINFISH

Numerous species of finfish belonging to the demersal, pelagic, and shark assemblages occur in and near the RI/MA WEA and the Montauk O&M facility. These include numerous EFH species and two ESA-listed species that are known or likely to occur within the SFWF and SFEC. The finfish resources of the region support diverse and highly valued commercial and recreational fisheries (see Section 3.5.1). BOEM has funded several surveys of finfish species occurrence in the RI/MA WEA, which are summarized by Guida et al. (2017). The EFH assessment prepared for the Project (BOEM 2021a) provides additional detail on federally managed fish species that occur in the geographic area.

Finfish can be divided into two general groupings, demersal and pelagic, based on their primary habitat association. Demersal species spend their adult life stage on or close to the ocean bottom and associate with specific types of benthic habitat. Examples include species like Atlantic cod, red and silver hake, and black sea bass that live on or near the seabed during one or more life stages and species like skates and flatfish that spend most of their lives directly on the seabed. Habitat preferences vary between species. For example, black sea bass, Atlantic cod, and haddock associate primarily with complex benthic habitats, while red hake and flounder use biogenic complex habitats, artificial reefs, and shell habitats as well as hard-bottom reefs in some portions of the region.

Pelagic fishes are generally schooling fish that occupy the mid- to upper water column as juveniles and adults. Pelagic species occupy the surface to midwater depths (0 to 3,281 feet [0 to 1,000 meters]) from the shoreline to the continental shelf and beyond. Examples include Atlantic herring, bluefish, and several shark species. Some demersal species, such as Atlantic cod and black sea bass, have pelagic eggs and larvae. Additionally, some pelagic species, such as Atlantic herring, have benthic eggs. Some purely pelagic species like tunas are highly migratory and only occur in the near-coastal and shelf surface waters of the Southern New England-New York Bight in the summer, taking advantage of the abundant prey in the warm surface waters.

These two groups encompass a diversity of species that associate with the full range of environment types that occur in the geographic area. Estuarine species, such as summer and winter flounder, are commonly found in nearshore areas, where freshwater inputs from large rivers mix with the ocean. Purely marine species are primarily found in offshore environments and include yellowfin tuna (*Thunnus albacares*), bluefin tuna (*Thunnus thynnus*), bluefish, swordfish, blue shark (*Prionace glauca*), common thresher shark

(*Alopias vulpinus*), and shortfin mako shark (*Isurus oxyrinchus*). Anadromous species spawn in freshwater and migrate to the open ocean to grow to adulthood, using estuarine and nearshore marine habitats for migration and larval and juvenile rearing. Four pelagic species of anadromous fish could be present in the geographic area: American shad (*Alosa sapidissima*), alewife (*Alosa pseudoharengus*), blueback herring (*Alosa aestivalis*), and Atlantic menhaden (*Brevoortia tyrannus*)(BOEM 2013; Petruny-Parker et al. 2015; Scotti et al. 2010). Additionally, striped bass (*Morone saxatilis*) are likely to use nearshore habitats, and Atlantic sturgeon would utilize demersal habitats. The catadromous American eel (*Anguilla rostrata*) also occurs as larvae, juvenile glass eels migrating to freshwater, and adults migrating to spawning habitats in the Sargasso Sea. This species uses pelagic habitats on the continental shelf for larval and juvenile metamorphosis, migration, feeding, and growth (Atlantic States Marine Fisheries Commission 2000).

The demersal and pelagic fish community structure of the mid-Atlantic and southern New England OCS is shifting due to a combination of factors, including climate change, fishing pressure, and modification of coastal and estuarine habitats (NOAA 2021). For example, the fish community structure in nearby Narraganset Sound has been changing over the past 6 decades, marked by dramatic declines in abundance followed by the slow rebuilding of large predators like sharks, the declining abundance of some demersal species (winter flounder, whiting, and red hake), and the increasing abundance for others (Atlantic butterfish, scup, black sea bass, and squid) (Collie et al. 2008; NOAA 2021). These shifts are mirrored throughout the mid-Atlantic and southern New England regions (Hare 2017; NOAA 2021).

Five ESA-listed fish species occur in the waters of the Northwest Atlantic OCS: giant manta ray (*Manta birostris*), Atlantic salmon, oceanic whitetip shark (*Carcharhinus longimanus*), Atlantic sturgeon (*Acipenser oxyrinchus oxyrinchus*), and shortnose sturgeon (*Acipenser brevirostrum*). Oceanic whitetip sharks are not known to occur in the SFWF and SFEC. This species could conceivably encounter Project vessels in open ocean waters as they travel to the Lease Area from Europe. BOEM (2021b) has concluded that vessel encounters would have no effect on this species; therefore, it is not considered further in this assessment. Only the giant manta ray and Atlantic sturgeon are expected to occur in the SFWF and SFEC and could be exposed to the effects of the Project. Refer to the Project biological assessment (BA) (BOEM 2021b) for a detailed assessment of the potential effects on these species.

The giant manta ray is a pelagic relative of the sharks, most commonly found in open ocean waters well to the south of the SFWF and SFEC. However, manta rays migrate seasonally over long distances, and the northern extent of their known range extends to upwelling zones along the edge of the continental shelf immediately to south of, and potentially including, the SFWF and SFEC. Critical habitat has not been designated for this species (NMFS et al. 2019). The Atlantic sturgeon is a large demersal, estuarine-dependent, anadromous species that historically spawned in medium-sized to large rivers on the U.S. Atlantic coast from Labrador to Florida (Atlantic Sturgeon Status Review Team 2007). Five separate distinct population segments (DPSs) of Atlantic sturgeon were listed under the ESA in 2012 (NOAA 2012): Chesapeake Bay (endangered), Carolina (endangered), New York Bight (endangered), South Atlantic (endangered), and Gulf of Maine (threatened). Atlantic sturgeon originating from rivers in Canada are currently not listed. The current marine range of Atlantic sturgeon extends from Labrador Inlet, Labrador, Canada, to Cape Canaveral, Florida (NOAA 2012). Designated critical habitat comprises the core riverine and estuarine habitats used by each DPS (NMFS et al. 2017), which does not occur in the area directly impacted by the SFWF and SFEC but overlaps with areas where Project vessels could transit.

3.4.2.2 Environmental Consequences

3.4.2.2.1 ISSUES, INDICATORS, AND SIGNIFICANCE CRITERIA

Table 3.4.2-1 lists the issues identified for this resource and the indicators and significance criteria used to assess impacts for this final EIS.

Table 3.4.2-1. Issues, Indicators, and Significance Criteria Used to Assess Impacts to Benthic Habitat, Essential Fish Habitat, Invertebrates, and Finfish

Issue	Impact Indicator	Significance Criteria
Underwater noise and vibration	Extent, frequency, and duration of noise above established effects thresholds, and/or other quantifiable effects as follows: Invertebrates: Eggs and larvae: 210 dB re 1 µPa Juvenile and adult longfin and shortfin squid: Behavioral response to particle motion effects up to 7 feet from monopile foundations Finfish: Varies by hearing group, see Table 3.4.2-4	Negligible: No measurable impacts to species or habitat would occur. Minor: Most impacts to species are avoided; if impacts occur, they may result in the loss of a few individuals. Impacts to sensitive habitats are avoided; impacts that do occur are short term or temporary in nature. Moderate: Impacts to species are unavoidable but would not result in population-level effects. Impacts to habitat may be short term, long term, or permanent and may include impacts to sensitive habitats but would not result in population-level effects to species that rely on them. Major: Impacts would affect the viability of the population and would not be fully recoverable. Impacts to habitats would result in population-level impacts to species that rely on them.
Crushing, burial, and entrainment	Estimated extent of potential disturbance, injury, and mortality-level effects on fish and invertebrates (including eggs and larvae) from crushing or burial by construction equipment and materials placement; entrainment by construction equipment; and burial effects from suspended sediment deposition.	
Seabed and water column alteration	Short-term and long-term effects on water column and benthic habitats by habitat displacement by monopiles; habitat modification by placement of scour protection and concrete mattresses; Short-term alteration of soft-bottom benthic habitat function; and long-term alteration of complex benthic habitat function	
Water quality impacts	Duration and intensity of suspended sediment impacts (quantitative)	
	Accidental spills, releases of trash and debris (qualitative assessment relative to baseline conditions)	
Artificial light	Extent and duration of artificial light effects (qualitative assessment relative to baseline conditions)	
Power transmission	Theoretical extent of potentially detectable electromagnetic field (EMF) and substrate heating effects, as follows: Benthic eggs and larvae, EFH: area exposed to magnetic field effects > 1,000 mG, electrical field effects > 500 mV/m Invertebrates: Benthic infauna: Magnetic fields > 1 mG, Inhabited substrates exposed to measurable heating effects Squid: > 800 mG Finfish: Theoretical extent of potentially detectable EMF effects by species group as follows:* Demersal and pelagic finfish and invertebrates: area exposed to magnetic field effects > 1,000 mG, electrical field effects 20 mV/m Electrosensitive species (sturgeon, skates, sharks): area exposed to magnetic field effects > 250 mG, electrical field effects 20 mV/m (at 60 Hz)	

Note: µPa = micropascal, dB = decibel, Hz = hertz, mG = milligauss, mV/m = millivolts per meter

* EMF sensitivity varies widely, no effect threshold guidance has been established. The minimum EMF levels needed to produce behavioral responses observed in available research are one or more orders of magnitude larger than the anticipated EMF effects likely to result from the Proposed Action. Electrosensitive fish can detect low-frequency bioelectric fields at very weak levels but are unable to detect higher frequency fields > 20 Hz (Bedore and Kajiura 2013).

3.4.2.2.2 NO ACTION ALTERNATIVE

Under the No Action alternative, BOEM would not approve the COP, and the Proposed Action would not be implemented. Existing environmental trends within the two geographic analysis areas would continue, potentially influenced by the development of planned future activities on the mid-Atlantic and southern New England OCS and associated coastal areas over the coming decade. These include other offshore wind and renewable energy projects and potential port improvements to support the development of this industry regionwide (see Appendix E). The potential impacts of these activities on existing conditions and trends would be limited to those IPFs that could conceivably occur within the geographic analysis areas.

This section provides a general description of these IPFs, recognizing the extent and significance of potential effects on conditions cannot be fully quantified for projects that are in the conceptual or proposal stage and have not been fully designed. The intent of this section is to provide a general overview of how future activities might influence future environmental conditions. If any or all of the future activities described in Appendix E proceed, each would be subject to independent NEPA analyses and regulatory approvals, and their environmental effects would be fully considered therein.

The Affected Environment section provides information on existing benthic habitat conditions, EFH, invertebrates, and finfish species occurring in the geographic area and vicinity and describes trends in habitat conditions, including the effects of past and present activities. Attachment 3 in Appendix E provides additional information regarding past and present activities contributing to current conditions in the geographic area. Attachment 3 in Appendix E also discloses future non-offshore wind activities and associated species impacts.

Future Activities (without the Proposed Action)

Accidental releases and discharges: Offshore wind energy development could result in the accidental release of water quality contaminants, trash, or other debris, which could theoretically lead to an increase in debris and pollution in the geographic analysis areas (see Section 3.3.2.2.2 [No Action Alternative] for characterization of existing marine pollution conditions). In general, the types of accidental hazardous materials releases associated with marine construction projects consist of fuels, lubricating oils, and other petroleum products. BOEM prohibits the discharge or disposal of solid debris into offshore waters during any activity associated with the construction and operation of offshore energy facilities (30 CFR 250.300). The USCG similarly prohibits the dumping of trash or debris capable of posing entanglement or ingestion risk (MARPOL, Annex V, Public Law 100−220 (101 Stat. 1458)). Compliance with these requirements would effectively minimize releases of trash and debris.

Increased vessel traffic associated with offshore renewable energy construction presents the potential for the inadvertent introduction of invasive species during discharge of ballast and bilge water. BOEM would require all Project construction vessels to adhere to existing state and federal regulations related to ballast and bilge water discharge, including USCG ballast discharge regulations (33 CFR 151.2025) and EPA National Pollutant Discharge Elimination System Vessel General Permit standards, effectively avoiding the likelihood of non-native species invasions through ballast water discharge. Considering these requirements and the dispersed distribution of planned offshore energy facilities, existing water quality trends are likely to continue.

The impacts from ongoing activities and future non-offshore wind activities stem from the increased potential for releases over the next 30 years due to increasing vessel traffic and ongoing, chronic releases. Future offshore wind activities would contribute to an increased risk of releases and impacts on benthic resources. The contribution from future offshore wind activities would represent a low percentage of the overall risk from ongoing activities. In context of reasonably foreseeable environmental trends, the combined impacts on benthic resources (mortality, decreased fitness, disease) from accidental releases and discharges are expected to be negligible, localized, and temporary due to the likely limited extent and duration of a release.

<u>Anchoring and new cable emplacement/maintenance</u>: Up to 1,627 acres could be affected by anchoring or mooring activities during offshore wind energy development within the EFH, finfish, and invertebrate geographic analysis area, as well as up to 27 acres within the benthic geographic analysis area. This offshore energy facility construction would involve direct disturbance of the seabed, leading to direct impacts on benthic, finfish, and invertebrate resources or degradation of sensitive habitats, including EFH. In general, however, these effects would be localized to the disturbance footprint and vicinity. The severity of these effects would vary depending on the species and life stage sensitivity to specific stressors that extend into the area, resulting in minor to moderate impacts on benthic resources. Such impacts are expected to be localized and temporary but could be permanent if they occur in eelgrass beds or hard-bottom habitats.

Future activities would also disturb up to 10,131 acres of seabed from cable installation within the EFH, finfish, and invertebrate geographic analysis area, as well as up to 1,702 acres within the benthic geographic analysis area, resulting in the long-term alteration of benthic habitat. The specific type and extent of habitat conversion and the resulting effects on benthic habitats, EFH, invertebrates, and finfish would vary depending on the project design and site-specific conditions. The widespread development of offshore renewable energy facilities would, however, create a distributed network of artificial reefs on the mid-Atlantic OCS. These reefs form biological hotspots that could support species range shifts and expansions, non-native species, and changes in biological community structure (Degraer et al. 2020; Methratta and Dardick 2019; Raoux et al. 2017). Those changes could influence fish and invertebrate community structure in the future, but the likelihood, nature, and significance of these potential changes are difficult to predict and a topic of ongoing research.

<u>Electromagnetic field (EMF)</u>: At least seven submarine power and communications cables cross the RI/MA WEA. These cables would presumably continue to operate and generate EMF effects under the No Action alternative. While the type and capacity of those cables is not specified, the associated baseline EMF effects can be inferred from available literature. Electrical telecommunications cables are likely to induce a weak EMF on the order of 1 to 6.3 microvolts per meter within 3.3 feet (1 meter) of the cable path (Gill et al. 2005). Fiber-optic communications cables with optical repeaters would not produce EMF effects.

Under the No Action alternative, up to 7,248 miles of cable would be added in the EFH, finfish, and invertebrate geographic analysis area, as well as up to 2,220 miles of cable within the benthic geographic analysis area, producing EMFs in the immediate vicinity of each cable during operations. BOEM anticipates that the proposed offshore energy projects would use high-voltage alternating current (HVAC) transmission, but high-voltage direct current (HVDC) designs are possible and could occur. BOEM would require these future submarine power cables to have appropriate shielding and burial depth to minimize potential EMF effects from cable operation. EMF effects from these future projects on benthic habitats, EFH, invertebrates, and finfish would vary in extent and significance depending on overall cable length, the proportion of buried versus exposed cable segments, and project-specific transmission design (e.g., HVAC or HVDC, transmission voltage, etc.). While EMFs are measurable within tens of feet of cable corridors, bottom-dwelling invertebrates (e.g., lobster) are impacted by the field as they temporarily pass over the cable location. Accordingly, EMF effects from future activities would be negligible. However, Hutchison et al. (2018, 2020c) have observed behavioral responses in lobster that were exposed to an EMF from an HVDC cable in a controlled environment, meaning that higher level (e.g., minor or moderate) effects could result should future projects use HVDC transmission.

Light: Artificial light can attract finfish and invertebrates and can influence biological functions (e.g., spawning) that are triggered by changes in daily and seasonal daylight cycles. Planned future activities include up to 2,547 offshore WTGs and OSS foundations in the EFH, finfish, and invertebrate geographic analysis area as well as up to 267 foundations within the benthic geographic analysis area. The construction and O&M of these structures would introduce new short-term and long-term sources of artificial light to the offshore environment in the form of vessel lighting and navigation and safety lighting on offshore WTGs and OSS foundations, respectively. BOEM has issued guidance for avoiding and minimizing artificial lighting impacts from offshore energy facilities and associated construction vessels (Orr et al. 2013) and has concluded that adherence to these measures should effectively avoid adverse effects on fish and other aquatic organisms. BOEM would require all future offshore energy projects to comply with this guidance. Given the minimal and localized nature of anticipated lighting effects under this guidance, the related effects from proposed future activities on habitat conditions are likely to be negligible.

Noise: Numerous proposed offshore wind project construction projects could be developed on the mid-Atlantic OCS between 2022 to 2030 (see Appendix E). This would result in noise-generating activities—specifically, impact pile driving, HRG surveys, construction and O&M vessel use, and WTG operation. BOEM believes it is reasonable to conclude that impact pile-driving, construction vessel, and HRG survey noise from future projects could adversely affect EFH, invertebrates, and finfish. In addition, construction noise impacts from future actions elsewhere in the mid-Atlantic OCS could adversely affect demersal and pelagic fish and invertebrates that migrate to or use the geographic analysis area during part of their life cycle. Due to the unknowns associated with proposed projects, the timing, extent, and severity of these effects on habitat and aquatic community structure cannot currently be quantified.

Tougaard et al. (2020) summarized available monitoring data on wind farm operational noise, including both older generation geared turbine designs and quieter modern direct drive systems like those proposed for the SFWF. They determined that operating turbines produce underwater noise on the order of 110 to 125 root mean square decibels (dB_{RMS}), occasionally reaching as high as 128 dB_{RMS}, in the 10-hertz (Hz) to 8-kilohertz (kHz) range. This is consistent with the noise levels observed at the Block Island Wind Farm (BIWF) (110 to 125 dB re 1 µPa sound pressure level [SPL] RMS; Elliot et al. 2019) and the range of values observed at European wind farms and is therefore representative of the range of operational noise levels likely to occur from future wind energy projects. More recently, Stober and Thomsen (2021) used monitoring data and modeling to estimate operational noise from larger (10 MW) current generation direct drive WTGs and concluded that these designs could generate higher operational noise levels than those reported in earlier research. This suggests that operational noise effects on finfish, including EFH species, could be more intense and extensive than those considered herein, but the findings have not been validated. In general, these noise levels are below established behavioral thresholds for most fish species, comparable to environmental baseline levels in busy marine traffic areas, and unlikely to be detectable to fish and invertebrates outside the respective wind farm footprints. The available information suggests the effects of operational underwater noise from future activities would occur for the life of the project but are not anticipated to have population-level effects and will be moderate.

Port utilization: The development of an offshore wind industry on the mid-Atlantic OCS may incentivize the expansion or improvement of regional ports to support planned and future projects. Activities like dredging and the expansion or development of new overwater structures could lead to adverse effects on coastal and estuarine habitats, finfish, and invertebrates, including EFH species. However, these localized habitat impacts would not affect benthic habitats within an associated geographic analysis area, due to the distance from shore.

Presence of structures: The future addition of up to 2,547 new WTG and OSS foundations in the EFH, finfish, and invertebrate geographic analysis area, as well as up to 267 foundations within the benthic geographic analysis area could result in artificial reef effects that influence benthic habitat and fish and invertebrate community structure within and in proximity to the project footprints. This could in turn influence the abundance and distribution of EFH species. While reef effects would largely be limited to the areas within and or close to wind farm footprints, the development of individual or contiguous wind energy facilities in nearby areas could produce cumulative effects that would be permanent and moderate beneficial for some species from habitat conversion and have minor adverse effects due to permanent habitat loss. New structures would attract structure-oriented fishes as long as the structures remain. Abundance of certain fishes may increase with temporary to permanent moderate impacts.

Hydrodynamic disturbance resulting from the broadscale development of large offshore wind farms is a topic of emerging concern because of potential effects on the Mid-Atlantic Bight cold pool. The cold pool is a mass of relatively cool water that forms in the spring and is maintained through the summer by stratification. The cold pool supports a diversity of fish and other marine species that are usually found farther north but thrive in the cooler waters it provides (Chen 2018; Lentz 2017). Changes in the size and seasonal duration of the cold pool over the past 5 decades are associated with shifts in the fish community composition of the Mid-Atlantic Bight (Chen 2018; Saba and Munroe 2019). Several lease areas within the RI/MA WEA are located on the approximate northern boundary of the cold pool. The potential effects of extensive wind farm development on features like the cold pool is a topic of emerging interest and ongoing research (Chen et al. 2016). Changes in cold pool dynamics resulting from future activities, should they occur, could conceivably result in changes in habitat suitability and fish community structure, but the extent and significance of these potential effects are unknown.

<u>Sediment deposition and burial and seabed profile alterations</u>: As previously noted, under the No Action alternative, up to 7,248 miles of cable would be added in the EFH, finfish, and invertebrate geographic analysis area, as well as up to 2,220 miles of cable within the benthic geographic analysis area. Cable placement and other related construction activities would disturb the seabed, creating plumes of fine sediment that would disperse and resettle in the vicinity. The resulting effects on benthic habitats, EFH, finfish, and invertebrates would be similar in nature to those observed during construction of the BIWF (Elliot et al. 2017) but would vary in extent and severity depending on the type and extent of disturbance and the nature of the substrates. These effects would be short term in duration, effectively ending once the sediments have resettled. Similarly, suspended sediment concentrations close to the disturbance could exceed levels associated with behavioral and physiological effects on fish and invertebrates but would dissipate with distance, generally returning to baseline conditions within a few hours. In theory, bed-disturbing activities occurring nearby (i.e., within a few hundred feet) could elevate suspended sediment levels, resulting in short-term, minor adverse effects on benthic habitat, EFH, finfish, and invertebrates.

<u>Climate change</u>: Global climate change is altering water temperatures, circulation patterns, and oceanic chemistry at global scales. These changes have affected habitat suitability for the invertebrate and finfish community of the geographic analysis area, including several EFH species. For example, several finfish species have shifted in distribution to the northeast, farther from shore and into deeper waters, in response to an overall increase in water temperatures and an increasing frequency of marine heat waves (NOAA 2021). Warmer water may influence finfish and invertebrate migration and may increase the frequency or magnitude of disease (Brothers et al. 2016; Hoegh-Guldberg and Bruno 2010). Ocean acidification, also a function of climate change, is contributing to reduced growth or the decline of zooplankton and other invertebrates that have calcareous shells (Pacific Marine Environmental Laboratory [PMEL] 2020). Climate change has also resulted in a significant increase in precipitation on the East Coast, increasing the amount of runoff and stormwater pollutants delivered by rivers to coastal and estuarine habitats. This has altered the character of these habitats in ways that have adversely affected some marine finfish and invertebrate species (NOAA 2021). These trends are expected to continue under the No Action alternative. The intensity of impacts resulting from climate change are uncertain but are anticipated to be minor to moderate.

Conclusions

Under the No Action alternative, BOEM would not approve the COP; Project construction and installation, O&M, and conceptual decommissioning would not occur; and potential impacts on benthic habitat, EFH, invertebrates, and finfish species associated with the Project would not occur. However, ongoing and future activities would have continuing temporary to long-term impacts on benthic habitat, EFH, invertebrates, and finfish species.

While the proposed Project would not be built as proposed under the No Action alternative, BOEM expects ongoing activities, future non-offshore wind activities, and future offshore wind activities to have continuing temporary to permanent impacts (disturbance, displacement, injury, mortality, reduced reproductive success, habitat degradation, habitat conversion) on benthic resources, finfish, invertebrates, and EFH, primarily through resource exploitation/regulated fishing effort, dredging, bottom trawling, bycatch, pile-driving noise, new cable emplacement, the presence of structures, and climate change.

Based on the analysis presented under the above IPFs, BOEM anticipates that the impacts of ongoing activities, especially seafloor disturbances caused by sediment dredging and fishing using bottom-tending gear, would be **moderate** for benthic resources. Reasonably foreseeable activities other than offshore wind include increasing vessel traffic; increasing construction, marine surveys, marine minerals extraction, port expansion, and channel deepening activities; and the installation of new towers, buoys, and piers would result in **minor** impacts for benthic resources. BOEM expects the combination of ongoing activities and reasonably foreseeable activities other than offshore wind to result in **moderate** impacts on benthic resources, primarily driven by ongoing dredging and fishing activities (see Appendix E, Attachment 3).

Likewise, BOEM anticipates that the impacts of ongoing activities, especially fishing, dredging, and climate change, would be **moderate for** EFH, invertebrates, and finfish species. In addition to ongoing activities, reasonably foreseeable activities other than offshore wind may also contribute to impacts on finfish, invertebrates, and EFH. Based on the same reasonably foreseeable activities noted above, BOEM anticipates that the impacts of reasonably foreseeable activities other than offshore wind would be **minor**. BOEM expects the combination of ongoing activities and reasonably foreseeable activities other than offshore wind to result in **moderate** impacts on finfish, invertebrates, and EFH, primarily driven by ongoing fishing activities.

The combined significance criteria in Table 3.1.1-1 and Table 3.1.1-2 are used to characterize the combined effects of all IPFs likely to occur under the No Action alternative. BOEM anticipates that the overall impacts associated with future offshore wind activities in the geographic analysis area combined with ongoing activities, reasonably foreseeable environmental trends, and reasonably foreseeable activities other than offshore wind would result in **moderate** adverse impacts and could potentially include **moderate** beneficial impacts on benthic resources due to the artificial reef effect. Future offshore wind activities are expected to contribute considerably to several IPFs, primarily new cable emplacement and the presence of structures—namely, foundations and scour/cable protection.

Likewise, BOEM anticipates that the overall impacts associated with future offshore wind activities in the geographic analysis area combined with ongoing activities, reasonably foreseeable environmental trends, and reasonably foreseeable activities other than offshore wind would result in **moderate** impacts and could potentially include **moderate beneficial** impacts for EFH, invertebrates, and finfish species. Future offshore wind activities are expected to contribute considerably to several IPFs, the most prominent being the presence of structures. The No Action alternative would forgo the fisheries monitoring that SFW has voluntarily committed to perform, the results of which could provide an understanding of the effects of offshore wind development; benefit future management of finfish, invertebrates, and EFH; and inform planning of other offshore developments. However, other ongoing and future surveys could still provide similar data to support similar goals.

3.4.2.2.3 PROPOSED ACTION ALTERNATIVE

Table 3.4.2-2 summarizes potential short-term and long-term benthic habitat disturbance by offshore Project components (Inspire Environmental 2021). As stated previously, Inspire Environmental (2020, 2021) has characterized benthic habitat conditions using extensive side-scan sonar and backscatter data to determine site-specific benthic habitat conditions.

Table 3.4.2-2. Short-Term and Long-Term Benthic Habitat Disturbance by Project Component

Project Component	Project Component Acres	Short-Term Disturbance		Long-Term Disturbance	
		Acres	%	Acres	%
SFWF*	13,700	1,217	8.9%	396	2.9%
SFEC†	4,944	630	12.7%	357	7.2%
O&M facility‡	0.9	0.034	3.8%	< 0.0001	0.04%
Total	18,645	1,847	9.9%%	754	4.0%

* Component acres are defined by the 13,700-acre SFWF Lease Area. Short-term disturbance area is based on 14.8 acres of foundation seabed preparation, 381.5 acres of seabed preparation for inter-array cable installation (estimated impacts plus a 20% contingency), and 821 acres of vessel-anchoring impacts in soft-bottom benthic habitat. Anchoring impact area is based on an estimated 182 anchoring events and 4.5 acres of benthic habitat disturbance per event. Long-term disturbance area is estimated based on 396 acres of seabed preparation and boulder relocation impacts (estimated impacts plus a 20% contingency), 0.4 acre of monopile foundations, and 31.7 acres of scour and cable protection placement within the seabed preparation footprint. Micrositing of foundation locations and cable routes may result in a greater percentage of cable installation impacts occurring in non-complex (soft-bottom habitat), decreasing the long-term habitat disturbance acreage below the estimate presented here.

† Short-term disturbance acres are based on 357.3 acres of SFEC seabed preparation (including installation trials), and 273 acres of short-term cofferdam construction impacts in soft-bottom benthic habitat (estimated impacts plus a 20% contingency). Long-term disturbance acres are based on 357.3 acres of seabed preparation and boulder relocation and 9.8 acres of cable protection placement within this footprint. Micrositing of cable routes may reduce long-term disturbance extent from this total.

‡ Component acres are defined by the approximate aquatic footprint of the Montauk O&M facility. Short-term disturbance is based on dredging impacts in soft-bottom benthic habitat. Long-term impacts are based on displacement of soft-bottom benthic habitat by five 24-inch-diameter steel piles.

Construction and Installation

Benthic Habitat

Noise and vibration: Benthic habitat is composed of various types of sediment, structural features that are formed by that sediment (e.g., interstitial spaces between boulders, sand waves, etc.), and organisms that reside in and on the sediment. Substrates and associated structural features are unaffected by underwater noise. Benthic invertebrates are sensitive only to the particle motion component of noise. Detectable particle motion effects on invertebrates are typically limited to within 7 feet (2 meters) of the source or less (Carroll et al. 2016; Edmonds et al. 2016; Hawkins and Popper 2014; Payne et al. 2007). Vibration from impact pile driving can also be transmitted through sediments. Recent research (Jones et al. 2020, 2021) indicate that longfin squid, an EFH species, can sense and respond to vibrations from impact pile driving at a greater distance based on sound exposure experiments. This in turn suggests that infaunal organisms, such as clams, worms, and amphipods, may exhibit a behavioral response to vibration effects over a larger area, but additional research is needed. Noise transmitted through water and/or through the seabed can cause injury and/or mortality to benthic resources in a limited area around each pile and can cause short-term stress and behavioral changes to individuals over a greater area. The affected areas would likely be recolonized in the short term, and the overall impact on benthic resources would be moderate.

Impact pile driving may also be used to install up to five 24-inch-diameter steel piles for moorage improvements at the Montauk O&M facility. This would result in similar vibration effects on benthic habitat potentially an unknown distance from the source, as bounded by surrounding shorelines.

Benthic habitat modification: The construction of the SFWF and SFEC would result in a range of temporary short-term and long-term impacts on benthic habitat. The estimated acres of construction-related impacts in each benthic habitat category are summarized by construction activity in Table 3.4.2-3. These values represent the best available estimate for the current Proposed Action design. However, micrositing will be used during construction to minimize impacts on complex benthic habitat to the greatest extent practicable. This would shift some of the projected impacts on complex benthic habitat to potentially complex and non-complex soft-bottom habitat.

Table 3.4.2-3. Acres of Benthic Habitat Disturbance by Habitat Type and Construction Activity

Construction Element	Maximum Construction Disturbance Footprint (acres)	Proportional Distribution of Impacts by Benthic Habitat Type		
		Complex	Potentially Complex	Soft Bottom
Monopile foundations and scour protection*	14.8	Monopile foundations and scour protection*	13%	35%
Inter-array cable and cable protection[‡]	318–382	Inter-array cable and cable protection[†]	10%	48%
Vessel anchoring	821	Vessel anchoring	Unknown	Unknown
SFEC installation and cable protection[‡]	457–549	SFEC installation and cable protection[‡]	1%	61%
Sea to shore transition	273	Sea to shore transition	–	100%
O&M facility	0.034	O&M facility	–	100%

* Approximately 0.925 acre of boulder relocation and seabed preparation could occur anywhere within a potential exposure area defined by a 200-meter radius around each foundation, which collectively have the proportional distribution of habitat types shown.

[†] Ranges represent the total standard and standard +20% contingency estimates of total benthic habitat impacts for inter-array cable and SFEC construction. The standard estimate is the total extent of overlapping habitat impacts from seabed preparation (boulder relocation) and placement of temporary cable protection. The proportional distribution of impacts by habitat type for each Project element is based on the habitat composition of the approved impact corridor for each Project element. The acres of habitat exposed to short- and long-term impacts would likely fall somewhere within this range. The total area impacted by placement of cable protection is 17.7 acres for the inter-array cable and 8.2 to 9.8 acres for the SFEC. These impacts would occur within the respective seabed preparation footprints for each Project component.

This section addresses temporary to short-term effects on soft-bottom benthic habitat resulting from seabed disturbance. While placement of the monopile foundations, scour protection, and concrete mattress cable protection are also elements of Project construction and installation, these features would remain in place throughout the operational life of the Project and would have long-term effects on habitat composition in all habitat types. These long-term effects are therefore considered under Operations and Maintenance and Conceptual Decommissioning.

Seabed preparation, cable trenching,[8] vessel anchoring, and short-term bed disturbance at the sea-to-shore transition site would also directly disturb soft-bottom benthic habitat by crushing and displacing epifaunal organisms on the bed surface and liquifying sand and mud sediments from the bed surface to depths of up to 6 feet, killing and displacing benthic infauna within the cable path. This process would also flatten sand waves and biogenic depressions that provide habitat for fish and invertebrates, including EFH species. Seabed preparation, cable trenching, and sea-to-shore transition construction effects would occur over up 1,204 acres of benthic habitat within the installation corridors for the inter-array cable and SFEC. Those impacts would occur in areas composed of 48% and 61% non-complex benthic habitat, respectively. Cable routes would be microsited in non-complex benthic habitat to the extent practicable; however, some cable installation impact acreage would also occur in complex or potentially complex benthic habitat within these installation corridors. Vessel anchoring would impact an estimated 821 acres of

[8] The potential equipment used for cable trenching (mechanical cutter, mechanical plow, and jet plow) are expected to have comparable effects to benthic habitat.

seabed. The distribution of these impacts by habitat type cannot be predicted with certainty, as vessel and anchor positioning are affected by wind and current conditions in real time. However, the vessel anchoring plan developed by the applicant will be used to identify and avoid impacts to complex benthic habitats to the greatest extent practicable. Impacts on soft-bottom benthic habitat are expected to recover within 18 to 24 months following initial disturbance, as a result of natural sediment transport processes (Daylander et al. 2012) and recolonization by benthic invertebrates from adjacent habitats. This estimate is based on observed recovery rates of sediment disturbance from cable trenching effects at the nearby BIWF (HDR 2020) and from similar types of bed disturbance in other regions (de Marignac et al. 2008).

Prior to construction, the seabed within the designated construction footprint would be cleared using a towed plow. The disturbance estimates presented above include seabed preparation effects on soft-bottom benthic habitat. Seabed preparation in complex and potentially complex benthic habitats would clear larger substrates like boulders and cobbles from the construction footprint. Sessile invertebrates and other benthic organisms would be damaged or killed as these substrates are rolled to the edge of the clearance area. Seabed preparation would impact a maximum of 382 and 549 acres of benthic habitat within the SFWF and SFEC construction footprints, respectively. Although the boulder relocation associated with seabed preparation is strictly a construction activity, relocating boulders within and between benthic habitat types constitutes a long-term habitat modification and is therefore addressed under O&M effects on benthic habitat in the following section.

O&M facility construction includes dredging an existing 0.034-acre berthing area from the existing depth of -5 feet mean lower low water (MLLW) to -12 feet MLLW to provide the draft needed for the 95-foot crew transfer vessel. This activity would change the depth profile of the site and kill or displace benthic organisms. This site is currently used as a commercial berthing area and is periodically dredged to maintain desired depths. Dredged materials would be dewatered in a contained area approximately 1,200 feet long × 26.2 feet wide (366 meters × 8 meters), placed landward of the plane of spring high water on the beach immediately to the west of the Montauk Harbor entrance. The dewatered materials would then be distributed adjacent to the dewatering area between the planes of mean high water and spring high water to nourish the beach. This area is currently used as a beneficial use placement site for materials from other maintenance dredging activities in Lake Montauk. Project O&M would include annual maintenance dredging to maintain the Project depth of -12 feet MLLW. As such, all the effects of O&M facility dredging and dredged material placement are considered in the following section under Operations and Maintenance and Conceptual Decommissioning.

<u>Suspended sediment impacts</u>: Jet plow trenching used to install the inter-array cable and SFEC, construction of the sea-to-shore transition, and O&M facility dredging would disturb the seabed and release plumes of suspended sediment into the water column. These sediments would be dispersed by the current and would settle back to the seabed within minutes to hours of the disturbance. The majority of water column effects would be limited to short-term total suspended solid (TSS) pulses below 100 milligrams per liter (mg/L). The highest TSS concentrations of 1,347 mg/L predicted to result from construction would dissipate quickly, lasting from minutes to hours (BOEM 2021a).

Suspended sediments will resettle on the seabed, blanketing the existing habitat with layers of fine sediment of varying thickness. Fine sediment deposition from inter-array cable construction could exceed 0.4 inch (10 millimeters [mm]) on up to 464 acres and 0.1 inch (3 mm) on up to 2,268 acres. Burial depths from SFEC construction could exceed 0.4 inch (10 mm) over 4.2 acres and 0.1 inch (3 mm) on 2,268 acres. Burial effects would cease within hours of initial bed disturbance. Inter-array cable installation impacts would occur intermittently over a 4-month construction window between May and December, while the SFEC would occur continuously over a period of approximately 2 months. The actual area of effect at a given moment during construction would be limited to the jet plow disturbance footprint and the sediment deposition zone downcurrent of the disturbance. The magnitude and duration of sediment effects must be considered in the context of the environmental baseline. As stated in Section 3.4.2.1.1, the sand and mud substrates on the mid-Atlantic OCS are continually reshaped by bottom currents. This means that these habitats and organisms associated with benthic habitat are regularly exposed to and therefore must be able to recover from burial by mobile sediments. In this context, the temporary to short-term effects of sediment deposition on benthic habitats would be negligible to minor.

Dredging associated with O&M facility construction and O&M would also generate suspended sediments that would resettle to the seabed. Suspended sediment concentrations would likely be similar to levels estimated by the USACE (2020) for maintenance dredging of the adjacent federal navigation channel, on the order of 282 mg/L within 6 feet of the bottom and dissipating to background within approximately 1,150 feet. Given the uncertainty about the potential type of dredging equipment used, potential TSS plumes from O&M facility construction are estimated to extend between 985 to 3,950 feet. While sediment deposition depths have not been estimated for O&M facility dredging, a comparison anticipating TSS concentrations from sea-to-shore transition construction suggests that burial depths of up to 0.4 inch (10 mm) could occur in close proximity to the dredging footprint. This could lead to negligible to minor effects on benthic habitats, as described above.

Essential Fish Habitat

BOEM (2021a) has developed a detailed assessment of the potential effects on EFH resulting from construction of the Proposed Action. EFH species include several species of demersal and pelagic finfish, benthic invertebrates (specifically Atlantic sea scallop, Atlantic surfclam, and ocean quahog), and pelagic invertebrates (specifically longfin and shortfin squid). Construction effects on EFH for these different species groups include the following:

- Benthic habitat disturbance
- Underwater noise and vibration impacts that exceed known thresholds for observable biological effects on EFH species and their prey organisms from the following noise sources:
    - Impact and vibratory pile driving
    - HRG surveys
    - Construction vessel noise
    - Dredging noise
- Temporary to short-term water quality effects from suspended sediments and sediment deposition on EFH species, prey organisms, and habitats

Several Project construction activities, including boulder relocation, placement of monopile foundations, scour protection, and concrete mattress cable protection, would also impact EFH species and their habitats. Because these elements are essential to the operation of the Project and they constitute a long-term habitat modification, their effects on EFH are addressed in the following section under Operations and Maintenance and Conceptual Decommissioning.

A detailed discussion of construction effects on each EFH species and their designated habitats is presented in the EFH assessment (BOEM 2021a). In general, effects on EFH resulting from the construction-related impact mechanisms listed above would be the same or similar in magnitude and extent to the effects on benthic habitat, invertebrates, and finfish and their habitats, as described in the preceding and following sections. These effects are temporary to short term in duration and range from negligible to minor in potential significance. Please see these respective sections for specific examples of potential effects on EFH species and habitats.

As discussed in Section 3.4.2.1.2, designated HAPC for summer flounder (SAV) could occur within the SFWF and SFEC. As stated in Appendix G, Table G-1, the applicant would avoid impacts to complex benthic habitats, including SAV, to the greatest extent practicable. This EPM should effectively avoid and minimize impacts to the extent that any effects on the summer flounder HAPC would be negligible.

Invertebrates

Construction of the Proposed Action would result in adverse effects on invertebrates from exposure to underwater noise; direct injury and mortality from crushing, burial, and entrainment; and exposure to elevated suspended sediments. These effects are described below.

Noise and vibration: Construction-related sources of noise and vibration that could affect invertebrates are impact and vibratory pile driving and HRG surveys. In general, mollusks and crustaceans are less sensitive to noise-related injury than many fish because they lack internal air spaces and are therefore less vulnerable to sound pressure injuries on internal organs than vertebrates (Popper et al. 2001). Most invertebrates are insensitive to hearing injury as they lack the specialized organ systems evolved by vertebrates to sense sound pressure (Popper et al. 2001). Current research suggests that some invertebrate species groups, such as cephalopods (e.g., octopus, squid), crustaceans (e.g., crabs, shrimp), and some bivalves (e.g., Atlantic scallop, Atlantic surf clam, ocean quahog) are capable of sensing sound through particle motion (Andre et al. 2011; Carroll et al. 2016; Edmonds et al. 2016; Hawkins and Popper 2014). Particle motion effects dissipate rapidly and are highly localized around the noise source, with detectable effects on invertebrates typically limited to within 3 to 6 feet of the source (Edmonds et al. 2016; Payne et al. 2007). Non-impulsive noise sources like vessel engines are less likely to produce behavioral effects in invertebrates.

While these conclusions reflect current knowledge, considerable uncertainty remains about sound sensitivity in some invertebrates. For example, squid exposed to 2 hours of continuous noise pulses ranging from 157 to 175 peak dB displayed damage to specialized sensory cells used for balance and orientation (Andre et al. 2011). More recently, Jones et al. (2020, 2021) determined that longfin squid, an EFH species, can likely sense and exhibit behavioral responses to vibration from impact pile driving transmitted through sediments potentially at a greater distance from the source, perhaps several hundred feet. They theorized that intense particle motion exposure could have indirect effects (e.g., impaired ability to detect predators or prey) on squid. These findings suggest that squid could experience injury or behavioral effects from intense underwater noise exposure, but evidence for this type of effect is limited and additional research is needed.

Squid within approximately 6.5 feet (2 meters) of HRG survey equipment may exhibit behavioral responses to particle motion effects, which equates to a total exposure area of 4,151 acres for pre-construction surveys of the SFWF and SFEC corridors. Assuming that bivalves, crustaceans, and other benthic invertebrates may be able to detect and respond to particle motion effects from impact pile driving within 16.4 feet (5 meters) of the source, this would equate to a total behavioral effect area for invertebrates, including prey organisms for EFH species, of less than 1 total acre for all 16 monopiles. Bivalve EFH species and other benthic invertebrate prey organisms are unlikely to be close enough to HRG survey equipment to detect particle motion effects from this noise source. These effects would be limited to temporary behavioral responses, most likely lasting for the duration of the noise impact and short periods (less than 30 minutes) following exposure. This would constitute a negligible effect on invertebrates.

Underwater noise may also affect invertebrate eggs and larvae. Popper et al. (2014) summarized available research on the sensitivity of finfish to underwater noise effects. They recommended thresholds for lethal injury and TTS effects by fish hearing group, including for fish eggs and larvae, which are summarized in Table 3.4.2-4. The applicability of the fish egg and larvae threshold to invertebrate eggs and larvae is unclear, but it is used here to estimate the range of potential effects. Noise impacts could be greater if they occur in important spawning habitat, occur during peak spawning periods, and/or result in reduced reproductive success in one or more spawning seasons, which could result in long-term effects to populations if one or more year classes suffer suppressed recruitment. However, pile driving could be restricted during peak spawning time. As shown in Table 3.4.2-5 in the following section (noise effects on finfish), impact pile driving is the only noise source with the potential to affect invertebrate eggs and larvae. Up to 163 acres surrounding each monopile foundation and 2,830 acres in total could be exposed to lethal noise effects on invertebrate eggs and larvae. Should impact pile driving be used for O&M facility construction, potentially lethal noise effects could occur over approximately 0.03 acre in total. These effects would be temporary in duration, occurring only during the activity. While mortality-level effects on invertebrate eggs and larvae could occur, these impacts are likely to be minor overall because 1) the area of effect is small relative to the available habitat, and 2) the loss of individuals would likely be insignificant relative to natural mortality rates for planktonic eggs and larvae, which can range from 1% to 10% per day or higher (White et al. 2014).

Table 3.4.2-4. Noise Exposure Thresholds for Finfish Lethal Injury, TTS, and Behavioral Effects

Fish Hearing Group	Threshold*				
	Lethal Injury, Peak*, †	Lethal Injury, Cumulative*, §	Recoverable Injury, Cumulative*, §	TTS*, §	Behavioral‡
Fish with swim bladder, involved in hearing	207	207	203	186	150
Fish with swim bladder, not involved in hearing	207	210	203	186	150
Fish without swim bladder	213	219	216	186	150
Eggs and larvae	210	207	None defined	None defined	N/A

* Thresholds from Popper et al. (2014).
† Values in dB re 1 µPa.
‡ Threshold from Fisheries Hydroacoustic Working Group (2008).
§ Values in dB re 1 $\mu Pa^2 s$.

<u>Crushing, Burial, and Entrainment</u>: Invertebrates within the construction footprint would be exposed to crushing and burial effects from seabed preparation, placement of monopiles, scour protection and concrete mattresses, cable installation, sea-to-shore transition construction, and vessel anchoring. The acres of construction-related bed disturbance are summarized by benthic habitat type in Table 3.4.2-3 in the Benthic Habitat section.

Invertebrates within these disturbance footprints could be exposed to crushing and burial effects. The extent and severity of exposure will vary by species and life stage–specific sensitivity and habitat association. For example, mobile pelagic invertebrates like longfin squid would likely be able to avoid being crushed during seabed preparation and materials placement or be overrun by the jet plow. In contrast, immobile eggs on the seabed, such as longfin squid eggs, would be vulnerable to these effects. Immobile or slow-moving benthic invertebrates (e.g., worms, anemones, surfclams, ocean quahogs) and immobile life benthic stages (e.g., longfin squid eggs) within the construction footprint would likely be killed by bed disturbance and could also be injured or killed by sediment deposition. Sessile invertebrates, like sponges and hydroids, attached to boulders and cobbles would be damaged or killed when boulders are relocated during seabed preparation and when scour and cable protection are placed in complex and potentially complex benthic habitats. Mobile benthic invertebrates, like adult lobsters and horseshoe crabs, would likely be able to avoid the jet plow but could be injured or killed by scour and cable protection placement.

The jet plow injects water into the sediments to liquify the seabed for cable installation. While the water intake, located near the water surface, is screened to avoid entraining (suctioning) small fish, it would unavoidably entrain and kill zooplankton and planktonic fish eggs and larvae. Zooplankton comprise a diverse group of invertebrate organisms, including larval life stages of crustaceans (crabs and lobsters), echinoderms (urchins and sand dollars), bivalves (clams and mussels), and other species; and invertebrates that spend their entire lives as zooplankton, such as calanoid copepods. Zooplankton are a central component of the food web and provide an important prey resource for many fish, filter feeding invertebrates, and even large marine mammals like humpback and North Atlantic right whale (NARW) (*Eubalaena glacialis*). Inspire Environmental (2019c) estimated potential plankton mortality based on jet plow intake volume and movement speed and documented plankton density. They calculated that over a billion fish eggs and 8.5 billion invertebrate zooplankton could be killed by entrainment impacts.

While construction impacts could injure or kill invertebrates on over 2,800 acres of benthic habitat (see Table 3.4.2-3) and kill billions of phytoplankton, these impacts must be placed into context to evaluate their significance. Invertebrates associated with soft-bottom habitat are likely to recover from disturbance within 18 to 24 months (de Marignac et al. 2008; Dernie et al. 2003; Desprez 2000; HDR 2020). In contrast, some invertebrates associated with complex benthic habitat, like sponges and hydroids, may take a decade or longer to fully recover (Auster and Langton 1999; Collie et al. 2005; Lukens and Selberg 2004; Tamsett et al. 2010). Accordingly, bed disturbance impacts could range from temporary and negligible for mobile invertebrates like adult squid and crabs; short term and minor for immobile or slow-moving invertebrates like clams, scallops, and worms in soft-bottom habitat; to long term for certain invertebrates associated with complex benthic habitat. The latter could be locally significant and, based on the long-term nature of the impact, would constitute a moderate impact.

While the volume of water used by the jet plow would likely approach 20 million cubic meters (Inspire Environmental 2019c), this represents a tiny fraction of the total habitat available to zooplankton. While distribution is not uniform, it is reasonable to conclude that 8.5 billion zooplankton represent a similarly small fraction of the total resource. Moreover, as stated in the previous section, zooplankton have high natural mortality rates, and losses of even several billion organisms may not be significant relative to natural mortality rates. On this basis, entrainment effects on invertebrates would be temporary and likely negligible.

The Proposed Action includes several EPMs, listed in Table G-1 in Appendix G, that would avoid and minimize impacts on invertebrates. These include design and siting of Project features to minimize the overall Project footprint and impacts on complex benthic habitat where practicable, establishing no-anchor areas to avoid sensitive habitats like observed squid spawning sites. These EPMs and additional mitigation measures would limit, but not completely avoid, crushing, burial, and entrainment impacts on invertebrates.

<u>Suspended sediment</u>: Seabed disturbance during cable installation, sea-to-shore transition construction, and O&M facility dredging would result in elevated suspended sediment concentrations in the water column and burial of benthic habitats as those sediments resettle to the bed surface. TSS concentrations and acres of benthic habitat exposed to different burial depths are summarized above under Benthic Habitat. As discussed, water column TSS concentrations could reach as high as 1,347 mg/L in limited areas but would dissipate quickly (within minutes) to less than 100 mg/L. TSS concentrations of this magnitude and duration are below levels associated with adverse effects on benthic invertebrates, eggs, and larvae (Wilber and Clarke 2001; Yang et al. 2017) and would therefore be negligible. Fine sediment deposition from SFWF construction could exceed 0.4 inch (10 mm) on up to 464 acres and 0.1 inch (3 mm) on up to 2,268 acres. Burial depths from SFEC construction could exceed 0.4 inch (10 mm) over 4.2 acres, and 0.1 inch (3 mm) on 2,268 acres. Invertebrates like burrowing bivalve clams and burrow-forming amphipods are highly tolerant to burial (Gingras et al. 2008; Johnson 2018). More sedentary invertebrates that cannot move within the sediment column as quickly, such as tube-dwelling polychaetas, could exhibit stress or mortality if buried (Johnson 2018). Some invertebrate species and their eggs and larvae could be

adversely affected by burial by as little as 0.4 inch (10 mm) of fine sediment (Wilber and Clarke 2001), but burial depths associated with stress are typically on the order of 2 inches or more (Johnson 2018). Given sediments within the SFWF and SFEC are mobile and continually reshaped by winter storm events (Daylander et al. 2012), the benthic invertebrate community is likely adapted to periodic burial effects. On this basis, sediment effects on invertebrates would be temporary and minor.

Potential discharges, spills, and trash: BOEM prohibits the discharge or disposal of solid debris into offshore waters during any activity associated with the construction and operation of offshore energy facilities (30 CFR 250.300). The USCG similarly prohibits the dumping of trash or debris capable of posing entanglement or ingestion risk (MARPOL, Annex V, Public Law 100−220 (101 Stat. 1458)). The Project would comply with these requirements (Jacobs 2021). Given these restrictions, the risk to benthic invertebrates from trash and debris from the Project is negligible.

Construction vessels also pose a potential risk for Project-related accidental spills. Small spills could occur during fuel transfers or collisions with other vessels or structures. SFW would follow strict oil spill prevention and response procedures during all Project phases, effectively avoiding the risk of significant spills. Given the low potential for spills and minimal risk of exposure to small temporary spills, the risk from construction-related petroleum spills is negligible.

Light: Light is an important cue in guiding the settlement of invertebrate larvae (Davies et al. 2015). Artificial light can change the behavior of aquatic invertebrates, although the direction of response can be species and life stage specific. Currently there are no artificial lighting sources present in the SFWF or SFEC, except for periodic vessel transit. The O&M facility would be sited in a developed commercial moorage with existing artificial lighting. Lights would be required on offshore platforms and structures, vessels, and construction equipment during construction of the SFWF. Consistent with BOEM guidance (Orr et al. 2013), construction vessels would implement lighting design and operational measures to eliminate or reduce lighting impacts on the aquatic environment. Although individual invertebrates may detect light effects from construction vessels and may exhibit behavioral responses (e.g., squid being attracted to the lights), these impacts are not expected to measurably affect invertebrates at population levels because of the limited area of impact at any given time and the limited duration of construction activities. Any resulting impacts on invertebrates would therefore be temporary and minor.

Finfish

Construction of the SFWF, SFEC, and Montauk O&M facility could result in potential impacts from 1) underwater noise; 2) crushing, burial, and entrainment; 3) suspended sediment exposure; 5) potential discharges, spills, and trash; and 6) artificial lighting effects.

Noise: Construction-related sources of noise and vibration that could affect finfish are impact and vibratory pile driving, HRG surveys, and vessel and dredging noise. Popper et al. (2014) compiled available research on underwater noise effects on fish and other aquatic life and established noise exposure thresholds for mortality, injury, and temporary threshold shift (TTS) in different species and life stages of fish based on sensitivity to sound. The Fisheries Hydroacoustic Working Group (2008) recommended a generalized threshold for behavioral effects on fish from noise exposure. These thresholds represent the current state of the science regarding potential noise effects on fish and are presented in Table 3.4.2-4 in the previous section (Invertebrates).[9]

[9] The noise thresholds in Table 3.4.2-5 represent the best available science regarding finfish sensitivity to injury-level noise effects. NMFS applies different threshold criteria developed by the Fisheries Hydroacoustic Working Group (2008) to evaluate underwater noise effects on ESA-listed species. The BOEM (2021b) BA for the Proposed Action alternative uses these more conservative thresholds to evaluate potential underwater noise effects on Atlantic sturgeon, manta rays, and their prey and forage species.

Table 3.4.2-4 organizes fish into groups based on the presence of a swim bladder and whether it is involved in hearing. Noise impacts on fish and invertebrates vary depending on the ability of the fish to detect sound pressure. Popper et al. (2014) reviewed the available research and developed a set of recommended injury thresholds for different groups of fishes and invertebrates depending on their specific biological sensitivity to sound. Fish with a swim bladder or other gas chamber involved in hearing (e.g., Atlantic herring and fish in the cod family) are considered hearing specialists and are the most sensitive to underwater noise impacts. Fish that have a swim bladder that is not directly involved in hearing, or hearing generalists, are intermediate in sensitivity to noise impacts. Fish species that lack swim bladders and similar gas-filled organs (e.g., sharks, rays, flatfish) are the least susceptible to underwater noise impacts. Eggs and larvae lack gas-filled organisms and are less susceptible to injury but are unable to avoid noise impacts because they are less mobile than adults.

The Proposed Action includes the installation of 16 monopile foundations using an impact hammer. The installation scenario considered in the analysis assumes 15 “standard” installations requiring approximately 4,500 pile strikes over 2 hours to achieve desired depth and one “difficult” installation requiring 8,000 pile strikes and up to 4 hours due to underlying substrate conditions. Denes et al. (2021) modeled construction noise likely to result from impact pile driving, vibratory pile driving, and construction vessel noise and how far noise exceeding the Popper et al. (2014) and Fisheries Hydroacoustic Working Group by noise source, hearing group, and effect level (Table 3.4.2-5).

Table 3.4.2-5. Maximum Potential Area Exposed to Construction Noise Exceeding Behavioral, TTS, and Lethal Injury Thresholds for Invertebrates and Finfish by Source

Exposure Category	EFH Species Category	Construction Noise Exposure Area by Source and Effect Category - total cumulative acres (instantaneous acres) *					
		Monopile Installation	HRG Surveys	Construction Vessels	Cofferdam Installation	O&M Pile Driving	O&M Dredging
Behavioral Effects	All finfish	204,037 (120,928)	1,627,335 (477)	24,891 (14.2)	420	621	2,315
	Squid	775 (195)	4,151 (< 0.002)	Insignificant	1.5	40	Insignificant
	Bivalves	1 (< 0.02)	Insignificant	Insignificant	0.37	0.37	Insignificant
TTS	All finfish	118,894 (58,744)	Within 16 feet of source	Insignificant	44.5	15.8	956
Lethal Injury	Fish with swim bladder involved in hearing	7,455 (163)	Insignificant	Insignificant	Insignificant	0.03	Insignificant
	Fish with swim bladder not involved in hearing	2,839 (163)	Insignificant	Insignificant	Insignificant	0.02	Insignificant
	Fish with no swim bladder	183 (12)	Insignificant	Insignificant	Insignificant	Insignificant	Insignificant
	Eggs and larvae	2,830 (163)	Insignificant	Insignificant	Insignificant	0.03	Insignificant

* Cumulative acres represent the total area exposed to noise effects for each noise source, instantaneous acres represent the exposure area at any given moment. For example, the instantaneous behavioral effect exposure area for HRG survey noise is 477 acres. The cumulative exposure area of 1,627,335 acres extends that instantaneous impact over 621 linear miles of HRG survey effort.

As shown, impact pile driving used to install the SFWF monopile foundations is the most intense source of noise resulting from the Project and would produce the most significant and extensive noise effects on fish. Pile driving would produce noise above the 150 dB_{PEAK} behavioral effects threshold on over 200,000 cumulative acres. While HRG survey noise would exceed the behavioral effects threshold over a larger cumulative area (1,627,335 acres), the continuously moving HRG vessels would distribute those impacts over 621 linear miles of survey effort. The instantaneous behavioral effects exposure area around the

HRG equipment would be smaller, approximately 477 acres. Monopile installation is the only activity likely to produce injury-level noise effects on fish over large areas, ranging from 183 to 7,455 cumulative acres for the least and most sensitive species groups, respectively. O&M facility construction could also produce injury-level effects but over a much smaller area (less than 0.1 acre).

Noise impacts on fish are likely to vary by species depending on general sensitivity to sound and how noise impacts overlap with sensitive life stages. Noise impacts could be greater if they occur in important spawning habitat, occur during peak spawning periods, and/or result in reduced reproductive success in one or more spawning seasons, which could result in long-term effects to populations if one or more year classes suffer suppressed recruitment. For example, Atlantic cod, hake, and black sea bass belong to the hearing specialist group and rely on sound for communication and other important behaviors. Alteration of the ambient noise environment could interfere with this ability, leading to potentially significant effects. Stanley et al. (2020) determined that noise from activities like impact pile driving could interfere with black sea bass communication during spawning but concluded that they would likely return to normal spawning behavior once the impact ceased.

In contrast, Atlantic cod rely on communication to spawn effectively, using low-frequency grunts to locate potential mates and signal fertility (Rowe and Hutchings 2006). Cod also select specific spawning locations and are known to spawn on Cox Ledge, in the vicinity of the SFWF (Inspire Environmental 2019d). Alteration of the ambient noise environment could interfere with communication and alter behavior in ways that could disrupt localized cod spawning aggregations (Dean et al. 2012; Rowe and Hutchings 2006), raising concerns about noise impacts from the Proposed Action. Monopile installation is the most extensive noise impact and the most likely to cause this potential effect. Impact pile driving would only occur from May through December. BOEM has documented the presence of spawning Atlantic cod within and in proximity to the SFWF in mid-December (Inspire Environmental 2019), indicating that pile driving could occur when maturing and mature spawning cod are present in the vicinity.

While HRG survey and construction vessel noise could occur during winter and early spring, the instantaneous noise exposure areas from these moving noise sources are small. This suggests that that any impacts on cod spawning would be limited in extent and short term in duration. Other hearing specialist species may be exposed to construction noise, but the consequences of exposure will vary depending on multiple factors. For example, monkfish spawn between May and December but do so over broad areas and likely multiple times per year (Johnson et al. 2008). Red hake spawn during summer, and the SFWF and SFEC is located within a broader area identified as a hotspot for spawning and larval dispersal (Northeast Fisheries Science Center [NEFSC] 2020). However, unlike cod, this species spawns in the water column and does not associate with specific benthic habitats and therefore has less potential for direct noise exposure.

Hearing generalist species have a swim bladder that is not directly involved in hearing. Species in this group may also use sound to communicate (Ladich and Schultz-Mirbach 2016; Popper et al. 2014). Examples of hearing generalists that occur in the SFWF and SFEC include ocean pout, butterfish, scup, and tunas. While the presence of a swim bladder makes these species susceptible to sound-related injury, they are less vulnerable than the hearing specialists. Impact pile driving is the only source of construction noise likely to cause injury in this group, with an effect area limited to approximately 2,840 cumulative acres (see Table 3.4.2-5). Fish that lack a swim bladder are the least vulnerable to noise impacts. While they have hearing organs and are susceptible to hearing injury, the lack of a swim bladder makes them less vulnerable to internal injuries leading to death (Popper et al. 2014). Examples of species in this hearing group that occur in the SFWF and SFEC include flatfishes (e.g., summer, winter, and yellowtail flounder), skates (e.g., little, barndoor, and winter skate), and sharks (e.g., sand tiger, tiger, and sandbar shark). Monopile installation is the only activity likely to cause injury-level noise effects on this species group within a cumulative exposure area of approximately 183 acres (see Table 3.4.2-5).

Fish eggs and larvae are potentially susceptible to injury and mortality from intense underwater noise. While available evidence is limited, Popper et al. (2014) defined injury criteria for eggs and larvae that are used in this final EIS to evaluate potential effects on both fish and invertebrates (see Table 3.4.2-4). Impact pile driving is the only construction noise source likely to produce injury-level effects on eggs and larvae. These impacts could occur over approximately 2,830 cumulative acres from monopile installation, and 0.03 acre from O&M facility construction. However, the extent and consequences of exposure are likely to vary. The instantaneous injury exposure area is relatively small (164 acres). Stationary eggs and larvae within this area would likely experience higher than natural levels of mortality. In contrast, eggs and larvae that drift with the current would not remain in the exposure area for extended periods and the additional impacts would not likely be significant relative to natural mortality rates on the order of 1% to 10% per day (White et al. 2014).

In summary, Project construction is likely to result in temporary to short-term noise impacts sufficient to cause a range of effects on finfish. These effects range from behavioral responses and temporary hearing threshold shifts to direct injury and mortality. The significance of these effects are likely to vary by species, depending on the number of individuals exposed and the degree to which noise impacts might interfere with important biological functions like spawning. As stated, timing restrictions would minimize adverse impacts on Atlantic cod spawning and likely avoid broader population-level effects. On balance, construction noise impacts on finfish would likely range from minor to moderate.

<u>Crushing, burial, and entrainment</u>: Finfish within the construction footprint would be exposed to crushing and burial effects from seabed preparation, placement of monopiles, scour protection and concrete mattresses, cable installation, sea-to-shore transition construction, and vessel anchoring. The acres of construction-related bed disturbance are summarized by benthic habitat type in Table 3.4.2-3 in the Benthic Habitat section.

Finfish within these disturbance footprints would be directly exposed to disturbance. Juvenile and adult fish are mobile and would likely avoid being harmed or killed by construction equipment and materials placement. In contrast, certain fish species, such as cod, ocean pout, pollock, and winter flounder, have benthic eggs and/or larvae that would be vulnerable to these effects. The extent of exposure would vary by species and habitat association. For example, cod and ocean pout eggs are typically found in complex benthic habitat, meaning that they are more likely to be exposed to boulder relocation and placement of scour and cable protection. Winter flounder lay their eggs in soft-bottom benthic habitat, which translates to greater exposure to jet plow, O&M facility dredging, and sea-to-shore transition construction.

The jet plow would entrain and kill pelagic fish eggs and larvae that are near the intake during operation. Inspire Environmental (2019c) estimated that over a billion fish eggs could be exposed to entrainment impacts, with exposure varying by species. For example, entrainment would kill an estimated 23,000 Atlantic cod larvae, a negligible number of haddock and pollock larvae, and up to 2.8 million Atlantic mackerel larvae. Effects on species like cod and mackerel must be placed into context to evaluate their significance. The total volume of water entrained by the plow (approximately 20 million cubic meters) represents a miniscule fraction of the billions of cubic meters of near-surface habitat on the mid-Atlantic OCS. A typical female cod lays over 1 million eggs (Alonso-Fernández et al. 2009), meaning that a spawning aggregation could produce hundreds of millions of eggs and larvae. The natural mortality rate for cod eggs and larvae is 10% to 20% and 6% each day (Mountain et al. 2008). The loss of 23,000 larvae would be negligible relative to natural conditions. Mackerel are abundant, and each female can produce between 300,000 and 2 million planktonic eggs (Morse 1980). The loss of 2.8 million eggs and larvae would be insignificant relative to the billions spawned in the region each year. On balance, entrainment of eggs and larvae would constitute a temporary and minor effect on finfish.

Suspended Sediment: The Project would result in temporary, elevated levels of suspended sediment near major bed-disturbing activities like cable installation. Anticipated water column sediment concentrations and burial depths resulting from this impact mechanism are described in the previous section (Invertebrates). TSS concentrations of the magnitude and duration anticipated are below levels associated with measurable adverse effects on finfish (Wilber and Clarke 2001; Yang et al. 2017) and would therefore be negligible. Juvenile and adult finfish associated with benthic habitats are unlikely to be significantly affected by sediment deposition at the burial depths anticipated, but benthic eggs and larvae of some species could be harmed (Kjelland et al. 2015; Michel et al. 2013; Wilber and Clarke 2001). While sensitivity varies widely, the eggs and larvae of some species can be killed by as little as 0.4 inch (10 mm) of sediment deposition. The eggs of certain species, like winter flounder, are particularly sensitive and can be killed by burial depths less than 0.1 inch (3 mm) (Michel et al. 2013). Given the temporary nature of the impact and limited extent of significant burial effects relative to the amount of habitat available, burial effects on benthic eggs and larvae would be minor.

Potential discharges, spills, and trash: Potential impacts from potential discharges, spills, and trash are the same as those discussed above in the Invertebrates section. In summary, BOEM and the USCG prohibit the discharge of trash and debris, and the Project EPMs (see Table G-1 in Appendix G) include specific measures for avoiding and minimizing accidental spills and discharges of hazardous substances. Therefore, there would be negligible Project-related adverse effects on fish from potential discharges, spills, and trash.

Light: Artificial lighting during construction at the SFWF and O&M facility would be associated with navigational and deck lighting on vessels from dusk to dawn. Lighting would be hooded and directed downward to avoid unnecessary illumination of the surrounding environment to the extent practicable. Reaction of finfish to this artificial light is highly species-dependent and could include attraction and/or avoidance of the area. Artificial lighting could disrupt the migration patterns of fish, increase risk of predation and disrupt predator prey interactions, and alter species richness and community composition in the affected area (Nightingale et al. 2006; Orr et al. 2013). However, these types of effects are most associated with bright permanent lights on nearshore and overwater structures. As stated in the previous section (Invertebrates), construction vessels would comply with BOEM guidance to eliminate or reduce measurable lighting effects on the aquatic environment. Construction lighting effects on finfish would be minimal, temporary, and therefore negligible.

Operations and Maintenance and Conceptual Decommissioning

Benthic Habitat

Project O&M would have continuing effects on benthic habitat conditions throughout the life of the Project. Most notably, the long-term presence of the structures would alter the character of the benthic habitat environment, converting existing soft-bottom benthic habitat into hard surfaces in the form of steel piles, rock scour protection, and concrete mattresses. These structures would become colonized by benthic organisms over time, leading to additional effects on benthic habitat conditions. Power transmission would generate EMF and substrate heating effects in proximity to the cables. These impact mechanisms and effects on benthic habitat are discussed further below.

Certain Project maintenance activities may also impact benthic habitat. For example, placement of additional scour protection may be required if erosion is observed around the monopile foundations. The inter-array cable and SFEC are not expected to require maintenance, but activities like reburial or placement of additional cable protection may be required if segments of cable become exposed by seabed movement. These maintenance activities would have similar adverse effects on benthic habitat to those described above for construction, but they would be periodic, limited in scale, and dispersed over a wide area. The berthing area at the Montauk O&M facility would be dredged annually to maintain desired depths, and dredged material would be used for beach nourishment. The annual dredging impacts are expected to be virtually the same as those described for Project construction, although the duration of dredging and volume of material removed each year would be smaller. This affected site is currently used for commercial fishing vessel moorage and is regularly dredged for maintenance purposes. Once desired depths have been achieved, future maintenance dredging of the O&M facility would not significantly change the area and frequency of maintenance dredging activities in Lake Montauk harbor relative to baseline conditions.

SFW monitoring measures, described in Section 2.1.1.7, would not measurably impact benthic resources because of the small intensity and scope of the surveys associated with the monitoring measures relative to impacts to benthic habitat from ongoing activities.

Long-term habitat conversion: Within the area directly affected through habitat conversion, the Proposed Action would alter existing benthic habitat, converting soft-bottom substrate to hard surfaces and vice versa. Benthic habitat impact acreage is summarized in Table 3.4.2-3. In general terms, SFWF and SFEC construction would permanently displace some benthic habitat within the monopile footprints, would alter the character of existing hard-bottom habitat exposed to reef effects, and would convert some soft-bottom benthic habitat to new hard surfaces in the form of scour protection and concrete mattresses. In total, an estimated 690 to 754 acres of benthic habitat within the area of direct effects would be exposed to long-term habitat conversion effects from monopile and inter-array cable and SFEC installation, and the subsequent placement of scour and cable protection within this footprint. Approximately, 0.4 acre of benthic habitat would be displaced by monopile foundations. Seabed preparation for monopile installation would modify approximately 14.8 acres of benthic habitat, and the subsequent placement of rock scour protection around the monopiles would permanently modify 14.0 acres within this footprint. Approximately 318 to 382 acres of benthic habitat would be modified by seabed preparation (boulder relocation) for inter-array cable construction, and 17.7 acres within this footprint would subsequently be modified by placement of cable protection. Seabed preparation for SFEC construction and pre-construction installation trials would modify approximately 357 acres of benthic habitat, and 8.2 to 8.9 acres of benthic habitat within this footprint would be modified by the subsequent placement of SFEC cable protection. The values presented as ranges represent the best current estimate of impacts and that estimate plus a 20% contingency based on the currently known Project configuration.

The distribution of habitat conversion impacts by benthic habitat type cannot be predicted with certainty, as pre-construction micrositing will affect where Project features are ultimately located. However, the habitat conversion impacts described above would occur within areas having the habitat composition shown in Table 3.4.2-3. In general, long-term impacts from boulder relocation are expected to occur in areas where boulders are most prevalent. However, boulder relocation may move boulders into soft-bottom (non-complex) habitat, changing its character. Cable protection would most likely be required in areas where hard substrates, such as boulder fields, prevent cable burial. This means that cable protection impacts are more likely to occur in complex benthic habitat, and those acres of impacts would overlap habitats previously impacted by boulder relocation. The values presented in this EIS likely overestimate the total acres of impacts that would occur, as micrositing of the foundations and cable routes would emphasize relocating Project features into soft-bottom benthic habitat where practicable. This would reduce the extent of long-term impacts. For example, adjusting cable routes to avoid complex benthic habitat may mean that less cable protection is ultimately required. Therefore, fewer acres of long-term habitat impacts would occur.

The introduction of 16 monopile foundations would alter pelagic habitats by introducing vertical hard surfaces into the water column. Over time the monopiles, the surrounding scour protection, and cable protection mattresses would become colonized by sessile invertebrates, such as mussels, tunicates, anemones, and sponges, creating complex habitat. Complex benthic habitat damaged during construction would also recover over time as benthic communities recover. Hutchison et al. (2020a) observed that turbine foundations at the BIWF developed dense colonies of mussels, extending from the surface to the scour protection on the seabed, within 3 years of construction. Other epifaunal species, such as hydroids, algae, and corals, had also started colonizing the structures. Shell hash and detritus falling from the foundations enriched the surrounding sediments, increasing biological productivity. Similar artificial reef effects have been observed at other offshore wind facilities (Causon and Gill 2018; Degraer et al. 2020; Langhamer 2012; Taormina et al. 2018). While benthic organisms colonized the BIWF relatively quickly, it could take a decade or more before damaged and newly introduced hard surfaces achieve full habitat function (Auster and Langton 1999; Collie et al. 2005; Lukens and Selberg; 2004; Tamsett et al. 2010). Offshore wind structures could in theory provide a foothold for harmful non-native species invasions. Non-native species have been observed at the BIWF and other wind farms (Hutchison et al. 2020a; Degraer et al. 2020), but negative impacts on native biological communities have yet to be demonstrated (Degraer et al. 2020).

The Proposed Action would permanently alter benthic habitats within the geographic analysis area, generating an array of effects on benthic habitat function. Soft-bottom habitats would be permanently displaced, while effects on complex and potentially complex benthic habitats would range from short term to long term or permanent. For example, some benthic species could take a decade or more to recover from damage and/or colonize new surfaces like concrete mattresses. Concrete mattresses used at the BIWF did not exhibit growth on the surface after 3 years but were observed to provide refuge space (HDR 2020). This would constitute a long-term reduction in benthic habitat function. In contrast, biologically productive reef effects like those observed at the BIWF would likely develop within 3 to 4 years after construction, continuing to mature over the life of the Project. These effects could be minor to moderate adverse and moderate beneficial, depending on how benthic habitat change influences the broader biological community.

<u>EMF and heat effects</u>: The inter-array cable and SFEC would generate EMF and substrate heating effects, altering the environment for organisms associated with those habitats. The cables would be contained in grounded metallic shielding to minimize electrical field effects and buried to target depths of 4 to 6 feet in soft-bottom benthic habitat (1.2 to 1.8 meters). Cable segments that cross unavoidable hard substrates will not be buried and will be laid on the bed surface covered with a concrete mattress for protection. EMF effects in these areas would be greater than for buried cable segments. EMF levels diminish rapidly with distance and would become indistinguishable from baseline conditions within about 26 feet (8 meters) of both buried and exposed cable segments (Exponent Engineering 2018). Hughes et al. (2015) and Emeana et al. (2016) evaluated the thermal effects of buried and exposed electrical transmission cables on the surrounding environment. They determined that heat from exposed cable segments would dissipate rapidly without measurably heating the underlying sediments. In contrast, the typical HVAC cable buried in sand and mixed sand and mud (i.e., soft-bottom benthic habitat) can heat sediments within 1.3 to 2 feet (0.4 to 0.6 meter) of the cable surface by +10 to 20 degrees Celsius (°C). EMF and substrate heating effects are summarized in Table 3.4.2-6.

Table 3.4.2-6. Behavioral, TTS, and Lethal Injury Thresholds for Invertebrates and Finfish by Source

Component	Installation	Total Cable Length (linear miles)	Magnetic Field		Electrical Field		Substrate Heating
			At Seabed	1 m above Seabed	At Seabed	1 m above Seabed	
Inter-array cable	Buried to target depth	15.6	21 mG	9 mG	1.4 mV/m	0.9 mV/m	+10 to +20°C within 0.4 to 0.6 m of cable
	On bed surface	5.8	65.1 Mg	27.9 mG	4.3 mV/m	2.8 mV/m	Negligible
SFEC	Buried to target depth	58.6	30 mG	21 mG	2.1 mV/m	1.4 mV/m	+10 to +20°C within 0.4 to 0.6 m of cable
	On bed surface	3.2	76.6 mG	53.6 mG	5.4 mV/m	3.6 mV/m	Negligible

The significance of EMF and cable heating on benthic habitat are best characterized in terms of how they might affect benthic invertebrates. These effects are evaluated in the following sections.

Conceptual decommissioning of the SFWF and SFEC components would follow the same relative sequence and time frame as construction but in reverse. The SFEC and inter-array cable would be removed from the seabed to recover valuable metals. Cable segments that cannot be removed successfully would be cut, capped, and buried. Rock and concrete blanket scour and cable protection would be removed and disposed of. The WTGs and OSS would be disassembled, and the foundation piles would be cut below the seabed using a cable saw. These conceptual decommissioning activities would produce short-term bed disturbance and suspended sediment effects similar to those described above for Project construction. The associated adverse effects on benthic habitat would be minor.

Conceptual decommissioning would reverse the artificial reef effect, converting approximately 50.2 acres (2.8% of the SFWF and SFEC footprints) from hard-bottom habitat back to soft-bottom habitat. Conceptual decommissioning effects on benthic habitat would be similar to those described above for construction, with damage to benthic organisms taking between 18 to 24 months to a decade or more to recover in soft-bottom and complex benthic habitats, respectively. Leftover shell hash and detritus from the reef effect would remain on the seabed after conceptual decommissioning. This would alter the character of the underlying sediments. Although this represents a long-term change from pre-Project conditions, localized alteration of sediment characteristics is unlikely to measurably change the ability of benthic habitat to support the biological community structure, which is relatively uniform across the diversity of substrate types that occur in the Lease Area (Guida et al. 2017). Therefore, the post–conceptual decommissioning adverse effects of the Project on benthic habitat would be negligible.

Essential Fish Habitat

BOEM (2021a) has developed a detailed assessment of the potential effects on EFH resulting from the O&M of the Proposed Action. EFH species include several species of demersal and pelagic finfish, benthic invertebrates (specifically Atlantic sea scallop, Atlantic surfclam, and ocean quahog), and pelagic invertebrates (specifically longfin and shortfin squid). Impact mechanisms affecting EFH for these different species groups from Project O&M include the following:

- Long-term habitat alteration
- Operational noise effects
- EMF and substrate heating effects
- Hydrodynamic effects

A detailed discussion of operational effects on each EFH species and their designated habitats is beyond the scope of this final EIS. The reader interested in this level of analysis is directed to the EFH assessment (BOEM 2021a). The following sections describe these impact mechanisms in detail and provide examples of their potential effects on representative invertebrate and finfish EFH species and their habitats.

Designated HAPC for summer flounder could occur within the SFWF and SFEC. HAPC for this species includes all native species of macroalgae as well as loose aggregations of algae and SAV wherever they are found within designated EFH (MAFMC et al. 1998). Project O&M could affect HAPC for this species by providing new hard substrates that may become colonized by algae. Should such habitats develop, they would become a component of HAPC by definition. This could in theory produce a beneficial effect on summer flounder HAPC lasting for the life of the Project. These habitat-forming surfaces would be removed during conceptual decommissioning, negatively affecting HAPC. These opposing effects would be long term in duration and moderate in significance.

Invertebrates

Long-term habitat alteration: The new hard structures created by SFWF monopiles, scour protection around the monopile foundations, and cable protection would displace existing habitat for invertebrates that use soft-bottom benthic habitat and create new habitats for invertebrates that colonize hard surfaces. As stated previously, approximately 0.12 acre of soft-bottom benthic habitat would be displaced by monopile foundations, 5.4 acres would be displaced by scour protection around the foundations, and 231.5 acres would be displaced concrete mattresses protecting exposed segments of the inter-array cable and SFEC. Those habitats would no longer be available to invertebrate infauna like tube worms and copepods and bivalves, including three EFH species (Atlantic surfclam, Atlantic sea scallop, and ocean quahog). Longfin squid, another invertebrate EFH species, also associate with soft-bottom benthic habitat.

Habitat for invertebrates that colonize hard surfaces or associate with complex benthic habitat would increase. Epibenthic organisms (e.g., mussels and anemones) and crustaceans that prefer hard-bottom habitat (e.g., American lobster and crab) would gain habitat, but as stated in the previous section (Benthic Habitat), it may take a decade or more for damaged or new habitats to fully recover habitat function. Degraer et al. (2020) have documented the development of diverse invertebrate communities on offshore wind structures. A diverse and biologically productive invertebrate community developed on turbine foundations at the nearby BIWF within 3 years after construction (Hutchison et al. 2020a). The structures were initially colonized by dense aggregations of mussels and barnacles, followed by corals, hydroids, anemones, and predatory invertebrates like crabs, sea stars, and snails. An invasive tunicate, already widespread and common in the region, is also present. As the reef effect matures over time, the diversity and biological productivity of the invertebrate community is expected to increase (Causon and Gill 2018). The resulting effects on invertebrates could be positive, negative, or neutral depending on a variety of factors. For example, the displacement of soft-bottom benthic habitat would constitute a limited but long-term moderate impact on invertebrates that use this habitat type. Some of these negative effects could be offset by organic enrichment and increased biological productivity in soft-bottom habitats at the edge of the reef effect zone (e.g., Hutchison et al. 2020a). Other invertebrate species, like those observed at the BIWF would gain new habitat and create opportunities for invertebrate species that would otherwise not be present in the offshore environment. Also, at the BIWF, concrete mattresses used to protect cable did not show any growth of invertebrate communities after 3 years (HDR 2020). To summarize, long-term habitat modification would create winners and losers, with some invertebrate species losing a small amount of habitat while others would gain. Negative population effects are unlikely to occur, as invertebrate species that lose habitat would still have abundant habitat available. On balance, the effects of habitat modification on invertebrates are likely to be beneficial, long term in duration, and moderate in significance for some species. However, the loss of some habitat from concrete mattresses would be an adverse minor to moderate long-term impact depending on the amount of cable protection used.

Invertebrates within the Montauk O&M facility footprint would be negatively affected by annual maintenance dredging of the 0.034-acre berthing area. As stated above under Benthic Habitat, this active commercial moorage is routinely dredged to maintain navigation, and the soft-bottom benthic habitats are subject to regular disturbance. Maintenance dredging would continue under the Proposed Action after the berthing area is dredged from the current depth of -5 feet to the desired depth of -12 feet MLLW. The O&M of the Proposed Action would therefore maintain current levels of disturbance and would not significantly alter baseline conditions for invertebrates. Therefore, the effects of O&M facility maintenance on invertebrates would be minor.

Operational noise: The SFWF would employ current generation direct-drive WTG designs that produce less underwater noise and vibration than older generation WTGs with gearboxes. Much of our current understanding about operational noise is based on the monitoring of wind farms in Europe that use these older generation designs. Although useful for generally characterizing potential noise effects, these data are necessarily representative of the noise produced by current generation designs (Elliot et al. 2019; Tougaard et al. 2020). Typical noise levels produced by older generation geared WTGs range from 110 to 130 dB_{RMS} with 1/3-octave bands in the 12.5- to 500-Hz range, sometimes louder under extreme operating conditions (Betke et al. 2004; Jansen and de Jong 2016; Madsen et al. 2006; Marmo et al. 2013; Nedwell and Howell 2004; Tougaard et al. 2009, 2020).

Elliot et al. (2019) summarized findings of operational noise monitoring from the BIWF. The BIWF employs five 6-MW direct-drive WTGs. Operational noise from the direct-drive WTGs at the BIWF were generally lower than older, lower capacity WTGs at European wind farms. Operational noise levels typically ranged from 110 to 125 dB_{RMS}, occasionally reaching as high as 128 dB_{RMS}, mostly at low frequencies ranging from 10 Hz to 8 kHz. Particle acceleration effects on the order of 10 to 30 dB re 1 $\mu m/s^2$ at a reference distance of 50 meters. These values are considered usefully representative of the underwater noise effects likely to result from SFWF operations.

Invertebrates lack specialized hearing organs and cannot sense sound pressure in the same way as fish and other vertebrates. Invertebrates can sense sound as particle motion, but particle motion effects dissipate rapidly and are usually undetectable within a few feet of the source. Certain species, specifically squid, may be more sensitive to sound than invertebrates as a group. However, the sound pressure and particle motion effects observed at the BIWF are well below levels associated with injury and behavioral responses in invertebrates and unlikely to cause measurable effects on these species. Moreover, the rapid development of benthic invertebrate communities on operational wind farms worldwide indicates that operational noise effects on invertebrates would be negligible.

EMF and substrate heating effects: The operation of the inter-array cable and SFEC would generate EMF and substrate heating effects that could affect benthic and pelagic invertebrates. These effects are summarized in Table 3.4.2-6.

The evidence for EMF effects on invertebrates is equivocal, varying considerably between species and based on the type and strength of EMF effects (Albert et al. 2020; Hutchison et al. 2020c). Several studies have observed no apparent behavioral responses in crustaceans and mollusks at EMF field strengths 10 to 100 times higher than the maximum levels likely to result from the Project. A handful of studies have observed apparent physiological effects on clams, mussels, and worms after a few hours of exposure to EMF levels well below those likely to result from the Project, while other studies have observed no apparent effects on the same types of organisms from much higher exposures over longer periods. These contradictory results are compounded by differences in study methods and the type of EMF exposure, making it difficult to draw any conclusions about the sensitivity of benthic infauna to EMF effects (Hutchison et al. 2020b). Given this uncertainty, the potential long-term effects on invertebrates that live in or directly on the seabed from Project-related EMFs could range from negligible to moderate.

While directed studies are lacking, there is little evidence that cephalopods like squid are sensitive to EMFs, even at exposure levels 10 times stronger than those likely to result from the Proposed Action (Love et al. 2015; Normandeau et al. 2011; Williamson 1995). This suggest that EMFs from the Project would have negligible effects on invertebrates like longfin and shortfin squid, both EFH species.

In addition to EMF effects, buried segments of the inter-array cable would generate sufficient heat to raise the temperature of the surrounding sediments by as much as 10 to 20°C above ambient temperatures within 1.3 to 2 feet (0.4 to 0.6 meter) of buried cable segments (see Benthic Habitat). Temperature changes of this magnitude could adversely affect Atlantic surfclam and ocean quahog (Acquafredda et al. 2019; Harding et al. 2008) as well as other benthic infauna species. However, the amount of suitable habitat exposed to these effects would be limited. Cable burial at 4 to 6 feet (1.2 to 1.8 meters) would limit substrate heating effects to depths 2 feet or more below the bed surface, below the depths inhabited by most invertebrate species. Cable segments at the transitions between fully buried and exposed cable segments would be buried at shallower depths, potentially exposing quahog and surfclam habitat and infaunal prey species to adverse thermal effects. However, these habitats would also be covered by concrete mattresses, meaning that the affected habitats would no longer be available to these species. On this basis, substrate heating would have a negligible effect on invertebrates.

Hydrodynamic effects: The presence of the SFWF monopile foundations and associated scour protection has the potential to affect hydrodynamic circulation at local scales. Vertical structures extending from the water surface will affect currents as they flow by the structures, creating turbulence. These turbulent wakes can extend from 200 to over 3,000 feet downcurrent, depending on site-specific conditions. That turbulence can increase mixing between bottom and surface layers, potentially affecting stratification, nutrient circulation, and larval dispersal (Carpenter et al. 2016; Floeter et al. 2017; Schultze et al. 2020). WTGs intercept wind energy that would otherwise contribute to mixing, with measurable effects extending 3 to 12 miles downwind from turbine arrays (van Berkel et al. 2020). While considerable uncertainty remains, these conclusions are most likely applicable to offshore wind facilities developed in environments with strong seasonal stratification (Miles et al. 2020; van Berkel et al. 2020).

Rhode Island Sound and the SFWF area are seasonally stratified, with warmer waters and higher salinity leading to strong stratification in the late summer and early fall. This stratification effect contributes to the formation of the Cold Pool, a band of cold, near-bottom water extending across much of the Middle Atlantic Bight from spring through fall (Lentz 2017). Mixing effects around pile foundations are masked in strongly stratified environments (Schultze et al. 2020; van Berkel et al. 2020), meaning that the same factors that form and maintain the Cold Pool are likely to limit the extent of measurable hydrodynamic effects. Localized mixing will still occur, however, bringing nutrients to the surface that can enhance phytoplankton growth and primary productivity at local scales (Floeter et al. 2017). The implications of these hydrodynamic effects for invertebrates are unclear. The limited research conducted to date has not been able to distinguish hydrodynamic effects on the fish and invertebrate community from natural variability (van Berkel et al. 2020). It is likely that filter-feeding invertebrate colonies that form on the monopile foundations would benefit from hydrodynamic effects that lead to localized increases in phytoplankton production (Slavik et al. 2019). This would in turn contribute to the reef effect described above, supporting the increased biological productivity of the invertebrate community that forms on and around the monopile foundations. Filter feeders would also eat the planktonic eggs and larvae of other fish and invertebrates, including EFH species. These impacts would be localized and unlikely to negatively affect the reproductive success of any invertebrate species.

For the purpose of this final EIS, measurable hydrodynamic effects would be expected occur within 600 to 1,300 feet downcurrent of each monopile. Given the relatively small number of monopile foundations at 1.1–linear mile spacing, the hydrodynamic effects of one monopile are not expected to influence the effects of another. Therefore, long-term hydrodynamic impacts would be localized to small areas within and downcurrent from the SFWF. The resulting effects on invertebrates would range from minor to moderate in significance, varying by species. The SFEC and O&M facility include no features that are likely to produce any measurable hydrodynamic impacts of significance for invertebrates.

Conceptual decommissioning: Project conceptual decommissioning would have similar effects on invertebrates to those described for the Proposed Action, but the extent and magnitude of these effects would differ.

The newly introduced surfaces are expected to develop a complex community of benthic invertebrates. The removal of these surfaces would injure or kill invertebrates attached to the surfaces or hiding in interstitial spaces and permanently alter benthic habitats within the conceptual decommissioning footprint. Mobile invertebrates living in association with these habitats may or may not survive, depending on their ability to reach other suitable habitats. As with Project construction, invertebrates associated with soft-bottom benthic habitats may recover relatively quickly, within 18 to 24 months after conceptual decommissioning is complete. In contrast, invertebrates associated with complex benthic habitat within the conceptual decommissioning footprint may take a decade or more to fully recover. That recovery could be inhibited if current trends in ocean habitat conditions resulting from climate change continue (Degraer et al. 2020). Collectively, Project conceptual decommissioning could have short- to long-term effects on invertebrates ranging in significance from minor to moderate.

Finfish

Long-term habitat alteration: The ongoing presence of monopiles, their foundations, and scour protection during Project O&M within the SFWF and SFEC would create an artificial reef effect.

The attractive effect of these artificial reefs on finfish is well documented (Degraer et al. 2020; Hutchison et al. 2020a; Kramer et al. 2015). In a meta-analysis of studies on wind farm reef effects, Methratta and Dardick (2019) observed an increase in the abundance of epibenthic and demersal fish species, while effects on pelagic species are less clear (Floeter et al. 2017; Methratta and Dardick 2019). Increased fish abundance around wind farm structures can also attract predators like seals (Russel et al. 2014).

Hutchison et al. (2020a) documented a significant increase in the abundance of black sea bass, an EFH species, around the BIWF. This species is known to associate with complex benthic habitat and artificial reef structures and is clearly benefiting from the habitat and foraging opportunities created by the artificial reef effect. Several other fish species have also been observed in abundance, including EFH species like Atlantic cod, scup, bluefish, monkfish, winter flounder, and dogfish. Atlantic striped bass and tautog, highly valued commercial and recreational fish species, have also been observed in abundance around the structures. Similar changes in fish community structure would likely occur at the SFWF as the reef effect matures. This indicates that while full recovery of complex benthic habitats damaged by Project construction could take a decade or more, those impacts could be offset over a shorter period of time by beneficial reef effects (see Benthic Habitat section).

The location of the Proposed Action on Cox Ledge, an area of complex benthic habitat used by a variety of highly valued fish species, has raised concerns about potential negative impacts on habitat function. The observations at the BIWF and other European wind farms (Hutchison et al. 2020a; Methratta and Dardick 2019) indicate that commercially valuable species like black sea bass, Atlantic cod, and pollock are likely to be attracted to the increased biological productivity these structures would create. While the available evidence to date suggests that the effects of long-term habitat alteration from wind farm development on finfish are generally beneficial at local and regional scales, considerable uncertainty remains about the potential for broader effects at population scales (Degraer et al. 2020). This could result in beneficial, neutral, or potentially negative effects. For example, increased feeding opportunities could translate to faster growth and increased reproductive success. Greater habitat productivity could also increase larval and juvenile survival within and around the affected habitats. Wind farms could also create "ecological traps" that compel fish to remain in habitats that are unfavorable for spawning and larval survival (Degraer et al. 2020). The latter could also have negative consequences if vulnerable populations of fish are concentrated together with their predators and/or increased fishing effort. Habitat use of European wind farms by cod and pollock has largely been seasonal (Reubens et al. 2014), indicating that negative effects on the migratory and spawning behavior is unlikely, at least for these species.

Beam trawling, placement of fixed gear and passive acoustic monitoring (PAM) mooring equipment, and the use of sediment profile and plan view imaging equipment may impact epibenthic and infauna associated with soft-bottom benthic habitat. This could in theory reduce the amount of prey available to marine fish, including Atlantic sturgeon. However, given the limited extent and duration of bottom-disturbing survey activities relative to the amount of habitat available on the mid-Atlantic OCS, these activities are unlikely to have a measurable effect on the feeding behavior and biological fitness of any individual fish. Vessel strikes or capture of individual fish in fisheries gear (from trawl and ventless trap and pot surveys) has the potential to result in injury and mortality, reduced fecundity, and delayed or aborted spawning migrations. However, the dispersed nature of Project monitoring vessel traffic and limited number of surveys reduces the potential for co-occurrence with individual fish. As such, risk of vessel strikes is assumed to be extremely low, and impacts, if any, would be insignificant (i.e., so minor that the effect could not be measured) (BOEM 2021c). Gillnet sampling poses a risk of injury or mortality to adult sturgeon, and a mortality event has already occurred during pre-construction gillnet sampling. A dead adult Atlantic sturgeon was recovered during a gillnet survey of the reference area to the west of the SFWF in May 2021. This evidence indicates that gillnet sampling is likely to result in adverse effects on Atlantic sturgeon.

In general, the potential effects of long-term habitat alteration on fish are likely to vary by species. The available evidence suggests that demersal fish species, including EFH species, are likely to benefit from increased habitat structure and biological productivity, while pelagic fishes may also benefit to a lesser extent. However, considerable uncertainty remains about the broader effects of this type of habitat alteration at population scales (Degraer et al. 2020). The Proposed Action is relatively small in scale compared to existing and planned wind farm developments, suggesting that broader population effects from this one facility are unlikely. These effects could become more significant when combined with those from other planned offshore energy developments in the future. On this basis, habitat alteration on finfish resulting from the Proposed Action are expected to be long term in duration and moderate in significance.

Operational noise: As discussed in the previous section for invertebrates, the SFWF would be expected to generate operational noise on the order of 110 to 125 dB_{RMS} within the 10-Hz to 8-kHz frequency range and particle acceleration effects on the order of 10 to 30 dB re 1 $\mu m/s^2$ at a reference distance of 50 meters. These noise effects are below injury and behavioral effects thresholds for all finfish species (see Table 3.4.2-4), indicating that potentially significant underwater noise effects from the SFWF on habitat suitability would be restricted to a small area around each monopile. For example, applying the practical spreading loss model (WSDOT 2020) to source noise level of 125 dB_{RMS} at 50 meters, noise levels exceeding the behavioral effects threshold for fish would be limited to within approximately 5 feet of the monopile surface. An individual fish belonging to the hearing specialist group would have to remain within a few inches of the pile surface for 24 hours to experience TTS. The same source would attenuate to an ambient noise levels of 90 to 95 dB_{RMS} within approximately 300 to 700 feet of each turbine.

Cod and other hearing specialist species are also potentially sensitive to particle motion effects. Elliot et al. (2019) compared observed particle motion effects at 164 feet (50 meters) from an operational BIWF turbine foundation to current research on particle motion sensitivity in fish. They concluded that particle motion effects could occasionally exceed the lower limit of observed behavioral responses in Atlantic cod and flatfish within these limits. However, the documented use of complex habitats created by the structures by cod, black sea bass, and other hearing specialist species at the BIWF and European wind farms (Hutchison et al. 2020a; Methratta and Dardick 2019) indicates that low-level operational noise effects are not causing avoidance responses. As stated previously (see Construction and Installation), Atlantic cod are sensitive to changes in the ambient noise environment during spawning (Dean et al. 2012; Rowe and Hutchings 2006). The low-frequency operational noise produced by WTGs overlaps the communication frequencies used by cod and other hearing specialist species like haddock (Stanley et al. 2017). This suggests that operational noise exceeding ambient levels could cause masking effects that reduce the effective communication range for these species and reduce reproductive success and future recruitment for species like cod and haddock.

The CTV used for Project maintenance would travel between the Montauk O&M facility and the SFWF approximately two times per week over the life of the Project. Noise levels generated by the CTV are expected to be on the order of 160 dB_{RMS} re 1 µPa/sec^2 at a reference distance of 1 meter, based on observed noise levels generated by working commercial vessels of similar size and class to the CTVs (Kipple and Gabriele 2003; Takahashi et al. 2019). 160 dB_{RMS} is below identified injury thresholds for all fish and invertebrate hearing groups, indicating that CTV noise is unlikely to cause injury-level effects on any fish species. This value does exceed the 158-dB threshold for TTS effects on hearing specialist fish species, but this threshold assumes 24 hours of continuous exposure. An individual fish is unlikely to remain close enough to the moving vessel hull long enough for any risk of injury to occur. The 160 dB_{RMS} source level may exceed the 150 dB_{PEAK} behavioral effects threshold in some cases, but those effects would be temporary in duration and limited in extent. The low-frequency noise produced by the vessel engine could also cause the same type of auditory masking effects as those described above for WTG operation. However, these effects must be considered against the baseline levels of vessel traffic. Thousands of commercial and recreational vessel trips pass through every year (see Section 3.5.6). Additionally, commercial and recreational fishing activity in and around the SFWF likely generates hundreds of vessel trips to and thousands of operational hours on an annual basis. In this context, O&M vessel use is not likely to significantly alter the ambient noise environment relative to the existing baseline.

Additionally, the relatively low-intensity, low-frequency sounds produced by Project survey vessels are unlikely to result in direct injury, hearing impairment, or other trauma to marine fish. Vessel noise may induce physiological stress responses or avoidance behaviors and could result in auditory masking of biologically significant sounds. However, due to the expected brief periods of exposure to vessel noise, BOEM anticipates that short-term exposure to vessel noise would not measurably alter the alter normal behavior patterns and would therefore be insignificant.

These findings indicate that measurable operational noise would result from the Proposed Action, producing effects detectable by finfish. Those effects are likely to vary in significance by species depending on hearing sensitivity. Effects on species that lack a swim bladder, like sharks, rays, and flatfish, and hearing generalist species like ocean pout, butterfish, scup, and tunas, are likely to be biologically insignificant and therefore minor. In contrast, operational noise could reduce the ability of hearing specialist species, like Atlantic cod, haddock, pollock, and hake, to communicate effectively within a few hundred feet of each turbine. The significance of these effects could range from minor to moderate depending on how each species uses the affected area during periods when communication is important.

<u>EMF and substrate heating effects</u>: The EMF and substrate heating effects anticipated to result from operation of the SFEC and inter-array cable are summarized above in the Benthic Habitat section (see Table 3.4.2-6). The EMF values displayed are the estimated maximum values that would occur at the seabed directly over to the cable. EMF strength would diminish rapidly with distance, becoming undetectable within approximately 30 feet of the cable path (Exponent Engineering 2018). These most intense EMF effects would occur immediately above exposed SFEC segments laid on the bed surface covered by an armoring blanket.

Hutchison et al. (2020b) reviewed available research on the sensitivity of various finfish species to EMF effects. They concluded that the available knowledge base on EMF effects on fish and invertebrates is insufficient to fully evaluate potential EMF effects from the widespread development of offshore renewable energy. Behavioral responses have been observed in some fish species exposed to EMFs, but clear relationships have yet to be established. Researchers studying EMF effects on fish have identified observable effects, but usually at test exposures ranging from tens to hundreds of times greater than the strongest exposures likely to result from the Project. The type of power source is also an important factor. HVAC produces a different type of field effect from HVDC that may not be as detectable by electrosensitive fish species.

BOEM has evaluated the potential sensitivity of commercially and recreationally important fish and invertebrate species to likely EMF levels generated by commercial wind farm transmission cables on the OCS (CSA Ocean Sciences Inc. and Exponent 2019). They determined that most fish species would not be measurably affected by transmission cable EMFs, and those species that are able to detect EMFs would not experience significant physiological or behavioral effects. Normandeau et al. (2011) concluded that the magnetite-based sensory organs of fish are expected unable to detect AC magnetic fields below 50 mG.

More recently, BOEM (2021a) compiled minimum EMF effect thresholds from available research for the EFH assessment. The minimum thresholds for observable physiological and behavioral effects are much higher than the minimum detection threshold suggested by Normandeau et al. (2011), on the order of 250 to over 1,000 mG. The BOEM (2021a) EMF effect thresholds used in the EFH assessment are summarized by species and life stage group in Table 3.4.2-7 and are applied here to evaluate potential EMF effects on finfish.

Table 3.4.2-7. Magnetic and Induced Electrical Field Levels Used to Evaluate Potential EMF Effects on Finfish

Species and Life Stage Group	Type of Effect	Magnetic Field	Induced Electrical Field (mV/m)	Source
Fish eggs and larvae	Survival and development	> 1,000 mG	> 500 mV/m	Brouard et al. 1996 Cameron et al. 1985
Finfish	Physiological and behavioral	> 950 mG	20 mV/m	Armstrong et al. 2015 Basov 1999 Bevelhimer et al. 2013 Orpwood et al. 2015
Sharks and skates	Behavioral	250–1,000 mG	< 2–5 mV/m*	Bedore and Kajiura 2013 Hutchison et al. 2020c Kempster et al. 2013

* This threshold only applies to induced electrical fields at frequencies below 20 Hz; the 60 Hz induced electrical field from the HVAC inter-array cable and SFEC would likely not be detectable by sharks, skates, and rays (Bedore and Kajiura 2013).

As shown, the minimum EMF thresholds associated with observable behavioral and/or physiological effects on finfish and fish eggs and larvae are at least an order of magnitude greater than the strongest magnetic and induced electrical field effects likely to result from the Proposed Action, at 76.6 mG and 5.4 millivolts per meter (mV/m), respectively. Potential magnetic field effects are also well below levels associated with behavioral responses in sharks and skates. Sharks, skates, and other electrosensitive species like sturgeon can detect very weak bioelectrical fields generated by their prey, even at field strengths below 2 mV/m. For example, Atlantic sturgeon have specialized electrosensory organs capable of detecting bioelectrical fields on the order of 0.5 mV/m (Normandeau et al. 2011). However, bioelectric fields typically operate at very low frequencies, on the order of 1 Hz or less. Electrosensitive fish like sharks are generally unable to detect electrical fields at frequencies greater than 20 Hz (Bedore and Kajiura 2013). This suggests that the 60 Hz electrical fields generated by the Proposed Action would not be detectable by electrosensitive species, even at the highest anticipated field strength of 5.4 mV/m.

Substrate heating impacts generated by the inter-array cable and SFEC are not likely to significantly affect finfish for the same reasons described in the previous section (Invertebrates). Heating effects from buried cable segments would not reach the bed surface and would not be detectable to fish. Substrate heating effects could reach the bed surface at transition points between buried and exposed cable segments. However, these transition areas and exposed cable segments would be covered by porous concrete mattresses limiting fish access. Small fishes using the interstitial spaces within the mattresses may be able to detect some cable heating effects, but only within the transition zones described.

Collectively, these findings indicate that long-term EMF effects on finfish would likely be below detectable levels and therefore negligible. Some substrate heating effects may be detectable to finfish, but only to certain fish using habitats in the transition zones between buried and exposed cable segments. These long-term effects would therefore be minor.

<u>Hydrodynamic effects</u>: Long-term hydrodynamic effects expected to result from the Proposed Action are similar to those described for invertebrates in the previous section. As discussed, the SFWF would be expected to produce measurable hydrodynamic effects would be expected occur within 600 to 1,300 feet downcurrent of each monopile. The limited research conducted to date has not been able to distinguish any hydrodynamic effects on fish populations from natural variability (van Berkel et al. 2020). While additional monitoring and research is needed, the likelihood of broader regional effects on fish and fish populations from the SFWF is minimal. This conclusion is based on the location of the Project in a location dominated by strong seasonal stratification (van Berkel et al. 2020), the relatively small number of monopile foundations, and the likelihood that any hydrodynamic effects would be localized around each foundation and not additive across the entire array (see Invertebrates). Therefore, long-term hydrodynamic impacts on finfish would likely be localized to small areas within and downcurrent from the SFWF. Effects on finfish are likely to vary by species, ranging from minor to moderate in significance.

The SFEC and O&M facility include no features that are likely to produce any measurable hydrodynamic impacts of significance for finfish.

Conceptual decommissioning: Conceptual decommissioning of the SFWF and SFEC would lead to impacts similar to those generated during construction, with the exception that there would be no pile-driving impacts. After the WTGs and OSS are removed, the monopile foundations would be cut below the bed surface using a cable saw. Pangerc et al. (2016) found that underwater noise levels produced by this type of equipment are difficult to distinguish from the associated construction vessel noise and are below levels that would cause injury or behavioral effects on fish or invertebrates. The impacts of short-term bed disturbance and water quality effects on fish would be similar to those caused by construction: negligible to minor.

Degraer et al. (2020) commented that the future decommissioning of offshore wind facilities could become controversial if they are shown to support high-value fish and invertebrate species. While this potential is acknowledged, this final EIS considers conceptual decommissioning as a component of the Proposed Action as required by BOEM for COP approval.

The removal of the monopile foundations and scour and cable protection would reverse the artificial reef effect provided by these structures. Portions of the Project footprint, primarily along the SFEC corridor, would return to near pre-Project conditions, as influenced by ongoing environmental trends. Soft-bottom benthic habitats would likely recover to full habitat function within 18 to 24 months of disturbance, while complex benthic habitats could take a decade or longer. Individual fish species (e.g., small fish sheltering in epibenthic structure on the monopiles) may be injured or killed during removal. The fish community that formed around the reef effect would be dispersed, and individuals that are unable to locate new suitable habitats may not survive. While the significance of these future effects for individual finfish species is difficult to predict, measurable long-term impacts on some species are almost certain to occur.

Impacts of this duration and magnitude would constitute a moderate effect on finfish. Any population-level impacts would constitute a major effect.

Potential impacts associated with regulated fishing are addressed in Section 3.5.1.2.2 (No Action Alternative).

Cumulative Impacts

Accidental releases and discharges: The Proposed Action could result in accidental releases of contaminants, trash/debris, or invasive species that could add to releases from other reasonably foreseeable projects. BOEM estimates that the Project would result in a negligible up to a 2% incremental increase in total chemical usage over the No Action alternative across all projects in the Atlantic OCS. When combined with other offshore wind projects, up to approximately 2.3 million gallons of coolants and 10.5 million gallons of oils and lubricants could cumulatively be stored within WTG foundations and the OSS within the EFH, finfish, and invertebrate geographic analysis area as well as up to 27,000 gallons of coolants and 300,000 gallons of oils and lubricants within the benthic geographic analysis area. However, all future offshore energy development projects would comply with BOEM and USCG regulations that prohibit dumping of trash and debris and require measures to avoid and minimize accidental spills. Project proponents would also be required to comply with other state and federal regulations to avoid the unintentional introduction of non-native species. The Proposed Action includes regular inspections of the SFWF to identify and remove derelict fishing gear and other trash and debris. Other future projects are expected to include similar measures in their O&M plans, creating an effective mechanism for identifying and removing derelict fishing gear and other dangerous marine debris from the environment. Collectively, the Proposed Action when combined with past, present, and reasonably foreseeable projects would result in negligible to minor beneficial cumulative effects on benthic habitats, EFH, invertebrates, and finfish from this impact mechanism.

Anchoring and new cable emplacement/maintenance: The Proposed Action would result in localized, minor to moderate incremental impacts to benthic habitats, finfish, invertebrates, and EFH through an estimated 821 acres of anchoring and mooring-related disturbance and 913 acres of cabling-related seabed disturbance. BOEM estimates a cumulative total of 2,448 acres of anchoring and mooring-related disturbance and 11,044 acres of cabling-related disturbance for the Proposed Action plus all other future offshore wind projects within the EFH, finfish, and invertebrate geographic analysis area. BOEM likewise estimates a cumulative total of 875 acres of anchoring and mooring-related disturbance and 2,615 acres of cabling-related disturbance for the Proposed Action plus all other future offshore wind projects within the benthic geographic analysis area. The duration and significance of these effects would vary depending on the types of habitats impacted. Impacts on soft-bottom benthic habitats and associated fish and invertebrate species would be expected to fully recover within 18 to 24 months, whereas impacts on complex benthic habitats could take a decade or more to fully recover.

Therefore, the Proposed Action when combined with past, present, and reasonably foreseeable projects would result in minor to moderate impacts to benthic habitats, EFH, invertebrates, and finfish.

EMF: The Proposed Action is not expected to produce significant EMF effects, as discussed in Section 3.4.2.2.3 (Proposed Action Alternative). BOEM anticipates that future offshore wind energy projects in the geographic analysis area would use HVAC transmission and apply similar design measures to avoid and minimize EMF effects on the environment. While uncertainties remain, future actions that produce EMF effects on the order of those generated by the Proposed Action are unlikely to have significant cumulative effects on benthic habitats, finfish, invertebrates, and EFH. Moreover, additive effects from multiple cables are likely to be limited to specific areas where cable routes cross. The standard design practice for subsea transmission cables is to maintain a minimum separation distance of 330 feet from existing transmission and communication cables, except where crossings are necessary. Therefore, cumulative EMF impacts resulting from the Proposed Action in combination with past, present, and reasonably foreseeable activities would largely be negligible, although minor effects could occur in limited areas.

Light: The Proposed Action would result in negligible incremental impacts to benthic habitats, finfish, invertebrates, and EFH through the installation of 16 lighted structures (15 WTGs and one OSS). This represents less than a 1% increase to conditions under the No Action alternative. BOEM estimates a cumulative total of 2,563 offshore WTGs and OSS foundations for the Proposed Action plus all other future offshore wind projects in the EFH, finfish, and invertebrate geographic analysis area, as well as up to 283 foundations within the benthic geographic analysis area. However, Project EPMs (see Table G-1 in Appendix G) include construction vessel light shielding and operational restrictions to limit light use to required periods and minimize artificial lighting effects on the environment. Therefore, the cumulative impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would be similar to those impacts described under the No Action alternative and would be negligible, mostly attributable to existing, ongoing activities.

Noise: The Proposed Action would result in localized, temporary, negligible to moderate incremental impacts to benthic habitats, finfish, invertebrates, and EFH through the generation of underwater noise. The Proposed Action would produce injury or behavioral-level noise effects on fish extending up to 84,233 feet from impact pile-driving activities. These effects could be additive to areas ensonified by other temporally or spatially overlapping future activities. BOEM estimates that underwater noise from the construction of up to 16 other offshore wind facilities would result in short-term injury or behavioral effects on finfish over a cumulative area of up to 7,000 square miles. Vessel noise may cause startle and avoidance responses in fish but would not cause injury. Invertebrate species are only sensitive to sound within the immediate vicinity of the source regardless of intensity. Exposed invertebrates would be killed by seabed disturbance from related construction activities, such as trenching and armor placement, so short-term underwater noise effects on these individuals would not occur. Therefore, the cumulative impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would be negligible to moderate.

Port utilization: Although dredging or in-water work for the Port of Montauk could be required for the Proposed Action, these actions would occur within heavily modified habitats. BOEM expect impacts to benthic habitats, finfish, invertebrates, and EFH due to the incremental increase in port expansion resulting from the Proposed Action to be negligible. Therefore, the incremental impact from the Proposed Action would be negligible, and the overall cumulative impact on the geographic analysis area for benthic habitats combined with past, present, and reasonably foreseeable future activities would be similar to the impacts under the No Action alternative and would also be negligible.

Presence of structures: The Proposed Action would result in long-term alteration of water column and seabed habitats, resulting in a diversity of effects on benthic habitat, finfish, invertebrates, and EFH. The 16 monopile foundations and other hard surfaces installed as part of the Proposed Action would create an artificial reef effect. The new offshore structures would also cause localized hydrodynamic effects that would influence primary and secondary productivity within and around this artificial reef. The reef effect would alter biological community structure, producing an array of effects on benthic habitat, finfish, and invertebrates, including several EFH species. Those effects could be positive or negative, varying by species, and would likely range from minor to moderate in significance.

The Proposed Action is limited in scale compared to some of the offshore renewable energy projects planned in the geographic analysis area. BOEM estimates the Proposed Action and other planned future projects will result in the development of 2,563 WTG and OSS foundations in the EFH, finfish, and invertebrate geographic analysis area as well as up to 283 foundations within the benthic geographic analysis area. Most of these projects are larger in scale than the Proposed Action, and many projects could be developed in adjacent lease areas. Depending on how they are located and distributed, the development of multiple large-scale projects could have broader scale cumulative effects on biological communities than the Proposed Action considered in isolation (Degraer et al. 2020; van Berkel et al. 2020). More research is needed to determine the likelihood and potential significance of broader cumulative effects on finfish, invertebrates, and EFH.

Sediment deposition and burial and seabed profile alterations: The Proposed Action would result in localized, temporary, and minor incremental impacts to benthic habitats, finfish, invertebrates, and EFH through an estimated 913 acres of seabed disturbance in the geographic analysis area. These actions would increase suspended sediment and potentially disturb, displace, or injure benthic habitat, finfish, and invertebrates. BOEM estimates a cumulative total of 11,044 acres of cabling-related disturbance for the Proposed Action plus all other future offshore wind projects within the EFH, finfish, and invertebrate geographic analysis area and 2,615 acres of cabling-related disturbance within the benthic geographic analysis area. While the suspended sediment effects from this seabed disturbance are not known, they are expected to be similar in magnitude and extent to those described for the Proposed Action. More extensive suspended sediment and deposition effects could occur in areas where mud and silts are more prevalent in bed sediments. Some projects may also include dredging for O&M facility development or related port improvements. Dredging may result in additional suspended sediment and deposition effects similar in nature to those described for O&M facility construction. When combined with other past, present, and reasonably foreseeable actions, the Proposed Action would result in moderate impacts.

Climate change: The types of impacts from global climate change described for the No Action alternative would occur under the Proposed Action, but the Proposed Action could also contribute to a long-term net decrease in greenhouse gas (GHG) emissions. This difference may not be measurable but would be expected to help reduce climate change impacts, resulting in minor to moderate incremental impacts. When combined with other past, present, and reasonably foreseeable actions, the Proposed Action would result in moderate impacts.

Other considerations: The Proposed Action could affect the endangered Atlantic sturgeon, consistent with the analysis in BOEM's BA for the Proposed Action (BOEM 2020a). Although individuals from the five DPSs of ESA-listed Atlantic sturgeon could be affected by the Proposed Action, no Atlantic sturgeon would be injured or killed. Individuals from these DPSs could be exposed to any of the effects described above on benthic habitats, finfish, and invertebrates that are pertinent to demersal fish species. The most significant impact for individual sturgeon would be underwater noise from pile driving; however, incremental Project effects to individual Atlantic sturgeon would be limited to temporary, minor behavioral effects and disturbance. For this reason, the Proposed Action impacts, when combined with past, present, and reasonably foreseeable future activities, would also be minor and not anticipated to result in adverse population-level consequences.

Adult and subadult endangered Atlantic sturgeon are expected to occur in the offshore waters of the geographic analysis area throughout the year but appear to be present in lower numbers in the summer (Dunton et al. 2015; Ingram et al. 2019; Savoy and Pacileo 2003; Stein et al. 2004). The threatened giant manta ray is expected to occur in the offshore waters south of the SFWF, within upwelling waters at the edge of the continental shelf break. The most prominent cumulative impacts on Atlantic sturgeon and giant manta ray are expected from exposure to pile-driving noise. Giant manta ray occurrence on the mid-Atlantic OCS is rare (NOAA 2017b), but occurrence in proximity to some proposed future actions within the geographic analysis area cannot be completely discounted.

Conclusions

Project construction and installation, O&M, and conceptual decommissioning would impact benthic resources by causing temporary habitat disturbance; permanent habitat conversion; and behavioral changes, injury, and mortality of benthic fauna. EFH, invertebrates, and finfish impacts associated with Proposed Action activities would be specific to the life stage and habitat requirements of a species. Activities that primarily impact benthic habitat (i.e., cable installation, scour protection) are not as likely to impact species or life stages that depend on pelagic habitats. Conversely, the above-mentioned activities are likely to displace or kill benthic species and life stages such as skates, flatfish, squid egg mops, and Atlantic sea scallops. The continued presence of foundations could affect pelagic habitat.

BOEM anticipates the impacts resulting from the Proposed Action alone would range from **negligible** to **moderate**, including the presence of structures, which may result in **moderate beneficial** impacts to some benthic resources. The most prominent IPFs are expected to be new cable emplacement, noise from pile driving, and the presence of structures. Despite benthic mortality and temporary or permanent habitat alteration, BOEM expects the long-term impact on benthic communities from construction and installation of the Proposed Action alone to be **moderate for benthic resources**, as the effects would be unavoidable but would not affect the viability of the population.

Likewise, BOEM anticipates the impacts resulting from Proposed Action alone would range from **negligible** to **moderate**, including the presence of structures, which may result in **moderate beneficial** impacts for some EFH, invertebrates, and finfish. Overall, the impacts of Proposed Action alone on finfish, invertebrates, and EFH would likely be **moderate**. Although some of the proposed activities and/or IPFs analyzed could overlap, BOEM does not anticipate that this would alter the overall impact rating because it would neither appreciably diminish the aforementioned impacts nor increase them to such a degree that a population-level impact on the affected resource would occur.

The Proposed Action would be more likely to impact benthic species, life stages, and EFH than pelagic species and EFH, since the majority of activities affect benthic habitat. Turbidity, especially associated with dredging, and water withdrawal from jet plowing could temporarily impact pelagic eggs and larvae and EFH. Pile-driving noise, although temporary, could impact all benthic and pelagic life stages. The operational phase of the Proposed Action alone could lead to uncertain but possibly beneficial effects on finfish, invertebrates, and EFH through altering the pelagic environment and through the reef effect. The adverse impacts associated with the construction and installation, operations and maintenance, and decommissioning of the Proposed Action alone are likely to be temporary and/or small in proportion to the overall habitat available regionally.

SFW may elect to pursue a course of action within the PDE that would cause less impact than the maximum-case scenario, but doing so would not likely result in different impact ratings than those described above.

In the context of other reasonably foreseeable environmental trends and planned actions, the incremental impacts under the Proposed Action resulting from individual IPFs would range from **negligible** to **moderate and moderate beneficial for some benthic resources**. The combined significance criteria in Table 3.1.1-1 and Table 3.1.1-2 are used to characterize the combined effects of all IPFs on benthic habitat. Applying these criteria, BOEM anticipates that the overall impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would result in **moderate** impacts to benthic resources in the geographic analysis area, because a notable and measurable adverse impact is anticipated, but most resources would likely recover when the impacting agents were gone and remedial or mitigating actions were taken. The main drivers for this impact rating are bottom temperature changes due to ongoing climate change, recurring bottom disturbance from bottom-tending fishing gear, mortality resulting from offshore construction, and the beneficial presence of structures.

Likewise, the incremental impacts under the Proposed Action resulting from individual IPFs would range from **negligible** to **moderate** and **moderate beneficial for some** finfish, invertebrates, and EFH. The combined significance criteria in Table 3.1.1-1 and Table 3.1.1-2 are used to characterize the combined effects of all IPFs on EFH, invertebrates, and finfish. Applying these criteria, BOEM anticipates that the overall impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would result in **moderate** impacts on finfish, invertebrates, and EFH in the geographic analysis area, because a notable and measurable impact is anticipated, but the resource would likely recover completely when the impacting agents were gone and remedial or mitigating action were taken. The main drivers for this impact rating are fishing mortality, climate change, recurring bottom disturbance from bottom-tending fishing gear, and mortality resulting from offshore construction.

The Proposed Action would contribute to the above overall impact ratings primarily through the temporary disturbance due to new cable emplacement and permanent impacts from the presence of structures (cable protection measures and foundations). Although some of the proposed activities and/or IPFs analyzed could overlap, BOEM does not anticipate that this would alter the overall impact rating.

SFW has committed to implement EPMs to reduce potential impacts on benthic finfish, invertebrates, and EFH resources (see Table G-1 in Appendix G). BOEM is considering various mitigation and monitoring measures developed through EFH consultation with NMFS, through coordination with other federal and state agencies, and in response to comments received on the draft EIS (see Table G-2 in Appendix G). While any or all of these additional measures would tend to reduce impacts, the overall significance level of impacts would remain the same even if they were all required as a condition of COP approval.

3.4.2.2.4 VESSEL TRANSIT LANE ALTERNATIVE

The Transit alternative would lead to the same types of impacts on benthic resources, EFH, invertebrates, and finfish from construction and installation, O&M, and conceptual decommissioning as described for the Proposed Action, because the same types of actions would take place within the same Lease Area. However, construction of this alternative would install four fewer foundations and associated inter-array cable segments. Fewer days of impact pile driving would be required, and the overall duration of construction activities would decrease. This would reduce the overall footprint of the Project and associated construction and operational effects on benthic habitat, EFH, invertebrates, and finfish, as compared to the Proposed Action.

Impacts on complex, potentially complex, and soft-bottom benthic habitats from seabed preparation and materials placement associated with the foundations proposed for removal would be eliminated. Micrositing would also be used to further reduce impacts to complex benthic habitats where practicable. Reducing the number of monopile foundations from 16 to 12 would produce a commensurate reduction in associated artificial reef and hydrodynamic effects on the environment. Therefore, BOEM anticipates the impacts resulting from the Transit alternative alone would range from negligible to moderate, including the presence of structures, which may result in moderate beneficial impacts to some benthic resources, EFH, invertebrates, and finfish.

Cumulative Impacts

As noted above, the Transit alternative would result in the same types of incremental impacts on benthic resources, EFH, invertebrates, and finfish as the Proposed Action. While the duration and extent of construction impacts and the physical extent of operational impacts would decrease slightly, the resulting effects of each impact mechanism on benthic habitat, EFH, invertebrates and finfish would be the same as those described for the Proposed Action. Therefore, the overall cumulative impacts of this alternative when combined with past, present, and reasonably foreseeable activities would result in moderate impacts on benthic resources, EFH, invertebrates, and finfish.

If the Transit alternative is implemented, proposed future offshore WTGs may need to be relocated or eliminated within lease areas to accommodate the proposed transit lanes. These shifts could shorten or increase vessel trips, transmission cable lengths, and installation times for other future projects, depending on what WTG changes occur. If WTG shifts result in changes that increase turbidity and sedimentation, alter water currents, or increase risks of inadvertent spills, these effects could increase cumulative impacts relative to the Proposed Action.

Conclusions

Although the Transit alternative would reduce the number of WTGs and their associated inter-array cables, which would have an associated reduction in impacts from construction and installation, O&M, and conceptual decommissioning, BOEM expects that the impacts resulting from the Transit alternative would be similar to the Proposed Action and range from **negligible** to **moderate adverse and moderate beneficial (for some species)**.

In context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that the Transit alternative’s incremental impacts would be similar to the Proposed Action (with individual IPFs leading to impacts ranging from **negligible** to **moderate adverse and moderate beneficial for some species**). The combined significance criteria in Table 3.1.1-1 and Table 3.1.1-2 are used to characterize the combined effects of all IPFs on benthic habitat, EFH, invertebrates, and finfish. Applying these criteria, BOEM anticipates that the overall impacts of the Transit alternative when combined with past, present, and reasonably foreseeable activities would result in **moderate** impacts on these resources.

3.4.2.2.5 FISHERIES HABITAT IMPACT MINIMIZATION ALTERNATIVE

The Habitat alternative would eliminate specific monopile locations from the SFWF Project and incorporate additional micrositing to minimize impacts on existing complex benthic habitat to the greatest extent practicable.

On June 7, 2021, NOAA provided its conservation recommendations to BOEM. NOAA recommended that proposed wind turbine locations WTG 1, WTG 5, WTG 15, WTG 16A, and WTG 17A (Figure 2.1.3-2a) be removed from consideration because they would result in substantial adverse impacts to complex habitats. NOAA also recommends that turbine locations WTG 2, WTG 4, WTG 6, WTG 8, WTG 9, WTG 10, WTG 12, WTG 13, WTG 14, OSS, and the associated inter-array cables be microsited into low multibeam backscatter return areas and that restrictions on seafloor disturbance (e.g. anchoring) during construction be required to avoid impacts to higher multibeam backscatter return areas.

On June 14, 2021, SFW provided BOEM with a proposed layout in response to the consistency determination of Rhode Island CRMC, which requires a reduction in the number of wind turbines by three. The proposed layout removes wind turbine locations WTG 5, WTG 6, WTG 9, WTG 16A, and WTG 17A (Figure 2.1.3-2b) from consideration. Micrositing is proposed at WTG 1, WTG 4, WTG 8, WTG 10, and WTG 15.

Tables 3.4.2-8. and 3.4.2-9 provide estimated foundation and inter-array impacts for the Proposed Action and the two layout options considered under the Habitat alternative.

Table 3.4.2-8. Estimated Benthic Impacts for Foundations

Foundations	Total Impact Area Estimate (acres)*	Short-Term to Long-Term Impacts (seabed preparation) (acres)[†]	Long-Term Impact Footprint (monopile and scour protection) (acres)	Proportional Distribution of Impacts by Benthic Habitat Type		
				Complex	Potentially Complex	Soft Bottom
Proposed Action	29.2	14.8	14.4	49%	9%	42%
Habitat alternative layout (a) Conservation Recommendations from NOAA	23.7	12.0	11.7	33%	7%	60%
Habitat alternative layout (b) SFW Technical Memorandum (June 14, 2021)	23.7	12.0	11.7	42%	11%	47%

* Total Impact Area Estimate: The sum total of short-term and long-term impacts; this is the sum of all overlapping impacts occurring at different periods in time.

[†] Short-Term to Long-Term Impact (seabed preparation): Total acreage of the 28-m-wide seabed preparation corridor; this represents the maximum estimated footprint for all overlapping impacts.

Table 3.4.2-9. Estimated Benthic Impacts for Inter-Array Cable

Inter-Array Cable	Total Cable Length (miles)	Total Impact Area Estimate (hort-term + long-term, acres)*	Short-Term Impact (cable installation, acres)[†]	Long-Term Impact (cable protection, acres)[‡]	Short-Term to Long-Term Impact (seabed preparation, acres)[§]	Proportional Distribution of Impacts by Benthic Habitat Type		
						Complex	Potentially Complex	Soft Bottom
Proposed Action	19.4	282.4	57.7	9.2	215.5	42%	10%	48%
Habitat alternative layout (a) Conservation Recommendations from NOAA	14.5	211.7	43.3	6.9	161.5	43%	13%	45%
Habitat alternative layout (b) SFW Technical Memorandum (June 14, 2021)	14.5	211.8	43.3	6.9	161.6	41%	11%	48%

* Total Impact Area Estimate: The sum total of short-term and long-term impacts; this is the sum of all overlapping impacts occurring at different periods in time.

[†] Short-Term Impact (cable installation): Total acreage of the 7.5-m-wide cable installation corridor, entirely contained within the seabed preparation corridor.

[‡] Long-Term Impact (cable protection): Estimated total acres of cable protection impacts, assuming impacts will occur over 10% of the 12-m-wide cable protection corridor (per the COP). Calculation assumes that cable protection will be required over an estimated 10% of IAC corridor length, as stated in the COP. The area covered by the 12-m-wide cable protection buffer is 92.4 acres for full buildout, 69.2 acres for the NMFS layout option, and 69.2 acres for the SFW layout option.

[§] Short-Term to Long-Term Impact (seabed preparation): Total acreage of the 28-m-wide seabed preparation corridor; this represents the maximum estimated footprint for all overlapping impacts.

Removal of three turbines (WTG 1, WTG 5, and WTG 15) as recommended by NMFS [layout (a)] reduces the impact to benthic habitat by 5.5 acres when compared to the Proposed Action. The removal of these foundations and associated scour protection reduces the impact to complex habitat and potentially complex habitat by 6.5 acres and 0.9 acre, respectively. In addition, an estimated 4.9 fewer nautical miles of inter-array cable would be installed, resulting in the reduction of impacts to 71 acres of habitat for both short-term and permanent impacts to habitat. The impacts to complex habitat would be reduced by 28 acres, both short term and long term, with approximately a 0.7-acre reduction of impacts to potentially complex habitat.

Removal of three turbines (WTG 5, WTG 6, and WTG 9) as proposed by SFW [layout (b)] reduces the impact to benthic habitat by 5.5 acres when compared to the Proposed Action. The removal of these foundations and associated scour protection reduces the impact to complex habitat by 4.3 acres and has similar impacts to potentially complex habitat. In addition, an estimated 4.9 fewer nautical miles of inter-array cable would be installed, resulting in the reduction of impacts to 71 acres of habitat for both short-term and permanent impacts to habitat. The impacts to complex habitat would be reduced by 32 acres, both short term and long term, with approximately a 4.9-acre reduction of impacts to potentially complex habitat.

Micrositing of the remaining turbines and inter-array cable would further reduce the impacts reported for the Proposed Action. Reducing impacts on complex benthic habitats would reduce the area exposed to long-term impacts from construction disturbance and artificial reef effects. However, some long-term impacts on complex benthic habitats would still occur. Reducing the number of monopile foundations from 16 to 13 would produce a commensurate reduction in associated artificial reef and hydrodynamic effects on the environment, as compared to the Proposed Action. Therefore, BOEM anticipates the impacts resulting from the Habitat alternative (for either layout option) alone would range from negligible to moderate, including the presence of structures, which may result in moderate beneficial impacts to some benthic resources, EFH, invertebrates, and finfish.

Cumulative Impacts

As noted above, the Habitat alternative under either layout option would incrementally reduce the extent of temporary, short-term and long-term impacts on the environment, with emphasis on reducing impacts on complex benthic habitat. Reduced impacts on benthic habitat would in turn incrementally reduce impacts on EFH, invertebrates, and finfish resulting from the construction and operation of the Project. However, the same impact mechanisms would still occur, generating the same types of effects at similar levels of significance to those described for the Proposed Action. Therefore, the overall cumulative impacts of this alternative when combined with past, present, and reasonably foreseeable activities would result in moderate impacts on benthic resources, EFH, invertebrates, and finfish.

Conclusions

BOEM anticipates that the Habitat alternative under either layout option would incrementally reduce the physical extent and duration of certain impact mechanisms relative to the Proposed Action. However, those impact mechanisms would still occur, and the resulting effects on benthic habitat, EFH, invertebrates, and finfish would still meet the criteria for **negligible** to **moderate** adverse and moderate beneficial (for some species) defined in Table 3.4.2-1. In context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that the Habitat alternative’s incremental impacts would be similar to the Proposed Action (with individual IPFs leading to impacts ranging from **negligible** to **moderate** adverse and **moderate beneficial** for some species).

The combined significance criteria in Table 3.1.1-1 and Table 3.1.1-2 are used to characterize the combined effects of all IPFs on benthic habitat, EFH, invertebrates, and finfish. Applying these criteria, BOEM anticipates that the overall impacts associated with the Habitat alternative under either layout option when combined with past, present, and reasonably foreseeable activities would result in **moderate** impacts on these resources.

3.4.2.3 Action Alternative Comparison

As discussed above, the impacts associated with Proposed Action alone do not change substantially under other evaluated action alternatives. Although the number of WTGs and their associated inter-array cables varies slightly, BOEM expects that benthic resource, EFH, invertebrate, and finfish impacts would range from **negligible** to **moderate** adverse and **moderate beneficial** (for some species) for all action alternatives.

In context of reasonably foreseeable environmental trends and planned actions, all action alternatives would occur within the same overall environment (e.g., ongoing and future activities). Therefore, impacts would only vary if the alternatives' incremental contributions differ. However, as noted above, BOEM expects that the incremental impact from any action alternative would be similar, with the level of individual impacts ranging from **negligible** to **moderate** adverse and moderate beneficial **(for some species)**, because the majority of the impacts result from ongoing activities and other future offshore wind projects. Applying the combined significance criteria in Table 3.1.1-1, the overall impact of any action alternative on benthic habitat, EFH, invertebrates, and finfish when combined with past, present, and reasonably foreseeable activities would be **moderate** on these resources, for the same reasons as noted under previous conclusion sections.

3.4.2.4 Mitigation

Table G-2 in Appendix G identifies the following potential additional mitigation measures:

- Use of noise reduction technologies and field verification during all impact pile-driving activities to achieve a required minimum attenuation (reduction) of 10 dB re 1 micropascal (μPa) to reduce noise impacts during construction.
- Use of a turbidity curtain during construction and O&M activities involving in-water work such as dredging at ports and at the O&M facility to minimize impacts on flora and fauna from suspended sediments.

If BOEM requires the above measures, then Project impacts to benthic habitat, EFH, invertebrates, and finfish could be further reduced, although impacts would still be negligible to moderate.

3.4.3 Birds

The reader is referred to Table 2.3.1-1 and Appendix H for a discussion of current conditions and potential impacts to birds from implementation of the Proposed Action and other considered alternatives.

3.4.4 Other Terrestrial and Coastal Habitats and Fauna

The reader is referred to Table 2.3.1-1 and Appendix H for a discussion of current conditions and potential impacts to other terrestrial and coastal habitats and fauna from implementation of the Proposed Action and other considered alternatives.

3.4.5 Marine Mammals

3.4.5.1 Affected Environment

This section evaluates marine mammal resources within the geographic analysis area—namely, the Scotian Shelf, Northeast Shelf, and Southeast Shelf Large Marine Ecosystems—which captures most of the movement range within U.S. waters for most species in this group (see Figure E-5 in Appendix E). Due to the size of the geographic analysis area, however, for the purposes of the analysis in this final EIS, the focus is on marine mammals that would be likely to have regular or common occurrences in the proposed SFWF and SFEC and could be impacted by Project activities (Figure C-32 in Appendix C

A diverse marine mammal community inhabits the Northwest Atlantic OCS region (the region). Fifty species, comprising six baleen whale species; 39 species of toothed whales, dolphins, and porpoises; four species of seals; and the West Indian manatee (*Trichechus manatus*), could occur, or are known to occur, in the region (BOEM 2014; CSA Ocean Sciences Inc. 2021). All these species are protected under the federal MMPA, and five are listed as endangered under the ESA. One species, West Indian manatee, is listed as threatened under the ESA. Of the six marine mammals listed under the ESA, critical habitat has been designated for only NARW and West Indian manatee. Manatee occurrence in the SFWF and SFEC is unlikely.

Table 3.4.4 1 identifies species known or expected to occur in the region and their likelihood and timing of occurrence in the SFWF and SFEC. The BA and request for incidental harassment authorization developed for the Proposed Action (BOEM 2021; CSA Ocean Associates 2020) provide detailed species descriptions and life history information for all marine mammal species likely to occur in the geographic analysis area. NOAA has summarized the most current information about marine mammal population status, occurrence, and use of the region in their 2019 and draft 2020 stock status reports for the Atlantic OCS and Gulf of Mexico (Hayes et al. 2020, 2021).

The final EIS analysis focuses on 15 marine mammal species that are known to regularly occur in and around the SFWF and SFEC (Figure C-32) where species may be impacted directly. Several of these species are highly migratory and only occur seasonally; some are present year-round; and some could be present year-round but display distinct seasonal peaks. The ESA-listed species expected to occur are NARW, fin whale (*Balaenoptera physalus*), sei whale (*Balaenoptera borealis*), and sperm whale (*Physeter macrocephalus*) (Davis et al. 2020; Kraus et al. 2016; NEFSC and Southeast Fisheries Science Center [SEFSC] 2018). Several other marine mammal species may occur in the general vicinity, including the ESA-listed blue whale (*Balaenoptera musculus*), which is known to occur in the region but primarily in waters along the edge of the OCS. Current status and population trends for marine mammal species that are expected to occur are summarized in Table 3.4.4 2.

Construction and operational noise are IPFs of particular concern. To this end, marine mammals have been organized into different hearing groups for the purpose of evaluating underwater noise impacts based on how they hear and their sensitivity to different types of noise consistent with NOAA (2018) guidance. Low-frequency cetaceans, including NARW and other baleen whales, hear and communicate in low-frequency bands from 7 Hz to 35 kHz. Mid-frequency cetaceans, including dolphins and other toothed whales, hear in the 150-Hz to 160-kHz range. High-frequency cetaceans, including the true porpoises, hear in the 275-Hz to 160-kHz range. Phocid pinnipeds (i.e., seals) hear in the 50-Hz to 86-kHz range.

Short-beaked common dolphin	*Delphinus delphis delphis*	Western North Atlantic	172,974	Unavailable	399	Significant	Hayes et al. (2020)
Bottlenose dolphin	*Tursiops truncatus truncatus*	Western North Atlantic - Offshore	62,851	Unavailable	28	Insignificant	Hayes et al. (2020)
		Western North Atlantic – Northern Coastal Migratory	6,639	Decreasing	12.2 to 21.5	Insignificant	Hayes et al. (2021)
Harbor porpoise	*Phocoena*	Gulf of Maine/Bay of Fundy	95,543	Unavailable	150	Significant	Hayes et al. (2020)
Harbor seal	*Phoca vitulina concolor*	Western North Atlantic	75,834	Unavailable	365	Significant	Hayes et al. (2020)
Gray seal	*Halichoerus grypus*	Western North Atlantic (U.S. population)	27,131	Increasing	953	Significant	Hayes et al. (2020)
Hooded seal	*Cystophora cristata*	Western North Atlantic	593,500	Increasing	5,199	Insignificant	Hayes et al. (2019)
Harp seal	*Pagophilus groenlandicus*	Western North Atlantic	7.4 million	Increasing	232,422	Unknown	Hayes et al. (2020)

* Most recently available stock size estimate, per cited reference.

[†] Increasing = beneficial trend, not quantified; Decreasing = adverse trend, not quantified; Unavailable = population trend analysis not conducted on this species.

[‡] Based on annual human-caused mortality as a percentage of potential biological removal (PBR): Significant = > 10% of PBR; Insignificant = < 10% of PBR. Statistic based on fishing-related mortality with inferred contribution from other sources (e.g., vessel collisions).

[§] Reflects human-caused mortality from all known sources, including fishing-related, vessel collisions, and other/unspecified. Per cited reference.

[¶] Species is ESA listed.

3.4.5.2 Environmental Consequences

3.4.5.2.1 ISSUES, INDICATORS, AND SIGNIFICANCE CRITERIA

Table 3.4.5-3 lists the issues identified for this resource and the indicators and significance criteria used to assess impacts for the EIS.

Table 3.4.5-3. Issues, Indicators, and Significance Criteria Used to Assess Impacts to Marine Mammals

Issue	Impact Indicator	Significance Criteria[¥]
Seabed and water column alteration	Affected water column and acres of seabed disturbance, potential for displacement effects	Negligible: The impacts on individual marine mammals and/or their habitat, if any, would be at the lowest levels of detection and barely measurable, with no perceptible consequences to individuals or the population. Minor: Impacts on individual marine mammals and/or their habitat are detectable and measurable; however, they are of low intensity, short term, and localized. Impacts on individuals and/or their habitat do not lead to population-level effects. Moderate: Impacts on individual marine mammals and/or their habitat are detectable and measurable; they are of medium intensity, can be short term or long term, and can be localized or extensive. Impacts on individuals and/or their habitat could have population-level effects, but the population can sufficiently recover from the impacts or enough habitat remains functional to maintain the viability of the species both locally and throughout their range. Major: Impacts on individual marine mammals and/or their habitat are detectable and measurable; they are of severe intensity, can be long lasting or permanent, and are extensive. Impacts to individuals and/or their habitat would have severe population-level effects, and compromise the viability of the species.
Long-term habitat alteration and hydrodynamic effects	Measurable extent of potential habitat and hydrodynamic effects, potential for regional effects	
Underwater noise from construction/conceptual decommissioning	Magnitude, duration, and extent of exposure above established effects thresholds, as noted below: Behavioral thresholds:* Impulsive source: 160 dB_{RMS} Non-impulsive source: 120 dB_{RMS} Injury thresholds Impact pile driving (dB_{PEAK}/dB c_{SEL}):[†] Low-frequency cetaceans: 219/183 Mid-frequency cetaceans: 230/185 High-frequency cetaceans: 202/155 Phocid pinniped: 218/185 Vibratory pile driving (dB c_{SEL}): Low-frequency cetaceans: 199 Mid-frequency cetaceans: 198 High-frequency cetaceans: 173 Phocid pinniped: 201	
Underwater noise from operation	Magnitude, duration, and extent of exposure above established effects thresholds, as noted below: Behavioral effect thresholds:[‡] 120 dB_{RMS} Permanent threshold shift (PTS) thresholds All species: Not applicable	
Airborne noise	Magnitude, duration, and extent of exposure above established effects thresholds, as noted below: Behavioral effect thresholds:[§] Harbor seals: 90 dB_{RMS} Other pinnipeds: 100 dB_{RMS} Cetaceans: Not applicable	
Vessel traffic	Qualitative estimate of potential collision risk	
Water quality impacts	Quantitative estimate of intensity and duration of suspended sediment effects	
	Qualitative analysis of potential discharges (fuel spills, trash, and debris) relative to baseline	

Issue	Impact Indicator	Significance Criteria[¥]
Artificial light	Intensity, frequency, and duration relative to baseline	
Power transmission	Theoretical extent of detectable EMF effects	

* Behavioral effect thresholds for impact and vibratory pile driving defined by the NMFS (NOAA 2019). Distance to thresholds modeled by Denes et al. (2021). dB_{RMS} = root mean square decibels re 1 µPa. Behavioral effects thresholds are unweighted,

† NOAA (2018) defines a permanent hearing threshold shift as the onset of physical injury from underwater noise exposure. NMFS has identified different PTS thresholds for the low-, mid-, and high-frequency cetacean, and phocid pinnipeds based on group-specific hearing sensitivity. Distance to PTS thresholds modeled by Denes et al. (2021). dB_{PEAK} = peak dB re 1 µPa. dB_{SEL} = cumulative SEL in dB re 1 $µPa^2$/second. Peak thresholds are unweighted, cumulative SEL thresholds are weighted by hearing group sensitivity.

‡ Onset of potential behavioral effects for vibratory pile driving defined by NOAA (2021), assuming WTGs similarly produce continuous low-frequency underwater noise. Distance to behavioral threshold for vibratory pile driving modeled by Denes et al. (2021).

§ Airborne exposure threshold (unweighted decibels) defined by NOAA (2018). Distance to phocid pinniped thresholds estimated using methods described by the Washington State Department of Transportation (2020). No airborne PTS threshold established for pinnipeds. No airborne thresholds established for cetaceans.

¥ These significance criteria are intended to serve NEPA purposes only, and they are not intended to incorporate similar terms of art used in other statutory or regulatory reviews. For example, the term “negligible” will be used for NEPA purposes as defined here and is not necessarily intended to indicate a negligible impact or effect under the MMPA. Similarly, the use of “detectable” or “measurable” in the NEPA significance criteria is not necessarily intended to indicate whether an effect is “insignificant” or “adverse” for purposes of ESA Section 7 consultation. For ESA Section 7 consultation, “insignificant effects” relate to the size of the impact and should never reach the scale where take occurs. Based on best judgment, a person would not be able to meaningfully measure, detect, or evaluate insignificant effects.

3.4.5.2.2 NO ACTION ALTERNATIVE

Under the No Action alternative, BOEM would not approve the COP and the Proposed Action would not be implemented. Existing environmental trends within the geographic analysis area would continue, potentially influenced by the development of planned future activities on the mid-Atlantic OCS and associated coastal areas over the coming decade. These include other offshore wind and renewable energy projects, and potential port improvements to support the development of this industry regionwide (see Appendix E).

This section provides a general description of these mechanisms, recognizing the extent and significance of potential effects on conditions cannot be fully quantified for projects that are in the conceptual or proposal stage and have not been fully designed. Where appropriate, certain potential effects resulting from these future actions can be generally characterized by comparison to effects resulting from the Proposed Action that are likely to be similar in nature and significance. The intent of this section is to provide a general overview of how future activities might influence future environmental conditions. Should any or all of the future activities described in Appendix E proceed, each would be subject to independent NEPA analyses and regulatory approvals and their environmental effects would be fully considered therein.

The Affected Environment section provides information on existing marine mammal species and habitat trends due to past and present activities. Attachment 3 in Appendix E also provides additional information regarding past and present activities and associated species impacts. Future, non-Project actions include offshore development projects, military activities, dredged material disposal, commercial fishing, and marine transportation.

Attachment 3 in Appendix E also discloses future non-offshore wind activities and associated marine mammal impacts. Impacts associated with future offshore wind activities are described below. These activities and their potential effects on marine mammals have been or will be subject to independent NEPA analysis as they are planned and developed.

Future Activities (without the Proposed Action)

Accidental releases and discharges: BOEM prohibits the discharge or disposal of solid debris into offshore waters during any activity associated with the construction and operation of offshore energy facilities (30 CFR 250.300). The USCG similarly prohibits the dumping of trash or debris capable of posing entanglement or ingestion risk (MARPOL, Annex V, Public Law 100−220 (101 Stat. 1458)).

BOEM also requires applicants to develop spill response and containment plans to quickly address accidental spills of fuels, lubricants, and other contaminants. While marine vessels are an inherent source of accidental releases of trash, debris, and contaminants, these requirements would effectively avoid and minimize these impacts such that the resulting effects to marine mammals would be negligible.

Entanglement in fishing gear is a substantial ongoing threat to marine mammals. Fisheries interactions are likely to have demographic effects on marine mammal species, with estimated global mortality exceeding hundreds of thousands of individuals each year (Read et al. 2006; Reeves et al. 2013; Thomas et al. 2016). In the Atlantic, bycatch occurs in various gillnet and trawl fisheries in New England and the Mid-Atlantic coast, with hotspots driven by marine mammal density and fishing intensity (Lewiston et al. 2014; NMFS 2018a). Entanglement in fishing gear has been identified as one of the leading causes of mortality in NARWs and may be a limiting factor in the species recovery (Knowlton et al. 2012). Entanglement may also be responsible for high mortality rates in other large whale species (Read et al. 2006).

BOEM anticipates that future projects would perform regular inspections to identify and remove derelict fishing gear and other marine debris from offshore structures, either as an EPM or a mitigation requirement. These inspections would provide a mechanism for removing harmful marine debris, reducing associated risks to marine mammals. Entanglement in or ingestion of marine debris is a significant source of human-caused mortality in many marine mammal species. For example, Baulch and Perry (2014) identified ingested debris as the likely cause of mortality in 22% of beached marine mammal carcasses. Approximately 50% of marine mammal species worldwide have been documented ingesting marine litter (Werner et al. 2016). Entanglement in commercial fishing gear has been identified as one of the leading causes of mortality in NARWs and may be a limiting factor in the species recovery, with 83% of observed individuals showing evidence of at least one and 53% showing evidence of multiple entanglements (Knowlton et al. 2012). Accordingly, future actions would likely aid in reducing risks to marine mammals from marine debris by removing derelict fishing gear, resulting in a minor beneficial effect to marine mammals.

<u>EMF</u>: At least seven submarine power and communications cables cross the RI/MA WEA. These cables would presumably continue to operate and generate EMF effects under the No Action alternative. While the type and capacity of those cables is not specified, the associated baseline EMF effects can be inferred from available literature. Electrical telecommunications cables are likely to induce a weak EMF on the order of 1 to 6.3 µV/m within 3.3 feet (1 meter) of the cable path (Gill et al. 2005). Fiber-optic communications cables with optical repeaters would not produce EMF effects.

Under the No Action alternative, up to 7,248 miles of cable would be added in the geographic analysis area, producing EMF in the immediate vicinity of each cable during operations. BOEM anticipates that the proposed offshore energy projects would use HVAC transmission, but HVDC designs are possible and could occur.

EMF effects on marine mammals from these future projects would vary in extent and magnitude depending on overall cable length, the proportion of buried versus exposed cable segments, and project-specific transmission design (e.g., HVAC or HVDC, transmission voltage, etc.). However, measurable EMF effects are generally limited to within tens of feet of cable corridors. BOEM would require these future submarine power cables to have appropriate shielding and burial depth to minimize potential EMF effects from cable operation. Therefore, effects on marine mammals are likely to range from negligible to minor, with minor effects only likely to occur under certain circumstances (i.e., in proximity to exposed HVDC transmission cables).

<u>New cable emplacement/maintenance</u>: Future offshore wind projects could disturb up to 10,131 acres of seabed while installing associated undersea cables, causing an increase in suspended sediment (see Appendix E, Attachment 4 for calculation details). Those effects would be similar in nature to those observed during construction of the BIWF (Elliot et al. 2017). While suspended sediment impacts would

vary in extent and intensity depending on project and site-specific conditions, measurable impacts are likely to be on the order of 500 mg/L or lower, lasting for minutes to hours, and limited in extent to within a few feet vertically and a few hundred feet horizontally from the point of disturbance. The resulting effects on marine mammals would likely be negligible to minor.

Noise: Numerous proposed offshore wind project construction projects could be developed on the mid-Atlantic OCS between 2022 to 2030 (see Appendix E). These activities include impact pile driving, HRG surveys, construction and O&M vessel use, and WTG operation. Based on the extent of noise impacts for these types of activities, it is reasonable to conclude that impact pile-driving, construction vessel, and HRG survey noise from these projects could adversely affect marine mammals. In addition, construction noise impacts from future actions could affect marine mammal use of the geographic analysis area, and/or the availability of fish and invertebrate prey resources.

As stated, future wind energy development projects would undergo independent NEPA analysis of both project-specific and cumulative effects. BOEM recently completed a programmatic ESA consultation for HRG survey activities supporting planned offshore wind energy development on the mid-Atlantic OCS from June 2021 through June 2031. In addition to project-specific EPMs, BOEM would require compliance with all mitigation and monitoring measures imposed as conditions of ESA and MMPA compliance and other federal regulations. That process is likely to result in additional measures to avoid and minimize adverse noise effects on marine mammals resulting from the various potential exposure scenarios described below.

Impulsive Noise***:*** Up to 2,547 new offshore structures associated with offshore wind development would be installed on the geographic analysis area under the No Action alternative (NMFS 2021). The anticipated construction windows for these projects would begin in 2022 and continue through 2030. Many of these structures would be installed using impact pile driving, producing high-intensity impulsive underwater noise at levels exceeding biologically significant effect thresholds for marine mammals. In addition, as stated above, noise impacts from future actions could affect marine mammal use of the geographic analysis area, and/or the availability of fish and invertebrate prey resources. These effects would vary in extent and intensity based on the scale and design of each project. Moreover, noise effects could increase in significance if individual marine mammals and/or their prey and forage resources experience repeated stressor exposures from multiple projects.

Marine mammals could experience any of the following three potential exposure scenarios under the No Action alternative:

- Concurrent exposure to noise from two or more impact hammers, operating within the same project or in adjacent projects
- Non-concurrent exposure to noise from multiple pile driving events within the same year
- Exposure to two or more concurrent or non-concurrent pile driving events over multiple years

Based on currently planned project schedules, the concurrent exposure scenario could occur under the No Action alternative and could result in impacts on marine mammals. The number of potential concurrent exposure days within the RI/MA WEA ranges from 106 to 357 assuming one foundation installation per project per day, and from 53 to 179 days assuming two foundations per project per day, depending on the year (see Table E-4 in Appendix E for details). Behavioral avoidance of noise impacts could also indirectly affect marine mammal use of the area, even if significant impacts do not occur therein.

In terms of broader regional effects, project construction in the Delaware and Maryland lease areas under the No Action alternative could generate up to 17 days of concurrent pile driving in 2023 and 129 days of concurrent pile driving in 2024, assuming one foundation per day (see Table E-4 in Appendix E for details). An individual marine mammal present in either of these areas on those days could be exposed to the noise from more than one pile driving event per day, repeated over a period of days.

Concurrent pile driving within and between future projects would increase the intensity and extent of sound exposure within the respective impact areas but would decrease the total number of days of stressor exposure in any given year. It may be desirable to plan for concurrent pile driving in order to avoid underwater noise impacts during critical periods when sensitive or particularly vulnerable populations (e.g., NARW) are most likely to be present. However, this could result in greater exposure for marine mammal species that are more likely to be present when concurrent pile driving occurs. These individuals may be more likely to suffer noise-related injuries and other adverse physiological and behavioral effects as a consequence. Physiological effects may include elevated chronic stress and depressed immune function (Erbe et al. 2018; Romano et al. 2004; Wright et al. 2007).

Under the second exposure scenario, individual marine mammals could be exposed to multiple non-concurrent pile-driving activities at different times within the same year. This scenario includes concurrent neighboring projects that time their respective pile-driving activities to occur on different days. Non-concurrent pile driving would decrease the intensity and extent of impulsive noise exposure but would increase the total number of exposure days. Given that multiple future actions are proposed for construction between 2022 and 2030 (see Table E-2 in Appendix E), it is likely that some individual marine mammals will experience two or more impact pile-driving noise exposure days within the same year.

In addition to impact pile driving, HRG surveys supporting project construction would also produce mobile impulsive underwater noise. BOEM (2021a) reviewed underwater noise levels produced by the available types of HRG survey equipment as part of a programmatic biological assessment for this and other activities associated with regional offshore wind energy development. NMFS (2021) concurred with BOEM's determination that planned HRG survey activities using even the loudest available equipment types would be unlikely to injure or measurably affect the behavior of ESA-listed marine mammals. The rationale supporting this conclusion also applies to non-listed marine mammal species. Specifically, the noise levels produced by HRG survey equipment are relatively low, meaning that an individual marine mammal would have to remain close to the sound source for extended periods of time to experience injury. This type of exposure is unlikely as the sound sources are continuously mobile and directional (i.e., pointed at the bottom). Moreover, consistent with BOEM requirements the applicant has developed a mitigation plan (SFW 2020) that includes protected species observer (PSO) monitoring of species-specific clearance zones around HRG survey activities and mandatory shutdown procedures to further minimize exposure risk. These measures would effectively avoid the risk of permanent threshold shift (PTS) or TTS effects on marine mammals from HRG survey activities. While individual marine mammals may be exposed to HRG survey noise sufficient to cause behavioral effects, those effects would be temporary in nature and unlikely to cause any perceptible longer-term consequences to individuals or populations.

As stated, considering the number and extent of projects planned in the geographic analysis area, it is likely that underwater noise impacts sufficient to cause adverse effects on marine mammals could occur under the No Action alternative. This could result from direct noise impacts that adversely affect marine mammals and/or their prey species, or from behavioral effects that alter marine mammal use of the area. The extent, duration, and significance of these effects would vary based on project specific factors. All future actions are expected to include EPMs to avoid and minimize impacts on marine mammals. Those actions are also likely to be required to comply with additional mitigation measures as a condition of permitting. When these factors are considered, the effects of impulsive noise exposure on marine mammals under the No Action alternative would range from minor to moderate, varying by species.

Non-impulsive Noise: Under the No Action alternative, several new sources of non-impulsive underwater noise would be introduced to the environment. These sources include vibratory pile driving used for various aspects of project construction, HRG surveys, helicopters and fixed-wing aircraft, construction and O&M vessel noise, and operational noise. These non-impulsive noise sources would add to other manmade sources of non-impulsive noise that account for the majority of ambient noise pollution in the marine environment. Continuous low-frequency sound from large vessel engines, specifically ocean-going cargo, tanker, and container vessels, is the primary source of ambient noise pollution in the marine environment (Basset et al. 2012). While smaller vessels, activities like vibratory pile driving, and offshore wind farm operations also generate non-impulsive noise, these sources are likely to account for a small percentage of ambient noise energy in the marine environment.

Construction and O&M vessels associated with planned offshore wind projects are the most likely sources of non-impulsive underwater noise impacts to occur in the geographic analysis area. Vibratory pile driving noise from the installation of cofferdams as part of cable installation for future projects could also occur in the geographic analysis area. Non-impulsive noise impacts on marine mammals resulting from these activities would vary in location, extent, and duration, as determined by the specific design and construction requirements for each project. The resulting effects on marine mammals would similarly range from minor to moderate, varying by marine mammal species.

Tougaard et al. (2020) summarized available monitoring data on wind farm operational noise, including both older generation geared turbine designs and quieter modern direct-drive systems like those proposed for the SFWF. They determined that operating turbines produce underwater noise on the order of 110 to 125 dB_{RMS}, occasionally reaching as high as 128 dB_{RMS}, in the 10-Hz to 8-kHz range. This is consistent with the noise levels observed at the BIWF (110 to 125 dB re 1 µPa SPL RMS; Elliot et al. 2019) and the range of values observed at European wind farms and is therefore representative of the range of operational noise levels likely to occur from future wind energy projects. More recently, Stober and Thomsen (2021) used monitoring data and modeling to estimate operational noise from larger (10 MW) current generation direct-drive WTGs and concluded that these designs could generate higher operational noise levels than those reported in earlier research. This suggests that operational noise effects on marine mammals could be more intense and extensive than those considered herein, but the findings have not been validated. As discussed in Section 3.4.4.2.3, operational noise from offshore wind turbines would typically attenuate below the 120 dB_{RMS} marine mammal behavioral disturbance and auditory masking threshold within approximately 120 feet and below existing ambient noise levels within a few to several hundred feet of each foundation, respectively. This indicates that operational noise effects from other future actions would likely be minor.

O&M vessels could travel through the geographic analysis area, generating underwater noise. More broadly, BOEM considers it unlikely that vessel noise from wind farm operations would be detectable and measurable, but short term and localized. Impacts on individuals and/or their habitat would not lead to population-level effects. On this basis, the effects of underwater noise from future O&M vessel activities would likely be minor.

Planned future actions may also employ helicopters and fixed-wing aircraft for initial site surveys, establishing and monitoring protected species exclusion zones during project construction, and for periodic facility inspections during project O&M. Aircraft associated with projects in the geographic analysis area could travel through and affect marine mammals. In general, marine mammal behavioral responses to aircraft most commonly occur at distances of less than 1,000 feet, and those responses are typically limited and likely insignificant (Patenaude et al. 2002). Similarly, aircraft could disturb hauled-out seals if aircraft overflights occur within 2,000 feet of a haul-out area. BOEM would require all aircraft operations to comply with current approach regulations for any sighted NARWs or unidentified large whale. Current regulations (50 CFR 222.32) prohibit aircraft from approaching within 1,500 feet of NARW. BOEM expects that most aircraft operations would occur above this altitude limit except under specific circumstances (e.g., helicopter landings on the service operations vessel or visual inspections of WTGs). Aircraft operations could result in temporary behavioral responses, including short surface durations, abrupt dives, and percussive behaviors (i.e., breaching and tail slapping) (Patenaude et al. 2002), but BOEM does not expect that these brief and infrequent exposures would result in biologically significant effects on marine mammals. On this basis, noise and disturbance effects on marine mammals from aircraft operations under the No Action alternative are expected to be negligible to minor.

Port utilization: The development of an offshore wind industry on the mid-Atlantic OCS may incentivize the expansion or improvement of regional ports to support planned and future projects. Port improvements could lead to an increase in vessel traffic during construction (see Vessel traffic), O&M, and conceptual decommissioning. The resulting change in vessel traffic in the geographic analysis area cannot be predicted because, while some ports have been identified as possibilities for expansion, no specific project plans have been proposed.

However, any future port expansion and associated increase in vessel traffic would be subject to independent NEPA analysis and regulatory approvals requiring full consideration of potential effects on marine mammals regionwide.

Presence of structures: The future addition of up to 2,547 new WTG and OSS foundations in the geographic analysis area would result in artificial reef and hydrodynamic effects that influence primary and secondary productivity and the distribution and abundance of fish and invertebrates community structure within and in proximity to project footprints. Depending on proximity and extent, hydrodynamic and reef effects from future actions could influence the availability of prey and forage resources for marine mammals. Project-specific effects would vary, recognizing that larger and/or contiguous projects could have more significant hydrodynamic effects and broader scales. This could in turn lead to more significant effects on prey and forage resources, but the extent and significance of these effects cannot be predicted based on currently available information.

The long-term presence of WTG structures could displace marine mammals from preferred habitats or alter movement patterns, potentially changing exposure to commercial and recreational fishing activity. The evidence for long-term displacement is unclear and varies by species. For example, Long (2017) studied marine mammal habitat use around two commercial wind farm facilities before and after construction and found that habitat use appeared to return to normal after construction. He cautioned that these findings were not definitive and additional research was needed. In contrast, Tielmann and Carstensen (2012) observed clear long-term (greater than 10 years) displacement of harbor porpoises from commercial wind farm areas in Denmark. Displacement effects remain a focus of ongoing study (Kraus et al. 2019). Other studies have documented apparent increases in marine mammal density around wind energy facilities. For example, Russel et al. (2014) found clear evidence that seals were attracted to a European wind farm, apparently attracted by the abundant concentrations of prey created by the artificial reef effect. Gray seals are particularly susceptible to entrapment in trawl fisheries (Lyssikatos 2015). If commercial trawling were to occur near wind farms, increased interactions and resulting mortality of gray seals might be anticipated.

Hayes et al. (2021) note marine mammals are following shifts in the spatial distribution and abundance of their primary prey resources driven by increased water temperatures and other climate-related impacts. These range shifts are primarily oriented northward and toward deeper waters. The widespread development of offshore renewable energy facilities may facilitate climate change adaptation for certain marine mammal prey and forage species. The artificial reefs created by these structures form biological hotspots that could support species range shifts and expansions and changes in biological community structure (Degraer et al. 2020; Methratta and Dardick 2019; Raoux et al. 2017). In contrast, broadscale hydrodynamic impacts could alter zooplankton distribution and abundance (van Berkel et al. 2020). There is considerable uncertainty as to how these broader ecological changes will affect marine mammals in the future, and how those changes will interact with other human-caused impacts. The effect of these IPFs on marine mammals and their habitats under the No Action alternative could be positive or negative, varying by species, and their significance is unknown.

The presence of structures could also concentrate recreational fishing around foundations, potentially increasing the risk of marine mammal entanglement in both lines and nets and increasing the risk of injury and mortality due to infection, starvation, or drowning (Moore and van de Hoop 2012). These structures could also result in fishing vessel displacement or gear shift. The potential impact to marine mammals from these changes is uncertain. However, if a shift from mobile gear to fixed gear occurs, there would be a potential increase in the number of vertical lines, resulting in an increased risk of marine mammal interactions with fishing gear. Entanglement in fishing gear has been identified as one of the leading causes of mortality in NARW and may be a limiting factor in the species recovery (Knowlton et al. 2012). Johnson et al. (2005) report that 72% of NARWs show evidence of past entanglements. Additionally, recent literature indicates that the proportion of NARW mortality attributed to fishing gear entanglement is likely higher than previously estimated from recovered carcasses (Pace et al. 2021). Entanglement may also be responsible for high mortality rates in other large whale species (Read et al. 2006). Abandoned or lost fishing gear may get tangled with foundations, reducing the chance that abandoned gear would cause additional harm to marine mammals and other wildlife, though debris tangled with WTG foundations may still pose a hazard to marine mammals. These potential long-term intermittent impacts would persist until decommissioning is complete and structures are removed.

Light: The addition of up to 2,547 new offshore structures in the geographic analysis area with long-term hazard and aviation lighting, as well as lighting associated with construction vessels, would increase artificial lighting. Orr et al. (2013) concluded that the operational lighting effects from wind farm facilities to marine mammal distribution, behavior, and habitat use were uncertain but likely negligible if recommended design and operating practices are implemented. BOEM would require wind farm developers to comply with the current design guidance for avoiding and minimizing artificial lighting effects. On this basis, BOEM anticipates artificial lighting impacts from future wind farm development and other offshore activities would be negligible.

Seabed and water column alteration: The future addition of up to 2,547 new WTG and OSS foundations in the geographic analysis area would result in artificial reef and hydrodynamic effects that influence primary and secondary productivity and the distribution and abundance of fish and invertebrates community structure within and in proximity to project footprints. Depending on proximity and extent, hydrodynamic and reef effects from future actions could influence the availability of prey and forage resources for marine mammals. Project-specific effects would be similar in nature across proposed offshore wind projects, recognizing that larger and/or contiguous projects could have more significant hydrodynamic effects and broader scales. This could in turn lead to more significant effects on prey and forage resources, but the extent and significance of these effects cannot be predicted based on currently available information.

Traffic: BOEM estimates that construction of future offshore wind projects would begin in earnest in 2021, peak in 2025, and conclude in 2030. Vessel activity could peak in 2024 with as many as 379 vessels involved in the construction of reasonably foreseeable projects (see Section 3.5.6.2.2 [No Action Alternative]).

Once future projects are operational, they would be serviced by CTVs making routine trips between the wind farms and port-based O&M facilities several times per week. Increased vessel traffic presents a potential increase in collision-related risks to marine mammals. BOEM anticipates that those risks would be minimized by project-specific EPMs and compliance with additional mitigation measures required as a condition of ESA and MMPA compliance. While these measures are likely to be effective avoiding adverse effects on sensitive species like NARW, they would not eliminate risks to other marine mammal species. Accordingly, effects to marine mammals from increased vessel activity could range from minor to moderate, recognizing that additional mitigation measures would likely be imposed if vessel operations result in unacceptable adverse effects.

Unplanned maintenance activities would require the periodic use of larger vessels of the same class used for project construction. Unplanned maintenance would occur infrequently dictated by equipment failures, accidents, or other events. The number and size of CTVs and number of trips per week required for planned maintenance would vary by project based on the number of WTGs. Vessel requirements for unplanned maintenance would also likely vary based on overall project size. These future actions would pose the same type of vessel-related collision risks to marine mammals as for planned trips, but the potential extent and number of animals potentially exposed cannot be determined without project-specific information. Accordingly, effects to marine mammals from increased vessel activity could range from minor to moderate, recognizing that additional mitigation measures would likely be imposed if vessel operations result in unacceptable adverse effects.

Climate change: Global climate change is an ongoing risk to marine mammals. Hayes et al. (2021) note marine mammals are being forced to adapt to changes in the spatial distribution and abundance of their primary prey resources. The range of habitats for many finfish, invertebrate, and zooplankton species on the mid-Atlantic OCS are shifting northward and toward deeper waters in response to changes in temperature regime, acidification, and other climate-driven effects on the ocean environment. The potential implications of these and other related environmental changes for marine mammals, and the ways in which they are likely to interact with the effects of regional offshore wind development, are complex and uncertain. This is particularly true when evaluating potential effects at the scale of the geographic analysis area. However, it is likely that some species are likely to adapt to these environmental changes more effectively than others. In contrast, populations that are already vulnerable, such as NARW, may face increased risk of extinction as a consequence of climate change and other factors.

Conclusions

Under the No Action alternative, BOEM would not approve the COP; Project construction and installation, O&M, and conceptual decommissioning would not occur; and potential impacts on marine mammals associated with the Project would not occur. However, ongoing and future activities would result in a range of temporary to long-term impacts (disturbance, displacement, injury, mortality, and reduced reproductive and foraging success) on marine mammals, primarily from exposure to construction-related underwater noise, vessel activity, and habitat changes resulting from artificial reef and hydrodynamic effects associated with offshore wind structures.

BOEM anticipates that impacts from ongoing activities, especially vessel traffic and noise, as well as fisheries gear interactions, would be **moderate**. In addition to ongoing activities, reasonably foreseeable activities other than offshore wind may also contribute to impacts on marine mammals. Reasonably foreseeable activities other than offshore wind include increasing vessel traffic; new submarine cable and pipeline installation and maintenance; marine surveys; marine minerals extraction; port expansion; channel-deepening activities; military readiness activities; and the installation of new towers, buoys, and piers. BOEM anticipates that the impacts of reasonably foreseeable activities other than offshore wind would be **moderate**. BOEM expects the combination of ongoing activities and reasonably foreseeable activities other than offshore wind to result in **moderate** impacts on marine mammals, primarily driven by ongoing noise impacts and interaction with commercial and recreational fisheries gear.

The combined significance criteria in Table 3.1.1-1 and Table 3.1.1-2 are used to characterize the combined effects of all IPFs likely to occur under the No Action alternative. BOEM anticipates that the impacts associated with future offshore wind activities in the geographic analysis area combined with ongoing activities, reasonably foreseeable environmental trends, and reasonably foreseeable activities other than offshore wind would result in **moderate** adverse effects because of the presence of structures and pile-driving noise and increased vessel traffic. Additionally, the presence of structures could potentially result in **minor beneficial** impacts on some marine mammal species. The majority of offshore structures in the geographic analysis area for marine mammals would be attributable to the offshore wind industry. The offshore wind industry would also be responsible for a majority of the impacts associated with new cable emplacement and EMF, but effects to marine mammals resulting from these IPFs would be localized and temporary and would not be expected to be biologically significant. The offshore wind industry would be responsible for a majority of the impacts associated with pile-driving noise, which could lead to moderate impacts to marine mammals in the geographic analysis area. However, overall, this conclusion assumes that irreversible impacts on individual marine mammals would not have negative significant consequences at the population level, or that any population-level effects would be recoverable.

The No Action alternative would forgo any long-term monitoring that SFW has committed to, or would be required to perform, the results of which could provide an understanding of the effects of offshore wind development, benefit future management of these resources, and inform planning of other offshore developments. BOEM acknowledges, however, that other ongoing and future monitoring and surveys could provide similar data to support similar goals.

3.4.5.2.3 PROPOSED ACTION ALTERNATIVE

Construction and Installation

Seabed and water column disturbance: Construction of the SFWF and SFEC Project components would physically disturb the water column and seabed. However, the area affected at any given time would be small and insignificant compared to current baseline levels of disturbance. Similarly, the water column and seabed in Lake Montauk would be disturbed during dredging and construction activities at the O&M facility. However, the affected area would be limited in size and relatively confined within the harbor (Stantec 2020), where routine maintenance dredging already occurs. Therefore, direct impacts from seabed disturbance are unlikely to measurably affect individual marine mammals. While indirect effects to fish and invertebrate prey resources would occur, these impacts are not likely to significantly affect the availability of prey and forage resources for marine mammals (see Section 3.4.2 [Benthic Habitat, Essential Fish Habitat, Invertebrates, and Finfish] for additional discussion). Therefore, seabed and water column disturbance during construction would have negligible to minor effects on marine mammals, varying in significance by species.

Noise: Construction of the SFWF and SFEC would produce short-term underwater and airborne noise with the potential to affect marine mammals. Construction noise sources include impact and vibratory pile driving, construction vessels, HRG survey equipment, and helicopters and fixed-wing aircraft.

Impact pile driving would be used to install the SFWF monopile foundations and may also be used to a limited extent to construct moorage improvements at the Montauk O&M facility. Vibratory pile driving may be used to construct the temporary cofferdam at the SFEC sea-to-shore transition and would also be used for O&M facility improvements. Construction vessels and HRG survey equipment would be used throughout SFWF and SFEC construction. Smaller construction vessels and dredging equipment would be used for O&M facility construction.

Impact hammer installation of the SFWF monopile foundations would produce the most intense underwater noise impacts with the greatest potential to cause injury-level effects on marine mammals. The action alternatives incorporate a range of EPMs that SFW has committed to in their COP Table ES-1 and are described in Appendix G, Table G-1.

Vibratory pile driving would generate intense non-impulsive noise impacts. Non-impulsive noise is less likely to cause injury to marine mammals, but the loud, continuous sound field generated by these sources can interfere with, or mask, communication and the ability to detect predators and locate prey (Hatch et al. 2012; Putland et al. 2017). HRG survey equipment is mobile, meaning that the sound source and the receptor, marine mammals, are moving in relation to one another. This tends to limit the duration of exposure such that injury-level effects are unlikely, but exposures exceeding behavioral and auditory masking thresholds may still occur. In contrast, vibratory pile driving used to install the temporary cofferdam at the SFEC sea-to-shore transition site would be stationary. While vibratory pile driving is lower in intensity than HRG survey equipment, the continuous noise it generates can cause auditory masking effects over great distances. Vessel engines also produce non-impulsive low frequency sound. While lower in intensity than vibratory pile driving, vessel engines operate continuously and can substantially alter the ambient noise environment.

Alternatively, SFW could use casing pipe for the temporary cofferdam, which would be installed using impact pile driving, which would result in less acoustic impact than vibratory pile driving to construct a cofferdam (Zeddies 2021).

Underwater noise impacts on marine mammals are evaluated using behavioral and injury-level thresholds for different marine mammal species groups developed by NMFS (NOAA 2018). Specific hearing loss thresholds are defined for different marine mammal species groups based on hearing sensitivity. These thresholds are summarized in Table 3.4.4 3. As shown, marine mammals are organized into four different groups based on hearing sensitivity, specifically the range of sound frequencies they are most sensitive to. NOAA (2018) has defined dual PTS and TTS criteria for each group that can be used to evaluate the potential for hearing injury from exposure to different types of noise exposure, such as instantaneous exposure to a single pile strike, cumulative exposure to multiple pile strikes or cumulative exposure to non-impulsive sources like vibratory pile driving or vessel noise (NOAA 2018). NMFS (NOAA 2018) has also defined threshold criteria for behavioral effects from impulsive and non-impulsive noise sources and for behavioral and auditory masking effects from non-impulsive noise sources (see Table 3.4.4 3).

Denes et al. (2021) developed sound source level estimates for monopile installation, vibratory pile driving used for sea-to-shore transition construction, and construction vessel noise. They then used those source values to estimate the distance required for that noise to attenuate to the marine mammal exposure thresholds shown in Table 3.4.4 3. The resulting values represent a radius extending around each noise source where potential injurious-level effects could occur. CSA Ocean Associates (2020) used similar methods to estimate an effect radius for HRG survey equipment. These effect radii are shown in Table 3.4.4 4. The single strike injury distances apply only to impact pile driving and represent how close a marine mammal would have to be to the source to be instantly injured by a single pile strike. The cumulative injury distances consider total estimated daily exposure, meaning a marine mammal would have to remain within that threshold distance over an entire day of exposure to experience hearing injury. The behavioral and auditory masking values are instantaneous exposure distances, meaning that any animal within the effect radius is assumed to have experienced a temporary to short-term adverse effect.

Table 3.4.5-4. Distance Required to Attenuate Underwater Construction Noise Below Marine Mammal Injury and Behavioral Effect Thresholds by Activity and Hearing/Species Groups

Construction Activity	Species Group	Exposure Distance to Single Strike Injury Threshold (feet)	Exposure Distance to Cumulative Injury Threshold (feet)	Exposure Distance to Behavioral Effect Threshold (feet)
Monopile foundation installation*	Low-frequency cetaceans	30	28,517	15,794

* Data from Denes et al. (2021). Values are maximum modeled effect distance estimates for difficult installation of an 11-meter monopile using an IHC S-4000 impact hammer with 10-dB attenuation. A difficult installation would nearly double the number of hammer strikes anticipated for a typical pile installation. The cumulative injury threshold distances for typical pile installation would be smaller, as described under Impulsive noise below.

† Sheet pile cofferdam installed using a vibratory hammer.

‡ Analysis considered use of dynamic positioning thrusters by construction vessels. This analysis did not consider the timing, frequency, and duration of noise from background vessel traffic in and near the Lease Area. Noise levels produced by construction vessels are expected to be similar to these background sources.

§ Distance to threshold estimated assuming the use of AZ-type sheet piles, with a maximum of 33 piles driven within a 24-hour period.

¥ Threshold distances based on the loudest type of HRG survey equipment, as summarized by CSA Ocean Sciences Inc. (2020).

¶ Calculated using the methods and associated analysis tools described in NOAA (2018).

The Proposed Action includes the installation of 16 monopile foundations using an impact hammer. The installation scenario considered in the analysis assumes 15 “standard” installations requiring approximately 4,500 pile strikes over 2 hours to achieve desired depth, and one “difficult” installation requiring 8,000 pile strikes and up to 4 hours due to underlying substrate conditions. After each pile is driven to depth, the construction vessel would attach appurtenant platforms and equipment and then reposition to the next foundation site. Under the most aggressive installation scenario a total of six foundations could be installed in 7 days. These exposures distance estimate reflect the planned use of a noise attenuation system that will reduce the source noise level by an average of 10 dB per hammer strike, which is achievable with currently available technologies (Bellman et al. 2020).

Monopile installation is the most likely source of permanent hearing injury and other temporary to short-term effects to marine mammals from Project-related underwater noise. The likelihood of injury depends on proximity to the noise source, the intensity of the source, the effectiveness of noise attenuation measures, and the duration of noise exposure. A detailed discussion of noise is provided in Vineyard Wind final EIS Section 3.4.1.1.1 (BOEM 2021b). For example, a low-frequency cetacean would have to remain 5.4 miles (28,517 feet) from the impact hammer operation over the 4 hours required for a difficult monopile installation to potentially experience permanent hearing injury, referred to as a PTS. Over a shorter time frame, the low-frequency cetacean would have to be closer to the pile to experience a PTS. Mid-frequency cetaceans and phocid pinnipeds are less sensitive to the intense, low-frequency sounds produced by impact pile driving and would have to be much closer to the source to be injured. For example, phocid pinnipeds would need to remain at 0.7 mile (3,750 feet) from the same noise source to experience cumulative injury. Aversion responses (avoidance of sound levels or acoustic sources that are disturbing or injurious) by marine mammals have been documented (Dunlop et al. 2017; Ellison et al. 2012; Southall et al. 2007). While avoidance responses are often variable and remain poorly understood, the available information suggests that mobile marine mammals are likely to leave areas where potentially harmful noise effects are occurring, thereby reducing risk of PTS and TTS.

Vibratory pile driving used during construction of the SFEC sea-to-shore transition would create a large exposure area for underwater noise in excess of the 120 dB_{RMS} threshold for behavioral effects from non-impulsive noise sources, extending outward in a semicircle up to 120,374 feet (22.8 miles) from the potential cofferdam sites (Denes et al. 2021) (see Figure C-32 in Appendix C). This noise source would be limited in duration, lasting no more than 18 hours per day over a maximum of 2 days (up to 36 hours total for installation and removal). Impulsive noise from HRG survey equipment (sparkers and boomers) and non-impulsive noise exceeding thresholds from construction vessels would extend outward from each source up to 463 and 48,077 feet (9.1 miles), respectively, and would occur intermittently over up to 60 total days.

As discussed above, the applicant-committed EPMs and additional mitigation measures would effectively minimize hearing impairment risks to most marine mammals from instantaneous and cumulative noise exposure. These measures emphasize protection of the critically endangered NARW, such as concentrating construction within a timing window when this species is least likely to be present. This timing window is not protective for all species, and some impact areas for PTS, TTS, and behavioral effects are large enough that the potential for individual exposure cannot be ruled out.

CSA Ocean Sciences Inc. (2020) developed estimates of the number marine mammals that could be exposed to potential adverse noise-related effects. They used a sophisticated exposure model to estimate the number of individuals by species that could be exposed to noise levels sufficient to elicit some degree of PTS (i.e., permanent hearing injury), TTS (i.e., a temporary and recoverable loss of hearing sensitivity), and other short-term physiological and behavioral effects from construction noise exposure over a 48-day work period, but the proposed work is planned for only 30-day work window. The modeled scenario included the planned use of noise attenuation system capable of achieving at least a 10-dB reduction in sound source level and timing restrictions to protect NARW but did not account for other measures to reduce exposure risk (i.e., clearance zone monitoring using PSOs and PAM, soft starts, and shutdown procedures). These results are summarized in Table 3.4.45.

Table 3.4.5-5. Estimated Number of Marine Mammals Experiencing a Permanent Threshold Shift and Temporary Threshold Shift or Behavioral Effects from Construction-Related Impact Pile Driving

Functional Hearing Group	Species	Estimated Number of Affected Individuals*		
		PTS Cumulative Sound Exposure	PTS from Peak Sound Pressure Exposure	TTS or Physiological Behavioral Effects
Low-frequency cetaceans	Fin whale	1	< 1	6
	Minke whale	1	< 1	10
	Sei whale	< 1	< 1	< 1
	Humpback whale	4	< 1	8
	NARW	< 1	< 1	4

Functional Hearing Group	Species	Estimated Number of Affected Individuals*		
		PTS Cumulative Sound Exposure	PTS from Peak Sound Pressure Exposure	TTS or Physiological Behavioral Effects
Mid-frequency cetaceans	Sperm whale	< 1	< 1	< 1
	Atlantic spotted dolphin	< 1	< 1	2
	Atlantic white sided dolphin	< 1	< 1	107
	Common bottlenose dolphin	< 1	< 1	43
	Common dolphin	< 1	< 1	197
	Risso's dolphin	< 1	< 1	<1
	Pilot whale	< 1	< 1	< 1
High-frequency cetaceans	Harbor porpoise	1	2	78
Phocid pinnipeds	Gray seal	< 1	< 1	60
	Harbor seal	< 1	< 1	54

Source: CSA Ocean Sciences Inc. (2020).

* Modeled exposure estimates based on impact hammer installation of 16 11-meter monopiles. Installation scenario assumes one difficult and 15 normal installations requiring 4 hours and 2 hours of pile driving, respectively, and use of a noise attenuation system achieving 10-dB effectiveness. Values < 1 indicate a modeled exposure estimate of greater than 0 but less than 0.5 individual, which is considered a result of zero for regulatory purposes.

† See impact significance criteria definitions in Table 3.4.4-3.

As shown, CSA Ocean Sciences Inc (2020) estimated that up to one fin whale, one sei whale, four humpback whales, and three harbor porpoises could experience PTS injury from exposure to cumulative and peak impact pile-driving noise under the Proposed Action. None of the other marine mammal species that occur in the noise impact area, including NARW, are likely to experience PTS (as indicated by an individual exposure estimate of < 1). Individuals from several species are likely to experience noise exposure sufficient to cause TTS or behavioral effects. TTS and behavioral exposures can have an array of adverse effects on marine mammals, even in the absence of overt behavioral responses. For example, a reduction in effective "communication space" caused by auditory masking can it more difficult to locate companions and maintain social organization (Cholewiak et al. 2018). This can increase physiological stress, leading to impaired immune function and other chronic health problems (Hatch et al. 2012; Rolland et al. 2012), and even lead to broader changes in distribution, and population fragmentation (Brakes and Dall 2016; Davis et al. 2017). These kinds of effects are most associated with long-term changes in the ambient noise environment, specifically from chronic exposure to noise from increasing levels of marine vessel traffic. All construction-related noise sources would cease once construction is completed, and any animals suffering from TTS or stress from auditory masking and behavioral exposure would be expected to recover fully within hours to days.

Using the significance criteria in Table 3.4.4-3, the construction noise exposures summarized in Table 3.4.4-5 would result in moderate effects on fin, minke, and humpback whales and harbor porpoises; and minor effects on NARW and Atlantic spotted, Atlantic white-sided, common bottlenose, and common dolphins. Construction noise effects on Risso's dolphin and sei, sperm, and pilot whales would be negligible. These are likely overestimates, in that they do not consider establishment and monitoring of clearance zones using PSOs and PAM, soft-start and shutdown procedures, and other planned measures to avoid and minimize exposure.

CSA Ocean Sciences Inc. (2020) did not explicitly consider exposure to vessel noise in their assessment. In general, construction vessel noise is unlikely to cause cumulative hearing injury in marine mammals because this would require prolonged exposure at close proximity to the source (i.e., within 400 feet for 24 hours). This is an unlikely scenario. For example, an animal swimming at 2.5 miles per hour, the lower end of average swim speeds for the NARW (Baumgartner and Mate 2005), would travel 400 feet in less than 2 minutes. Moving vessels produce lower noise levels, further reducing the potential for injury-level exposure. Animal movement would also reduce exposure to potential behavioral and auditory masking effects. For example, a marine mammal moving away from a stationary construction vessel at 2.5 miles per hour would clear the maximum potential behavioral exposure zone within approximately 4 hours. As stated above, available data suggests that mobile marine mammals would avoid behavioral disturbances like those resulting from vessel noise, meaning that the duration of exposure to noise from slow-moving, or closely clustered and stationary construction vessels would be limited. Moreover, a substantial portion of construction vessel activity would occur in an area having high existing levels of vessel traffic. In these areas, construction vessel noise would contribute to, but may not substantially alter, ambient noise generated by existing large vessel traffic in the vicinity. While some individual marine mammals may experience short-term behavioral and auditory effects from vessel noise exposure, these effects would be short term in duration and broader stock or population-level impacts are unlikely. Therefore, construction vessel noise impacts on marine mammals would likely be minor.

Construction of the O&M facility would include dredging to bring the proposed berthing area to suitable depth for crew transport and maintenance vessels, and vibratory pile driving to install five 2-foot-diameter steel piles. A limited number of impact hammer strikes may be used to complete installation of each pile. Pile driving used to install moorage improvements at the Montauk O&M facility could cause cumulative injury exposure and instantaneous behavioral effects in seals that remain within 103 feet and 4,460 feet of the activity, respectively. Dredging would also generate underwater noise. However, the O&M facility site, other berthing areas in Lake Montauk Harbor, and the federal navigation channel adjacent to the site are routinely dredged to maintain desired depths. Dredging noise effects on marine mammals from O&M facility construction would therefore be negligible relative to this baseline. Vibratory and impact pile-driving noise would be limited in duration and contained entirely within Lake Montauk by the surrounding shorelines (BOEM 2021). Gray and harbor seals, harbor porpoise, and potentially some dolphin species may occur in Lake Montauk and could be exposed to O&M facility construction effects. The larger whales, including the ESA-listed species (see 3.4.4-1), are not likely to occur in Lake Montauk (USACE 2019). Based on the noise levels produced by 24-inch piles and the limited duration of vibratory and pile driving, injury-level effects on seals are unlikely to occur. Behavioral-level effects on small numbers of individual seals and porpoises may occur, but these effects would not be significant at the population level and therefore minor.

Impact pile-driving noise could kill or injure or temporarily alter the distribution of fish and invertebrate prey (see Section 3.4.2 [Benthic Habitat, Essential Fish Habitat, Invertebrates, and Finfish), leading to indirect effects on marine mammal prey resources. These effects would be limited in extent, short term, and are unlikely to measurably affect the amount of prey available to marine mammals across the OCS. Therefore, the indirect adverse effects of underwater noise on marine mammal prey species would be negligible to minor.

Pile driving also produces airborne noise. NMFS has established a behavioral threshold of 90 dB_{RMS} for harbor seals and 100 dB_{RMS} for other otariid and phocid pinniped exposure to airborne noise sources like pile driving (NOAA 2018). No equivalent airborne noise behavioral thresholds have been established for other marine mammal species. Harbor and gray seals are the only pinniped species group expected to occur in the SFWF and SFEC. Based on methods described by the Washington State Department of Transportation (2020), behavioral-level effects could be experienced within approximately 500 and 10 feet from impact and vibratory pile-driving locations, respectively. However, because seals would experience behavioral- and injury-level exposures to underwater noise at greater distance, behavioral-level exposure to airborne noise is unlikely to occur as an independent effect. Moreover, marine mammal observers would monitor the affected area for seals and would halt construction if individuals are observed within these limits, further minimizing the risk of seal exposure to airborne noise impacts (Baker et al. 2013; Jacobs 2021). On this basis, airborne noise effects on seals would be negligible.

Helicopters and fixed-wing aircraft may also be used during Project construction. In general, marine mammal behavioral responses to aircraft most commonly occur at distances of less than 1,000 feet and those responses are typically limited and likely insignificant (Patenaude et al. 2002). Similarly, aircraft could disturb hauled-out seals if aircraft overflights occur within 2,000 feet of a haul-out area. BOEM would require all aircraft operations to comply with current approach regulations for any sighted NARWs or unidentified large whale. Current regulations (50 CFR 222.32) prohibit aircraft from approaching within 1,500 feet of NARW. BOEM expects that most aircraft operations would occur above this altitude limit except under specific circumstances (e.g., helicopter landings on the service operations vessel). Aircraft operations could result in temporary behavioral responses, including short surface durations, abrupt dives, and percussive behaviors (i.e., breaching and tail slapping) (Patenaude et al. 2002), but BOEM does not expect that these exposures would result in biologically significant effects on marine mammals. On this basis, noise and disturbance effects on marine mammals from aircraft operations under the No Action alternative are expected to be minor.

<u>Suspended sediment and sediment deposition</u>: Seabed disturbance during cable installation, sea-to-shore transition construction, and O&M facility dredging would result in elevated suspended sediment concentrations in the water column. Vinhateiro et al. (2018) modeled the magnitude and extent of anticipated TSS concentrations resulting from SFWF and SFEC construction. Maximum water column TSS concentrations could range between 500 and 1,347 mg/L in close proximity to the disturbance within a few select areas but would dissipate quickly (within minutes) to less than 100 mg/L. The majority of water column effects would be limited to short-term TSS pulses below than 100 mg/L, occurring in plumes extending approximately 6 to 12 feet off the seabed and up to 330 feet downcurrent. TSS concentrations would dissipate to background conditions within approximately 1 to 2 hours after disturbance. These modeled estimates are similar to those developed for BIWF construction. The observed extent of TSS impacts at the BIWF turned out to be far lower than the modeled estimates (Elliot et al. 2017), indicating that the potential impacts described here are likely conservative. Both the modeled TSS effects, which are conservatively high, and the observed TSS effects were short term and within the range of baseline variability. Dredging activities at the O&M facility would also result in temporary TSS plumes. However, these effects would be short term (i.e., a few hours) due to the low mobility of sediments (primarily sand) in the proposed dredge area (Stantec 2020; USACE 2020).

Available information on marine mammal sensitivity to TSS indicates that water quality impacts would have negligible effects on marine mammals. First, periodic TSS concentrations on the order of 100 mg/L at or near the seabed are within the range of baseline variability. Marine mammals that forage on or near the seabed are unlikely to be affected by a short-term increase in TSS that are comparable to existing conditions. For example, researchers have observed that visually impaired grey and harbor seals are able to navigate and locate prey just as effectively as their fully sighted counterparts (McConnell et al. 1999; Newby et al. 1970; Todd et al. 2015), indicating that short-term visual impairment would have no measurable effect on foraging ability. While research on TSS sensitivity in dolphins and large whales is generally lacking, these species developed the ability to echolocate by evolving in environments having variable and often low visibility (Tyack and Miller 2002). This suggests that a short-term reduction in visibility would have no meaningful effects on communication, foraging, and predator avoidance, particularly given that measurable TSS impacts would be limited to within 10 to 12 feet of the seabed.

These factors indicate that marine mammal exposure to water quality effects resulting from construction of the Proposed Action would be limited. Those species that are exposed to elevated TSS would be unlikely to experience measurable effects on behavior, foraging success, or communication. On this basis, water quality effects on marine mammals resulting from Project construction would be negligible.

Vessel traffic: Construction and monitoring vessels pose a potential collision risk to marine mammals, and the noise and disturbance generated by vessel presence may temporarily displace individual marine mammals from preferred habitats.

Based on information provided by SFW, Project construction would require an estimated total of 50 large construction vessel trips between the Port of New London, Connecticut, and the SFWF over the 2-year construction period, or approximately six trips per month. BOEM estimates that at least six vessel trips originating from European ports are likely and an additional 20 trips are possible over the 2-year construction period. Up to four vessel trips could originate from other U.S. ports, including Paulsboro, NJ; Sparrows Point or Baltimore, MD; Norfolk, VA; or possibly other ports on the Atlantic coast or Gulf of Mexico, but BOEM considers this to be unlikely based on current understanding. BOEM estimates that four vessel trips could originate from the Montauk O&M facility site (unlikely), and two additional vessel trips could originate from other unspecified worldwide ports (possible). In addition, approximately 620 linear miles of pre-construction HRG surveys are anticipated to support micrositing of the WTG foundations and cable routes. HRG surveys could occur during any month of the year and would require a maximum of 60 total vessel days. The construction vessels used for Project construction are described in Section 3.1.3.1 and Table 3.1-6 in the COP. Typical large construction vessels used in this type of project range from 325 to 350 feet in length, from 60 to 100 feet in beam, and draft from 16 to 20 feet (Denes et al. 2021).

In total, Project construction would require an estimated 311 one-way vessel trips (approximately 156 round trips) between construction sites and area ports in Rhode Island or Connecticut, and 66 additional one-way trips from other ports, as described above. Large construction vessels would account for an estimated 153 of these one-way trips, with the remainder comprising CTVs and other small support vessels. BOEM (2021) developed a representative analysis of construction vessel effects on regional traffic volume by evaluating the potential increase in transits across a set of analysis cross sections relative to baseline levels of vessel traffic. These cross sections are shown in 3.4.4-1.

BOEM (2021) assumed that the construction vessel trip estimates summarized above would be evenly divided between cross sections 13, 17, and 20 when leaving the SFWF and SFEC construction areas (cross section 20 is under the scale bar), and all vessels traveling to Rhode Island ports would travel through cross section 5 (see Figure 3.4.4-1). Applying this assumption, construction vessel activity would result in 51 additional vessel transits through cross section 13 per year (relative to 31 baseline transits), 51 additional vessel trips through cross section 17 (relative to 60 baseline transits), and 51 additional vessel trips through cross section 20 (relative to 51 baseline transits). Once in the shipping lanes, construction vessel traffic would modestly increase annual vessel traffic by 155 trips (relative to 1,296 baseline transits). These estimates are not fully representative, however, as they do not consider fishing vessel traffic. Over 200 fishing vessels account for 3,000 additional vessel trips each year. In summary, this assessment indicates that construction vessels would likely increase vessel traffic to some degree, and large vessel traffic would measurably increase during the 2-year construction period. This indicates the potential for increased risk of marine mammal collisions in the absence of planned mitigation measures and other requirements.

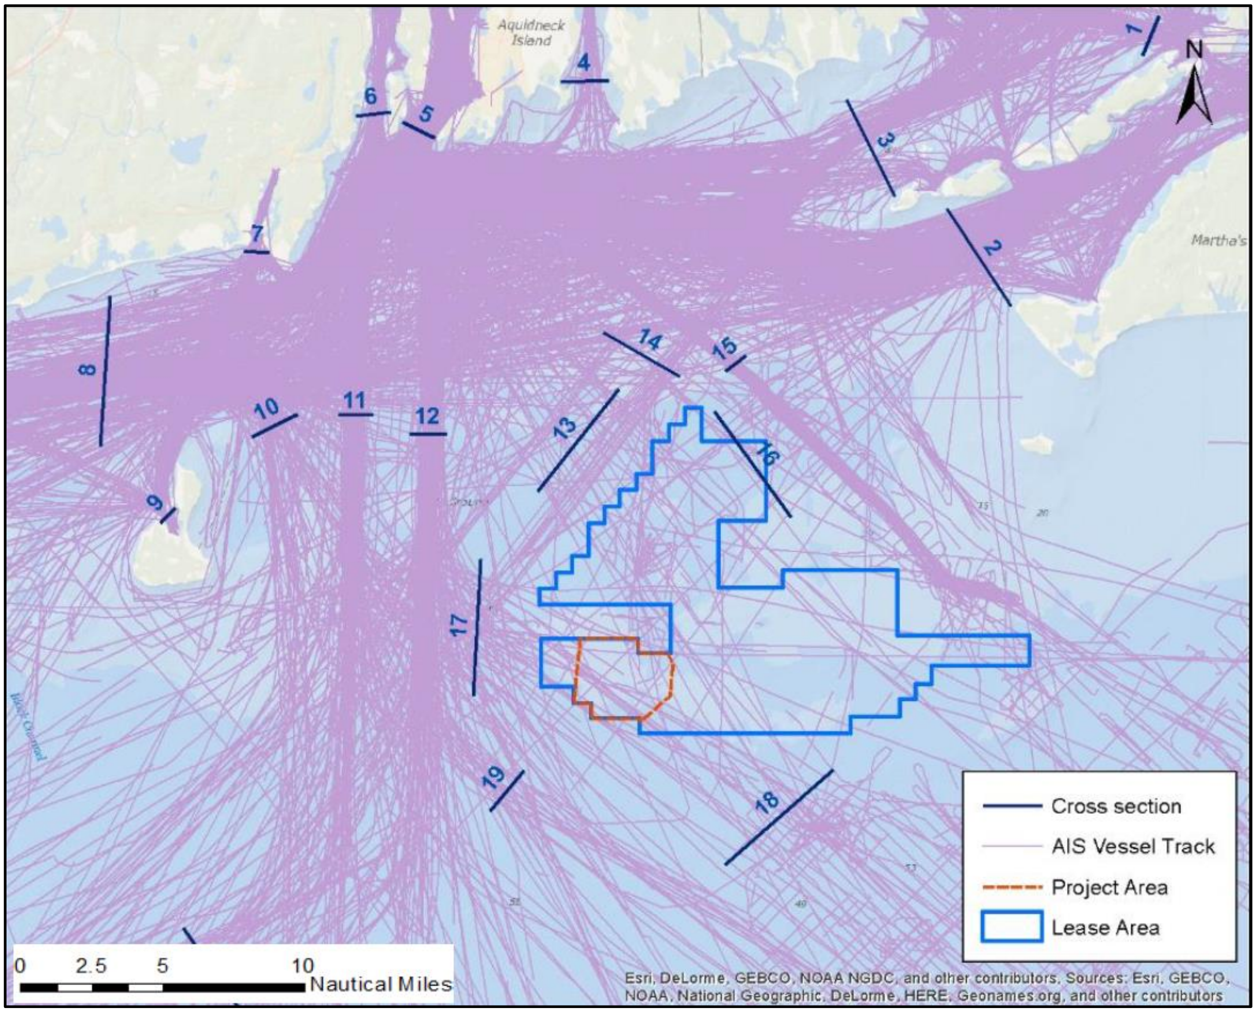

Figure 3.4.5-1. AIS vessel traffic tracks for June 2016 to July 2017 and analysis cross sections used for traffic pattern analysis (DNV GL 2018).

Vessel collisions are a major source of mortality and injury for many marine mammal species (Hayes et al. 2021; Laist et al. 2001; Rockwell et al. 2017), indicating the importance of protective measures to minimize risks to vulnerable species. If a vessel strike does occur, the impact on marine mammals would range from negligible to major depending on the species and severity of the strike. However, the applicant has committed to a range of EPMs to avoid vessel collisions with marine mammals (see Appendix G, Table G-1). These include strict adherence to NOAA guidance for collision avoidance and a combination of additional measures, including speed restrictions to 10 knots or less for all vessels at all times between November 1 and April 30, speed restrictions to 10 knots or less in Dynamic Management Areas (DMAs). All vessel crews would receive training to ensure these EPMs are fully implemented for vessels in transit. Once on station, the construction vessels either remain stationary when installing the monopiles and WTG/OSS equipment or move slowly (i.e., at less than 10 knots) when traveling between foundation locations. Cable laying and HRG survey vessels also move slowly, with typical operational speeds of less than 1 and approximately 4 knots, respectively.

Based on the low density of marine mammals in the SFW Lease Area and a maximum of 156 round trips during construction and installation, there is a low risk of encountering a marine mammal. The operational conditions combined with planned EPMs (see Appendix G for all vessel strike avoidance measures) will minimize collision risk during construction and installation. During periods of low visibility, trained crew would use increased vigilance to avoid marine mammals. Because vessel strikes are not an anticipated outcome given the relatively low number of vessel trips and monitoring and mitigation activities to avoid encountering marine mammals, BOEM concludes vessel strikes are unlikely to occur. Therefore, there is no anticipated effect on marine mammals. In the event of an unanticipated vessel strike of a marine mammal by any vessel supporting the Project, Orsted must immediately cease the activities until BOEM is able to review the circumstances of the incident and determine what, if any, additional measures are appropriate to ensure compliance with all applicable laws (e.g., ESA, MMPA) and COP approval conditions.

The presence of construction vessels and associated noise and disturbance may cause short-term displacement of marine mammals from preferred habitats. Long (2017) observed temporary marine mammal displacement from offshore wind energy construction sites on the Scottish coast, apparently due to vessel-related disturbance. Habitat use within the affected areas returned to normal after construction was completed, indicating that any such displacement effects would be short term in duration. On this basis vessel displacement effects on marine mammals could range from minor to moderate, recognizing that some portion of these effects are also likely the result of construction noise, as described above.

Marine debris and accidental spills: Construction vessels pose a theoretical source of marine debris and entanglement risk and accidental discharges of petroleum products and other toxic substances. Marine debris are a known source of adverse effects to marine mammals (Laist 1997; NOAA-MDP 2014a, 2014b). BOEM prohibits the discharge or disposal of solid debris into offshore waters during any activity associated with the construction and operation of offshore energy facilities (30 CFR 250.300). The USCG similarly prohibits the dumping of trash or debris capable of posing entanglement or ingestion risk (MARPOL, Annex V, Public Law 100−220 (101 Stat. 1458)). The applicant would follow strict oil spill prevention and response procedures during all Project phases and has developed a detailed spill response and containment plan as a Project EPM. These regulatory requirements and EPMs would effectively avoid releases of abandoned marine debris, although potential for entanglement associated with active commercial or recreational fishing gear would still exist and would avoid and minimize impacts from accidental spills such that adverse effects on marine mammals are unlikely to occur. Therefore, effects on marine mammals from this impact mechanism would be negligible.

Operations and Maintenance and Conceptual Decommissioning

The operational effects of the Project include the physical presence of the SFWF turbine and substation foundations, alteration of benthic habitat by rock armoring and scour protection, underwater and airborne noise from the operating turbines, O&M vessel traffic and associated underwater noise, and annual maintenance dredging of the O&M facility, water quality degradation due to maintenance dredging, EMF effects generated by the inter-array cable and SFEC, and artificial lighting on the WTG and substation towers.

Project construction and conceptual decommissioning would involve similar vessels, equipment, and methods, and, except for noise, would produce similar effects. Pile driving would not be required for conceptual decommissioning. The monopile foundations would be cut at 15 feet below the seabed in accordance with 30 CFR 585.910 using a cable saw or an internal abrasive waterjet cutting tool and returned to shore for recycling. Noise produced by cutting equipment is generally indistinguishable from engine noise (Pangerc et al. 2016), and therefore would not lead to additional effects beyond vessel noise.

Displacement effects: The presence of SFWF monopile foundations over the life of the Project would alter the character of the ocean environment, and their presence could affect marine mammal behavior; however, the likelihood and significance of these effects are difficult to determine. Long (2017) compiled a statistical study of seal and cetacean (including porpoises and baleen whales) behavior in and around Scottish marine energy facilities. The study found evidence of displacement during construction, but habitat use appeared to return to previous levels once construction was complete and the projects were in operation. Long cautioned that observational evidence was limited for certain species and further research would be required to draw a definitive conclusion about operational effects. Delefosse et al. (2017) reviewed marine mammal sighting data around oil and gas structures in the North Sea and found no clear evidence of species attraction or displacement. Long (2017) found no observable long-term displacement effects on seals, porpoises, dolphins, or large whales, from a network of wave energy converters installed on the Scottish coast, but these findings may not be applicable to offshore wind structures. Other studies have documented apparent changes in marine mammal behavior around wind energy facilities. For example, Russel et al. (2014) found clear evidence that seals were attracted to a European wind farm, apparently attracted by the abundant concentrations of prey created by the artificial reef effect. Gray seals are particularly susceptible to entrapment in trawl fisheries (Orphanides 2020). If commercial trawling were to occur near wind farms, increased interactions and resulting mortality of gray seals might be anticipated. Some research has suggested long-term displacement of species like harbor porpoise, but the evidence is mixed, and observed changes in abundance may be more indicative of general population trends than an actual wind farm effect (Nabe-Nielsen et al. 2011; Tielmann and Carstensen 2012; Vallejo et al. 2017).

The 16 SFWF monopile foundations would be placed in a grid-like pattern with spacing of approximately 1.0 (0.9 to 1.1) nm between turbines. Based on documented lengths (Wynne and Schwartz 1999), the largest NARW (59 feet [18 meters]), fin whale (79 feet [24 meters]), sei whale (59 feet [18 meters]), and sperm whale (59 feet [18 meters]) would fit end-to-end between two foundations spaced at 1 nm 100 times over. This simple assessment of spacing relative to animal size indicates that the physical presence of the monopile foundations is unlikely to pose a barrier to the movement of large marine mammals, and even less likely to impede the movement of smaller marine mammals. On this basis, BOEM concludes that the presence of the SFWF monopile foundations would pose a negligible risk of displacement effects on marine mammals. However, this determination does not consider the potential effects of operational noise, which are addressed further below.

<u>Habitat alteration and hydrodynamic effects</u>: The presence of the SFWF could also cause indirect effects on marine mammals by changing the distribution and abundance of preferred prey and forage species. Monopiles and scour protection would create an artificial reef effect (Degraer et al. 2020), likely leading to enhanced biological productivity and increased abundance and concentration of fish and invertebrate resources (Hutchison et al. 2020). This could alter predator-prey interactions in and around the facility with uncertain and potentially beneficial or adverse effects on marine mammals. For example, fish predators like seals and porpoises could benefit from increased biological productivity and abundant concentrations of prey generated by the reef effect (e.g., Russel et al. 2014).

The presence of vertical structures in the water column could cause localized hydrodynamic effects that could influence the distribution and abundance of fish and planktonic prey resources (van Berkel et al. 2020). Turbulence presence of vertical structures in the water column could lead to localized changes in circulation and stratification patterns, with potential implications for primary and secondary productivity and fish distribution. These effects and their implications for fish, invertebrates, and primary and secondary productivity are discussed in detail in Section 3.4.2.2.3. In summary, the SFWF and SFEC is characterized by strong seasonal stratification, which is expected to limit measurable hydrodynamic effects to within 600 to 1,300 feet downcurrent of each monopile. Localized turbulence and upwelling effects around the monopiles are likely to transport nutrients into the surface layer, potentially increasing primary and secondary productivity. That increased productivity could be partially offset by the formation of abundant colonies of filter feeders on the monopile foundations. While the net impact of these interactions are difficult to predict, they are not likely to result in more than localized effects on the abundance of zooplankton. The 0.9- to 1.1-nm spacing between monopiles ensures that their respective turbulent zones would not overlap. Recent modeling of hydrodynamic effects suggests that surface currents could be affected by the presence of multiple wind farms, potentially impacting the distribution of larvae (Johnson et al., 2021). When considered relative to the broader oceanographic factors that determine primary and secondary productivity in the region, localized impacts on zooplankton abundance and distribution are not likely to measurably affect the availability of prey resources for marine mammals.

In summary, long-term reef and hydrodynamic effects resulting from the Proposed Action could result in minor beneficial effects on fish-eating marine mammals like dolphins and seals that benefit from increased prey abundance around the structures and negligible effects on marine mammals that forage on plankton and forage fish.

Survey fisheries gear (trawl surveys, gillnet and ventless trap and pot gear, and the anchoring lines and buoys used to secure PAM equipment) could also pose an entanglement risk to marine mammals. Post-ROD gillnet and ventless trap and pot surveys would employ the use of both weak link and weak rope technologies that are consistent with recommendations from NMFS. As such, impacts to marine mammals are expected to be negligible based upon the limited number of associated buoy lines and the implementation of risk reduction measures such as no wet storage of fishery monitoring gear; pot gear sampling in July to September will not occur in order to minimize interactions with protected species (e.g., large whales, sea turtles); no buoy lines floating at the surface; all sampling gear will be hauled at least once every 30 days; all gear will be removed from the water at the end of each sampling season; all groundlines will be constructed of sinking line; and all gillnet strings will be anchored with a Danforth-style anchor with a minimum holding strength of 22 pounds. For trawl surveys, large whale species have the speed and maneuverability to avoid oncoming mobile gear (NMFS 2016), and due to the few proposed trawl survey and short tow times, impacts are anticipated to be negligible.

Acoustic telemetry receiver systems pose a negligible risk of harm to marine mammals. Based on the type of equipment and the fact that a small number of receivers deployed (10 in total) would be distributed over a large area, BOEM considers the effects of this Project element on marine mammals to be negligible. Similarly, moored and autonomous PAM systems will use the best available technology to reduce any potential risks of entanglement. PAM system deployment would avoid and minimize impacts. Therefore, the effects of this type of survey equipment on marine mammals are negligible.

Operational noise: Offshore WTGs produce continuous non-impulsive underwater noise during operation, mostly in lower frequency bands below 8 kHz. The low-frequency sounds produced by WTGs are within the range of hearing sensitivity and audible communication frequencies used by many species of marine mammals (NOAA 2018), indicating that this impact mechanism could be a potential source of behavioral and auditory masking effects on marine mammal species.

Tougaard et al. (2020) summarized available monitoring data on wind farm operational noise, including both older generation geared turbine designs and quieter modern direct-drive systems like those proposed for the SFWF. They determined that operating turbines produce underwater noise on the order of 110 to 125 dB re 1 µPa at a reference distance of 50 meters, occasionally reaching as high as 128 dB re 1 µPa, in the 10-Hz to 8-kHz range. This is consistent with the noise levels observed at the BIWF (Elliot et al. 2019) and the range of values observed at European wind farms. More recently, Stober and Thomsen (2021) used monitoring data and modeling to estimate operational noise from larger (10 MW) current generation direct-drive WTGs and concluded that these designs could generate higher operational noise levels than those reported in earlier research. This suggests that operational noise effects on finfish, including EFH species, could be more intense and extensive than those considered herein, but the findings have not been validated.

The potential for behavioral and auditory masking effects on marine mammals can be evaluated by estimating the area exposed to WTG operational noise above the 120 dB_{RMS} behavioral effects threshold for non-impulsive noise sources (3.4.4-3). Applying the practical spreading loss model and the general rule of thumb for estimating dB_{RMS} from dB re 1 µPa (WSDOT 2020),[10] the maximum predicted operational noise

[10] Sound source values in dB_{RMS} can be estimated by subtracting 10 dB from peak source values in dB re 1 µPa (WSDOT 2020).

level of 128 dB_{RMS} would attenuate below 120 dB_{RMS} within approximately 120 feet of each turbine foundation. This suggests that behavioral and masking effects could occur within a small radius around each turbine.

However, it is also probable that operational noise would change the ambient sound environment within the wind farm environment in ways that could affect habitat suitability. This impact can be evaluated by estimating the area exposed to operational noise above the existing environmental baseline. Kraus et al. (2016) measured ambient noise conditions at three locations adjacent to the proposed SFWF over a 3-year and identified baseline levels of 102 to 110 dB re 1 µPa.[11] Maximum operational noise levels typically occur at higher wind speeds when baseline noise levels are higher due to wave action. Applying the same approach described above, the minimum and maximum operational noise levels of 110 and 128 dB_{RMS} would attenuate to the 102 to 110 re 1 µPa baseline within approximately 120 to 560 feet of each turbine, respectively.

Operational noise could interfere with communication and echolocation, reducing feeding efficiency in the areas within a few hundred feet of the monopiles under some conditions. Any such effects would likely be dependent on hearing sensitivity and the ability to adapt to low-intensity changes in the noise environment. For example, based on known hearing sensitivity (Johnson 1967; NOAA 2018), mid-frequency cetaceans like dolphins are likely to be less sensitive to the low-frequency sounds generated by operational WTGs. Dolphins vocalize in low to mid frequencies, suggesting the possibility of partial masking effects, but these species are also known to shift vocalization frequencies to adapt to natural and anthropogenic conditions (David 2006; Quintana-Rizzo 2006).

On balance, any operational noise effects from the SFWF are likely to be of low intensity and highly localized. Jansen and de Jong (2016) and Tougaard et al. (2009) concluded that marine mammals would be able to detect operational noise within a few thousand feet of WTGs, but the effects would have no significant impacts on individual survival, population viability, distribution, or behavior. The findings provided above indicate that operational noise effects would attenuate to ambient levels within a few hundred feet of each foundation, but operational noise could cause auditory masking effects for marine mammals within 120 feet of each turbine. This suggests the potential for a reduction in effective communication space within the wind farm environment for marine mammals that communicate primarily in frequency bands below 8 kHz. This localized, long-term impact would constitute a moderate effect on marine mammals belonging to the low-frequency cetacean hearing group.

The O&M facility would require annual maintenance dredging to maintain CTV berths. Dredging would be completed with the use of a barge-mounted crane or excavator fitted with a clamshell bucket. Seals would likely avoid the area during dredging activities as a result of underwater noise. Montauk Harbor is periodically dredged to maintain navigational access (USACE 2019), meaning that this form of disturbance already commonly occurs. Because underwater and airborne noise would not differ from background noise from existing vessel traffic and harbor maintenance activities, noise and disturbance associated with maintenance dredging noise is not expected to have a meaningful impact on marine mammals; therefore, the effects to marine mammals would be negligible.

BOEM anticipates that underwater noise generated by vessels used for Project monitoring would overlap the hearing range of fin, NARW, sei, and sperm whales and would be audible to these species. However, the noise levels generated by these smaller Project vessels are below the hearing injury threshold of marine mammals; therefore, vessel noise from Project monitoring activities is not expected to result in injury-level effects. Vessel traffic during post-ROD monitoring, and associated noise impacts, could result in repeated localized, intermittent, short-term impacts on marine mammals and result in brief behavioral responses that would be expected to dissipate once the vessel or the individual has left the

[11] These are 50th and 90th percentile values for monitoring locations RI-1, RI-2, and RI-3, as reported by Kraus et al. (2016).

area. BOEM expects that these brief responses of individuals to passing vessels would be infrequent given the patchy distribution of marine mammals, the limited number of planned vessel trips, and the negligible effect of survey activities on baseline levels of vessel traffic in the action area.

<u>Water quality degradation</u>: Annual maintenance dredging activities at the O&M facility would temporarily elevate TSS levels in the area surrounding the dredge footprint. However, these effects would be short term (lasting only a few tide cycles) due to the low mobility of sediments (primarily sand) in the proposed dredge area (Stantec 2020). Therefore, the resulting adverse impacts to marine mammals would be negligible because these species are mobile and forage over large areas, and their ability to feed would not be measurably affected by short-term and limited TSS effects.

<u>EMF</u>: Exponent Engineering, P.C. (2018) modeled EMF levels that could be generated by the SFEC and inter-array cable. They estimated induced magnetic field levels ranging from 13.7 to 76.6 mG on the bed surface above the buried and exposed SFEC cable and 9.1 to 65.3 mG above the inter-array cable, respectively. Induced field strength would decrease effectively to 0 mG within 25 feet of each cable. By comparison, the earth's natural magnetic field is more than five times the maximum potential EMF effect from the Project (see Figure F-8 in Appendix F). Background magnetic field conditions would fluctuate by 1 to 10 mG from the natural field effects produced by waves and currents. The maximum induced electrical field experienced by any organism close to the exposed cable would be no greater than 0.48 mV/m (Exponent Engineering, P.C. 2018). BOEM has conducted literature reviews and analyses of potential EMF effects from offshore renewable energy projects conducted (CSA Ocean Sciences Inc. 2021; Inspire Environmental 2019; Normandeau et al. 2011). These and other available reviews and studies (Gill et al. 2005; Kilfoyle et al. 2018) suggest that most marine species cannot sense low-intensity electric or magnetic fields generated by the HVAC power transmission cables commonly used in offshore wind energy projects. Normandeau et al. (2011) concluded that marine mammals are unlikely to detect magnetic field intensities below 50 mG, suggesting that these species would be insensitive to EMF effects from Project electrical cables. Project-related EMFs would be below this threshold and therefore undetectable, except for those areas where the cables lie on the bed surface. The area exposed to magnetic field effects greater than 50 mG would be small, extending only a few feet from the cable. The 50-mG detection threshold is theoretical and an order of magnitude lower than the lowest observed magnetic field strength resulting in observed behavioral responses (Normandeau et al. 2011). These factors indicate that the likelihood of marine mammals encountering detectable EMF effects is low, and any exposure would be below levels associated with measurable biological effects. Therefore, EMF effects on marine mammals would be negligible.

<u>Artificial lighting</u>: The SFWF would introduce stationary artificial light sources in the form of navigation, safety, and work lighting. BOEM (Orr et al. 2013) summarized available research on potential operational lighting effects from offshore wind energy facilities and developed design guidance for avoiding and minimizing lighting impacts on aquatic life, including marine mammals. They concluded that the operational lighting effects to marine mammal distribution, behavior, and habitat use were negligible if recommended design and operating practices are implemented. The applicant has incorporated this guidance into the Project design and will use only the minimum type and amount of lighting required by regulation (see Appendix G, Table G-1). Therefore, BOEM anticipates that operational lighting effects on marine mammals would be negligible.

<u>Vessel traffic</u>: SFW has estimated that Project O&M would involve up to seven CTV trips per month, or approximately 2,500 vessel trips over the lifetime of the Project, originating from the Montauk O&M facility. The current Project plan includes a single 95-foot-long CTV to service the SFWF over the life of the Project. The majority of O&M vessel trips would be conducted by the 95-foot CTV, with larger vessels making less frequent trips (an average of four round trips annually) to repair scour protection or replace damaged WTGs on an as needed basis.

Project fishery monitoring activities are expected to represent a very small increase in regional vessel traffic. As detailed in Appendix G of the final EIS (BOEM 2021c), all survey vessels would comply with speed restrictions and other minimization measures to minimize risk of collision with marine mammals, making the risk of vessel strikes from Project monitoring vessels unlikely.

As described in the previous section, the applicant has voluntarily committed to specific EPMs, including vessel timing and speed restrictions to avoid and minimize vessel-related risks to marine mammals (see Appendix G, Table G-1). Based on the low density of marine mammals in the SFW Lease Area and a maximum of seven round trips during construction and installation, there is a low risk of encountering a marine mammal. The operational conditions combined with planned EPMs (see Appendix G for all vessel strike avoidance measures) will minimize collision risk during construction and installation. During periods of low visibility, trained crew would use increased vigilance to avoid marine mammals. Because vessel strikes are not an anticipated outcome given the relatively low number of vessel trips and monitoring and mitigation activities are effectively designed and implemented, as required. BOEM concludes vessel strikes are unlikely to occur and therefore there is no anticipated effect on marine mammals. In the event of an unanticipated vessel strike of a marine mammal by any vessel supporting the Project, Orsted must immediately cease the activities until BOEM is able to review the circumstances of the incident and determine what, if any, additional measures are appropriate to ensure compliance with all applicable laws (e.g., ESA, MMPA) and COP approval conditions.

<u>Conceptual decommissioning</u>: Project conceptual decommissioning would generate the same types of impact mechanisms as those described above for Project construction, except that impact pile driving would not occur. Conceptual decommissioning would require a similar number of marine construction vessels of the same or similar class as used during construction. Conceptual decommissioning activities would produce similar short-term effects on marine mammals from construction noise and disturbance and suspended sediment effects. The associated disturbance would be similar to that described above for construction, with the exception that pile driving would not be required. The monopiles would be cut below the bed surface for removal using a cable saw or abrasive waterjet. Noise levels produced by this type of cutting equipment are generally indistinguishable from engine noise generated by the associated construction vessel (Pangerc et al. 2016). On this basis, short-term effects on marine mammals from conceptual decommissioning would from negligible to moderate.

Conceptual decommissioning would result in long-term habitat changes that could impact marine mammals in a variety of ways. For example, as discussed in Section 3.4.2.2.3, the removal of the monopile foundations and scour and cable protection would reverse the artificial reef effect provided by these structures and remove or disperse the associated biological community. Marine mammal species accustomed to the foraging opportunities provided this community would have to adapt. In contrast, any marine mammal displacement effects caused by operational noise or structure presence would be reversed. In short, conceptual decommissioning effects on marine mammals could be positive or negative, are likely to vary by species, and are difficult to predict at this time. The environmental effects from conceptual decommissioning would be considered in independent NEPA analysis and associated regulatory approvals, which will benefit from improved knowledge about the effects of offshore wind facilities on the environment gained through monitoring of this and other facilities developed on the mid-Atlantic OCS.

Cumulative Impacts

<u>Accidental releases and discharges</u>: Existing and planned future offshore wind-energy development could result in the accidental release of water quality contaminants, trash, or other debris, which could theoretically lead to an increase in debris and pollution in the geographic analysis area (see Section 3.3.2.2.2 [No Action Alternative] for characterization of existing marine pollution conditions). In general, the types of accidental hazardous materials releases associated with marine construction projects include fuels, lubricating oils, and other petroleum products. BOEM prohibits the discharge or disposal of solid

debris into offshore waters during any activity associated with the construction and operation of offshore energy facilities (30 CFR 250.300). The USCG similarly prohibits the dumping of trash or debris capable of posing entanglement or ingestion risk (MARPOL, Annex V, Public Law 100‒220 (101 Stat. 1458). Compliance with these requirements would effectively minimize releases of trash and debris.

Increased vessel traffic associated with offshore renewable energy construction presents the potential for the inadvertent introduction of invasive species during discharge of ballast and bilge water. BOEM would require all project construction vessels to adhere to existing state and federal regulations related to ballast and bilge water discharge, including USCG ballast discharge regulations (33 CFR 151.2025) and EPA National Pollutant Discharge Elimination System Vessel General Permit standards, effectively avoiding the likelihood of non-native species invasions through ballast water discharge. When these factors are considered, BOEM expects that cumulative effects on marine mammals in the geographic analysis area from accidental spills and releases of trash and debris would be negligible.

EMF: BOEM estimates that the Proposed Action in combination with planned future actions would result in the installation of 7,335 cumulative miles of undersea transmission cables within the r geographic analysis area, concentrated within and between the WEAs and nearby shorelines. BOEM anticipates that most planned facilities will use HVAC transmission, but some may use HVDC. BOEM would require all future projects to use cable designs and EPMs to minimize EMF impacts on the environment. While the range of EMF impacts would vary by project, they are expected to be similar in magnitude to those described for the Proposed Action. Standard design practices for offshore energy cables would avoid cable crossings where practicable and would ensure a minimum separation of 330 feet between parallel cable paths. This would effectively avoid additive EMF effects from multiple cables. On this basis, cumulative EMF effects on marine mammals resulting from the Proposed Action combined with existing, planned, and reasonably foreseeable activities would be negligible.

New cable placement: The Proposed Action would result in localized, temporary, negligible incremental impacts to marine mammals through an estimated 913 acres of cabling-related seabed disturbance and associated increased suspended sedimentation within the geographic analysis area. BOEM estimates a cumulative total of 11,044 acres of seabed disturbance for the Proposed Action plus all other future offshore wind projects in the geographic analysis area. No population-level effects on marine mammals are expected from reduced water quality. Therefore, the Proposed Action when combined with past, present, and reasonably foreseeable activities would result in negligible cumulative effects on marine mammals.

Noise: BOEM estimates a cumulative total of 2,563 offshore WTGs and OSS foundations will be developed in the geographic analysis area for marine mammals between 2022 and 2030. This total comprises foundations from the Proposed Action and up to 2,547 foundations associated with existing (BIWF) and planned state and federal offshore wind energy projects on the OCS between North Carolina and Maine (see Appendix E, Table E-3).

Section 3.4.4.2.2 (No Action Alternative) provides an overview of potential concurrent construction activities in the geographic analysis area. The development of each of these projects would involve the same types of project planning and construction activities described for the Proposed Action in Section 3.4.4.2.3 (i.e., HRG surveys, vessel and aircraft activity, impact and vibratory pile driving, etc.). Each action would generate underwater noise of the same general type and intensity as the Proposed Action, scaled in extent to the size of each facility. Each future project would be anticipated to result in adverse effects on individual marine mammals, up to and including PTS, and TTS, auditory masking and behavioral impacts. Construction noise would also contribute to short-term displacement effects, as described above.

All future actions would be subject to the same independent NEPA analysis and regulatory approvals as the Proposed Action. BOEM would require all projects to incorporate the same types of EPMs included in the

Proposed Action to avoid and minimize harmful noise effects and anticipates that additional mitigation measures similar to those described in Appendix G, Table G-2, would be imposed as conditions of ESA and MMPA compliance and other federal regulatory approvals. While these measures would avoid and minimize impacts to marine mammals to the greatest extent practicable, some unavoidable impacts on individuals are likely to occur. The impacts of each project would result in minor to moderate effects on marine mammals, varying by species. BOEM anticipates that future MMPA approvals would consider the combined effects of future projects against the known status of individual marine mammal stocks and populations and would require mitigation measures to avoid major effects on any species. Therefore, BOEM concludes that the cumulative effects of construction noise on marine mammals would be moderate.

As discussed in Sections 3.4.4.2.2 (No Action Alternative) and 3.4.4.2.3 (Proposed Action Alternative), operational noise from offshore wind turbines is expected to be limited in intensity and extent. Operational noise exceeding the 120 dB_{RMS} behavioral disturbance and auditory masking threshold would be limited to within 120 feet of each turbine, although detectable noise above ambient levels could extend up to 560 feet or more. The Proposed Action combined with all existing and planned future actions would place over 2,500 noise-generating structures in the geographic analysis area, distributed between designated WEAs. These structures would contribute to and potentially increase ambient noise within each WEA, albeit at levels generally not associated with adverse effects on marine mammals. However, the 120 dB_{RMS} threshold may not adequately represent the potential for adverse effects of chronic noise exposure (e.g., Cholewiak et al. 2018; Hatch et al. 2012; Jensen et al. 2009; Putland et al. 2017). While the potential for broader effects is unclear, at this time BOEM has no basis to conclude that the cumulative effects of low-level operational noise would result in more than minor effects on any marine mammal species.

<u>Port utilization</u>: The development of an offshore wind industry on the mid-Atlantic OCS may incentivize the expansion or improvement of regional ports to support planned and future projects in the geographic analysis area. These future actions, should they occur, may involve activities like dredging and the expansion or development of new structures that could lead to adverse effects on coastal and estuarine habitats used by marine mammals and their prey species. These projects could result in cumulative effects on marine mammals, but the extent and significance of these effects cannot be evaluated because no project proposals have been developed. However, the environmental effects resulting from any future port expansions would be evaluated in independent NEPA analysis, ESA and MMPA compliance documents, and other regulatory approvals for each project. This would include an evaluation of the potential cumulative effects of port expansion in conjunction with the Proposed Action and other offshore wind development in the geographic analysis area.

<u>Presence of structures</u>: BOEM estimates a cumulative total of 2,563 offshore WTGs and OSS foundations will be developed in the broader geographic analysis area for marine mammals between 2022 and 2030. This total comprises foundations from the Proposed Action and up to 2,547 foundations associated with existing (BIWF) and planned state and federal offshore wind energy projects on the OCS between North Carolina and Maine (see Appendix E, Table E-3). Section 3.4.4.2.2 (No Action Alternative) provides an overview of potential concurrent construction activities in the geographic analysis area between 2022 and 2030.

Project construction is likely to result in short-term displacement effects on marine mammals from the areas affected by disturbance from vessel activity, foundation installation, HRG surveys, and related activities. Several projects would be constructed concurrently, potentially resulting in individual marine mammals being exposed to multiple episodes of habitat displacement. BOEM anticipates that the construction schedules for all future projects would employ the same types of timing restrictions to protect NARW as those included in the Proposed Action, with modifications as needed to adapt to ongoing shifts in the seasonal distribution of this species (e.g., Davis et al. 2017, 2020). However, timing restrictions for NARW would not be protective for all marine mammal species. It is anticipated these projects would also employ a similar range of EPMs and mitigation measures to avoid and minimize impacts to marine mammals, but some level of short-term displacement is likely to occur, and some individual animals are likely to be exposed to multiple episodes of displacement. The significance of these potential impacts is unclear, but when all protective measures are considered, cumulative effects are likely to range from minor to moderate varying by species.

BOEM anticipates that future projects within the RI/MA WEA would be constructed using 1-nm foundation spacing similar to the Proposed Action. As discussed in the previous section, the physical presence of foundations spaced at 1 nm is unlikely to pose a barrier to movement for even the largest marine mammal species. However, the broadscale development of offshore energy structures would introduce an extended network of biologically productive artificial reefs, most generating low levels of non-impulsive sound that are detectable to marine mammals within a few hundred feet. While the individual effects of each turbine would be minor, the broader implications of these habitat changes for marine mammals are unclear. Displacement effects that result in increased interactions between vulnerable populations marine mammals and commercial shipping and/or fishing activity could have significant long-term cumulative effects. Given these uncertainties the potential for displacement effects is unknown, but there is currently no basis to conclude that these impacts would result in moderate to major long-term effects on any species.

Light: The Proposed Action when combined with planned future activities would develop up to 2,563 offshore WTGs and OSS foundations in the geographic analysis area. The construction, operation, and maintenance of these structures would introduce new short-term and long-term sources of artificial light to the offshore environment in the form of vessel lighting and navigation and safety lighting on the structures, respectively. BOEM has issued guidance for avoiding and minimizing artificial lighting impacts from offshore energy facilities and associated construction vessels (Orr et al. 2013) and has concluded that adherence to these measures should effectively avoid adverse effects on fish and other aquatic organisms. BOEM requires all offshore energy projects to comply with this guidance. Given the minimal and localized nature of anticipated lighting effects under this guidance, the cumulative effects from the Proposed Action and existing and planned future activities on marine mammals would be negligible.

Seabed and water column alteration: The broad scale development of up to 2,563 offshore energy structures in the geographic analysis area would introduce a broadly distributed network of biologically productive artificial reefs to the marine environment. Each concentration of foundations would be expected to develop a diverse community of fish and invertebrates and promote increased biological productivity in proximity to the structures (Degraer et al. 2020; Hutchison et al. 2020; Methratta and Dardick 2019). The abundance of fish and invertebrate prey resources created by this reef effect are likely to attract predatory marine mammals, particularly seals (e.g., Russel et al. 2014) and potentially dolphins and porpoises. Increased fish biomass around the structures could attract commercial and recreational fishing activity, leading to increased interactions between humans and marine mammals.

The new wind energy structures would also cause hydrodynamic effects. The geographic analysis area is characterized by strong seasonal stratification, conditions that tend to limit the hydrodynamic influence of individual foundation structures (van Berkel et al. 2020). As discussed in the previous section, the Proposed Action is not anticipated to result in additive hydrodynamic effects. However, broader scale development of contiguous projects could have more extensive effects. For example, Afsharian et al. (2020) modeled the potential effects from installation of over 400 offshore wind turbines in Lake Erie and determined that their cumulative effect on wind energy could disrupt circulation patterns and affect seasonal stratification and water temperatures over broad scales. However, these findings may not be applicable to the open ocean where circulation patterns are strongly influenced by tides and ocean currents.

At present, currently available information suggests that hydrodynamic effects of foundation structures are likely to be localized and not additive when spaced at 1 nm in environments with strong seasonal stratification (van Berkel et al. 2020). Recent modeling of hydrodynamic effects suggests that surface currents could be affected by the presence of multiple wind farms potentially impacting the distribution of larvae (Johnson et al. 2021). There is insufficient information to determine if this conclusion is valid for broader scale development at the levels planned within the geographic analysis area. Therefore, at this time there is no basis to conclude that the cumulative hydrodynamic impacts of Proposed Action in combination with planned and foreseeable future actions would have a measurable effect on marine mammals and their prey and forage species.

In summary, the cumulative effects of long-term habitat alteration and hydrodynamic impacts on marine mammals are unclear, may be positive or negative, could range from negligible to moderate, and are likely to vary considerably by species. There is currently no basis to conclude that these impact mechanisms would result in major effects on any marine mammal species.

Traffic: BOEM estimates that up to 379 construction vessels could be active within the geographic analysis area between 2022 and 2030. In theory, an increase in vessel traffic would present a commensurate increase in collision-related risks to marine mammals. However, as discussed above for project construction, the majority of vessel operations would occur at speeds of less than 10 knots. In addition, BOEM anticipates that all future projects would adhere to all mandatory and voluntary vessel speed restrictions in posted DMAs and Seasonal Management Areas and would implement additional EPMs and measures similar to those described for the Proposed Action during construction and throughout the operational life of the Project (see Appendix G, Table G-1) to avoid marine mammal collisions. BOEM has concluded that these measures would effectively avoid adverse impacts on marine mammals from construction and operational vessel traffic. Therefore, the cumulative effects of increased vessel traffic on marine mammals would be negligible.

Climate change: Global climate change is altering water temperatures, circulation patterns, and oceanic chemistry at global scales. Several marine species, including fish, invertebrates, and zooplankton, prey resources for marine mammals, have shifted northward in distribution over the past several decades (NOAA 2021). Ocean acidification, also a function of climate change, has negatively affected some zooplankton species (PMEL 2020). Marine mammals are modifying their behavior and distribution in response to these broader observed changes (Davis et al. 2017, 2020; Hayes et al. 2020, 2021). These trends are expected to continue, with complex and potentially adverse consequences for many marine mammal species. The Proposed Action in combination with existing and planned future actions would result in the development of a network of artificial reefs distributed across the geographic analysis area. The biological hotspots created by these artificial reefs are expected to influence fish and invertebrate community structure at local scales and may also influence the ability of certain fish and invertebrate species to shift and expand their ranges in response to climate change. This could in turn result in cumulative effects on marine mammals that could be positive or negative depending on a number of complex factors. The nature and potential significance of these effects to marine mammals is unknown and likely to vary by species depending on a number of complex factors.

Conclusions

The construction, O&M, and conceptual decommissioning of the Proposed Action would have **negligible** to **moderate** adverse impacts and could potentially include **minor beneficial** impacts. Adverse impacts are expected to result mainly from pile-driving noise and increased vessel traffic. Beneficial impacts are expected to result from the presence of structures.

In the context of reasonably foreseeable environmental trends in the geographic analysis area, impacts from ongoing and planned actions, including the Proposed Action, are expected to be several times greater than the incremental impacts of the Proposed Action alone. The incremental impacts of the Proposed Action alone would not add to the impacts of the No Action alternative because, under the planned action scenario described in Appendix E, as the total capacity of offshore wind development in the geographic analysis area for marine mammals would be the same whether the Proposed Action goes forward or not. Thus, the primary differences between the Proposed Action and the No Action alternative are the locations and times (years) in which the impacts would occur.

In the context of other reasonably foreseeable environmental trends and planned actions, the incremental impacts under the Proposed Action resulting from individual IPFs would range from **negligible** to **moderate**, depending on the species, and may potentially include **minor beneficial** impacts. The combined significance criteria in Table 3.1.1-1 and Table 3.1.1-2 are used to characterize the combined effects of all IPFs marine mammals. Applying these criteria, BOEM anticipates that the overall impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would result in **moderate** adverse and **minor** to **moderate** beneficial effects on marine mammals because a notable and measurable impact is anticipated, but the resource would likely recover completely when IPF stressors are removed or remedial or mitigating actions are taken. The main drivers for this impact rating are pile-driving, vessel, and construction noise; increased vessel traffic associated with the expanded planned action scenario; and ongoing climate change. The Proposed Action would contribute to the overall impact rating primarily through noise-related IPFs and increased vessel traffic.

3.4.5.2.4 VESSEL TRANSIT LANE ALTERNATIVE

The Transit alternative would lead to the same types of impacts on marine mammals from construction and installation, O&M, and conceptual decommissioning activities as described for the Proposed Action. However, this alternative would reduce the number of monopile foundations by four and remove approximately 4 nm of associated inter-array cable from the Project, slightly reducing the construction impact footprint and installation period. Fewer days of impact pile driving and less bed disturbance would be required, and the overall duration of construction activities would decrease. This would reduce the overall footprint of the Project and associated construction and operational effects on marine mammals, as compared to the Proposed Action.

Operational impacts of the Transit alternative on marine mammals would also be incrementally reduced relative to the Proposed Action. Removing three WTGs[12] would reduce operational noise impacts exceeding the 120 dB_{RMS} behavioral and auditory masking threshold in an approximate 120-foot radius around each foundation. Less habitat would be altered and impacted by operational noise, artificial lighting, and EMFs from the inter-array cable. The smaller overall Project footprint would reduce the extent of anticipated long-term reef and hydrodynamic effects on the local environment. Conceptual decommissioning effects would likewise be similar in magnitude but reduced in extent and duration relative to the Proposed Action.

On balance, the Transit alternative would incrementally reduce the extent and duration of potential construction and installation, O&M, and conceptual decommissioning impacts on marine mammals. This may reduce the number of animals exposed to potentially adverse effects, but some individual animals would still be exposed to those effects at the same levels of significance under the criteria described in 3.4.4-3. On this basis, BOEM concludes the Transit alternative would result in negligible to moderate adverse impacts and could potentially include minor beneficial impacts.

Cumulative Impacts

As stated, the Transit alternative would result in a range of effects to marine mammals of the same general magnitude and significance as those described for the Proposed Action, except that the extent and

[12] The Transit alternative would remove four foundations in total, and would combine a WTG and OSS on a single monopile, reducing the number of operational WTGs relative to the Proposed Action alternative.

duration of some impacts would be slightly reduced. The Transit alternative would reduce the total number of offshore structures planned in the geographic analysis area from an estimated 2,563 to 2,559. This incremental reduction would slightly reduce the extent and duration of some anticipated cumulative impacts but not to the extent that the Transit alternative would alter any of the impact-level conclusions reached for the Proposed Action. On this basis, BOEM anticipates that the cumulative effects of the Transit alternative on marine mammals would be essentially the same as those described for the Proposed Action: negligible to moderate adverse, depending on the species, and potentially minor beneficial.

Conclusions

The Transit alternative would reduce the number of WTGs and their associated inter-array cable segments relative to the Proposed Action. This would in turn result in an incremental reduction in effects on marine mammals from certain construction and installation, O&M, and conceptual decommissioning impacts. However, BOEM expects that any incremental reduction in impacts would not change the resulting effects on marine mammals to the extent necessary to alter the impact-level conclusions for any impact mechanism. Therefore, BOEM concludes that the effects of the Transit alternative on marine mammals would result in **negligible to moderate** adverse impacts, depending on the species, and could potentially include **minor beneficial** impacts.

In the context of other reasonably foreseeable environmental trends and planned actions, the incremental impacts under the Transit alternative resulting from individual IPFs would range from **negligible** to **moderate**, depending on the species, and may potentially include **minor beneficial** impacts. The combined significance criteria in Table 3.1.1-1 and Table 3.1.1-2 are used to characterize the combined effects of all IPFs marine mammals. Applying these criteria, BOEM anticipates that the overall impacts associated with the Transit alternative when combined with past, present, and reasonably foreseeable activities would result in the same level of effects as those described for the Proposed Action. Therefore, the Transit alternative would result in **moderate** adverse and **minor** to **moderate** beneficial effects on marine mammals.

3.4.5.2.5 FISHERIES HABITAT IMPACT MINIMIZATION ALTERNATIVE

The Habitat alternative under either layout option would eliminate specific monopile locations from the SFWF Project and incorporate additional micrositing to minimize impacts on existing complex benthic habitat to the greatest extent practicable. The potential design and micrositing scenarios under consideration and resulting changes in associated benthic habitat disturbance are discussed in detail in Section 3.4.2.2.5.

The Habitat alternative under either layout option would eliminate three foundation sites from the Project design. Micrositing would be used at 10 of the remaining foundation sites to minimize impacts on complex benthic habitats. Micrositing would not be required at the remaining three foundation sites. The removal of three foundations would eliminate four inter-array cable segments and approximately 3 nm of associated construction impacts. The removal of three foundations would reduce the construction impact footprint and installation period relative to the Proposed Action. Fewer days of impact pile driving and less bed disturbance would be required, and the overall duration of construction activities would decrease. This would reduce the overall footprint of the Project and associated construction and operational effects on marine mammals, as compared to the Proposed Action.

Operational impacts of the Habitat alternative under either layout option on marine mammals would also be incrementally reduced relative to the Proposed Action. Removing three WTGs[13] would reduce

[13] The Habitat alternative would remove three foundations in total under either layout option. BOEM anticipates that the applicant would combine a WTG and OSS on a single monopile, reducing the number of operational WTGs relative to the Proposed Action alternative.

operational noise impacts exceeding the 120 dB_{RMS} behavioral and auditory masking threshold in an approximate 120-foot radius around each foundation. Less habitat would be altered and impacted by operational noise, artificial lighting, and EMFs from the inter-array cable. The smaller overall project footprint would reduce the extent of anticipated long-term reef and hydrodynamic effects on the local environment. Conceptual decommissioning effects would likewise be similar in magnitude but reduced in extent and duration relative to the Proposed Action.

On balance, the Habitat alternative under either layout option would incrementally reduce the extent and duration of potential construction and installation, O&M, and conceptual decommissioning impacts on marine mammals. This may reduce the number of animals exposed to potentially adverse effects, but some individual animals would still be exposed to those effects at the same levels of significance under the criteria described in 3.4.4-3. On this basis, BOEM concludes Habitat alternative under either layout option would result in negligible to moderate adverse impacts and could potentially include minor beneficial impacts.

Cumulative Impacts

As stated, the Habitat alternative under either layout option would result in a range of effects to marine mammals of the same general magnitude and significance as those described for the Proposed Action, except that the extent and duration of some impacts would be slightly reduced. The Transit alternative would reduce the total number of offshore structures planned in the geographic analysis area from an estimated 2,563 to 2,560. This incremental reduction would slightly reduce the extent and duration of some anticipated cumulative impacts, but not to the extent that the Habitat alternative would alter any of the significance determinations reached for the Proposed Action. On this basis, BOEM anticipates that the cumulative effects of the Habitat alternative under either layout option on marine mammals would be essentially the same as those described for the Proposed Action: negligible to moderate adverse, depending on the species, and potentially minor beneficial.

Conclusions

The Habitat alternative under either layout option would reduce the number of WTGs and their associated inter-array cable segments relative to the Proposed Action. This would in turn result in an incremental reduction in effects on marine mammals from certain construction and installation, O&M, and conceptual decommissioning impacts. However, BOEM expects that any incremental reduction in impacts would not change the resulting effects on marine mammals to the extent necessary to alter the significance determination for any impact mechanism. Therefore, BOEM concludes that the effects of the Habitat alternative under either layout option on marine mammals would result in **negligible to moderate** adverse impacts and could potentially include **minor beneficial** impacts.

In the context of other reasonably foreseeable environmental trends and planned actions, the incremental impacts under the Habitat alternative resulting from individual IPFs would range from **negligible** to **moderate**, depending on the species, and may potentially include **minor beneficial** impacts. The combined significance criteria in Table 3.1.1-1 and Table 3.1.1-2 are used to characterize the combined effects of all IPFs marine mammals. Applying these criteria, BOEM anticipates that the overall impacts associated with the Habitat alternative when combined with past, present, and reasonably foreseeable activities would result in the same level of effects as those described for the Proposed Action. Therefore, the Habitat alternative under either layout option would result in **moderate** adverse and **minor** to **moderate** beneficial effects on marine mammals.

3.4.5.3 Action Alternative Comparison

As discussed above, the impacts associated with Proposed Action alone do not change substantially under other evaluated action alternatives. Although the number of WTGs and their associated inter-array cables varies slightly, BOEM expects that impacts to marine mammal from Project construction and installation, O&M, and conceptual decommissioning would range from **negligible** to **moderate** for all action alternatives, varying in significance by species, and may potentially include **minor beneficial** impacts.

The action alternatives represent a relatively small component of the existing, planned and reasonably foreseeable future actions in the geographic analysis area, accounting for 12 to 16 of the up to 2,563 offshore wind energy structures planned for the mid-Atlantic OCS. In this context, the differences between the action alternatives are small relative to the broader cumulative effect of other actions and ongoing environmental trends within the geographic analysis area, and the incremental differences between them are not likely to measurably alter the overall extent and significance of combined cumulative effects on marine mammals.

On this basis, BOEM concludes that while the action alternatives may result in slightly different effects on the environment, and the number of individual marine mammals exposed to Project-related IPFs may vary between alternatives, those differences would not lead to different impact-level conclusions for any IPF following the criteria provided in 3.4.4-3. The effects of each alternative would range from **negligible** to **moderate** for Project construction and installation, O&M, and conceptual decommissioning, with the effect determinations for specific IPFs varying by species, and potentially including **minor beneficial** impacts.

Based on this rationale, BOEM concludes that the combined effects of each action alternative are effectively the same. Applying the combined significance criteria in Table 3.1.1-1 and Table 3.1.1-2, the overall impacts of each action alternative when combined with past, present, and reasonably foreseeable activities would result in **moderate** adverse and **minor** to **moderate** beneficial effects on marine mammals because a notable and measurable impact is anticipated, but the resource would likely recover completely when IPF stressors are removed or remedial or mitigating actions are taken.

3.4.5.4 Mitigation

BOEM has identified the mitigation measures that would likely be required as conditions of federal regulatory approvals to further avoid and minimize potential adverse effects on marine mammals. These measures are summarized in Appendix G, Table G-2. Mitigation requirements include additional time-of-year restrictions, expanded exclusion zone protocols, daily pre-construction surveys, additional vessel speed limits, and expanded vessel strike avoidance measures. The expanded exclusion zone protocols include minimum visibility requirements to ensure PSO effectiveness (e.g., time-of-day and weather restrictions). Construction vessel and O&M vessel crew training, vessel observer requirements, and educational awareness would also reduce impacts by increasing the effectiveness of mitigation and monitoring measures. Specifications for monitoring plan design, data collection, and reporting would improve coordination with regulatory agencies and improve the effectiveness of planned EPMs and ensure that should any incidental take of marine mammals occur, it would not exceed the take exemptions approved under the ESA and MMPA. Per (30 CFR 585.633(b)), additional mitigation measures above and beyond those listed in Appendix G, Table G-2 may be required if monitoring data indicate that adverse effects on marine mammals are greater than anticipated. Mitigation and monitoring requirements are prescribed by NMFS in ITAs under Section 101(a)(5) of the MMPA and through ESA consultation.

3.4.6 Sea Turtles

The reader is referred to Table 2.3.1-1 and Appendix H for a discussion of current conditions and potential impacts to sea turtles from implementation of the Proposed Action and other considered alternatives.

3.4.7 Wetlands and Other Waters of the United States

The reader is referred to Table 2.3.1-1 and Appendix H for a discussion of current conditions and potential impacts to wetlands and other WOTUS from implementation of the Proposed Action and other considered alternatives.

3.5 SOCIOECONOMIC AND CULTURAL RESOURCES

3.5.1 Commercial Fisheries and For-Hire Recreational Fishing

3.5.1.1 Affected Environment

3.5.1.1.1 COMMERCIAL FISHERIES

The following analysis focuses on commercial fisheries in the SFWF and SFEC. The primary source of data was summarized Vessel Trip Report (VTR) data provided by NMFS (2021a). The summary VTR data includes catch estimates by fishing location combined with NMFS estimates of revenue using ex-vessel price data drawn from commercial fisheries dealer reports. A second source of data was the website at NMFS (2021b), which summarizes commercial fisheries data for each proposed WEA along the U.S. Atlantic coast. In addition, figures developed by BOEM based on NMFS Vessel Monitoring System (VMS) data provided by NMFS (2019) are included in the analysis. Additional information on the data sources used in this analysis is presented in Appendix F.

To understand the relative importance of the SFWF and offshore SFEC to regional fisheries, the commercial fishing revenue sourced from each area is compared to the total commercial fishing revenue reported by the NMFS Greater Atlantic Regional Fisheries Office for federally permitted commercial fishing activity in the New England and Mid-Atlantic regions. These two regions include all coastal states from Maine to North Carolina. In addition, to provide further geographical context for the commercial fisheries operating in the SFWF and along the offshore SFEC, commercial fishing revenue in the RI-MA WEAs by FMP fishery, gear type, and port is presented below. The description of commercial fishing in the RI-MA WEAs also includes a discussion of the area of high value fisheries that was excluded from possible leasing for wind energy development in order to reduce conflict with both commercial and recreational fishing activities.

To the extent that data are available, the commercial fishing described here includes federally permitted fishing activity in both state and federal waters. Data on the average annual revenue of federally permitted vessels by FMP fishery, gear type, and port of landing are summarized in the tables below and Figure C-7 through Figure C-28 in Appendix C. In general, the data presented focuses on those FMP fisheries, species, gear types, and ports that are relevant to commercial fishing activity in the SFWF and offshore SFEC. Additional details on the data and methodology used to develop the tables and figures are provided in Appendix F.

Regional Setting

Commercial fisheries operating in federal waters off the Mid-Atlantic and New England regions are known for large catches of a variety of species, including Atlantic herring, clams, squid, sea scallops, skates, summer flounder, groundfish, monkfish, lobster, and Jonah crab. These fishery resources are harvested with a broad assortment of fishing gear, including mobile gear (e.g., bottom trawl, dredge, midwater trawl) and fixed gear (e.g., gillnet, pot, bottom longline, seine, hand line). The fishery resources are managed under several FMPs, consisting of the Sea Scallop FMP, Monkfish FMP, Northeast Multispecies (large- and small-mesh) FMP,[14] Skate FMP, and Red Crab FMP (NEFMC 2019); Surfclam/Ocean Quahog FMP, Mackerel/Squid/Butterfish FMP, Spiny Dogfish FMP, Bluefish FMP, Golden and Blueline Tilefish FMP, Summer Flounder/Scup/Black Sea Bass FMP, and River Herring FMP (MAFMC 2019); Atlantic Herring FMP and Highly Migratory Species FMP (NMFS 2020b); and Lobster FMP and Jonah Crab FMP (ASMFC 2019).[15] These FMP fisheries are referred to frequently throughout the final EIS and therefore the author-date citations are provided here at first mention only.

One way that fishery resources contribute to regional economies is through direct ex-vessel revenue or through revenue generated when a commercial fishing boat lands or unloads a catch. Table 3.5.1-1 shows the average annual revenue by FMP fishery during 2008–2019, the time period for which the most recent data are available. Although there is substantial variability in the year-to-year harvest of various species, on average, federally permitted commercial fishing activity generated approximately $952.4 million in average revenue annually from 2008 to 2019, with the Sea Scallop FMP accounting for more than half (54%) of the total while the American Lobster FMP fishery accounted for 10% and Northeast Multispecies (large-mesh) FMP fishery accounted for 8% of the total. The row labeled “Other FMPs, non-disclosed species, and non-FMP fisheries” comprised 11% of the total average annual revenue.[16]

[14] The Northeast Multispecies (large-mesh) fishery is composed of the following species: Atlantic cod, haddock, pollock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice (*Hippoglossoides platessoides*), Atlantic halibut (*Hippoglossus hippoglossus*), Acadian redfish (*Sebastes fasciatus*), Atlantic wolffish (*Anarhichas lupus*), ocean pout, and white hake (*Urophycis tenuis*). The Northeast Multispecies small-mesh fishery is composed of five stocks of three species of hakes: northern silver hake and southern silver hake (*Merluccius bilinearis*), northern red hake and southern red hake (*Urophycis chuss*), and offshore hake (*Merluccius albidus*). Southern silver hake and offshore hake are often grouped together and collectively referred to as “southern whiting.”

[15] The regional setting includes the jurisdictions of two regional fishery management councils created under the Magnuson-Stevens Fishery Conservation and Management Act: the MAFMC manages fisheries in federal waters off the coasts of New York, New Jersey, Pennsylvania, Delaware, Maryland, Virginia, and North Carolina, and the NEFMC manages fisheries in federal waters off the coasts of Maine, New Hampshire, Massachusetts, Rhode Island, and Connecticut. The two councils manage species with many FMPs that are frequently updated, revised, and amended, and they coordinate with each other to jointly manage species across jurisdictional boundaries. Some of the managed fisheries of each council extend into state waters. Therefore, the councils work with the ASMFC, which comprises the 15 Atlantic coast states and coordinates the management of marine and anadromous resources found in the states’ marine waters. In addition, the lobster and Jonah crab fisheries are cooperatively managed by the states and the NMFS under the framework of the ASMFC (ASMFC 2019).

[16] This row includes revenues from the three federal FMP fisheries: 1) Surfclam/Ocean Quahog, 2) Red Crab, and 3) River Herring. In addition, this row includes data for species from listed FMPs that could not be disclosed due to confidentiality rules and revenues from federally permitted vessels operating in other fisheries that are not federally managed. NMFS cannot disclose data to the public unless it includes information from three or more vessels and three or more dealers/buyers. Also note that data for the Surfclam/Ocean Quahog FMP fishery is included in this row in spite of its relatively high annual average value ($60.0 million) for reasons of consistency—revenues for the FMP fishery could not be reported for any of the other SFWF-related tables.

Table 3.5.1-1. Commercial Fishing Revenue of Federally Permitted Vessels in Mid-Atlantic and New England Fisheries by FMP Fishery (2008–2019)

FMP Fishery	Peak Annual Revenue ($1,000s)	Average Annual Revenue ($1,000s)
American Lobster	$117,251.0	$93,250.1
Atlantic Herring	$32,856.3	$25,929.7
Bluefish	$1,820.4	$1,275.3
Golden and Blueline Tilefish	$6,583.4	$5,553.9
Highly Migratory Species	$4,008.4	$2,219.4
Jonah Crab	$17,082.7	$9,607.8
Mackerel, Squid, and Butterfish	$74,576.6	$51,911.7
Monkfish	$28,943.7	$20,597.3
Northeast Multispecies (large-mesh)	$105,418.2	$73,331.4
Sea Scallop	$661,233.5	$518,891.6
Skate	$10,217.1	$7,448.4
Northeast Multispecies (small-mesh)	$13,499.5	$11,261.1
Spiny Dogfish	$5,237.2	$2,975.4
Summer Flounder, Scup, Black Sea Bass	$45,205.7	$39,807.4
Other FMPs, non-disclosed species and non-FMP fisheries*	$95,261.9	$88,377.6
All FMP and non-FMP fisheries	**$1,132,912.7**	**$952,438.3**

Source: Developed using data from NMFS (2021a).

Note: Revenue is adjusted for inflation to 2019 dollars. Peak annual revenue is calculated independently for all rows, including the total row.

* Includes revenue from FMP fisheries that are not listed, from species that were not disclosed within listed FMP fisheries and from species in non-FMP fisheries harvested by federally permitted vessels.

Table 3.5.1-2. Commercial Fishing Landings (pounds) of Federally Permitted Vessels in Mid-Atlantic and New England Fisheries by Species (2008–2019)

Species	FMP Fishery	Peak Annual Landings	Average Annual Landings (pounds)
Skates	Skate	674,625	448,302
Atlantic herring	Atlantic Herring	1,002,287	294,448
Monkfish	Monkfish	231,519	125,597
Scup	Summer Flounder, Scup, Black Sea Bass	155,338	95,932
Loligo squid	Mackerel, Squid, and Butterfish	236,158	78,375
Silver hake	Northeast Multispecies (small-mesh)	128,101	58,822
Atlantic mackerel	Mackerel, Squid, and Butterfish	322,243	40,825
Sea scallops	Sea Scallop	73,382	35,164
Spiny dogfish	Spiny Dogfish	66,968	33,109
Summer flounder	Summer Flounder, Scup, Black Sea Bass	54,032	32,891
Yellowtail flounder	Northeast Multispecies (large-mesh)	57,655	25,271
Cod	Northeast Multispecies (large-mesh)	35,157	18,462
American lobster	American Lobster	35,471	17,863
Winter flounder	Northeast Multispecies (large-mesh)	41,948	16,741

Species	FMP Fishery	Peak Annual Landings	Average Annual Landings (pounds)
Red hake	Northeast Multispecies (small-mesh)	22,803	15,766
Bluefish	Bluefish	30,749	12,769
Jonah crab	Jonah Crab	28,305	11,586
Butterfish	Mackerel, Squid, and Butterfish	18,680	11,157
Black sea bass	Summer Flounder, Scup, Black Sea Bass	12,187	7,024
Striped bass	No federal FMP	11,550	6,880

Source: Developed using data from NMFS (2021a).

Table 3.5.1-3 shows the average annual revenue by gear type for the 2008–2019 period. Scallop dredge gear accounted for 51% of the revenue generated by all gear in the New England and Mid-Atlantic regions. Bottom trawl gear and pot-other gear (including pot gear used in the Lobster FMP fishery) also each generated over $115 million in average annual revenue.

Table 3.5.1-3. Commercial Fishing Revenue of Federally Permitted Vessels in Mid-Atlantic and New England Fisheries by Gear Type (2008–2019)

Gear Type	Peak Annual Revenue ($1,000s)	Average Annual Revenue ($1,000s)
Dredge-clam	$65,768.2	$61,333.5
Dredge-scallop	$615,168.5	$489,410.9
Gillnet-sink	$44,624.9	$30,031.6
Handline	$6,222.2	$4,754.5
Pot-other	$146,203.6	$115,055.2
Trawl-bottom	$229,153.5	$187,199.3
Trawl-midwater	$26,600.8	$18,995.8
All other gear*	$62,406.3	$47,305.8
All gear types	**$1,135,221.1**	**$954,086.5**

Source: Developed using data from NMFS (2021a).

Notes: Revenue is adjusted for inflation to 2019 dollars. Peak annual revenue is calculated independently for all rows, including the All gear types row.

* Includes revenue from federally permitted vessels using longline gear, seine gear, other gillnet gear, and unspecified gear.

Commercial fishing fleets are important to coastal communities in the Mid-Atlantic and New England regions by generating employment and income for vessel owners and crews, as well as by creating demand for shoreside products and services to maintain vessels and process seafood products. In 2017, total seafood landings in the New England and mid-Atlantic regions, including landings from non–federally permitted vessels, were valued at $1.80 billion. The region is also home to aquaculture production and research that provides employment and business opportunities for coastal communities. In New England, the seafood industry generated $5.6 billion in personal and proprietor income, while that impact totaled $3.8 billion in the mid-Atlantic (NMFS 2020c). Table 3.5.1-4 shows the average annual revenue by port of landing for the 2008–2019 period. New Bedford accounted for approximately 40% of the total commercial fishing revenue in the New England and Mid-Atlantic regions, and Cape May and Narragansett/Point Judith accounted for 9% and 5%, respectively.

Table 3.5.1-4. Commercial Fishing Revenue of Federally Permitted Vessels in Mid-Atlantic and New England Fisheries and Level of Fishing Dependence by Port

Port and State	Peak Annual Revenue ($1,000s)	Average Annual Revenue ($1,000s)	Commercial Fishing Engagement Categorical Ranking*	Commercial Fishing Reliance Categorical Ranking§
Chilmark/Menemsha, MA	$656.1	$753.4	Medium	High

Sources: NMFS (2021a); NOAA Fisheries Office of Science and Technology (2019).

Note: Commercial fishing revenue data are for the 2008–2019 period; levels of fishing dependency are for 2018. Revenue is adjusted for inflation to 2019 dollars. Peak annual revenue is calculated independently for all rows, including the All New England/Mid-Atlantic ports row.

* Commercial fishing engagement measures the presence of commercial fishing through fishing activity as shown through permits, fish dealers, and vessel landings. A high rank indicates more engagement. NA indicates that no information is available.

† Includes other ports that had reported landings from federally permitted vessels fishing in the RI-MA WEAs or offshore SFEC in 5 or fewer of the 12 years for the 2008–2019 period.

‡ Includes all other ports that had landings from federally permitted vessels fishing in the New England and Mid-Atlantic regions.

§ Commercial fishing reliance measures the presence of commercial fishing in relation to the population size of a community through fishing activity. A high rank indicates more reliance. NA indicates that no information is available.

Table 3.5.1-4 also presents the level of commercial fishing engagement and reliance of the community in which the port is located. These rankings portray the level of dependence of commercial fishing to the community. As shown in the table, the rankings differ across communities, with Cape May ranking high for both commercial fishing engagement and reliance, and Westport and Point Pleasant ranking low for the two indices. Information regarding how the rankings were determined for each community is provided in the community profiles available at NMFS (2021d). These profiles present the most recent data available for key indicators for New England and mid-Atlantic fishing communities related to dependence on fisheries and other economic and demographic characteristics. Selected socioeconomic characteristics of communities with fishing ports that could be affected by the Project are also presented in Section 3.5.3 (Demographics, Employment, and Economics) and Section 3.5.4 (Environmental Justice).

RI-MA WEAs

The SFWF is located in the RI-MA WEAs. Table 3.5.1-5 shows the average annual revenue in the RI-MA WEAs by FMP fishery for the 2008–2019 period. On average, federally permitted commercial fishing activity in the RI-MA WEAs annually generated an average of $2.6 million in revenue, with the Monkfish FMP and Sea Scallop FMP fisheries each accounting for 14% of the total, while the Lobster FMP fisheries accounted for 12%. The Mackerel, Squid, and Butterfish FMP, Skate FMP, Northeast Multispecies (large-mesh) FMP, and Summer Flounder, Scup, Black Sea Bass FMP fisheries also accounted for between 6% and 9% of the revenue. Table 3.5.1-5 also shows the percentage of each FMP fishery's total revenue in the Mid-Atlantic and New England regions that came from the RI-MA WEAs during the 2008–2019 period. The areas accounted for about 3.06% of the Skate FMP fishery's total revenue, and 1.8% of the Monkfish FMP fishery's total revenue. In total, the RI-MA WEAs accounted for approximately 0.28% of the total revenue across all FMP fisheries in the Mid-Atlantic and New England regions (see Table 3.5.1-1).[17]

Table 3.5.1-5. Commercial Fishing Revenue of Federally Permitted Vessels in the RI-MA WEAs by FMP Fishery (2008–2019)

FMP Fishery	Peak Annual Revenue ($1,000s)	Average Annual Revenue ($1,000s)	Average Annual Revenue as a Percentage of Total Revenue from the Mid-Atlantic and New England Regions
American Lobster	$536.4	$319.7	0.34%
Atlantic Herring	$205.9	$64.7	0.25%
Bluefish	$8.0	$4.6	0.36%
Golden and Blueline Tilefish	$4.2	$1.7	0.03%
Highly Migratory Species	$20.1	$3.4	0.15%
Jonah Crab	$105.4	$39.5	0.41%
Mackerel, Squid, and Butterfish	$545.1	$172.6	0.33%
Monkfish	$589.6	$376.1	1.83%
Northeast Multispecies (large-mesh)	$334.2	$159.5	0.22%
Sea Scallop	$955.4	$375.5	0.07%
Skate	$401.4	$228.0	3.06%
Northeast Multispecies (small-mesh)	$176.0	$105.3	0.94%
Spiny Dogfish	$41.5	$18.9	0.64%

[17] The RI-MA WEAs include the lease areas for Revolution Wind (OCS-A 0486), Sunrise Wind (OCS-A 0487), and the SFWF.

FMP Fishery	Peak Annual Revenue ($1,000s)	Average Annual Revenue ($1,000s)	Average Annual Revenue as a Percentage of Total Revenue from the Mid-Atlantic and New England Regions
Summer Flounder, Scup, Black Sea Bass	$359.2	$217.3	0.55%
Other FMPs, non-disclosed species, and non-FMP fisheries*	$1,425.1	$548.3	0.62%
All FMP and non-FMP fisheries	$3,508.9	$2,635.2	0.28%

Source: Developed using NMFS (2021e).

Notes: Revenue is adjusted for inflation to 2019 dollars. Peak annual revenue is calculated independently for all rows, including the All FMP and non-FMP fisheries row.

* Includes revenue from FMP fisheries that are not listed, from species that were not disclosed within listed FMP fisheries, and from species in non-FMP fisheries harvested by federally permitted vessels.

In terms of pounds landed, the top species harvested in the RI-MA WEAs were skates, red hake, and monkfish (Table 3.5.1-6).

Table 3.5.1-6. Commercial Fishing Landings of Federally Permitted Vessels in the RI-MA WEAs by Species (2008–2019)

Species	FMP Fishery	Peak Annual Landings (pounds)	Average Annual Landings (pounds)	Average Annual Landings as a Percentage of Total Landings from the Mid-Atlantic and New England Regions
American lobster	American Lobster	98,668	61,780	0.32%
Atlantic herring	Atlantic Herring	1,515,176	496,739	0.32%
Bluefish	Bluefish	11,672	6,894	0.38%
Jonah crab	Jonah Crab	125,727	50,681	0.43%
Atlantic mackerel	Mackerel, Squid, and Butterfish	869,176	84,108	0.45%
Butterfish	Mackerel, Squid, and Butterfish	64,004	26,347	0.81%
Loligo squid	Mackerel, Squid, and Butterfish	377,422	108,355	0.44%
Monkfish	Monkfish	387,218	236,946	2.43%
Striped bass	No federal FMP	2,868	774	0.14%

Winter flounder	Northeast Multispecies (large-mesh)	39,481	16,422	0.45%
Yellowtail flounder	Northeast Multispecies (large-mesh)	115,197	28,632	1.32%
Red hake	Northeast Multispecies (small-mesh)	87,104	34,751	2.56%
Silver hake	Northeast Multispecies (small-mesh)	302,684	165,990	1.18%
Sea scallops	Sea Scallop	115,003	37,400	0.07%
Skates	Skate	1,248,078	749,989	3.52%
Spiny dogfish	Spiny Dogfish	169,487	91,473	0.68%
Black sea bass	Summer Flounder, Scup, Black Sea Bass	12,144	7,180	0.40%
Scup	Summer Flounder, Scup, Black Sea Bass	222,655	104,438	0.96%
Summer flounder	Summer Flounder, Scup, Black Sea Bass	82,239	33,353	0.36%

Source: Developed using data from NMFS (2021a).

Table 3.5.1-7 shows the average annual revenue in the RI-MA WEAs by gear type for the 2008–2019 period. Together, bottom trawl gear and gillnet-sink gear accounted for approximately 44% of the revenue generated by commercial fishing activity in the RI-MA WEAs, while the clam and scallop dredge gears and pot-other gear generated from 12% to 16%. The areas also accounted for about 1.9% of gillnet-sink gear total revenue in the Mid-Atlantic and New England regions.

Table 3.5.1-7. Commercial Fishing Revenue of Federally Permitted Vessels in the RI-MA WEAs by Gear Type (2008–2019)

Gear Type	Peak Annual Revenue ($1,000s)	Average Annual Revenue ($1,000s)	Average Annual Revenue as a Percentage of Total Revenue from the Mid-Atlantic and New England Regions
Dredge-clam	$604.9	$454.7	*0.74%*
Dredge-scallop	$938.6	$339.6	0.07%
Gillnet-sink	$916.2	$567.1	1.89%
Handline	$34.7	$7.8	0.16%
Pot-other	$590.5	$414.2	0.36%
Trawl-bottom	$1,166.0	$689.7	0.37%
Trawl-midwater	$185.0	$61.6	*0.32%*
All other gear*	$1,435.5	$338.4	0.72%
All gear types	**$3,509.1**	**$2,873.1**	**0.30%**

Source: Developed using data from NMFS (2021a).

Notes: Revenue is adjusted for inflation to 2019 dollars. Peak annual revenue is calculated independently for all rows, including the All gear types row. Gear types shown in *italics* indicate that fewer than 12 years but more than 5 years of data were used to calculate the estimates.

* Includes revenue from federally permitted vessels using longline gear, seine gear, other gillnet gear, and unspecified gear.

Table 3.5.1-8 shows the ports at which fish and shellfish caught in the RI-MA WEAs during the 2008–2019 period were landed. Together, New Bedford and Port Judith accounted for 67% of the revenue generated by commercial fishing activity in the RI-MA WEAs. Little Compton and Westport were the ports most dependent on the RI-MA WEAs, with 13.5% and 7.5%, respectively, of their total commercial fishing revenue in the Mid-Atlantic and New England regions derived from the areas.

Table 3.5.1-8. Commercial Fishing Revenue of Federally Permitted Vessels in the RI-MA WEAs by Port (2008–2019)

Port and State	Peak Annual Revenue ($1,000s)	Average Annual Revenue ($1,000s)	Average Annual Revenue as a Percentage of Total Revenue from the Mid-Atlantic and New England Regions

Other ports*	$348.6	$132.3	0.04%
All ports	**$3,509.1**	**$2,659.0**	**0.28%**

Source: Developed using data from NMFS (2021a).

Notes: Revenue is adjusted for inflation to 2019 dollars. Peak annual revenue is calculated independently for all rows, including the All ports row. Ports shown in *italics* indicate that fewer than 12 years but more than 5 years of data were used to calculate the estimates. NA indicates that the number cannot be calculated with the available data.

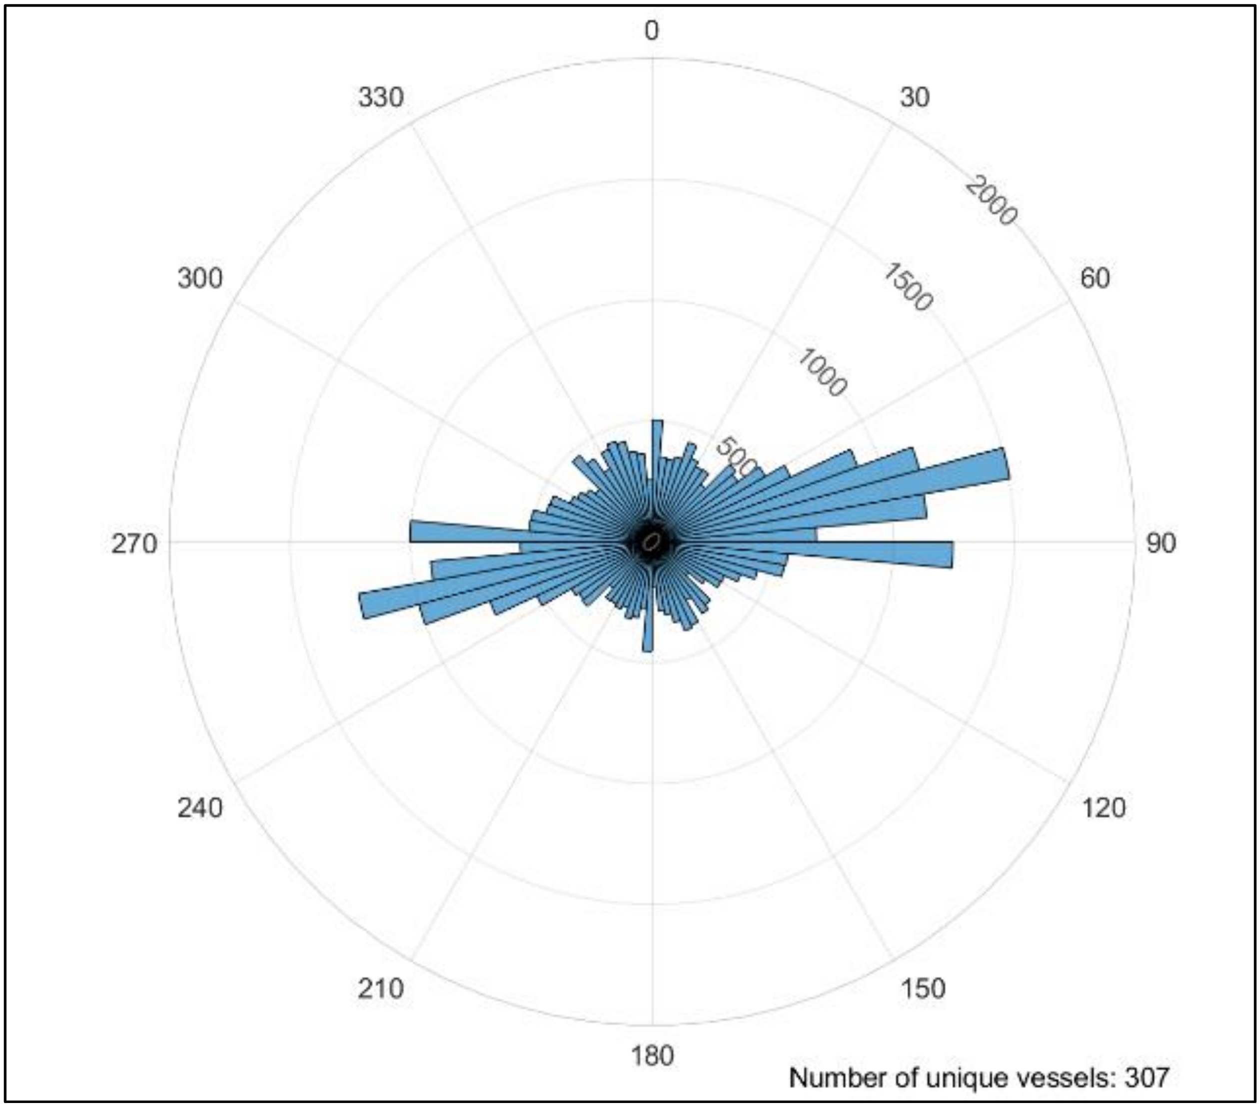
* Includes ports with NA in the table and other unlisted ports that had landings from federally permitted vessels fishing in the RI-MA WEAs during the 2008–2019 period.

In 2010, during the first stage of the public process for BOEM's call for nominations and information to establish the WEA that would eventually become the RI-MA WEAs, all of Cox Ledge was included in the area considered for leasing (i.e., call area). However, BOEM held a lengthy stakeholder and scientific review process that identified "high-value" fishing grounds and excluded those areas from the RI-MA WEAs (BOEM 2012; Smythe et al. 2016). Over the 2008–2019 period, the excluded area accounted for approximately 22% of the revenue generated by all fisheries in the call area. It accounted for 32% of the Sea Scallop FMP fishery revenue and 25% of the Monkfish FMP fishery revenue in the call area (NMFS 2021a). For the Sea Scallop and Monkfish FMP fisheries combined, the revenue per square mile in the excluded area was approximately 50% higher than that in the RI-MA WEAs in 2007–2018 (BOEM 2020).

The NMFS VMS data are a good source for understanding the spatial distribution of fishing vessels in the RI-MA WEAs. As discussed in Appendix F, from 2014 through 2019, vessels with VMS accounted for a substantial portion (90% or greater) of landings in several federally permitted fisheries in the Mid-Atlantic and New England regions, including the Sea Scallop, Monkfish, Atlantic Herring, Mackerel/Squid/Butterfish, Northeast Multispecies (large- and small-mesh), Spiny Dogfish, Summer Flounder/Scup/Black Sea Bass, and Surfclam/Ocean Quahog FMP fisheries. VMS-enabled vessels represented approximately 11% of landings in the Lobster and 14 % in the Jonah Crab FMP fisheries (NMFS 2021a). During the 2014–2019 period, an average of 340 VMS-enabled vessels operated in Atlantic WEAs. Of these vessels, an average of 101 (30%) fished in the RI-MA WEAs, including an average of two vessels fishing for Atlantic herring; 10 vessels fishing for monkfish; 22 vessels fishing for multispecies (groundfish); and 22 vessels fishing for sea scallops (NMFS 2019).

Based on data provided by NMFS (2019), polar histograms (Figure 3.5.1-1 and Figure 3.5.1-2) showing the directionality of VMS-enabled vessels fishing in the RI-MA WEAs were developed using the information conveyed in individual position reports (pings) over the January 2014–August 2019 period. Vessels moving at speeds less than 5 knots were assumed to be actively fishing. The larger bars in the polar histograms represent a greater number of position reports showing fishing vessels moving in a certain direction within the RI-MA WEAs. The polar histograms differ with respect to their scales.

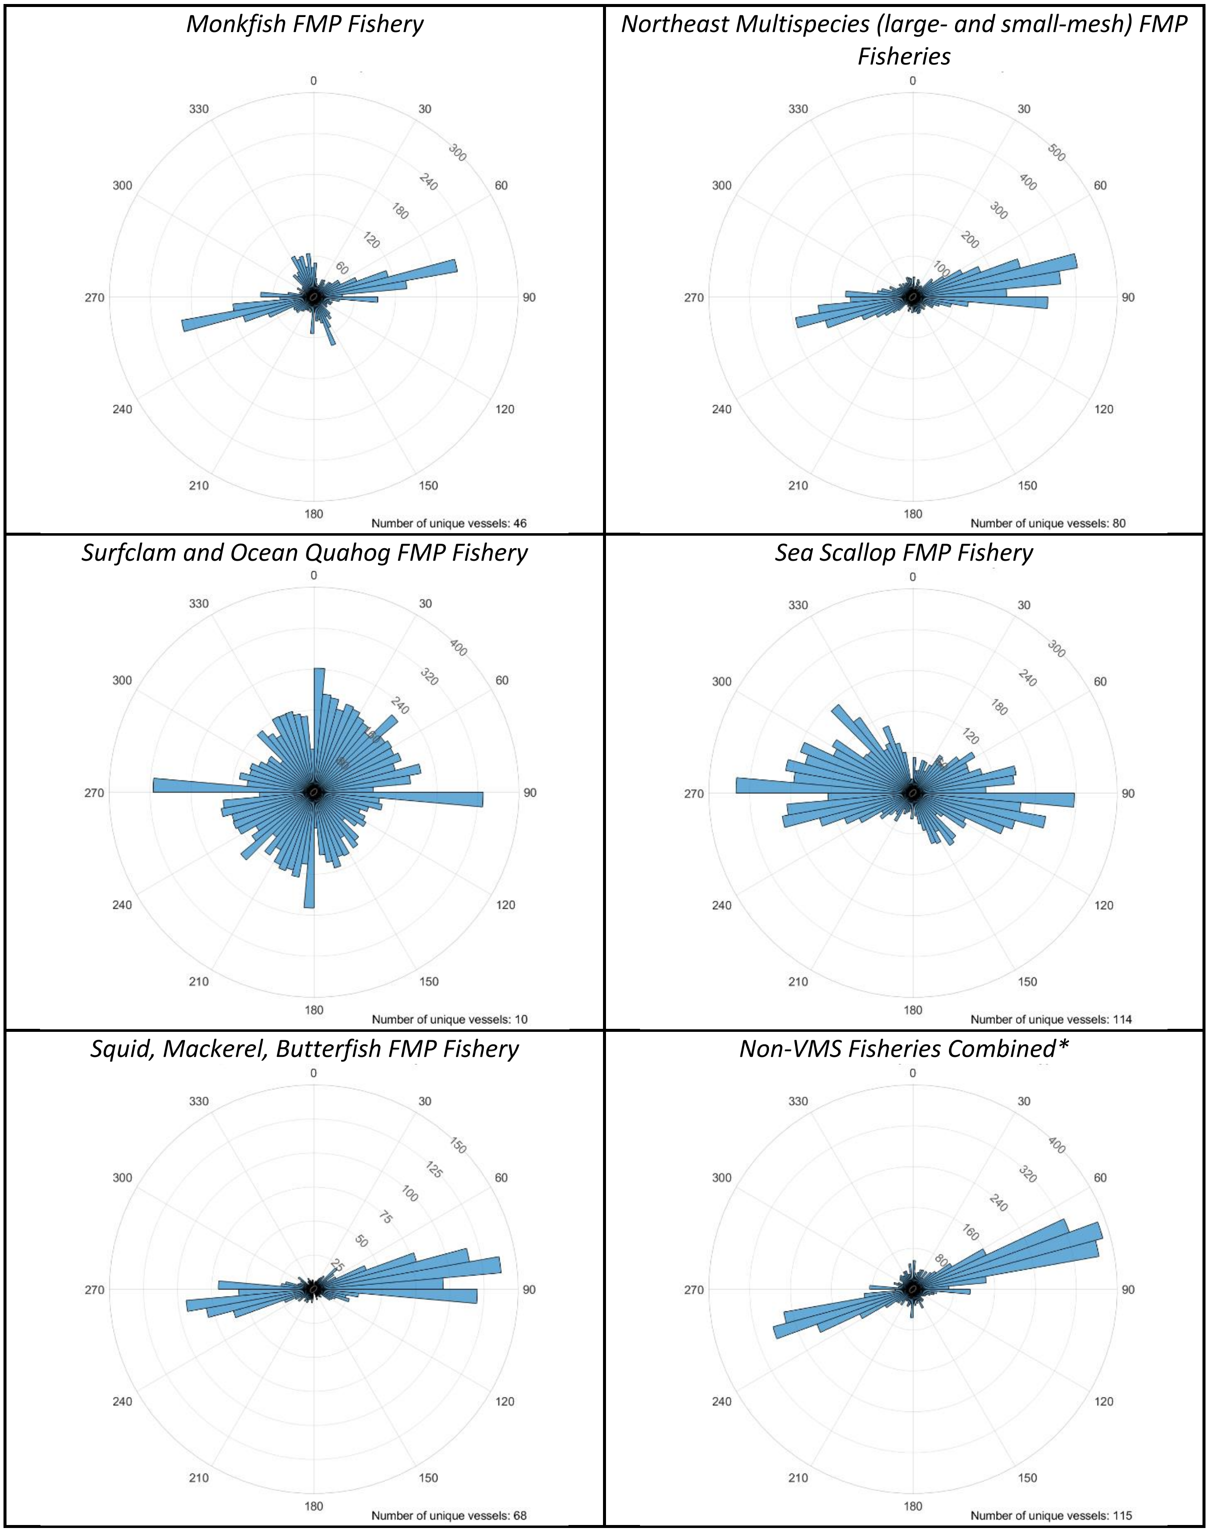
Figure 3.5.1-1 shows most of the 307 unique vessels operating in the RI-MA WEAs followed a slightly northeast–southwest fishing pattern.



Source: Developed by BOEM using VMS data provided by NMFS (2019).

Figure 3.5.1-1. VMS bearings of vessels actively fishing within the RI-MA WEAs, all FMP fisheries combined, January 2014–August 2019.

Figure 3.5.1-2 shows that the orientation of vessels fishing within the RI-MA WEAs varied somewhat by FMP fishery, but in most fisheries, vessels followed a slightly northeast–southwest fishing pattern.



* These are fishing vessels that are transmitting VMS data after having declared themselves as participating in a non-VMS fishery—(e.g. Lobster, Jonah Crab, River Herring, etc.).

Source: Developed by BOEM using VMS data provided by NMFS (2019).

Figure 3.5.1-2. VMS bearings of vessels actively fishing within the RI-MA WEAs by FMP fishery, January 2014–August 2019.

SFWF Lease Area and Offshore SFEC

The commercial fisheries that are most active in the Lease Area and along the offshore SFEC encompass a wide range of FMP fisheries, gears, and landing ports (Table 3.5.1-9 though Table 3.5.1-16). GIS data available from BOEM (2020a) for the 2007–2018 period suggest that most FMP fisheries do not have a high intensity of revenue within the Lease Area and along the offshore SFEC compared with nearby waters. As shown in Figures C-7 to C-17 in Appendix C, across all FMP fisheries, revenue intensity did not exceed $101 to $500 average annual revenue per 0.09 square mile anywhere in the Lease Area. With respect to the offshore SFEC, average annual revenue per 0.09 square mile was in the range of $501 to $1,000 for the Surfclam/Ocean Quahog FMP, Northeast Multispecies (large-mesh), and Monkfish FMP fisheries and was as high as $1,001 to $2,500 for the Sea Scallop FMP fishery; but these high revenues were derived in only small sections of the cable corridor. For all other FMP fisheries, revenue intensity along the offshore SFEC did not exceed $101 to $500 average annual revenue per 0.25 km^2. As shown in Figure C-7 to Figure C-17 in Appendix C, the revenue intensity levels for many FMP fisheries were higher in large expanses of ocean outside the Lease Area and offshore SFEC corridor but within 20 nm of the two areas. In terms of gear types (see Figures C-18 and C-19 in Appendix C), the revenue intensity for mobile gear was in the range of $501 to $1,000 for much of the offshore SFEC, while the revenue intensity for fixed gear was low along the entire cable corridor. In the Lease Area the revenue intensity was low for mobile gear, but for fixed gear it was in the range of $501 to $1,000 in the southern portion of the area. Additional details on the data and methodology used to develop the revenue intensity figures are provided in Appendix F.

Table 3.5.1-9 provides additional information on the average annual revenue in the Lease Area by FMP fishery. On average, federally permitted commercial fishing activity in the Lease Area annually generated $185.6 thousand in revenue during the 2008–2019 period, with the Monkfish FMP fishery accounting for 16% of the total, while the Sea Scallop FMP fishery accounted for 15%, and the Lobster FMP fishery both accounted for 14% of the total revenue. In terms of the percentage of each FMP fishery's total revenue in the Mid-Atlantic and New England regions that came from the Lease Area during the 2008–2019 period, the area accounted for about 0.22% of the Skate FMP fishery's total revenue and around 0.15% of the Monkfish FMP fishery's total revenue. In total, the Lease Area accounted for approximately 0.02% of the total revenue across all FMP fisheries in the Mid-Atlantic and New England regions (see Table 3.5.1-1). As shown in Table 3.5.1-9, the Summer Flounder, Scup, Black Sea Bass; Monkfish; and Skate FMP fisheries accounted for the highest number of vessels fishing in the Lease Area. The average annual revenue of vessels fishing in the Lease Area was highest for vessels participating in the Sea Scallop, Highly Migratory Species, and Atlantic Herring FMP fisheries.

Table 3.5.1-9 also shows the catch revenue in the SFWF MWA, which encompasses the Lease Area and also includes all anchoring and mooring areas that could be used during the construction of the SFWF. Due to the larger size of the MWA, the catch revenue in the area is estimated to be $232.3 thousand, 125% of that for the Lease Area alone. The increase in revenue between the two areas is highest for the Sea Scallop FMP fishery.

Table 3.5.1-9. Commercial Fishing Revenue of Federally Permitted Vessels in the SFWF Lease Area and MWA by FMP Fishery (2008–2019)

FMP Fishery	Peak Annual Revenue in the SFWF Lease Area ($1,000s)	Average Annual Revenue in the SFWF Lease Area ($1,000s)	Average Annual Revenue in the SFWF Lease Area as a Percentage of Total Revenue from the Mid-Atlantic and New England Regions	Average Number of Vessels in the SFWF Lease Area	Average Annual Revenue per Vessel in the SFWF Lease Area	Average Annual Revenue in the MWA ($1,000s)
American Lobster	$48.2	$25.0	0.03%	85	$295	$31.6
Atlantic Herring	*$12.8*	*$5.1*	*0.02%*	*16*	*$319*	$5.9

Source: Developed using data from NMFS (2021a).

To analyze differences in the economic importance of fishing grounds in the SFWF Lease Area across the commercial fishing fleet, information was obtained from NMFS (2021a) that summarized the number of federally permitted commercial fishing vessels fishing in the Lease Area each year during the 2008–2019 period and the percentage of each vessel's annual total fishing revenue that came from within the area. The complete analysis of differences in economic dependency on the Lease Area across vessels is provided in Appendix F. As shown in the appendix, the vessel-level annual revenue percentages were divided into quartiles, which were created by ordering the data from the lowest to highest percentage and then dividing the data into four groups of equal size. The 1st quartile represents the lowest 25% of ranked percentages, while the 4th quartile represents the highest 25%. In addition, NMFS (2021a) reported the number of "outlier" vessels in the distribution of percentage of revenue. In the context of this analysis, an outlier is a vessel that derived an exceptionally high proportion of its annual revenue from the Lease Area in comparison to other vessels that fished in the area.[18]

[18] Technically, an outlier in a boxplot distribution is an observation that is more than 1.5 times the length of the box away from either the 1st quartile (Q1) or 3rd quartile (Q3). Specifically, if an observation is less than Q1 – (1.5 × IQR) or greater than Q3 + (1.5 × IQR), it is an outlier; where IQR = interquartile range = Q3 – Q1.

As shown in Table F-6 in Appendix F, from 2008 through 2019, an average of 249 vessels per year fished in the Lease Area, with a high of 284 vessels in 2008 and a low of 213 vessels in 2019. The average annual number of outliers was 37 (15% of all vessels), with a high of 49 outliers in 2014 (18% of all vessels) and a low of 21 outliers in 2019 (9% of all vessels).

Three-quarters of the vessels that fished in the Lease Area derived less than 0.2% of their total annual revenue from the area (NMFS 2021f). The highest percentage of total annual revenue coming from within the Lease Area by an outlier varied from year to year, ranging from 39% in 2016 to 5% in 2012 (NMFS 2021f). Over the 2008–2019 period as a whole, the average maximum revenue percentage among outliers was 24% (NMFS 2021f). Although outliers derived a high proportion of their annual revenue from the Lease Area in comparison to other vessels that fished in the area, Figure F-1 in Appendix F shows that in any given year, the revenue percentage for the majority of outliers was below 5%. From 2008 through 2019, the average percentage of all vessels fishing in the Lease Area that derived 5% or more of their total fishing income from the Lease Area was around 2%. During any given year, the highest percentage, which occurred in 2008, was 5%, while the lowest was less than 1%. In short, some vessels depended heavily on the Lease Area, but most vessels derived a small percentage of their total annual revenue from the area.

In addition to assessing the differences in the level of economic dependency on fishing grounds in the Lease Area across vessels, the analysis examined the relationship between vessels' average annual percentage of total revenue inside the area and their average annual total fishing revenue during the 2008–2019 period. As shown in Table F-7 in Appendix F, average annual total revenue per vessel was negatively correlated with average annual revenue percentage. Vessels in the 4th quartile (i.e., vessels with a higher level of economic dependence on fishing grounds in the Lease Area) tended to have lower total commercial fishing incomes. In short, the Lease Area generally accounted for a higher proportion of the revenue of vessels that had lower total commercial fishing revenue.

Table F-7 in Appendix F also shows the average annual revenue per vessel in the Lease Area and the Mid-Atlantic and New England regions as a whole. The highest average annual revenue per vessel in the Mid-Atlantic and New England regions are from vessels in the first quartile; annual average revenue per vessel declines with each successive quartile. Average annual revenue per vessel in the Mid-Atlantic and New England regions in the 4th quartile ($219,899) was 22% of the annual average revenue per vessel in the 1st quartile ($1,009,953). Average annual revenue per vessel within the Lease Area shows an opposite trend across quartiles. The highest average annual revenue per vessel from the Lease Area was among outliers. The average vessel in the 4th quartile Lease Area had an average annual revenue of around $2,175. This was 1% of the 4th quartile annual average revenue per vessel in the Mid-Atlantic and New England region as a whole. In other words, if the average vessel in the 4th quartile was displaced from the Lease Area, on average they would likely need to increase their revenue in other fishing areas by 1% to maintain their level of annual fishing income. Vessels that were outliers on average earned $3,208 per year from the Lease Area. Sufficient information was not available for this analysis to calculate the percentage of revenue needed to maintain current levels of fishing revenue if outlier vessels are displaced from the Lease Area.

Table 3.5.1-11 provides the average annual revenue in the Lease Area and MWA by gear type for the 2008–2019 period. Together, gillnet-sink, bottom trawl, and pot-other gear accounted for approximately 69% of the revenue generated by commercial fishing activity in the Lease Area. The area accounted for about 0.15% of the gillnet-sink gear's total revenue in the Mid-Atlantic and New England regions.

Table 3.5.1-11. Commercial Fishing Revenue of Federally Permitted Vessels in the SFWF Lease Area and MWA by Gear Type (2008–2019)

Gear Type	Peak Annual Revenue in the SFWF Lease Area ($1,000s)	Average Annual Revenue in the SFWF Lease Area ($1,000s)	Average Annual Revenue as a Percentage of Total Revenue from the Mid-Atlantic and New England Regions in the SFWF Lease Area	Average Annual Revenue in the MWA ($1,000s)
Dredge-clam	NA	NA	NA	*NA*
Dredge-scallop	$897.0	$26.1	0.01%	$36.9
Gillnet-sink	$313.8	$46.5	0.15%	$56.0
Handline	$24.6	$1.6	0.03%	$1.8
Pot-other	$187.2	$39.3	0.03%	$48.4
Trawl-bottom	$800.2	$43.6	0.02%	$55.4
Trawl-midwater	*$118.9*	*$4.5*	*0.02%*	*$5.2*

All gear types	**$292.7**	**$185.5**	**0.02%**	**$232.3**

Source: Developed using data from NMFS (2021a).

Notes: Revenue is adjusted for inflation to 2019 dollars. Peak annual revenue is calculated independently for all rows, including the All gear types row. Gear types shown in *italics* indicate that fewer than 12 years but more than 5 years of data were used to calculate the estimates. Otherwise, estimates are based on 12 years of data. NA indicates that the number cannot be calculated with the available data.

* Includes revenue from federally permitted vessels using longline gear, seine gear, other gillnet gear, and unspecified gear, as well as listed gear, for years when they cannot be disclosed (NA).

Table 3.5.1-12 shows the ports at which fish and shellfish caught in the Lease Area and MWA during the 2008–2019 period were landed. Together, Point Judith, New Bedford, Little Compton, and Newport accounted for approximately 68% of the revenue generated by commercial fishing activity in the Lease Area. Little Compton and Westport were the ports most dependent on the Lease Area, with 1.3% and 0.8%, respectively, of their total commercial fishing revenue in the Mid-Atlantic and New England regions derived from the area.

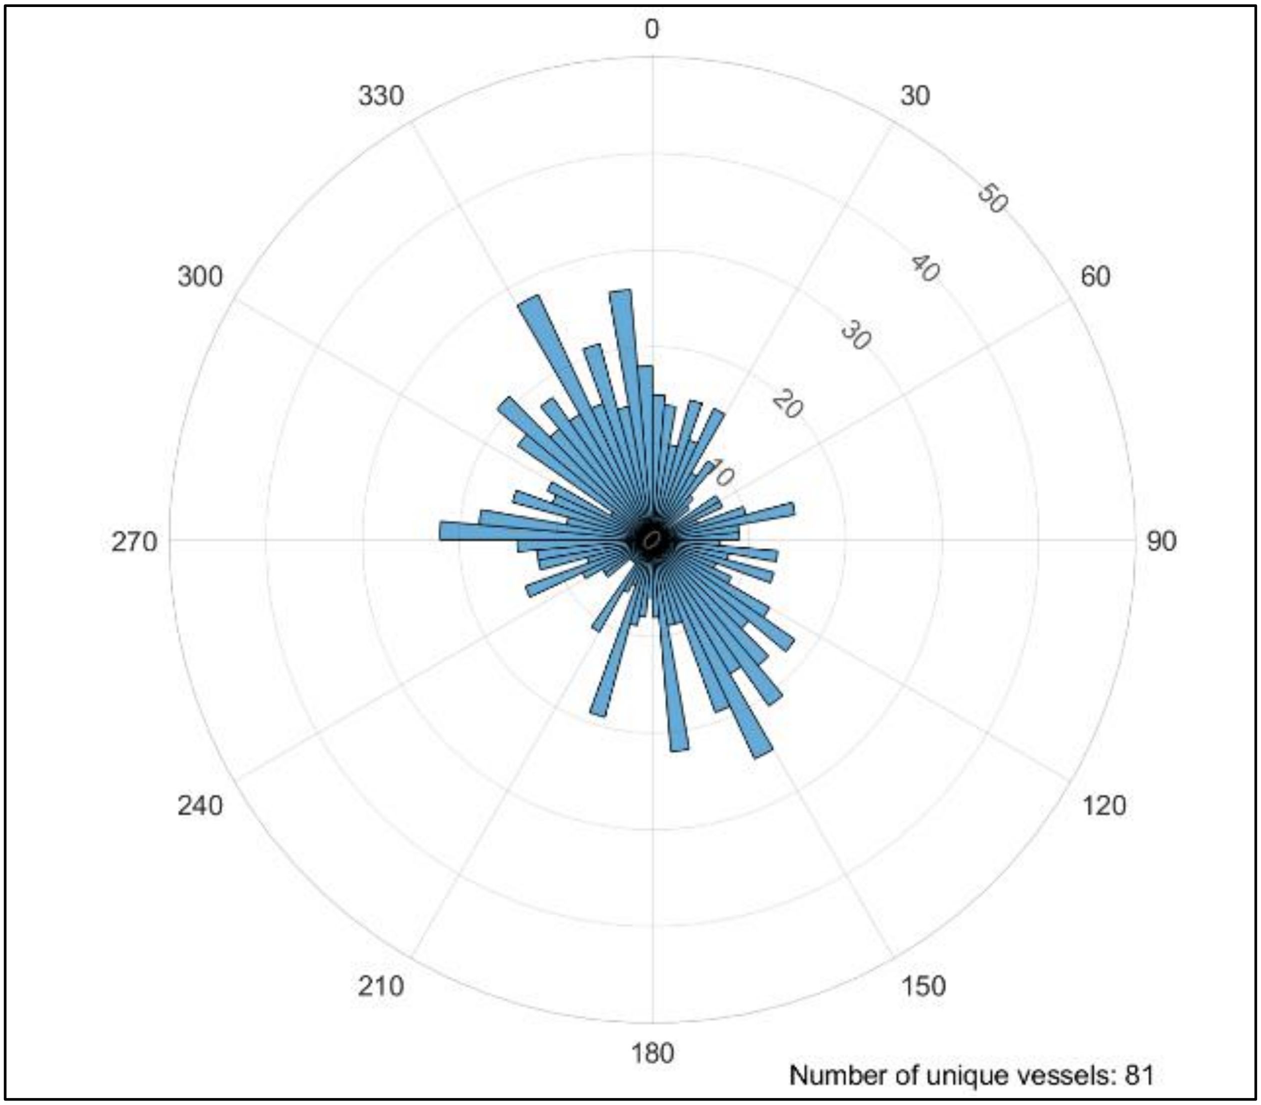
Notes: Revenue is adjusted for inflation to 2019 dollars. Ports shown in *italics* indicate that fewer than 12 years but more than 5 years of data were used to calculate the estimates. Otherwise, estimates are based on 12 years of data. NA indicates that the number cannot be calculated with the available data.

* Includes ports with NA in the table and other unlisted ports that had landings from federally permitted vessels fishing from these areas in 2008–2019.

As in the RI-MA WEAs, the NMFS VMS data are a good source for understanding the spatial distribution of fishing vessels in the MWA. During the 2017–2019 period, an average of 16 (5%) of the 340 VMS-enabled vessels operating in Atlantic WEAs fished in the MWA, including an average of two vessels fishing for monkfish; one vessel fishing for multispecies (groundfish); and two vessels fishing for sea scallops (NMFS 2019).

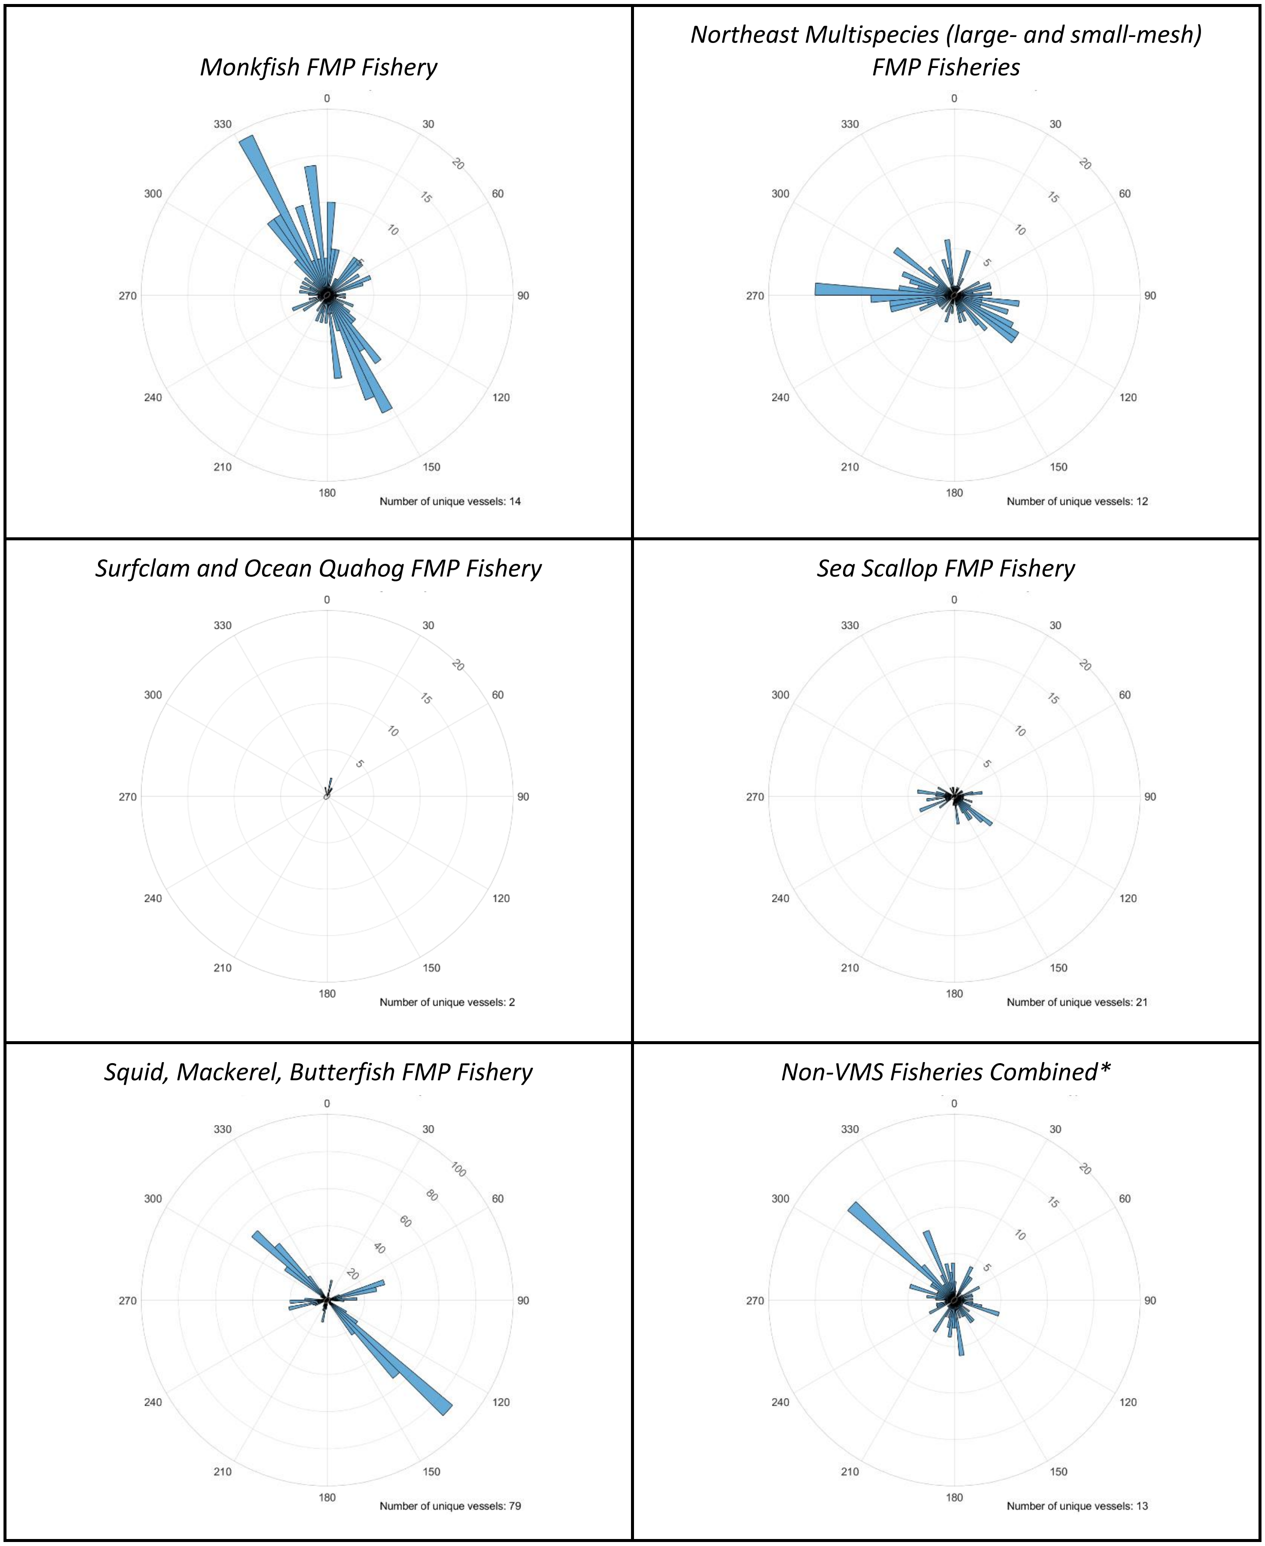
Polar histograms (Figure 3.5.1-3 and Figure 3.5.1-4) showing the directionality of VMS-enabled fishing vessels operating in the MWA were developed using the same methodology described above. Figure 3.5.1-3 shows that most of the 81 unique vessels operating in the Lease Area followed a slightly northwest–southeast fishing pattern.

Figure 3.5.1-4 shows that the orientation of vessels fishing within the MWA varied by FMP fishery, but in most fisheries, vessels followed a northwest–southeast fishing pattern.



Source: Developed by BOEM using VMS data provided by NMFS (2019).

Figure 3.5.1-3. VMS bearings of vessels actively fishing within the MWA, all FMP fisheries combined, January 2014–August 2019.



* These are fishing vessels that are transmitting VMS data after having declared themselves as participating in a non-VMS fishery—e.g. lobster, Jonah crab, river herring, etc.

Source: Developed by BOEM using VMS data provided by NMFS (2019).

Figure 3.5.1-4. VMS bearings of vessels actively fishing within the MWA by FMP fishery, January 2014–August 2019.

Table 3.5.1-13 presents the average annual revenue in the 2-km zone around the offshore SFEC by FMP fishery for the 2008–2019 period, assuming the SFEC would come ashore at Beach Lane. The Beach Lane route is the longer of the two SFEC options; based on data from BOEM (2020a), the average annual catch revenue for the Hither Hills route was estimated to be about 91% of that for the Beach Lane route. As noted above, the available data suggest that the offshore SFEC crosses an area of relatively high intensity of revenue from sea scallop fishing. On average, federally permitted commercial fishing activity in the offshore SFEC area annually generated $1.28 million in revenue, with the Sea Scallop FMP fishery accounting for 33% of the total. The Summer Flounder, Scup, Black Sea Bass FMP fishery accounted for 15% of the total while the Monkfish FMP and Northeast Multispecies (large-mesh) FMP fisheries each accounted for 10% of the total revenue. In terms of the percentage of each FMP fishery's total revenue in the Mid-Atlantic and New England regions that came from the offshore SFEC area during the 2008–2019 period, the area accounted for about 1.01% of the Skate FMP fishery's total revenue, 0.73% of the Bluefish FMP fishery's total revenue, and 0.61% of the Monkfish FMP fishery's total revenue. In total, the offshore SFEC area accounted for approximately 0.13% of the total revenue across all FMP fisheries in the Mid-Atlantic and New England regions (see Table 3.5.1-1).

Table 3.5.1-13. Commercial Fishing Revenue of Federally Permitted Vessels in the Offshore SFEC with Beach Lane Landing Site by FMP Fishery (2008–2019)

FMP Fishery	Peak Annual Revenue ($1,000s)	Average Annual Revenue ($1,000s)	Average Annual Revenue as a Percentage of Total Revenue from the Mid-Atlantic and New England Regions
American Lobster	$71.6	$33.9	0.04%
Atlantic Herring	$89.8	$32.0	0.12%
Bluefish	$26.4	$9.3	0.73%
Golden and Blueline Tilefish	$36.3	$9.8	0.18%
Highly Migratory Species	$1.1	$0.3	0.01%
Jonah Crab	$9.5	$5.0	0.05%
Mackerel, Squid, and Butterfish	$251.3	$90.5	0.17%
Monkfish	$192.1	$125.6	0.61%
Northeast Multispecies (large-mesh)	$196.4	$115.3	0.16%
Sea Scallop	$899.7	$413.9	0.08%
Skate	$115.6	$74.9	1.01%
Northeast Multispecies (small-mesh)	$47.5	$25.7	0.23%
Spiny Dogfish	$10.1	$3.5	0.12%
Summer Flounder, Scup, Black Sea Bass	$258.4	$187.2	0.47%
Other FMPs, non-disclosed species, and non-FMP fisheries*	$328.2	$130.9	0.15%
All FMP and non-FMP fisheries	$1,766.3	$1,257.9	0.13%

Source: Developed using data from NMFS (2021a).

Notes: Revenue is adjusted for inflation to 2019 dollars. Peak annual revenue is calculated independently for all rows, including the All FMP and non-FMP fisheries row.

* Includes revenue from federal FMPs that are not listed, from species that were not disclosed within listed FMPs, and harvests from species in non-FMP fisheries harvested by federally permitted vessels.

In terms of pounds landed, the top species harvested along the offshore SFEC were Atlantic herring and skates (Table 3.5.1-14).

Table 3.5.1-14. Commercial Fishing Landings of Federally Permitted Vessels in the Offshore SFEC by Species (2008–2019)

Species	FMP	Peak Annual Landings (pounds)	Average Annual Landings (pounds)	Average Annual Landings as a Percentage of Total Landings from the Mid-Atlantic and New England Regions
American lobster	American Lobster	12,565	6,376	0.03%
Atlantic herring	Atlantic Herring	777,251	234,645	0.15%
Bluefish	Bluefish	29,995	11,648	0.64%
Jonah crab	Jonah Crab	11,776	6,411	0.05%
Atlantic mackerel	Mackerel, Squid, and Butterfish	171,753	29,951	0.16%
Butterfish	Mackerel, Squid, and Butterfish	12,997	7,934	0.24%
Loligo squid	Mackerel, Squid, and Butterfish	183,515	60,245	0.24%
Monkfish	Monkfish	105,685	79,498	0.82%
Striped bass	No Federal FMP	11,442	6,714	1.25%
Cod	Northeast Multispecies (large-mesh)	28,643	12,889	0.17%
Winter flounder	Northeast Multispecies (large-mesh)	38,468	14,685	0.40%
Yellowtail flounder	Northeast Multispecies (large-mesh)	51,255	20,350	0.94%
Red hake	Northeast Multispecies (small-mesh)	16,323	10,444	0.77%
Silver hake	Northeast Multispecies (small-mesh)	61,981	32,810	0.23%
Sea scallops	Sea Scallop	84,124	37,851	0.08%
Skates	Skate	572,624	326,497	1.53%
Spiny dogfish	Spiny Dogfish	44,886	17,755	0.13%
Black sea bass	Summer Flounder, Scup, Black Sea Bass	10,776	5,462	0.30%
Scup	Summer Flounder, Scup, Black Sea Bass	145,722	82,150	0.76%
Summer flounder	Summer Flounder, Scup, Black Sea Bass	45,874	27,704	0.30%

Source: Developed using data from NMFS (2021a).

Table 3.5.1-15 provides the average annual revenue in the offshore SFEC area by gear type for the 2008–2019 period. Together, scallop dredge, bottom trawl and gillnet-sink gear types accounted for approximately 80% of the revenue generated by commercial fishing activity in the offshore SFEC area. The area accounted for about 0.60% of gillnet-sink gear total revenue in the Mid-Atlantic and New England regions, and 0.32% of handline gear total revenue.

Table 3.5.1-15. Commercial Fishing Revenue of Federally Permitted Vessels in the Offshore SFEC with Beach Lane Landing Site by Gear Type (2008–2019)

Gear Type	Peak Annual Revenue ($1,000s)	Average Annual Revenue ($1,000s)	Average Annual Revenue as a Percentage of Total Revenue from the Mid-Atlantic and New England Regions

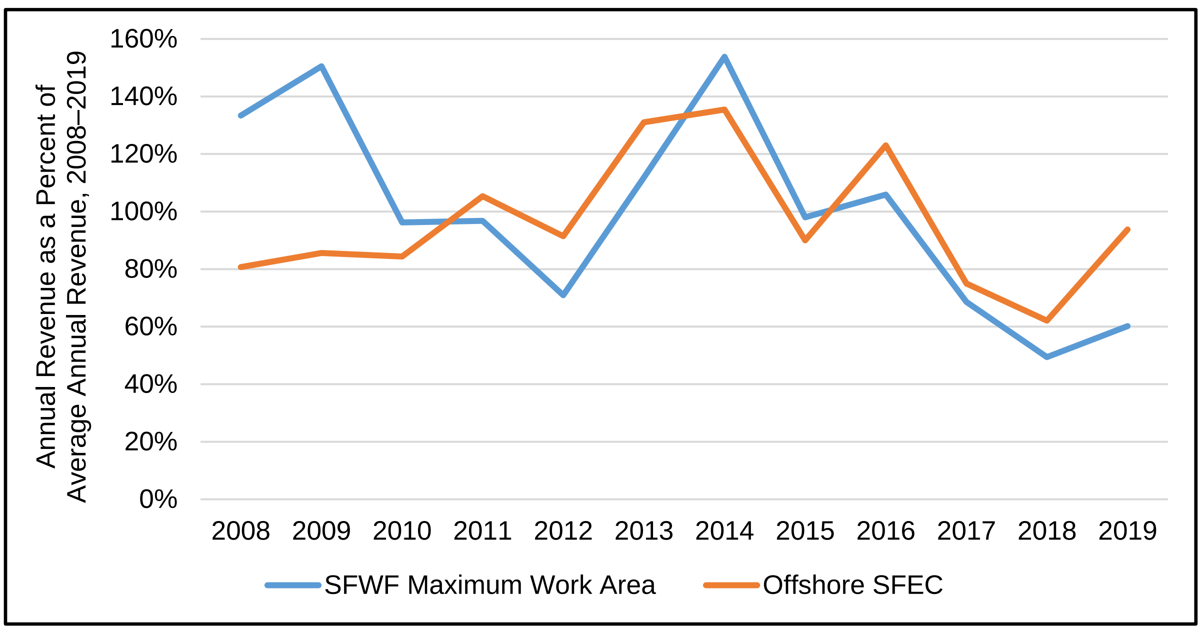
Source: Developed using data from NMFS 2021a).

Notes: Revenue is adjusted for inflation to 2019 dollars. Ports shown in *italics* indicate that fewer than 12 years but more than 5 years of data were used to calculate the estimates. Otherwise, estimates are based on 12 years of data.

* Includes ports with NA in the table and unlisted ports that had landings from federally permitted vessels fishing in the offshore SFEC in the period 2008–2019.

VTR data describe most commercial fishing activity in both state and federal waters by vessels that have a federal permit or a state and federal fishing permit. However, those vessels with only state permits are not included in the VTR data set. Nevertheless, state permit holders must report their catch to state agencies, including the statistical area within which fishing occurred. Based on commercial fishing data collected by the NYSDEC, CH2M HILL (2018) estimated catches of New York State–permitted fishermen in statistical areas 167 and 168. These two areas encompass the state fishery fishing grounds that could be affected by the offshore SFEC. Together, the two statistical areas represent important state fishing grounds for a variety of species. The greatest average pounds landed for the years 2007 to 2016 in these statistical areas included striped bass (total approximately 205,000 pounds), longfin inshore squid (approximately 43,000 pounds), skate (approximately 26,000 pounds), bluefish (about 23,000 pounds), and lobster (approximately 13,000 pounds). The top ports where fishermen landed their catch after fishing in the two areas were Moriches, Shinnecock Indian Reservation, and Montauk, New York (CH2M HILL 2018).

Figure 3.5.1-5 shows that there was considerable interannual variability in commercial fishing revenue in the SFWF MWA and offshore SFEC in the period 2008–2018.



Source: Developed using data from NMFS (2021a).

Figure 3.5.1-5. Interannual variability of commercial fishing revenue of federally permitted vessels in the SFWF MWA and offshore SFEC, 2008–2019.

3.5.1.1.2 FOR-HIRE RECREATIONAL FISHING

For-hire recreational fishing boats are operated by licensed captains for businesses that sell recreational fishing trips to anglers. These boats include both party (head) boats, defined as boats on which fishing space and privileges are provided for a fee, and charter boats, defined as boats operating under charter for a price, time, etc. and the participants are part of a preformed group of anglers (NMFS 2021g). A comprehensive list of species that are targeted by for-hire boats within the Rhode Island Ocean Special Management Plan area was developed through an iterative process, using catch data and correspondence with recreational charter boat captains (State of Rhode Island Coastal Resources Management Council 2010). As shown in Table 3.5.1-17, for-hire boats target a wide range of pelagic, highly migratory, and demersal species.

Table 3.5.1-17. Species Targeted by For-Hire Recreational Fishing Boats in the Rhode Island Ocean Special Management Plan Area

Column 1 of 4	Column 2 of 4	Column 3 of 4	Column 4 of 4
Atlantic bonito	False albacore	Blue shark	Tautog
Atlantic cod	Pollock	Thresher shark	Bluefin tuna
Black sea bass	Scup	Striped bass	Yellowfin tuna
Bluefish	Shortfin mako	Summer flounder	Winter flounder

Source: State of Rhode Island Coastal Resources Management Council (2010).

Recreational fishing in the region occurs year-round but is most intensive from April through November (Tetra Tech 2016). Early in spring, most of the Rhode Island–based party and charter boats target the migratory stocks of the Mid-Atlantic such as striped bass, summer flounder, and black sea bass. During late spring, party and charter boats are almost exclusively targeting cod, with most of the cod fishing occurring on Cox Ledge and south of Block Island (State of Rhode Island Coastal Resources Management Council 2010). Cod fishing on Cox Ledge is also popular in the summer as the water warms and cod start to congregate on the ledge (Plaia 2009). However, most summer recreational fishing is focused on striped bass and bluefish, with some boats targeting summer flounder closer to shore. Later in the summer, some of the boats move farther offshore to target sharks, which are generally caught anywhere from 20 to 50 miles offshore. Sharks targeted include blue, mako, and thresher sharks, with most shark fishing being catch and release. Some tuna fishing also takes place in an area east of Block Island and northwest of Cox Ledge known as the Mud Hole or Deep Hole. Starting in September, much of the fishing switches to sea bass and scup around Block Island or to striped bass closer to shore (State of Rhode Island Coastal Resources Management Council 2010). Many recreational fishermen participate in organized sportfishing tournaments during the year. For example, the Rhode Island Saltwater Anglers Association sponsors 15 tournaments per year as well as a “Yearlong Tournament” targeting the majority of recreational species in the Rhode Island Ocean Special Management Plan Area (State of Rhode Island Coastal Resources Management Council 2010).

As shown in Figure C-6 in Appendix C, which presents spatial data indicating the relative intensity of charter fishing activity, the number of charter fishing trips is fairly low in the RI-MA WEAs but comparatively high along much of the offshore SFEC route.

Most for-hire boats fishing near the RI-MA WEAs are based in Rhode Island. However, party and charter boats from New York, Connecticut, and Massachusetts also regularly fish in or near the RI-MA WEAs. For-hire recreational fishing is an integral part of each of these states’ coastal tourism industries. During the 2007–2012 period, annual for-hire boat revenue averaged $15.6 million in Rhode Island, $86.2 million in New York, $14.5 million in Connecticut, and $62.4 million in Massachusetts. However, of the 16,569 average annual for-hire boat trips that left from ports in the four states each year during the 2007–2012 period, only 0.9% occurred in or near the RI-MA WEAs (Kirkpatrick et al. 2017).

The 70 square miles of Cox Ledge excluded from the RI-MA WEAs is important to for-hire recreational fishing as well as commercial fisheries. Table 3.5.1-18 presents data on party/charter recreational fishing reported on Cox Ledge during various time periods. The data suggest that a small number of for-hire recreational fishing businesses fish relatively intensively on Cox Ledge, with each individual business generating on the order of $9,400/year in the area. The revenue reported on Cox Ledge is consistently high across all time periods studied (NEFMC and NMFS 2016).

Table 3.5.1-18. For-Hire Recreational Fishing Activity on the Portion of Cox Ledge Excluded from Wind Energy Development by Time Period

Time Period	Average Annual Revenue	Average Revenue Per Trip	Average Annual Number of Permit Holders	Average Annual Number of Anglers
2006–2014	$95,911	$2,385	10	887
2010–2014	$88,928	$2,257	9	816
2012–2014	$64,696	$2,521	6	587

Source: NEFMC and NMFS (2016).

The following two tables focus on for-hire recreational fishing catch and effort in the SFWF using VTR data provided by NMFS.[19] To understand the relative importance of the SFWF Lease Area to regional for-hire recreational fishing, Table 3.5.1-19 compares the landings reported in the Lease Area to the total for-hire recreational fishing landings in the New England and Mid-Atlantic regions during the 2008–2018 period. For all species, the Lease Area accounted for a small percentage (≤ 0.01%) of the total landings in the for-hire recreational fishery.

Table 3.5.1-19. Average Annual For-Hire Recreational Fishing Landings in the Mid-Atlantic and New England Regions and SFWF Lease Area by Top Species (2008–2018)

Area	Black Sea Bass	Bluefish	Atlantic Cod	Cunner	Scup	Striped Bass	Summer Flounder	Spiny Dogfish	All Others
Landings in New England and Mid-Atlantic regions (number of fish)	336,280	243,599	119,341	4,806	606,230	44,107	76,384	7,205	762,662
Landings in SFWF Lease Area (number of fish)	17	2	11	0	1	4	0	0	177
SFWF Lease Area landings as a percentage of total New England and Mid-Atlantic landings	0.01%	0.00%	0.01%	0.00%	0.00%	0.01%	0.00%	0.00%	0.02%

Source: Developed using data from NMFS (2021a).

Notes: Landings are reported in number of fish kept on party/charter trips. Only species that were landed in the SFWF Lease Area are included in the table.

Table 3.5.1-20 compares the angler trips reported in the Lease Area to the total angler trips for the New England and mid-Atlantic regions. Over the 2008–2018 period, the Lease Area accounted for relatively few angler trips across all states.

[19] NMFS requires all federally permitted party and charter boats with a permit to fish for Atlantic bluefish, black sea bass, scup, summer flounder, tilefish, Atlantic mackerel, squid, and/or butterfish to submit a VTR for every fishing trip (50 CFR 648.7).

Table 3.5.1-20. For-Hire Recreational Fishing Effort in Mid-Atlantic and New England Ports and SFWF Lease Area by Port State (2008-2018)

Year	All New York Ports	All Rhode Island Ports	All Connecticut Ports	All Massachusetts Ports	All NY, RI, CT, MA Ports
New England and Mid-Atlantic Regions (number of angler trips)					
2008	91,970	24,050	19,112	57,121	192,253
2009	130,928	21,660	17,889	47,387	217,864
2010	167,230	23,566	18,516	60,127	269,439
2011	168,969	24,866	13,230	53,867	260,932
2012	171,237	24,558	15,885	52,063	263,743
2013	174,419	22,953	15,321	46,918	259,611
2014	171,736	24,944	20,681	40,230	257,591
2015	172,937	24,509	21,209	28,475	247,130
2016	173,236	23,903	20,959	28,605	246,703
2017	163,422	18,088	15,610	27,920	225,040
2018	121,959	19,572	16,957	21,332	179,820
SFWF Lease Area (number of angler trips)					
2008	37	9	0	0	46
2009	0	6	0	0	6
2010	0	0	7	0	7
2011	30	21	0	0	51
2012	18	0	0	0	18
2013	22	0	0	0	22
2014	6	3	0	0	9
2015	5	91	0	12	108
2016	38	0	0	0	38

2018	8	10	0	0	18

Source: Developed using data from NMFS (2021a).

Notes: The term "angler trips" refers to the number of reported passengers on party/charter VTRs. Only port states that reported angler trips in the SFWF Lease Area are included in the table.

3.5.1.2 Environmental Consequences

3.5.1.2.1 ISSUES, INDICATORS, AND SIGNIFICANCE CRITERIA

Table 3.5.1-21 lists the issues identified for this resource and the indicators and significance criteria used to assess impacts for the final EIS.

Table 3.5.1-21. Issues, Indicators, and Significance Criteria Used to Assess Impacts to Commercial Fisheries and For-Hire Recreational Fishing

<table>
<tr><th>Issue</th><th>Impact Indicator</th><th>Significance Criteria</th></tr>
<tr><td>Port access</td><td>Vessel traffic congestion and reduced access to high-demand port services</td><td rowspan="4">Negligible: No measurable impacts would occur.
Minor: Adverse impacts to the affected activity or community could be avoided with EPMs and impacts would not disrupt the normal or routine functions of the affected activity or community. Once the impacting agent is eliminated, the affected activity or community would return to a condition with no measurable effects.
Moderate: Impacts to the affected activity or community are unavoidable, but EPMs would reduce impacts substantially during the life of the Project. The affected activity or community would have to adjust somewhat to account for disruptions due to impacts of the Project, or, once the impacting agent is eliminated, the affected activity or community would return to a condition with no measurable effects if proper remedial action is taken.
Major: The affected activity or community would experience substantial disruptions, and, once the impacting agent is eliminated, the affected activity or community could retain measurable effects indefinitely, even if remedial action is taken.</td></tr>
<tr><td>Fishing access</td><td>Increased operating costs (e.g., additional fuel to arrive at more distant locations; additional crew compensation due to more days at sea); lower revenue (e.g., less-productive area; less-valuable species); increased conflict among fishermen; avoidance of area by fishermen because of safety concerns</td></tr>
<tr><td>Loss of or damage to fishing gear</td><td>Costs of gear repair or replacement; lost fishing revenue while gear is being repaired or replaced</td></tr>
<tr><td>Change in catch of target species</td><td>Change in revenue due to change in catch</td></tr>
</table>

3.5.1.2.2 NO ACTION ALTERNATIVE

The Affected Environment section provides information on existing commercial fisheries and for-hire recreational fishing occurring in the geographic analysis area and describes trends in conditions, including the effects of past and present activities. Attachment 3 in Appendix E provides additional information regarding past and present activities contributing to current conditions in the geographic area. Attachment 3 in Appendix E also discloses future non-offshore wind activities and associated commercial fisheries and for-hire recreational fishing impacts. Impacts associated with future offshore wind activities are described below.

Future Activities (without the Proposed Action)

Future offshore wind facilities in the New England and Mid-Atlantic regions could increase the magnitude, geographic extent, duration, and frequency of the impacts to commercial fisheries and for-hire recreational fishing caused by ongoing and future non-offshore wind activities. Two sources of assumptions are used with respect to future offshore wind development: Table E-4 in Attachment 4 of Appendix E is used for forecasts of project footprint acres and lengths of inter-array and export cables, and Table E-4 in Appendix E provides updated forecasts of numbers of wind turbine foundations.

Port utilization and traffic: Construction of offshore wind energy projects would require port facilities for staging and installation vessels, including crew transfer, dredging, cable lay, pile driving, survey vessels, and, potentially, feeder lift barges and heavy lift barges. All of these vessels would add traffic to port facilities and would require berthing. The additional vessel volume in construction ports could cause vessel traffic congestion, difficulties with navigating, and an increased risk for collisions, together with reduced access to high-demand port services (e.g., fueling and provisioning) by existing port users, including commercial fishing vessels. These potential adverse impacts could cause some vessel operators to change routes or use an alternative port. However, future offshore wind projects are expected to result in only a small incremental increase in vessel traffic, with a peak of 379 vessels during Project construction over a 10-year time frame (see Section 3.5.6.2.2 [No Action Alternative] for additional details).

The installation of offshore components for offshore wind energy projects and the presence of construction vessels could also temporarily restrict fishing vessel movement and thus transit and harvesting activities within lease areas. To safeguard mariners from the hazards associated with installation of these offshore components, it is expected that most, if not all, offshore wind energy projects would create safety zones around construction areas. When safety zones are in effect, fishing vessels could either forfeit fishing revenue or relocate to other fishing locations and continue to earn revenue. However, vessels that chose to relocate could incur increased operating costs (e.g., additional fuel to arrive at more distant locations; additional crew compensation due to more days at sea) and/or lower revenue (e.g., less-productive area; less-valuable species).

Once offshore wind projects are completed, some commercial fishermen may avoid the lease areas if large numbers of recreational fishermen are drawn to the areas by the prospect of higher catches. WTG foundations and associated scour protection may produce an artificial reef effect, potentially increasing fish and invertebrate abundance within a facility's footprint (see Section 3.4.2 [Benthic Habitat, Essential Fish Habitat, Invertebrates, and Finfish]). According to ten Brink and Dalton (2018), the influx of recreational fishermen into the BIWF caused some commercial fishermen to cease fishing in the area because of vessel congestion and gear conflict concerns. If these concerns cause commercial fishermen to shift their fishing effort to areas not routinely fished, conflict with existing users could increase as other areas are encroached. In general, the potential for conflict among commercial fishermen due to fishing displacement may be higher for fishermen engaged in fisheries that have regulations that constrain where fishermen can fish, such as the lobster fishery. However, the potential for vessel congestion and gear conflict may also increase if mobile species targeted by commercial fishermen, such as Atlantic herring, Atlantic mackerel, squid, tuna, and groundfish, are attracted to offshore wind energy facilities by the artificial reef effect, and fishermen targeting these species concentrate their fishing effort in offshore wind farm lease areas as a result. Overall, the adverse effects of offshore wind energy-related port expansion and traffic on commercial and for-hire fishing vessels are expected to be long term and moderate.

Anchoring: BOEM estimates approximately 1,627 acres of seabed would be disturbed by anchoring associated with offshore wind activities. Anchoring vessels used in the construction of offshore wind energy projects would pose a navigational hazard to fishing vessels. All impacts would be localized (within a few hundred meters of anchored vessel) and temporary (hours to days). Although anchoring impacts would occur primarily during Project construction, some impacts could also occur during O&M and conceptual decommissioning. Therefore, the adverse effects of offshore wind energy–related anchoring on commercial fisheries and for-hire recreational fishing are expected to be long term and moderate.

Presence of structures: The presence of structures can lead to impacts on commercial fisheries and for-hire recreational fishing through allisions, entanglement or gear loss/damage, fish aggregation, habitat conversion, navigation hazards (including transmission cable infrastructure), and space use conflicts. These impacts may arise from buoys, met towers, foundations, scour/cable protection, and transmission cable infrastructure. Using the assumptions in Appendix E Attachment 4, future offshore wind energy projects under the No Action alternative would include 2,547 foundations, 2,815 acres of seabed disturbance due to foundation and scour protection, and 2,292 acres of new hard protection atop cables. Projects may also install more buoys and met towers. BOEM anticipates that structures would be added intermittently over an assumed 10-year period and that they would remain until conceptual decommissioning of each facility is complete.

The presence of the WTG foundations and associated scour protection would convert existing sand or sand with mobile gravel habitat to hard bottom, which in turn would reduce the habitat for target species that prefer soft-bottom habitat (e.g., squid, summer flounder, and surfclams) and increase the habitat for target species that prefer hard-bottom habitat (e.g., lobster, striped bass, black sea bass, and cod). Where

WTG foundations and associated scour protection produce an artificial reef effect and attract finfish and invertebrates, the aggregation of species could increase the catchability of target species (Kirkpatrick et al. 2017). Although species that rely on soft-bottom habitat would experience a reduction in favorable conditions, the impacts from structures are not expected to result in population-level impacts (see Section 3.4.2 [Benthic Habitat, Essential Fish Habitat, Invertebrates, and Finfish]). Overall, localized adverse or beneficial impacts on target species populations from habitat alteration would have a negligible to minor effect on the catch of for-hire recreational and commercial fisheries.

The USCG has stated that it does not plan to create exclusionary zones around offshore wind facilities during their operation (BOEM 2018). However, because of the height of wind turbines above the ocean surface, they would be visually detectable at a considerable distance during the day and easily detected by vessels equipped with radar regardless of the time of day. To further ensure navigational safety, all structures would have appropriate markings and lighting in accordance with USCG and International Association of Marine Aids to Navigation and Lighthouse Authorities guidelines, and NOAA would chart wind turbine locations and could include a physical or virtual automatic identification system (AIS) at each turbine. Some fishing vessels operating in or near offshore wind facilities may experience radar clutter and shadowing. Most instances of interference can be mitigated through the proper use of radar gain controls (DNV-GL 2021). See also Section 3.5.6 [Navigation and Vessel Traffic].

Notwithstanding these safety measures, some fishermen have commented that because of safety considerations, they would not enter an offshore wind array during inclement weather, especially during low-visibility events (Kirkpatrick et al. 2017). Moreover, mechanical problems, such as loss of steerage, could result in an allision with a WTG as the vessel drifts during repair (DNV-GL 2021).

In addition, a potential effect of the presence of the offshore cables and wind turbines associated with offshore wind energy development is the entanglement and damage or loss of commercial and recreational fishing gear. Cable protection in the form of rock placement, concrete mattresses, or half-shell could cause a potential safety hazard should gear snag or hook on these seabed structures. Economic impacts to fishing operations associated with gear damage or loss include the costs of gear repair or replacement, together with the fishing revenue lost while gear is being repaired or replaced. In addition, comments from the fishing industry have included concerns that fishing vessel insurance companies may not cover claims for incidents within a wind energy facility resulting in gear damage or loss, or they may increase premiums for vessels that operate within wind farm areas.

Given that mobile fishing gear is actively pulled by a vessel over the seafloor, the chance of snagging this gear type on Project infrastructure is much greater than if—as in the case of fixed gear—the gear was set on the infrastructure or waves or currents pushed the gear into the infrastructure. The risk of damage or loss of deployed gear as a result of offshore wind development could impact mobile and fixed-gear commercial fisheries and for-hire recreational fishing. Inter-array and export cables would be buried below the seabed approximately 5 to 8 feet; however, BOEM assumes that no more than 10% of the cables may not achieve the proper burial depth and would require cable protection in the form of rock placement, concrete mattresses, or half-shell. Mobile bottom-tending gear (trawl and dredge gear) could get hung up on these cable protection measures, and the cost of these impacts would vary depending on the extent of damage to the fishing gear.

With respect to fishing vessel maneuverability restrictions (including risk of allisions) within WDAs, fishermen have expressed specific concerns about fishing vessels operating trawl gear that may not be able to safely deploy gear and operate in a WDA given the size of the gear, the spacing between the WTGs, and the space required to safely navigate, especially with other vessels present and during poor weather conditions. Trawl and dredge vessel operators have commented that less than 1-nm spacing between WTGs may not be enough to operate safely due to maneuverability of fishing gear and gear not directly following in line with vessel orientation, Clam industry representatives state that their operations require a minimum distance of 2 nm between WTGs, in alignment with the bottom contours, for safe operations (BOEM 2021). Navigating through the WDAs would not be as problematic for for-hire recreational fishing vessels, which tend to be smaller than commercial vessels and do not use large external fishing gear (other than hook and line) that makes maneuverability difficult. However, trolling for highly migratory species (e.g., bluefin tuna, swordfish) may involve deploying many feet of lines and hooks behind the vessel and then following large pelagic fish once they are hooked, which pose additional navigational and maneuverability challenges around WTGs (BOEM 2021).

Fishing vessel operators unwilling or unable to travel through areas where offshore wind facilities are located or deploy fishing gear in those areas may be able to find suitable alternative fishing locations and continue to earn revenue. This could result in increased operating costs (e.g., additional fuel to arrive at more distant locations; additional crew compensation due to more days at sea) and/or lower revenue (e.g., fishing in a less-productive area or for a less-valuable species). However, if, at times, a fishery resource is only available within the wind facility, some fishermen, primarily those using mobile gear, may lose the revenue from that resource for the time the resource is inaccessible. These impacts could remain until conceptual decommissioning of each facility is complete, although the magnitude of the impacts would diminish over time if fishing practices adapt to the presence of structures.

An accurate assessment of the extent of the effects of planned offshore wind energy projects on commercial fisheries and for-hire recreational fishing would depend on project-specific information that is unknown at this time, such as the actual location of offshore activities with lease areas and the arrangement of WTGs. However, it is possible to estimate the amount of commercial fishing revenue that would be “exposed” as a result of offshore wind energy development. Estimates of revenue exposure quantify the value of fishing that occurs in the footprint areas of individual offshore wind farms. Therefore, these estimates represent the fishing revenue that would be foregone if fishing vessel operators opt to no longer fish in these areas and cannot capture that revenue in a different location. Revenue exposure estimates should not be interpreted as measures of actual economic impact. Actual economic impact would depend on many factors—foremost, the potential for continued fishing to occur within the footprint of the wind farm, together with the ecological impact on target species residing within the project areas. Economic impacts also depend on a vessel’s ability to adapt to changing where it fishes. For example, if alternative fishing grounds are available nearby and could be fished at no additional cost, the economic impact would be lower. In addition, it is important to note that there may be cultural and traditional values to fishermen from fishing in certain areas that go beyond expected profit. For example, some fishermen may gain utility from being able to fish in locations that are known to them and also fished by their peers; the presence of other boats in the area can contribute to the fishermen’s sense of safety.

Table 3.5.1-22 shows the annual commercial fishing revenue exposed to offshore wind energy development in the New England and Mid-Atlantic regions by FMP fishery from 2020 through 2030. The amount of revenue at risk increases as proposed offshore wind energy projects are constructed and come online according to the timeline set forth in Table E-4 of Appendix E. The largest impacts in terms of exposed revenue are expected to be in the Sea Scallop, Surfclam/Ocean Quahog, and Mackerel/Squid/Butterfish FMP fisheries. The total average annual exposed revenue over the 2020–2030 period represents around 6% of the total average annual revenue of the FMP fisheries in the New England and Mid-Atlantic regions during the 2008–2019 period (see Table 3.5.1-1). The maximum exposed revenue—which is projected to occur as early as 2026 when construction on the last of the foreseeable projects could begin—represents about 1.0% of the total regional revenue. In general, fisheries do not have high relative revenue intensity within the lease areas compared with nearby waters because lease areas were chosen to reduce potential use conflicts between the wind energy industry and fishermen (Ecology and Environment, Inc. 2013).

With respect to impacts to individual fishing operations, those vessels that derive a small percentage of their total revenue from areas where offshore wind facilities would be located or are able to find suitable alternative fishing locations would likely experience long-term, minor adverse impacts. For those fishing vessels that derive a large percentage of their total revenue from areas where offshore wind facilities would be located, choose to avoid these areas once the facilities become operational, and are unable to find suitable alternative fishing locations, the adverse impacts would be long term and moderate to major. NMFS (2021f) determined for each federally permitted commercial fishing vessel that fished in New England/Mid-Atlantic offshore wind energy development lease areas the percentage of the vessel's total fishing revenue that came from within each area during the 2008–2019 period. It is estimated that over that period, only 0.9% of the vessels that fished in one or more of the lease areas generated more than 50% of their total fishing revenue for the year from one or more of the areas. According to the data presented, in each lease area there was one or more vessels that earned a substantial (> 5%) portion of their revenue from fishing in the area. Some vessels derived more than half of their revenue from fishing in a particular lease area. However, 75% of the vessels fishing in any given lease area derived less than 0.9% of their total revenue from the area. Given that a majority of fishing vessels derive a small percentage of their total revenue from any one lease area or would be able to relocate to other fishing locations, the overall adverse impact of offshore wind energy development on fishing access by commercial fishing vessels is expected to be long term and moderate.

New cable emplacement/maintenance: BOEM estimated that offshore export and inter-array cable emplacements for offshore wind facilities could result in temporary displacement of fishing vessels and disruption of fishing activities in up to 8,603 acres (see Appendix E, Attachment 4). Installation of offshore cables for each offshore wind energy facility would require temporary rerouting of all vessels, including commercial and for-hire recreational fishing vessels, away from areas of active construction.

Construction activities related to offshore wind energy development that disturb the seabed, together with activities that reduce water quality, increase underwater noise, or introduce artificial lighting, could result in a behavioral response from some target species. In turn, these responses could decrease catchability for a fishery, such as fish not biting at hooks or changed swim height. For any given offshore wind energy project, the impacts of behavioral responses on target species catch in commercial and for-hire recreational fisheries are expected to be confined to a small area, and they are expected to end shortly after construction activities end. Details regarding potential lighting and noise impacts to finfish, invertebrates, and EFH are described in Section 3.4.2.2.2 (No Action Alternative).

Table 3.5.1-22. Annual Commercial Fishing Revenue Exposed to Offshore Wind Energy Development in the New England and Mid-Atlantic Regions under the No Action Alternative by FMP Fishery

FMP Fishery ($1,000s)	2020	2021	2022	2023	2024	2025	2026	2027	2028	2029	2030

Other FMPs, non-disclosed species, and non-FMP fisheries*	$0.4	$0.4	$0.4	$271.0	$626.5	$678.5	$943.9	$943.9	$943.9	$943.9	$943.9
All revenues of federally permitted vessels	$0.7	$0.7	$0.7	$1,840.1	$4,328.2	$6,597.7	$9,061.7	$9,061.7	$9,061.7	$9,061.7	$9,061.7

Sources: Developed using data from Table E-3 in Appendix E and data from NMFS (2021e).

Notes: Revenue is adjusted for inflation to 2019 dollars and is estimated based on the annual average revenue by FMP from 2008 through2019. “–“ indicates the value is zero; “$0” indicates the value is positive but less than $500.

* Includes revenues from all FMPs that did not have more than 5 years of data in the period (2008–2019) within a given WEA. Also includes all species not assigned to an FMP, as listed in the table.

Fishermen have raised concerns regarding the behavioral impacts of EMF generated by submarine cables on target fish and invertebrates. In particular, there is apprehension that EMF could slow or deviate migratory species from their intended routes, with subsequent potential problems for populations if they do not reach essential feeding, spawning, or nursery grounds (Kirkpatrick et al. 2017). To date, however, effects on representative sensitive species indicate that although some marine species are observed to respond to EMF, the responses have not risen to the level at which critical impacts on marine organism behavior are reported (BOEM 2018) (see also Section 3.4.2 [Benthic Habitat, Essential Fish Habitat, Invertebrates, and Finfish]). There is no evidence to indicate that EMF from undersea AC power cables adversely affects commercially and recreationally important fish species within the southern New England area (CSA Ocean Sciences Inc. and Exponent 2019).

In addition, as discussed above, a potential effect of the presence of the offshore cables associated with offshore wind energy development is the entanglement and damage or loss of commercial and recreational fishing gear. Economic impacts to fishing operations associated with gear damage or loss include the costs of gear repair or replacement, plus the fishing revenue lost while gear is being repaired or replaced. To avoid these economic impacts, some vessel operators may not trawl or dredge over inter-array or export cables, but this could result in increased operating costs (e.g., additional fuel to arrive at more distant locations; additional crew compensation due to more days at sea) or lower revenue (e.g., fishing in a less-productive area or for a less-valuable species). Overall, the adverse effects to commercial and for-hire fishing vessels as a result of new cable emplacement/maintenance associated with offshore wind energy development are expected to be long term and moderate.

Regulated fishing effort: Regulated fishing effort refers to fishery management measures necessary to maintain maximum sustainable yield under the Magnuson-Stevens Fishery Conservation and Management Act. This includes quota and effort allocation management measures. Offshore wind development could influence regulated fishing effort through two primary pathways: by changing fishing behavior to such an extent that overall harvest levels are not as predicted and by impacting NMFS's scientific surveys on which management measures are based. If NMFS's scientific survey methodologies are not adapted to sample within wind energy facilities, then there could be increased uncertainty in scientific survey results, which would increase uncertainty in stock assessments and quota setting processes (see Section 3.5.7 [Navigation and Vessel Traffic] for additional details). Future spatial management measures may change in response to changes in fishing behavior due to the presence of structures. Impacts on management processes would in turn have short-term or long-term impacts on commercial and for-hire recreational fisheries' operations.

Other offshore wind projects could also require implementation of mitigation and monitoring measures identified in records of decision. Identification and analysis of specific measures is speculative at this time; however, these measures could further impact NMFS's continuing ongoing scientific research surveys or protected species surveys due to increased vessel activity and/or in-water structures. Overall, changes in fishery management measures due to offshore wind energy development are expected to have short-term or long-term, minor to moderate adverse effects to commercial fisheries and for-hire recreational fishing.

Climate change: Impacts on commercial fisheries and for-hire recreational fishing are expected to result from climate change events such as increased magnitude or frequency of storms, shoreline changes, ocean acidification, and water temperature changes. Risks to fisheries associated with these events include habitat or distribution shifts, disease incidence, and risk of invasive species. If these risk factors result in a decrease in catch or increase in fishing costs (e.g., transiting time), the profitability of businesses engaged in commercial fisheries and for-hire recreational fishing would be adversely affected. The catch potential for the temperate Northeast Atlantic is projected to decrease between now and the 2050s (Barange et al. 2018). Hare et al. (2016) predict that climate change would affect northeast fishery species differently. For approximately half of the 82 species assessed, the authors report that overall climate vulnerability is high to very high; diadromous fish and benthic invertebrate species exhibit the greatest vulnerability. In addition, most species included in the assessment have a high potential for a change in distribution in response to projected changes in climate. Adverse effects of climate change are expected for approximately half of the species assessed, but some species are expected to be beneficially affected (e.g., increase in stock distribution or productivity). The intensity of the impacts of climate change to commercial fisheries and for-hire recreational fishing is anticipated to qualify as minor to major for those fishing operations targeting species adversely affected by climate change, and the beneficial impacts are anticipated to qualify as minor to major for those fishing operations targeting species beneficially affected by climate change.

The economies of communities reliant on marine species that are vulnerable to the effects of climate change could be adversely affected. If the distribution of important fish stocks changes, it could affect where commercial and for-hire recreational fisheries are located. Furthermore, coastal communities with fishing businesses that have infrastructure near the shore could be adversely affected by sea level rise (Colburn et al. 2016; Rogers at al. 2019). Because future offshore wind facilities would produce less GHG emissions than fossil fuel–powered generating facilities with similar capacities, the reduction in GHG emissions from the Proposed Action when combined with other future offshore wind projects (or avoidance of increased GHG emissions from equivalent fossil fuel–powered energy production) would result in long-term beneficial impacts to fishing operations that target species adversely affected by climate change. However, the benefits would not be measurable. Section 3.3.1 (Air Quality) describes the expected contribution of offshore wind to climate change.

Conclusions

Under the No Action alternative, BOEM would not approve the COP; Project construction and installation, O&M, and conceptual decommissioning would not occur; and potential impacts on commercial fisheries and for-hire recreational fishing associated with the Project would not occur. However, ongoing and future activities would have continuing temporary to long-term impacts on commercial fisheries and for-hire recreational fishing, primarily through climate change, fisheries management, other offshore development and vessel activity, and port use.

BOEM anticipates that reasonably foreseeable offshore wind activities would have long-term, moderate to major adverse impacts on commercial fisheries and minor to moderate adverse impacts on for-hire recreational fishing. These impacts would occur due to the increased presence of offshore structures (cable protection measures and foundations) that could reduce fishing access and increase the risk of fishing gear damage/loss. The extent of adverse impacts would vary by fishery and fishing operation due to differences in target species, gear type, and predominant location of fishing activity. The impacts could also include long-term beneficial impacts for some for-hire recreational fishing operations due to the artificial reef effect. With mitigation measures implemented across all offshore wind projects, including WTG spacing and orientation measures, offshore cable burial, and financial compensation programs for fishing interests, the **moderate** to **major** impact rating for commercial fisheries could decrease to **moderate**.

As described in Appendix E, Attachment 3, BOEM anticipates that the range of impacts for ongoing activities and reasonably foreseeable activities other than offshore wind would be **moderate** to **major**. The **major** impact rating for some fisheries and fishing operations is primarily driven by regulated fishing effort and climate change.

Considering all the IPFs together, BOEM anticipates that the impacts associated with future offshore wind activities in the geographic analysis area combined with ongoing activities, reasonably foreseeable environmental trends, and reasonably foreseeable activities other than offshore wind would result in an overall **major** adverse impact because some commercial fisheries and fishing operations would experience substantial disruptions indefinitely even if remedial action is taken. This impact rating is primarily driven by climate change, regulated fishing effort, and the presence of offshore structures. **Moderate** impacts on for-hire recreational fishing would occur due to the presence of structures (gear loss, navigational hazard, and space use conflicts). The majority of offshore structures in the geographic analysis area would be attributable to the offshore wind industry. However, given the array of measures available to mitigate impacts of offshore wind projects to commercial fisheries and for-hire recreational fishing, BOEM expects that regulated fishing effort and climate change will continue to be the most impactful IPFs controlling the sustainability of commercial and for-hire recreational fisheries in the area.

3.5.1.2.3 PROPOSED ACTION ALTERNATIVE

Construction and Installation

Potential Impacts to Port Access

The COP considers several port facilities located in New York, Rhode Island, Massachusetts, and Connecticut for offshore Project construction, staging, and fabrication as well as crew transfer and logistics support. Construction of the Project would require a range of vessels, including vessels for transferring crew, transporting heavy cargo, and conducting heavy lifts as well as multipurpose vessels and barges (Jacobs 2021). Although final port selection has not been determined at this time, the list of affected commercial ports could include ports used by commercial fishing vessels and for-hire recreational fishing vessels. For example, fishing ports that could be used during construction, O&M, or conceptual decommissioning of the SFWF or offshore SFEC include Montauk, New London, Point Judith, and New Bedford (Jacobs 2021). During the facility design report phase, SFW would finalize commercial ports to be used to support offshore installation activities for the SFWF and offshore SFEC.

If SFW used multiple ports to support Project construction activities, related congestion impacts in any one port would be reduced. Moreover, SFW would establish a marine coordination center to harmonize Project vessel movements with non-Project vessels and implement communication protocols to minimize adverse impacts on other users of a construction port. As a result, the adverse impact on commercial fisheries and for-hire recreational fishing would be temporary and minor.

Anchoring vessels used in the construction of the Project would pose a navigational hazard to fishing vessels. All impacts would be localized (within a few hundred meters of an anchored vessel) and temporary (hours to days). While anchoring impacts would occur primarily during Project construction, some impacts could also occur during O&M and conceptual decommissioning. Anchoring would lead to temporary and minor impacts to commercial fisheries and for-hire recreational fishing.

Potential Impacts to Fishing Access

The installation of offshore Project components and the presence of construction vessels could temporarily restrict vessel movement and thus transit and harvesting activities in the SFWF and along the offshore SFEC. To safeguard mariners from the hazards associated with construction of the Project, SFW would establish any necessary safety zones during construction around each location where the WTG towers and subsea cables would be installed in navigable waters via consultation under the navigational risk assessment (see Table G-1 in Appendix G). Non-construction vessels would be prohibited from entering into, transiting through, mooring in, or anchoring within the safety zones while construction vessels and associated equipment are working on-site. Non-construction vessels would be able to safely transit around these safety zones. The safety zones implementation dates are pending and would depend on the SFWF Project schedule and duration of the expected construction phase. To allow fishing vessels to alter their plans if needed to avoid impacted areas, SFW would publicize safety zones in advance via a local notice to mariners. In addition, SFW would communicate in advance where and when construction activities are scheduled to take place.

When safety zones are in effect, fishing vessels could either forfeit fishing revenue or relocate to other fishing locations and continue to earn revenue. However, vessels that chose to relocate could incur increased operating costs (e.g., additional fuel to arrive at more distant locations; additional crew compensation due to more days at sea) or lower revenue (e.g., less-productive area, less-valuable species). In addition, if the fishing effort is shifted to areas not routinely fished, conflict with existing users could increase as other areas are encroached. The competition would be higher for fishermen engaged in fisheries with regulations that constrain where fishermen can fish, such as the lobster fishery. The potential for conflict due to fishing displacement is lower among fishermen targeting mobile species such as Atlantic herring, Atlantic mackerel, squid, tuna, and groundfish. In a given year, however, it is possible that the center of the exploitable biomass, or the portion of a fish population available to fishing gear, of one or more of these species would occur within the SFWF or along the offshore SFEC during construction. During these occurrences, fishermen could be adversely impacted because of restricted access to the available fish population within the Project construction area. Given the small size of the offshore areas affected during construction, the likelihood of this co-occurrence in time and space is low, as is the likelihood of increased conflict and competition from a temporary displacement of fishing activities.

It is difficult to predict the ability of fishing operations displaced by Project construction activities to locate alternative fishing grounds that would allow them to maintain revenue targets while continuing to minimize costs. However, the available data suggest the presence of alternative productive fishing grounds in close proximity to the SFWF and offshore SFEC. As described in Section 3.5.1.1.1, Figures C-7 to C-17 in Appendix C show that for many FMP fisheries, the revenue intensity levels in large expanses of ocean within 20 nm of the Lease Area and offshore SFEC corridor are comparable to or higher than those within the two areas.

Based on data presented in Table 3.5.1-9 through Table 3.5.1-16, it is possible to calculate the amount of commercial fishing revenue that would be exposed as a result of construction activities in the SFWF MWA and along the offshore SFEC, assuming that it would come ashore at Beach Lane (the longer of the two SFEC options). As discussed in Section 3.5.1.2.2 (No Action Alternative), estimates of revenue exposure represent the fishing revenue that would be foregone if fishing vessel operators cannot capture that revenue in a different location. Table 3.5.1-23 and Table 3.5.1-24 show the annual revenue at risk in the SFWF MWA and along the offshore SFEC during each year of the 2-year (2021–2022) Project construction phase by FMP fishery and gear type, respectively. The largest impacts in terms of exposed revenue as a percentage of total revenue in the New England and Mid-Atlantic regions would be in the Skate, Bluefish, and Monkfish FMP fisheries. Gillnet-sink, handline, and bottom trawl gear would be the gear types most affected in terms of exposed revenue as a percentage of total revenue in the New England and Mid-Atlantic regions. The annual exposed revenue represents approaches 0.16% of the total average annual revenue of the FMP fisheries in the New England and Mid-Atlantic regions during the 2008–2019 period, as reported in Table 3.5.1-1. The amount of commercial fishing revenue that would be exposed assuming the offshore SFEC comes ashore at Hither Hills was estimated to be $1.37 million across all FMP fisheries, or 7.7% lower than under the Beach Lane option.

Table 3.5.1-23. Annual Commercial Fishing Revenue Exposed in the MWA and Offshore SFEC with Beach Lane Landing during Project Construction by FMP Fishery (2008–2019)

FMP Fishery	Peak Annual Revenue ($1,000s)	Average Annual Revenue ($1,000s)	Average Annual Revenue as a Percentage of Total Revenue from the Mid-Atlantic and New England Regions
American Lobster	$132.0	$65.5	0.07%
Atlantic Herring	$103.2	$37.9	0.15%
Bluefish	$26.7	$9.6	0.76%
Golden and Blueline Tilefish	$36.5	$10.0	0.18%
Highly Migratory Species	$14.7	$2.3	0.10%
Jonah Crab	$15.4	$8.3	0.09%
Mackerel, Squid, and Butterfish	$292.9	$104.9	0.20%
Monkfish	$249.4	$161.8	0.79%
Northeast Multispecies (large-mesh)	$235.2	$131.6	0.18%
Sea Scallop	$935.9	$452.6	0.09%
Skate	$156.3	$95.1	1.28%
Northeast Multispecies (small-mesh)	$54.9	$34.1	0.30%
Spiny Dogfish	$12.4	$5.1	0.17%
Summer Flounder, Scup, Black Sea Bass	$274.7	$206.0	0.52%
Other FMPs, non-disclosed species, and non-FMP fisheries*	$342.6	$164.6	0.19%
All FMP and non-FMP fisheries	$2,123.1	$1,489.3	0.16%

Source: Developed using data from NMFS (2021a).

Notes: Revenue is adjusted for inflation to 2019 dollars. Peak annual revenue is calculated independently for all rows, including the All FMP and non-FMP fisheries row.

* Includes revenue from FMP fisheries that are not listed, from species that were not disclosed within listed FMP fisheries, and from species in non-FMP fisheries harvested by federally permitted vessels.

Table 3.5.1-24. Annual Commercial Fishing Revenue Exposed in the MWA and Offshore SFEC with Beach Lane Landing during Project Construction by Gear

Gear Type	Peak Annual Revenue ($1,000s)	Average Annual Revenue ($1,000s)	Average Annual Revenue as a Percentage of Total Revenue from the Mid-Atlantic and New England Regions
Dredge-clam	*$290.7*	*$98.8*	*0.16%*
Dredge-scallop	$897.0	$432.1	0.09%
Gillnet-sink	$313.8	$237.3	0.79%
Handline	$26.3	$17.2	0.36%
Pot-other	$187.2	$105.5	0.09%
Trawl-bottom	$818.6	$524.5	0.28%

Gear Type	Peak Annual Revenue ($1,000s)	Average Annual Revenue ($1,000s)	Average Annual Revenue as a Percentage of Total Revenue from the Mid-Atlantic and New England Regions
Trawl-midwater	*$118.9*	*$32.4*	*0.17%*
All other gear*	$305.3	$80.6	0.17%
All gear types	$2,124.1	$1,528.3	0.16%

Source: Developed using data from NMFS (2021a).

Notes: Revenue is adjusted for inflation to 2019 dollars. Peak annual revenue is calculated independently for all rows, including the All gear types row.

Gear types shown in *italics* indicate that fewer than 12 years but more than 5 years of data were used to calculate the estimates. Otherwise, estimates are based on 12 years of data.

* Includes revenue from federally permitted vessels using longline gear, seine gear, other gillnet gear, and unspecified gear, as well as listed gear, for years when they cannot be disclosed.

Table 3.5.1-25 shows the annual revenue at risk in the SFWF MWA and along the offshore SFEC (with the Beach Lane landing) during the Project construction phase by port based on data presented in Tables Table 3.5.1-12 through Table 3.5.1-16. The largest impacts in terms of exposed revenue as a percentage of total commercial fishing revenue in the Mid-Atlantic and New England regions would be in the ports of New Shoreham (3.6%), Little Compton (2.8%), and Tiverton (2.2%). As shown in Table 3.5.1-4, the communities in which these ports are located have a low to medium dependence on commercial fishing.

Table 3.5.1-25. Annual Commercial Fishing Revenue Exposed in the MWA and Offshore SFEC with Beach Lane Landing during Project Construction by Port

Port and State	Peak Annual Revenue ($1,000s)	Average Annual Revenue ($1,000s)	Average Annual Revenue as a Percentage of Total Revenue from the Mid-Atlantic and New England Regions
Chilmark/Menemsha, MA	$5.6	$1.3	0.27%
Fairhaven, MA	*$38.5*	*$8.2*	*0.07%*
New Bedford, MA	$645.7	$377.3	0.10%
Fall River, MA	*$5.6*	*$3.1*	*0.28%*
Westport, MA	$30.7	$15.0	1.15%
New Shoreham, RI	*$9.8*	*$3.6*	*3.62%*
Tiverton, RI	*$42.2*	*$25.4*	*2.21%*
Little Compton, RI	$102.8	$56.6	2.84%
Newport, RI	$109.6	$68.3	0.77%
Point Judith, RI	$640.8	$469.1	1.02%
New London, CT	$95.4	$32.9	0.50%
Stonington, CT	$56.7	$33.4	0.32%
Montauk, NY	$358.6	$261.3	1.41%
Shinnecock/Hampton Bays, NY	$85.4	$46.5	0.68%
Cape May, NJ	*$29.3*	*$8.6*	*0.01%*
Point Pleasant, NJ	$48.2	$18.8	0.06%
Hampton, VA	*$7.2*	*$4.7*	*0.03%*
Newport News, VA	*$6.1*	*$2.1*	*0.01%*

Port and State	Peak Annual Revenue ($1,000s)	Average Annual Revenue ($1,000s)	Average Annual Revenue as a Percentage of Total Revenue from the Mid-Atlantic and New England Regions
Beaufort, NC	*$8.6*	*$2.9*	*0.11%*
Other ports*	$175.8	$62.1	0.02%
All New England/Mid-Atlantic ports	$2,124.1	$1,501.2	0.16%

Source: Developed using data from NMFS (2021a).

Notes: Revenue is adjusted for inflation to 2019 dollars. Peak annual revenue is calculated independently for all rows, including the All New England/Mid-Atlantic ports row.

Ports shown in *italics* indicate that fewer than 12 years but more than 5 years of data were used to calculate the estimates. Otherwise, estimates are based on 12 years of data.

* Includes unlisted ports that had landings and data from non-disclosed years from listed ports harvested by federally permitted vessels fishing in the offshore SFEC or in the MWA.

Revenue exposure estimates should not be interpreted as measures of actual economic impact. Actual economic impact would depend on many factors—foremost, the ability of vessels to adapt to changing where they fish, together with the ecological impact on target species residing within the project areas (see Potential Impacts to Target Species Catch below). Fishing vessel operators may be able to find suitable alternative fishing locations and continue to earn revenue. However, as noted above, this shift in fishing effort could result in increased operating costs and/or lower revenue.

As described in Section 3.5.1.2.2 (No Action Alternative), it is also important to note that there may be cultural and traditional values to fishermen from fishing in certain areas that go beyond expected profit. For instance, some fishermen may gain utility from being able to fish in locations that are known to them and also fished by their peers; the presence of other boats in the area can contribute to the fishermen's sense of safety.

The amount of fishing activity that could be affected during Project construction as a result of reduced fishing access is a small fraction of the amount of fishing activity in the New England and Mid-Atlantic regions as a whole. As described above, the annual exposed revenue represents about 0.16% of the total average annual revenue of the FMP fisheries in the New England and Mid-Atlantic regions during the 2008–2019 period. Nevertheless, some individual operators of commercial fishing or for-hire recreational fishing businesses could experience adverse economic impacts as a result of reduced fishing access. For those fishing vessels that choose to avoid areas closed by safety zones during Project construction, historically derived a large percentage of their total revenue from these areas, and are unable to find suitable alternative fishing locations, the adverse impacts on any given fishing operation would be temporary and major.

As discussed in the description of the SFWF Lease Area and offshore SFEC in Section 3.5.1.1.1, an average of 249 vessels per year fished in the SFWF Lease Area over the 2008–2019 period. Three quarters of the vessels that fished in the Lease Area derived less than 0.2% of their total annual fishing revenue from the area. From 2008 through 2019, the average percentage of vessels that derived 5% or more of their total fishing income from the Lease Area was around 2%. During any given year, the highest percentage of vessels that derived 5% or more of their revenue was 5%, while the lowest was less than 1%. In short, some vessels depended heavily on the Lease Area, but most vessels derived a small percentage of their total annual revenue from the area.

Those fishing vessels that derive a small percentage of their total revenue from areas where safety zones would be in effect or are able to relocate to other fishing locations and continue to earn revenue would experience temporary, minor adverse impacts. Given that these vessels would likely constitute a large majority of affected vessels during Project construction, the adverse impact on fishing access by commercial fishing vessels would be temporary and moderate.

It is estimated that during Project construction, the revenue exposure for any given port would not exceed 3.62% of its total revenue from the mid-Atlantic and New England regions (Table 3.5.1-25). Considering this low revenue of risk across ports, together with the small number of vessels that depend heavily on the Lease Area, the impacts to other fishing industry sectors, including seafood processors and distributors and shoreside support services, are expected to be temporary and minor to moderate.

Potential Impacts to Fishing Gear

As discussed above, non-construction vessels would be prohibited from entering into, transiting through, mooring in, or anchoring within the safety zones while construction vessels and associated equipment are working on- site. As described in Appendix B (South Fork Wind Farm Fisheries Communication and Outreach Plan) of Jacobs (2021), SFW has developed a financial compensation policy to be used when interactions between the fishing industries and Project activities or infrastructure cause undue interference with fishing gear. The use of this policy for qualifying gear interactions that may occur during construction is considered part of the Proposed Action and would reduce any adverse impacts to temporary, negligible to minor.

Potential Impacts to Target Species Catch

During Project construction, temporary or permanent habitat alterations could occur, but the impact of these alterations on invertebrate and fish populations would be negligible to minor (see Section 3.4.2 [Benthic Habitat, Essential Fish Habitat, Invertebrates, and Finfish]). Construction activities that disturb the seabed could result in the injury or mortality of sedentary species such as sea scallops and surfclams. Given that the area affected by seafloor disturbance would be a small fraction of the available habitat, the impact to sedentary species habitat would not be measurably altered compared to the environmental baseline. Therefore, the number of individual organisms affected would also be limited. Moreover, the populations of these species are expected to recover quickly through migration and recolonization from adjacent, undisturbed habitat. Therefore, the adverse impacts to fisheries that target these species would be negligible to minor.

Construction activities that disturb the seabed, together with activities that reduce water quality, increase underwater noise, or introduce artificial lighting, could result in a behavioral response from some target species (see Section 3.4.2 [Benthic Habitat, Essential Fish Habitat, Invertebrates, and Finfish]). In turn, these responses could decrease catchability for a fishery, such as fish not biting at hooks or changing swimming behaviors. The impacts of these behavioral responses on target species catch are expected to be confined to a small area, and they are expected to end shortly after construction activities end. Other impacts, such as vessel and pile-driving noise, could cause some target species to temporarily move away from the source and disperse to other areas. These species are expected to return to the area after the construction phase. Given the short-term impact and relatively small area involved, behavioral responses that could change target species catchability are expected to have a minor adverse impact on commercial fisheries and for-hire recreational fishing.

Construction activities could overlap with the spawning habitat and/or spawning season of a number of target species, leading to potential short-term or long-term adverse impacts to the productivity/recruitment success of these species (see Section 3.4.2 [Benthic Habitat, Essential Fish Habitat, Invertebrates, and Finfish]). Therefore, the adverse impact on the catch of commercial and for-hire recreational fisheries targeting these affected species would be short term or long term and moderate.

Operations and Maintenance

Potential Impacts to Port Access

In comparison to the construction phase, the O&M of the Project would require a more limited number of vessels (approximately six) (Jacobs 2021), with most vessels used for routine O&M. Given the relatively low number of Project vessel trips anticipated during operations, the increase in vessel traffic in ports during operation would be small. Therefore, the adverse impacts on the accessibility of port facilities by commercial fishing vessels and for-hire recreational fishing vessels would be long term but negligible.

Potential Impacts to Fishing Access

Under current regulations, the USCG is responsible for determining any type of safety or exclusionary zone around any structure placed in the open ocean. The USCG has stated that it does not plan to create exclusionary zones around offshore wind facilities, with the exception of safety zones during construction and conceptual decommissioning (BOEM 2018). However, the presence of the SFWF WTGs could result in de facto exclusion if fishing vessel operators are not—or perceive that they are not—able to safely navigate the area around the wind turbines.

The navigational safety risk assessment prepared for the Project indicates that it is technically possible to fish and transit through the SFWF (DNV-GL 2021). The WTG layout at the SFWF is designed to provide at least 1 nm of sea room between WTGs which provides sufficient room for most vessels to transit through and safely maneuver within the SFWF (DNV-GL 2021). However, BOEM is cognizant that maneuverability within the SFWF may vary depending on factors such as vessel size, fishing gear or method used, or environmental conditions. In addition, operating within the SFWF when other vessels and gear types are present may restrict vessel maneuverability.

Because of the height of wind turbines above the ocean surface, they would be visually detectable at a considerable distance during the day and easily detected by vessels equipped with radar regardless of the time of day. To further ensure navigational safety, all structures would have appropriate markings and lighting in accordance with USCG and International Association of Marine Aids to Navigation and Lighthouse Authorities guidelines, and wind turbine locations would be charted by NOAA and could include physical or virtual AIS at each turbine. Some fishing vessels operating in or near the SFWF may experience radar clutter and shadowing. Most instances of interference can be mitigated through the proper use of radar gain controls (DNV-GL 2021). See also Section 3.5.6 (Navigation and Vessel Traffic).

Notwithstanding these safety measures, some fishermen have commented that because of safety considerations, they would not enter an offshore wind array during inclement weather, especially during low-visibility events (Kirkpatrick et al. 2017). Moreover, mechanical problems, such as loss of steerage, could result in an allision with a WTG as the vessel drifts during repair (DNV-GL 2021). Aside from these potential navigational issues, some commercial fishermen may avoid the SFWF if large numbers of recreational fishermen are drawn to the area by the prospect of higher catches. According to ten Brink and Dalton (2018), the influx of recreational fishermen into the BIWF caused some commercial fishermen to cease fishing in the area because of vessel congestion and gear conflict concerns. In addition, if these concerns cause commercial fishermen to shift their fishing effort to areas not routinely fished, conflict with existing users could increase as other areas are encroached. In general, the potential for conflict among commercial fishermen due to fishing displacement may be higher for fishermen engaged in fisheries that have regulations that constrain where fishermen can fish, such as the lobster fishery. However, the potential for vessel congestion and gear conflict may also increase if mobile species targeted by commercial fishermen, such as Atlantic herring, Atlantic mackerel, squid, tuna, and groundfish, are attracted to the SFWF, and fishermen targeting these species concentrate their fishing effort in offshore wind farm lease areas as a result.

It is also important to note that there are also cultural and traditional values to fishermen from fishing that go beyond expected profit. For example, it is advantageous for fishermen to be able to fish in locations that are known to them and also fished by their peers. Also, the presence of other boats in the area can contribute to the fishermen's sense of safety. Some fishermen may choose to not fish in the area due to their perception of risk. Impacts on commercial fisheries may affect the economic health, as well as the cultural identity and values and therefore the well-being, of individuals and communities that identify as "fishing" communities. Impacts to cultural and traditional values are not quantifiable but are qualitatively considered when assessing the impacts of the Proposed Action.

Based on data presented in Table 3.5.1-9 through Table 3.5.1-12, it is possible to calculate the amount of commercial fishing revenue that would be exposed as a result of O&M activities in the SFWF. The impacts to fishing access in the offshore SFEC area during O&M are expected to be negligible because SFW would bury all cables to a target depth of 4 to 6 feet beneath the seabed (Jacobs 2021:3-34). The largest impacts in terms of exposed revenue as a percentage of total revenue in the New England and Mid-Atlantic regions would be in the Skate FMP and Monkfish FMP fisheries. The annual exposed revenue represents about 0.02% of the total average annual revenue of the FMP fisheries in the New England and Mid-Atlantic regions during the 2008–2019 period, as reported in Table 3.5.1-1. Gillnet-sink gear would be the gear type most affected in terms of exposed revenue as a percentage of total revenue in the New England and Mid-Atlantic regions. With respect to ports, the largest impacts in terms of exposed revenue as a percentage of total commercial fishing revenue in the Mid-Atlantic and New England regions would be in the ports of Little Compton (1.3%) and Westport (0.8%). As shown in Table 3.5.1-4, the communities in which these ports are located have a low to medium dependence on commercial fishing. As discussed above, revenue exposure estimates should not be interpreted as measures of actual economic impact. The actual economic impact to commercial fisheries during Project O&M would depend on many factors—foremost, the potential for continued fishing to occur in the SFWF. Fishing vessel operators unwilling or unable to travel through the SFWF or deploy fishing gear in the area may be able to find suitable alternative fishing locations and continue to earn revenue. However, this shift in fishing effort could result in increased operating costs (e.g., additional fuel to arrive at more distant locations; additional crew compensation due to more days at sea) or lower revenue (e.g., fishing in a less-productive area or for a less-valuable species).

It is difficult to predict the ability of fishing operations displaced by Project O&M activities to locate alternative fishing grounds that would allow them to maintain revenue targets while continuing to minimize costs. However, the available data suggest the presence of alternative productive fishing grounds in close proximity to the SFWF and offshore SFEC. As described in Section 3.5.1.1.1, Figures C-7 to C-17 in Appendix C show that for many FMP fisheries, the revenue intensity levels in large expanses of ocean within 20 nm of the Lease Area and offshore SFEC corridor are comparable to or higher than those within the two areas.

As described above, the amount of fishing activity that could be affected during Project O&M is a small fraction of the amount of fishing activity in the New England and Mid-Atlantic regions as a whole. However, for those fishing vessels that choose to avoid the SFWF, historically derived a large percentage of their total revenue from the area, and are unable to find suitable alternative fishing locations, the adverse impacts would be long term and major. While a small number of commercial fishing vessels fish heavily in the Lease Area, three quarters of the vessels fishing in the area derived less than 0.2% of their total revenue from the area during the 2008–2019 period (see description of SFWF Lease Area and Offshore SFEC in Section 3.5.1.1.1). From 2008 through 2019, the average percentage of vessels that derived 5% or more of their total fishing income from the Lease Area was around 2%. During any given year, the highest percentage of vessels that derived 5% or more of their revenue was 5%, while the lowest was less than 1%. In short, some vessels depended heavily on the Lease Area, but most vessels derived a small percentage of their total annual revenue from the area. Therefore, during Project O&M the adverse impact on fishing access by commercial fishing vessels would be long term and moderate overall but up to major for a relatively small number of vessels.

It is estimated that during Project O&M, the revenue exposure for any given port would not exceed 1.3% of its total commercial fishing revenue from the mid-Atlantic and New England regions (Table 3.5.1-12). Considering this low revenue of risk across ports, together with the small amount of vessels and fishing activity that would be affected during Project O&M, the impacts to other fishing industry sectors, including seafood processors and distributors and shoreside support services, would be long term **minor** to **moderate**.

Potential Impacts to Fishing Gear

A potential effect of the offshore cables and wind turbines is the entanglement and damage or loss of commercial and recreational fishing gear. Economic impacts to fishing operations associated with gear damage or loss include the costs of gear repair or replacement, together with the fishing revenue lost while gear is being repaired or replaced.

The Project would result in the installation of 139 miles (224 km) of offshore export cable and 28 miles (45 km) of inter-array cable. SFW would reduce the occurrence of accidental snagging of fishing gear by burying all cables to a target depth of 4 to 6 feet beneath the seabed (Jacobs 2021:3-34). In areas where seabed conditions might not allow for cable burial, other methods of cable protection would be employed, such as articulated concrete mattresses or rock placement. This additional cable protection would be used for up to 2% of the offshore SFEC, where burial depth may be less than 4 feet, and for seven locations where the offshore SFEC would cross utility crossings (Jacobs 2021). Although it is possible that cables could become uncovered during extreme storm events or other natural occurrences, burial to target depth would minimize the risk of exposure and potential damage. SFW would also conduct remote surveys of cable placements to confirm cables remain buried and that rock placement and concrete mattresses remain secured and undamaged. Surveys would be conducted by SFW annually along all cable placements for the first 3 years and biennially thereafter. This survey would identify the need for any remedial action by SFW to re-secure cables. SFW would provide BOEM with cable monitoring reports within 45 calendar days following inspection as well as after major storm events.

Long-term, minor to moderate adverse impacts to some commercial fishing operations—in particular, operations that employ mobile bottom-tending gear (such as bottom trawl or dredge)—are expected because of the potential for gear damage or loss from the Project. Given the small offshore footprint of the SFWF and offshore SFEC, the number of adversely affected fishing operations would be small. Additionally, the WTGs would be laid out in rows that run from east to west in order to 1) avoid gear conflict between fishermen who use mobile gear and those who use fixed gear, and 2) create predictable lanes within which boats with mobile gear can fish. As stated in Table G-2 in Appendix G, SFW is committed to a spacing of approximately 1.15 miles (1.8 km), or 1 nm, between turbines. In addition, as described in Appendix B (South Fork Wind Farm Fisheries Communication and Outreach Plan) of Jacobs (2021), SFW has developed a financial compensation policy for use when interactions between the fishing industries and Project activities or infrastructure cause undue interference with fishing gear. The use of this financial compensation program for damage to or loss of fishing gear during operation would reduce any moderate impacts to negligible or minor levels.

Potential Impacts to Target Species Catch

During Project O&M, temporary or permanent habitat alterations could occur (see Section 3.4.2 [Benthic Habitat, Essential Fish Habitat, Invertebrates, and Finfish]). The presence of the WTG foundations and associated scour protection would convert existing sand or sand with mobile gravel habitat to hard bottom, which in turn would reduce the habitat for target species that prefer soft-bottom habitat (e.g., squid, summer flounder, and surfclams). In total, the Project would result in an estimated 203 acres (0.82 km^2) of seabed disturbance as a result of the addition of scour protection and installation of offshore export and inter-array cables. Given the small footprint of the SFWF and offshore SFEC, any localized adverse impacts on target species populations from habitat alteration would have a negligible to minor effect on the catch of for-hire recreational and commercial fisheries.

The WTG foundations and associated scour protection could also produce an artificial reef effect and attract finfish and invertebrates, thereby providing new opportunity for for-hire recreational fishing businesses and certain types of commercial fishing. Considering the addition of scour protection, the maximum footprint of each foundation would be approximately 49,087 square feet (Jacobs 2021). Although the effects of artificial reefs on species abundance are uncertain, aggregation of species could increase the catchability of target species (Kirkpatrick et al. 2017). Smythe et al. (2021) found that the enhanced fishing experience created by the BIWF led to the establishment of new for-hire recreational fishing businesses and benefited existing ones. With respect to the Project, it is expected that the reef effect of the WTG foundations would have long-term, negligible to minor beneficial impacts to commercial fisheries and for-hire recreational fishing, depending on the extent to which the foundations attract targeted species. Additionally, species may alter their migratory behaviors due to the presence of food or shelter associated with the structures. The potential for disruption of inshore to offshore migratory patterns of important species like lobster and black sea bass has been identified as a topic of concern (see Section 3.4.2 [Benthic Habitat, Essential Fish Habitat, Invertebrates, and Finfish]). This potential effect would have long-term, negligible to minor adverse impacts to commercial fisheries and for-hire recreational fishing, depending on the extent to which the foundations alter the migratory behaviors of targeted species.

Fishermen have raised concerns regarding the behavioral impacts of EMF generated by submarine cables on target fish and invertebrates. In particular, there is apprehension that EMF could slow or deviate migratory species from their intended routes, with subsequent potential problems for populations if they do not reach essential feeding, spawning, or nursery grounds (Kirkpatrick et al. 2017). To date, however, effects on representative sensitive species indicate that although some marine species are observed to respond to EMF, the responses have not risen to the level at which critical impacts on marine organism behavior are reported (BOEM 2018). No evidence indicates that EMF from undersea AC power cables adversely affects commercially and recreationally important fish species within the southern New England area (CSA Ocean Sciences Inc. and Exponent 2019). To mitigate any possible effects on target fish and invertebrates, all cables would be wrapped in a sheath that eliminates direct electric fields and reduces magnetic and induced-electric fields (Jacobs 2021). Consequently, EMF from Project cables are expected to have long-term, negligible to minor impacts on commercial and for-hire recreational fisheries (see also Section 3.4.2 [Benthic Habitat, Essential Fish Habitat, Invertebrates, and Finfish]).

Noise caused by vessels during SFWF maintenance could have temporary and minor adverse impacts on commercial fisheries and for-hire recreational fishing similar to the noise effects described for the construction phase.

Conceptual Decommissioning

Conceptual decommissioning of the SFWF and offshore SFEC would have similar impacts on commercial fisheries and for-hire recreational fishing as construction. Within 2 years of cancellation, expiration, or other termination of the Lease, the lessee would remove or decommission all facilities, projects, cables, pipelines, and obstructions and clear the seabed of all obstructions created by activities on the leased area (Jacobs 2021:1-19). Any cut and cleared cables would typically have the exposed ends weighted with clump anchors so that the cables cannot be snagged by fishing gear. Removal of structures that produce an artificial reef effect would result in loss of any beneficial fishing impacts that could have occurred during O&M.

Cumulative Impacts

Port utilization and traffic: The Project would add vessel traffic in ports and resulting delays or restrictions in access to ports due to increased vessel use to conditions under the No Action alternative. This would result in localized, short-term, minor incremental impacts on commercial fisheries and for-hire recreational fisheries. BOEM estimates a peak of 379 vessels due to offshore wind project construction and operations over a 10-year time frame, plus an additional 13 vessels from the Proposed

Action. However, future offshore wind projects would result in only a small increase in vessel traffic and the risk of vessel collisions is expected to remain low. Therefore, cumulative impacts associated with the Project when combined with past, present, and reasonably foreseeable future activities would be minor.

Impacts associated with noise and fish populations are discussed in Section 3.4.2.2.3 (Proposed Action Alternative).

Anchoring: The Proposed Action would incrementally add 821 acres of anchoring/mooring to conditions under the No Action alternative. This would result in localized, temporary, minor incremental impacts on commercial fisheries and for-hire recreational fisheries. BOEM estimates a total of 2,448 acres of anchoring and mooring-related disturbance for the Proposed Action plus all other future offshore wind projects. All impacts would be localized (within a few hundred meters of an anchored vessel) and temporary (hours to days). Therefore, the Proposed Action when combined with past, present, and reasonably foreseeable future activities would result in minor impacts to commercial fisheries and for-hire recreational fishing.

Presence of structures and new cable emplacement/maintenance: As summarized in Table E-4 in Appendix E and discussed in Section 3.5.1.2.2 (No Action Alternative), offshore wind energy development could result in the construction of 1,869 additional offshore foundations through 2030. The Project would account for up to 16 of these structures (15 WTGs and one OSS). In addition, up to 6,266 miles (8,311 acres of seabed disturbance) of offshore export and inter-array cables could be installed to support future offshore wind projects (see Appendix E Attachment 4). The Project would add an additional 82.5–86.9 miles of cable (913 acres) to this total. Installation of offshore cables would require temporary rerouting of all vessels, including commercial and for-hire recreational fishing vessels, away from areas of active construction.

As a result of the addition of these new structures and cables in the Lease Area and offshore SFEC, the Proposed Action could result in localized, temporary impacts to commercial fisheries and for-hire recreational fishing due to potential increased space use conflicts, navigational hazards, entanglement, and gear loss/damage.

Fishing revenue would be foregone if these impacts cause fishing vessel operators to no longer fish in these areas, and they cannot capture that revenue in a different location. If the Project is not included, the total commercial fishing revenue exposed at the end of the Project development timeline for all planned offshore wind energy lease areas in the New England and Mid-Atlantic regions is estimated to be about $9.06 million per year by 2026 (Table 3.5.1-22). Based on the data in Table 3.5.1-9, the Proposed Action would increase the commercial fishing revenue at risk to $9.25 million per year, an increase of approximately 2.0%, which represents a minor, incremental impact.

Construction activities that disturb the seabed, together with activities that reduce water quality, increase underwater noise, or introduce artificial lighting, could result in a behavioral response from some target species. In turn, these responses could decrease catchability for a fishery, such as fish not biting at hooks or changed swim height. For any given offshore wind energy project, the impacts of behavioral responses on target species catch in commercial and for-hire recreational fisheries are expected to be confined to a small area, and they are expected to end shortly after construction activities end.

Temporary or permanent habitat alterations could also occur during offshore wind farm operation. The presence of the WTG foundations and associated scour protection would convert existing sand or sand with mobile gravel habitat to hard bottom, which in turn would reduce the habitat for target species that prefer soft-bottom habitat (e.g., squid, summer flounder, and surfclams) and increase the habitat for target species that prefer hard-bottom habitat (e.g., lobster, striped bass, black sea bass, and cod). Where WTG foundations and associated scour protection produce an artificial reef effect and attract finfish and invertebrates, the aggregation of species could increase the catchability of target species (Kirkpatrick et al. 2017).

Regulated fishing effort: The cumulative impacts of regulation of fishing effort to commercial fisheries and for-hire recreational fishing would be the same as under the No Action alternative (see Table 3.11-1 in Attachment 3 of Appendix E). The Proposed Action would not alter these impacts.

Climate change: The types of impacts from global climate change to commercial fisheries and for-hire recreational fishing described for the No Action alternative would occur under the Proposed Action (see Table 3.11-1 in Attachment 3 of Appendix E), but the Proposed Action could also contribute to a long-term net decrease in GHG emissions. This difference may not be measurable, but would be expected to help reduce climate change impacts, resulting in a minor to moderate incremental impact.

Conclusions

Project construction and installation, O&M, and conceptual decommissioning could alter port and fishing access, as well as affect transit and harvesting activities, fishing gear interactions, and target species catch. BOEM anticipates that the adverse impacts of the Proposed Action on commercial fisheries and for-hire recreational fishing would vary by fishery and fishing operation due to differences in target species, gear type, and predominant location of fishing activity. It is conceivable that some of the small number of fishing operations that derive a large percentage of their total revenue from areas where Project facilities would be located will choose to avoid these areas once the facilities become operational. In the event that these fishing operations are unable to find suitable alternative fishing locations, they could experience long-term, substantial disruptions. However, it is estimated that the majority of vessels would only have to adjust somewhat to account for disruptions due to impacts. In addition, the impacts of the Proposed Action could include long-term, **minor** beneficial impacts for some for-hire recreational fishing operations due to the artificial reef effect. Therefore, BOEM expects that the impacts resulting from the Proposed Action alone would be **negligible** to **major**, depending on the fishery and fishing operation, with the overall impact to commercial fisheries and for-hire recreational fishing being **moderate**.

Considering all the IPFs together, BOEM anticipates that the overall impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would result in an overall **major** adverse impact because some commercial and for-hire recreational fisheries and fishing operations would experience substantial disruptions indefinitely even if remedial action is taken. This impact rating is primarily driven by climate change, regulated fishing effort, and the presence of offshore structures. The majority of offshore structures in the geographic analysis area would be attributable to the offshore wind industry. However, given the array of measures available to mitigate impacts of offshore wind projects to commercial fisheries and for-hire recreational fishing, BOEM expects that regulated fishing effort and climate change will continue to be the most impactful IPFs controlling the sustainability of commercial and for-hire recreational fisheries in the area.

3.5.1.2.4 VESSEL TRANSIT LANE ALTERNATIVE

The overall effect of elimination of WTGs within a 4-nm-wide vessel transit lane would be a lower estimated exposed commercial fishing revenue during Project construction and operations in comparison to the Proposed Action. Based on data from NMFS (2021a), it is estimated that the revenue at risk under the Transit alternative across all FMP fisheries during the construction phase would be about 5% lower than under the Proposed Action. During O&M, the revenue at risk would be around 45% lower than under the Proposed Action.

Although the Transit alternative would reduce the number of WTGs and their associated inter-array cables, BOEM expects that the impacts resulting from the alternative alone would be negligible to major, depending on the fishery and fishing operation, with the overall impact to commercial fisheries and for-hire recreational fishing being moderate. In addition, the alternative could include long-term, minor beneficial impacts for some for-hire recreational fishing operations due to the artificial reef effect.

Cumulative Impacts

If the Transit alternative is implemented, impacts related to allision and collision risk could be reduced throughout all lease areas. However, some commercial and recreational fishing and boating could still occur within the transit lanes, and recreational fishing vessels could congregate alongside the transit lanes, possibly increasing risks of collisions and allisions in these areas. Additionally, implementation of all recommended transit lanes could require offshore wind developers to alter their site plans to accommodate the six transit corridors, thereby potentially causing construction delays. These delays could create increased adverse cumulative effects to commercial fisheries and for-hire recreational fishing if they result in an increased level of overlapping construction activities. However, because the impacts to commercial fisheries and for-hire recreational fishing due to climate change, regulated fishing effort, and the presence of structures would not be measurably different under the Transit alternative, the cumulative impacts to commercial fisheries and for-hire recreational fishing would be major.

Conclusions

Although the Transit alternative would reduce the number of WTGs and their associated inter-array cables, BOEM expects that the impacts resulting from the alternative alone would be similar to the Proposed Action: **negligible** to **major**, depending on the fishery and fishing operation, with the overall impact to commercial fisheries and for-hire recreational fishing being **moderate**.

The overall impacts of the Transit alternative when combined with past, present, and reasonably foreseeable activities would therefore be the same level as under the Proposed Action: **major**.

3.5.1.2.5 FISHERIES HABITAT IMPACT MINIMIZATION ALTERNATIVE

Because it would reduce the number of WTG sites, the Habitat alternative under either layout option would improve the ability of commercial fishing vessels to access the waters around the Lease Area relative to the Proposed Action. Consequently, the level of commercial fishing revenue exposed to offshore wind energy development would be less than under the Proposed Action.

The Habitat alternative under either layout option is not anticipated to lead to a measurable change in impacts to invertebrates and finfish targeted by commercial fisheries and for-hire recreational fishing compared to impacts under the Proposed Action (see Section 3.4.2 [Benthic Habitat, Essential Fish Habitat, Invertebrates, and Finfish]). A reduction in the number of WTGs would diminish the artificial reef effect of Project structures during O&M, but the decrease in these beneficial effects to for-hire recreational fishing would likely be negligible. Therefore, the impact to commercial fisheries and for-hire recreational fishing would not be measurably different than under the Proposed Action: negligible to major, depending on the fishery and fishing operation, with the overall impact to commercial fisheries and for-hire recreational fishing being moderate. In addition, the alternative could include long-term, minor beneficial impacts for some for-hire recreational fishing operations due to the artificial reef effect.

Cumulative Impacts

As noted above, the Habitat alternative under either layout option would result in incremental impacts to commercial fisheries and for-hire recreational fishing at quantities and durations similar to, or slightly reduced from, the Proposed Action. Therefore, the cumulative impacts to commercial fisheries and for-hire recreational fishing would be similar: major.

Conclusions

Although the Habitat alternative under either layout option would reduce the number of WTGs and their associated inter-array cables, BOEM expects that the impacts resulting from the alternative alone would be similar to the Proposed Action: **negligible** to **major**, depending on the fishery and fishing operation, with the overall impact to commercial fisheries and for-hire recreational fishing being **moderate**. In addition, the alternative could include long-term, **minor** beneficial impacts for some for-hire recreational fishing operations due to the artificial reef effect.

The overall impacts of the Habitat alternative when combined with past, present, and reasonably foreseeable activities would therefore be the same level as under the Proposed Action: **major**.

3.5.1.3 Action Alternative Comparison

As discussed above, the impacts associated with Proposed Action alone do not change substantially under other evaluated action alternatives. Although the number of WTGs and their associated inter-array cables varies slightly, BOEM expects that the overall impact to commercial fisheries and for-hire recreational fishing would be **moderate** for all action alternatives. This impact rating is driven mostly by changes to fish distribution/availability due to ongoing climate change, reduced stock levels due to ongoing fishing mortality, and permanent impacts due to the presence of structures (cable protection measures and foundations).

In context of reasonably foreseeable environmental trends and planned actions, all action alternatives would occur within the same overall environment (e.g., ongoing and future activities). Therefore, impacts would only vary if the alternatives' incremental contributions differ. However, as noted above, BOEM expects that the incremental impact from any action alternative would be similar. Therefore, the overall impact of any action alternative to commercial fisheries and for-hire recreational fishing when combined with past, present, and reasonably foreseeable activities would be **major**, because the fishing industry would experience unavoidable disruptions beyond what is normally acceptable, but mitigation, including financial compensation and uniform spacing and layout across adjacent projects, could reduce impacts if adopted for future offshore wind projects.

3.5.1.4 Mitigation

Monitoring of the SFEC cable and cable protection, where applicable, would further reduce the expected negligible to moderate impacts on commercial fisheries by ensuring that the cable remains buried and that cable protection is intact, thereby reducing the potential for mobile fishing gear hangs. See Table G-2 in Appendix G for details. In addition, as described in Appendix B (South Fork Wind Farm Fisheries Communication and Outreach Plan) of Jacobs (2021), SFW has also developed a financial compensation policy for use when interactions between the fishing industries and Project activities or infrastructure cause undue interference with fishing gear.

3.5.2 Cultural Resources

The Cultural Resources section addresses marine and terrestrial archaeological and other visually sensitive cultural resources located within the viewshed of Project elements, also referred to as viewshed resources. All other visual resources are addressed in the Visual Resources section (Section 3.5.9).

3.5.2.1 Affected Environment

3.5.2.1.1 MARINE RESOURCES

BOEM defines the area of potential effects (APE) for the marine resources geographic analysis area (or APE for marine resources) as the depth and breadth of the seabed potentially impacted by bottom-disturbing activities within the SFWF and associated MWA and the offshore SFEC corridor (Figure E-11). A phase I marine archaeological survey and assessment of the marine resources geographic analysis area was conducted between 2017 and 2020 (Gray & Pape 2020, 2021). The investigation included a high-resolution geophysical marine survey using a magnetometer/gradiometer, a side-scan sonar, a multibeam echo-sounder, and both shallow and medium penetration sub-bottom profilers followed by an archaeological vibracoring and geoarchaeological analysis. Four shipwreck archaeological sites were identified during the survey within the SFWF MWA (Gray & Pape 2020, 2021; Table 3.5.2-1). No historic period marine archaeological resources were identified within the SFEC. The survey additionally identified eight ancient submerged landform features (Table 3.5.2-2). Three of those features are located within the SFWF MWA and five are located within the SFEC.

These ancient submerged landform features are discrete and discontinuous locations that may contain preserved evidence of formerly terrestrial landscape features that have survived erosion during marine transgression. Although these features exhibit high archaeological potential, no evidence of human occupation associated with the ancient submerged landform features was identified in core samples taken during the submerged cultural resources investigation (Gray & Pape 2020:6-5). These features may derive their significance from reasons other than their archaeological potential, however, such as their potential contribution to a broader culturally significant landscape.

Table 3.5.2-1. Shipwreck Archaeological Sites Identified within the Marine Resources Geographic Analysis Area

Contact Number	Location	Site Dimensions (feet)	Description
Contact 28	SFWF MWA	16.0 × 5.5 × 4.5	An apparent bow and wheelhouse area
Contact 32	SFWF MWA	30.0 × 7.5 × 2.8	A well contained and articulated vessel
Contact 30	SFWF MWA	33.6 × 22.0 × 1.0	Debris scatter with linear and rectangle components
Contact 112	SFWF MWA	15.3 × 11.8 × 1.8	Apparent wreck scatter; "appears unnatural due to its linearity"

Source: Gray & Pape (2020:Table 5-1; Table 5-2; Table 6-1; pp. 5-10, 5-12, 6-1).

Table 3.5.2-2. Ancient Submerged Landform Features Identified within the Marine Resources Geographic Analysis Area

Designation	Location	Description
SFEC-CF-13	SFEC MWA	Ancient submerged landform; "single paleo-stream valley"
SFEC-CF-9	SFEC MWA	Ancient submerged landform; "single paleo-stream valley"
SFEC-CF-7	SFEC MWA	Ancient submerged landform; "single paleo-stream valley"
SFEC-CF-5	SFEC MWA	Ancient submerged landform; "two paleo-stream valleys"
SFEC-CF-3	SFEC MWA	Ancient submerged landform; "two similar sized paleo-stream valleys"
SFWF-PL-1	SFWF MWA	Ancient submerged landform; intact terrestrial surface underlying a marsh and or estuary deposit"

Designation	Location	Description
SFWF-PL-2	SFWF MWA	Ancient submerged landform; intact terrestrial surface underlying a marsh and or estuary deposit
SFWF-PL-3	SFWF MWA	Ancient submerged landform: “oxbow cut-off stream”

Source: Gray & Pape (2020:Table 5-7, Table 5-12; Table 5-15; Table 6-2; Table 6-3; Table 6-4; pp. 5-34, 5-35, 5-36, 5-37, 5-74, 5-75, 5-76, 5-77, 5-80, 6-3, 6-5, 6-7).

3.5.2.1.2 TERRESTRIAL RESOURCES

A phase I terrestrial archaeological survey was conducted within the SFEC corridor, SFEC landfall locations, and interconnection facility, whereas a Phase IA desktop assessment was completed for the O&M facility locations (EDR 2020a, 2020b; Jacobs 2021). BOEM defines the APE for terrestrial resources by the depth and breadth of terrestrial areas potentially impacted by any ground-disturbing activities within the footprint of the export cable landings, SFEC onshore corridor, interconnection facility, and O&M facilities (see Table 2.1.1-1, Table 2.1.1-2, and Table 2.1.1-3).

The Phase I archaeological survey conducted for the onshore interconnection facility, SFEC corridor, and SFEC landfall locations resulted in the identification of no potential archaeological resources. The archaeological survey within the SFEC onshore corridor determined that portions of the analysis area that fall within the LIRR ROW were previously disturbed from railroad construction activities and landscape modification. Because of this, these areas are determined to have low archaeological potential and no additional investigations are recommended. Discrete portions of the SFEC onshore corridor within public road ROWs may have experienced minimal excavation during the roadway construction (EDR 2020b). As a result, a Phase IB supplemental archaeological survey for these discrete sections of paved road ROWs was completed by EDR in 2020, including hand excavation of shovel test pits within the grassy and unpaved portions of the road ROWs adjacent to the pavement (i.e., with no disturbance of roadways) (EDR 2020c). EDR’s approach included systematic shovel tests for a portion of Beach Lane – Route A and a portion of Hither Hills – Route B (as recommended by EDR 2020b). Additional systematic shovel tests were also conducted by EDR at the interconnection facility. None of the testing efforts resulted in the identification of any potential archaeological resources.

SFW is considering three onshore sites for the proposed O&M facility. Two are at the Quonset Business Park/Quonset Point, North Kingston, Rhode Island, and one is at Montauk Harbor, East Hampton, New York.

The Quonset Point O&M facility site falls within the Quonset Business Park, which includes a NRHP-eligible historic property within its property boundaries: the Quonset Point Naval Air Station. The Quonset Point Naval Air Station currently serves as a Rhode Island Air National Guard Base. The Air National Guard Base is an active military base with modern structures and equipment (EDR 2020a). As a result of land development since the mid-twentieth century, the Quonset Point O&M facility site possesses low potential for intact or undisturbed archaeological resources (EDR 2020a). The Quonset Business Park/Quonset Point site was intermittently settled until it was developed as a U.S. Naval Reservation and construction battalion center in the 1940s and 1950s, wherein the property was extensively disturbed and the shoreline was extended (human-made land) to create the pieces of land that are proposed for the O&M facility components (EDR 2020a). Therefore, although the proposed construction site falls within a known NRHP-eligible historic property, the potential for ground-disturbing activities to affect buried cultural resources is low because the area of proposed construction has been previously disturbed or is fill material.

The Montauk Harbor O&M facility site has no previously identified archaeological resources (EDR 2020a). The Montauk Harbor site was developed in the mid-twentieth century as a working harbor and seafood operation and is currently occupied by a small commercial fishing and packing operation. As a result of the use of dredge fill in some portions and land development from the mid- through late twentieth century overall, this site possesses low potential for archaeological resources, as does the adjacent seabed where additional dredging is proposed; therefore, no additional archaeological investigations are recommended (EDR 2020a).

3.5.2.1.3 VIEWSHED RESOURCES

This section addresses visually sensitive cultural resources located within the viewshed of Project elements, referred to as *viewshed resources*. All other visual resources are addressed in the Visual Resources section (Section 3.5.9).

BOEM defines the APE for visual impact analysis, hereafter the APE for viewshed resources, as the geographic areas from which the offshore and onshore Project components could be seen. Onshore components (e.g., interconnection facility and O&M facilities) have a viewshed radius of 1 mile around the facility. Offshore components (e.g., WTGs) have a viewshed radius of 40 miles around the edge of the WMA (Figure E-10). The 1-mile and 40-mile radiuses represent the maximum limit of theoretical visibility for each respective Project component. Within these radiuses, the APE for viewshed resources includes only those geographic areas with potential visibility and excludes areas with obstructed views of Project facilities within those respective limits, as assessed through a viewshed analysis (EDR 2020d, 2021). Viewshed analysis applied GIS modeling to take into account the true visibility of the Project (e.g., visual barriers such as topography, vegetation, and non-historic structures that obstruct the visibility of the Project) (EDR 2018, 2019).

For the onshore components viewshed, the historic architectural resources survey identified four historic architectural properties within the APE for viewshed resources. These comprise three at the Montauk Harbor O&M facility site, one at the Quonset Business Park/Quonset Point O&M facility site, and none at the SFEC landfall locations and interconnection facility (EDR 2018, 2019). The following summarizes the results from the historic architectural resources survey of the onshore components viewshed:

- At the SFEC landfall locations and interconnection facility, no historic properties were identified within the APE for viewshed resources.
- At the Montauk Harbor O&M facility site, three historic properties were identified in the APE for viewshed resources (one that is NRHP-listed and two that are NRHP eligible).
- At the Quonset Business Park/Quonset Point O&M facility site, one historic property was identified within the APE for viewshed resources and is NRHP eligible.

The Historic Resources Visual Effects Analysis (HRVEA) for the WTGs and OSS identified 113 historic sites and districts in the APE for viewshed resources. This analysis assessed the visibility of a WTG from the water level to the tip of an upright rotor blade at a height of 840 feet and further considered how distance and curvature of the Earth affect visibility as space between the viewing point and WTGs increases.[20] Of the 113 historic sites and districts in the APE that could be susceptible to visual impacts from the Project, 39 are listed on the NRHP (seven of which are National Historic Landmarks). The remaining 74 are considered eligible for the NRHP and, of these, 33 are in Rhode Island and 41 are in Massachusetts. Examples of these include the following:

- National Historic Landmarks, e.g., Block Island Southeast Lighthouse National Historic Landmark
- NRHP-listed districts, e.g., Old Harbor Historic District in Block Island

[20] The PDE presented in the COP indicates a maximum WTG height of 840 feet from sea level to blade tip for the Proposed Action. Additional cumulative visual simulations conducted by EDR (2020c) and appended to the *Cumulative Historic Resources Visual Effects Analysis* (SWCA 2021) are based on WTG blade tip height of 873 feet for modeling potential future blade tip heights of reasonably foreseeable future offshore WTGs constructed in the geographic analysis area.

- NRHP-listed properties, e.g., Gay Head Light
- Those considered NRHP eligible based on state-level documentation, e.g., Gay Head - Aquinnah Shops (historic district), Vaill Cottage, Spring House Hotel in the Old Harbor Historic District, Spring House Hotel Cottage, the Spring Street Historic District, and the Capt. Mark L. Potter House within that district

Additionally, three of the 74 are considered Traditional Cultural Properties (TCPs) (EDR 2021). These are the Nantucket Sound TCP, the Chappaquiddick Island TCP, and the Vineyard Sound and Moshup's Bridge TCP, all of which are represented by broad, complex cultural landscapes and connected seascapes.

3.5.2.2 Environmental Consequences

3.5.2.2.1 ISSUES, INDICATORS, AND SIGNIFICANCE CRITERIA

Table 3.5.2-3 lists the issues identified for cultural resources and the indicators and significance criteria used to assess impacts for the final EIS. The final EIS incorporates the criteria for assessing adverse effects under Section 106 of the National Historic Preservation Act (NHPA), including the special requirements for protecting National Historic Landmarks. These criteria and requirements are listed and described in 36 CFR 800.5(a) and 36 CFR 800.10. Cultural resources included on, or eligible for, the NRHP are defined as *historic properties* (54 USC 300308; 36 CFR 800.16(l)). National Historic Landmarks are designated by the Secretary of the Interior in recognition of their national significance and are NRHP-listed historic properties (pursuant to 36 CFR 65). An impact would adversely affect cultural resources and be significant if the impact alters any characteristic of a historic property that qualify the property for NRHP inclusion in a manner that would diminish its historic integrity.

Table 3.5.2-3. Issues, Indicators, and Significance Criteria Used to Assess Impacts to Cultural Resources

Issue	Impact Indicator	Significance Criteria
Seabed disturbance and potential marine resource damage	Qualitative analysis of pre-contact sites/cultural materials impacted Qualitative analysis of known or potential shipwrecks impacted Qualitative analysis of landforms with high archaeological sensitivity impacted	Across all Issues and Indicators Negligible: No significant impacts would occur (i.e., effects on historic properties pursuant to 36 CFR part 800 would not rise to the level of being adverse effects). Minor: Significant impacts to NRHP characteristics could be avoided with environmental protection measures (i.e., with use of EPMs, no adverse effect would result). Moderate: EPMs would minimize, but not fully resolve, significant impacts to NRHP characteristics (i.e., alteration diminishing important historic property characteristics, yet the adversely affected property remains NRHP eligible). Major: Significant impacts to NRHP characteristics are unavoidable even with EPMs (i.e., alteration or loss of an important characteristic to an extent that it no longer supports the adversely affected property's NRHP eligibility).
Terrestrial ground disturbance: potential damage to cultural resources	Qualitative discussion of potential for impacts to unknown resources	
Viewshed disturbance: potential impact to identified historic properties	Qualitative assessment of NRHP-listed/eligible sites (historic properties) within view of Project	
Nighttime lighting: potential impact to identified historic properties	Qualitative assessment of NRHP-listed/eligible sites (historic properties) within view of Project	

3.5.2.2.2 NO ACTION ALTERNATIVE

The Affected Environment section provides information on existing cultural resources, including within the context of trends in past and present activities where pertinent. Attachment 3 in Appendix E also provides additional information regarding past and present activities and associated cultural resource impacts. Future, non-Project actions include proposed offshore wind energy development activities, undersea transmission lines and pipelines, dredging and port improvements, and onshore wind energy developments. Attachment 3, also in Appendix E, discloses future non-offshore wind activities and associated cultural resources impacts. Impacts associated with future onshore and future offshore wind activities are described below.

Future Activities

Marine Resources

Under the No Action alternative, construction and installation, O&M, and conceptual decommissioning activities of reasonably foreseeable offshore projects could adversely impact potentially significant submerged cultural resources. However, federal law requires that offshore energy developers submit archaeological survey results and assessment of seafloor impacts to potential submerged cultural resources when bottom-disturbing activities are planned (Evans 2009:44). Submerged cultural resource surveys identify significant resources and support a determination of their NRHP eligibility. Based on the results of those surveys and assessments, future offshore wind activities could be designed to avoid impacting known submerged cultural resources or minimize impacts to varying degrees. Repeated or multiple impacts from a combination of reasonably foreseeable offshore projects to submerged cultural resources, or the larger submerged landforms within which they are identified, would result in cumulative impacts to these resources. Within its EPMs, SFW prioritizes the avoidance of ancient submerged landforms; however, avoidance may not be feasible everywhere, particularly along the export cable. The SFWF and SFEC are estimated to result in 913 acres of cabling-related seabed disturbance, and BOEM estimates an additional 10,131 acres of cabling-related disturbance for all other future offshore wind projects. The amount of seabed disturbance provides a relative indicator of the potential for ancient submerged landform impacts; as seabed disturbance area increases, the likelihood of unavoidable impacts to ancient submerged landscapes increases. Combined, other reasonably foreseeable offshore wind projects would result in over 90% of the cabling-related seabed disturbance, and the SFWF and SFEC would result in less than 10% of the disturbance. Therefore, other reasonably foreseeable offshore wind projects combined would result proportionately in nearly 10 times the additional impact risk to ancient submerged landforms over that of the SFWF and SFEC. Where impacts to potentially significant submerged cultural resources cannot be avoided, other measures to minimize and mitigate impacts would be required. Under the No Action alternative, reasonably foreseeable future projects could result in minor to major and cumulative impacts to these marine resources.

<u>Accidental releases</u>: The accidental release of hazardous materials and any associated cleanup could impact submerged cultural resources. However, most releases would not measurably contribute to resource impacts because of the low probability of occurrence, low persistence time, and EPMs implemented to prevent releases (see Section 3.3.2.2.2 [No Action Alternative] for details). Although not expected, a large-scale accidental release and associated cleanup could result in permanent, geographically extensive, and large-scale impacts on marine resources.

<u>Anchoring</u>: Anchoring, gear use, and dredging associated with ongoing commercial or recreational marine activities and development of offshore wind projects could cause adverse impacts on submerged cultural resources. BOEM estimates that up to 4 acres of anchoring could occur under the No Action alternative within the APE for marine resources. Deploying and repositioning anchors and seafloor gear

with associated wire rope, cable, and chain could impact the bottom surface and potentially disturb shipwrecks and other marine archaeological resources resulting in the irreversible loss of historical and archaeological data. Although BOEM would be able to add mitigation measures for future offshore wind projects, the potential for permanent, minor to major impacts on submerged cultural resources to result from future commercial and/or recreational activities remains.

New cable emplacement/maintenance and presence of structures: New offshore cable placement could also occur, as described in Attachment 4 in Appendix E and discussed under the Marine Resources section of Section 3.5.2.2.2. In addition to general horizontal acreage of seabed disturbance, the extent of potential impacts to marine resources increases with depth of disturbance into the seabed. New offshore cabling could result in up to 359 acres of seabed disturbance from cable trenching in the greater BOEM Lease Area OCS-A 0486 surrounding the SFWF. Additionally, reasonably foreseeable offshore wind projects located in BOEM Lease Area OCS-A 0486 would add an estimated 102 in-water structures with foundations in the seabed. As described in Section 3.5.2.1 and Appendix E, the Lease Area and the APE for marine resources contain a number of shipwrecks, related debris fields, and ancient submerged landform features, which future offshore construction activities could impact. BOEM and relevant State Historic Preservation Officers would require projects to avoid known resources through the creation of avoidance buffers around identified shipwrecks or remote-sensing magnetic anomalies or acoustic targets that could represent shipwreck resources. These measures would avoid or minimize impacts to submerged cultural resources. However, in some cases, the number, extent, and dispersed character of ancient submerged landform features could make avoidance impossible. Consequently, offshore construction could result in permanent, minor to major impacts on sensitive ancient submerged landform features, if present.

Climate change: Factors related to climate change, including sea level rise, increased storm severity/frequency, increased sedimentation and erosion, and ocean acidification, could also result in long-term and permanent impacts on cultural resources. Some archaeological sites on the OCS have already experienced the effects of climate change because they were inundated when the last ice age ended (BOEM 2012:3-423). Contemporary federal studies on the adverse effects of climate change on shallow water shipwrecks point to accelerated decomposition (National Ocean Service 2020). Conversely, the incremental contribution of offshore wind energy projects on reducing global warming and climate change–related impacts could help minimize these climate change impacts.

Terrestrial Resources

Under the No Action alternative, reasonably foreseeable onshore projects could impact two aboveground historic resources (the East Hampton Railroad Station and the Montauk Lighthouse) through physical disturbance that could affect the setting or character of a site that make it eligible for NRHP listing. Depending on the degree of disturbance, future onshore projects could result in negligible to moderate impacts to aboveground historic resources.

Ground disturbance: Reasonably foreseeable onshore activities could physically disturb archaeological sites. However, surveys have identified no archaeological sites in the APE for terrestrial resources, and analysis shows that most of the APE for terrestrial resources has been previously disturbed; therefore, the risk of potentially encountering undisturbed archaeological deposits or previously unidentified cultural resources is low. For this reason, potential impacts from ground-disturbing activities would be limited to previously undocumented cultural resources, if present. Reasonably foreseeable projects that are subject to federal laws and regulations would also require the identification of cultural resources, an assessment of Project impacts, and the address of significant impacts (or adverse effects under 36 CFR part 800) to historic properties before proceeding. If BOEM selects the No Action alternative, reasonably foreseeable future cumulative impacts to terrestrial cultural resources could range from negligible to long term and major, depending on whether resources are absent or alternatively are present and adversely impacted. These resources include aboveground historic buildings or structures and unidentified archaeological sites.

Accidental releases: Construction of reasonably foreseeable onshore projects could result in the accidental release of hazardous materials or debris; however, releases would generally be short term, localized, and in limited amounts (see Section 3.3.2.2.2 [No Action Alternative]). Such an accidental release could result in impacts to terrestrial cultural resources associated with the cleanup of contaminated soils. Indirect physical impacts would be long term and negligible to major depending on the nature and size of the accidental release, its spatial relationship to the cultural resource impacted, and the extent and intensity of cleanup activities required. Archaeological resources are more likely to experience indirect physical impacts through damage to or destruction of cultural materials during the removal of contaminated soils than are aboveground standing structures. Other indirect but primarily short-term impacts could include noise, vibration, and dust as well as visual impacts associated with cleanup activity. These short-term impacts are expected to be negligible to minor and minimized or avoided through application of state and local laws and regulations regarding air quality (see Section 3.3.1.2.2 [No Action Alternative]). Noise levels would be consistent with existing ambient noise conditions. Overall, impacts to terrestrial cultural resources from construction-related activities would be expected to be limited because of the low probability of an accidental release occurrence, the low volumes of material typically released in individual incidents, EPMs used to prevent release, and the localized nature of such events (see Table G-1 in Appendix G).

Climate change: As noted in marine resources, climate change could result in long-term and permanent impacts on terrestrial resources. Sea level rise could lead to the inundation of historic standing structures and increased storm severity and frequency would be expected to increase the severity and frequency of damage to coastal historic standing structures. A number of historic lighthouses in the viewshed resources APE, including Block Island Southeast Lighthouse and Gay Head Light, have already been moved to set them back farther from coastal erosion (EDR 2021). Increased erosion along coastlines could lead to the collapse of coastal historic architectural properties as erosion undermines structural integrity. Ocean acidification could impact traditional uses of the Vineyard Sound and Moshup's Bridge TCP. However, the incremental contribution of offshore wind energy projects on slowing or arresting global warming and climate change–related impacts could help minimize these potential adverse impacts. In addition, no known archaeological sites are present in the APE for terrestrial resources, which is also heavily disturbed, and therefore potential adverse impacts from climate change are unlikely and would be limited to previously undocumented resources.

Viewshed Resources

Light: Reasonably foreseeable future offshore wind projects would also impact viewshed resources from navigational and aviation lighting. Impacts from lighting would be most visible at night and from cultural resources that are along shorelines or on elevated locations with unobstructed views. A limited number of cultural resources would be affected and would include those for which the nighttime sky is a contributing element to historic integrity, such as resources on the shores of Martha's Vineyard and Block Island. Reasonably foreseeable offshore wind projects could locate WTGs a minimum of 12 miles from shore at Nomans Land Island and from 19 to 20 miles from Block Island and Martha's Vineyard. These distances between the areas with viewshed resources and the nearest SFWF lighting sources would limit the intensity of lighting impacts. The intensity of lighting impacts would also be limited by the number, luminosity, and proximity of existing light sources near the resources (building and street lights, onshore vehicle and offshore vessel lights). The intensity of lighting impacts would further be limited by atmospheric and environmental conditions (clouds, fog, and waves) that could partially or completely obscure or diffuse sources of light from offshore and onshore wind projects. Construction lighting and conceptual decommissioning lighting associated with both onshore and offshore wind facilities would have temporary, intermittent, and localized impacts, whereas operations lighting would have longer term, continuous, and localized impacts, where not adequately obscured or diffused. Implementing EPMs could reduce impacts from lighting (see Table G-1 in Appendix G). Under the No Action alternative, reasonably foreseeable future projects would have negligible to moderate, short-term to long-term cumulative impacts on viewshed resources.

Presence of structures: For the onshore viewshed, if BOEM selects the No Action alternative, the construction and installation, O&M, and conceptual decommissioning of reasonably foreseeable onshore infrastructure would introduce new elements to the viewshed that could compromise the historic integrity of known historic properties. These known resources are introduced within the Affected Environment for Viewshed Resources in Section 3.5.2.1.3 and also include the SFEC landfall locations and interconnection facility and the three potential O&M facility locations. For the offshore viewshed, if BOEM selects the No Action alternative, the construction and installation, O&M, and conceptual decommissioning of reasonably foreseeable offshore wind projects could locate WTGs beginning approximately 12 miles from shore, resulting in visual impacts to historic properties that would be long term, continuous from minor to major, and minimized with distance. The cumulative HRVEA presents models of the visibility for WTG construction at 1,038 potential locations for reasonably foreseeable future projects in the RI/MA WEA (SWCA 2021), although an estimated 1,294 WTGs and OSS would be constructed across these locations (see Attachment 4 in Appendix E). From all modelled WTG locations for other reasonably foreseeable future projects, up to 546 WTGs would be visible from viewshed resources at risk of significant visual impacts within the APE (SWCA 2021). Proportionately, the combined full build-out of other reasonably foreseeable offshore wind projects would construct 97% of WTGs visible from affected historic properties in the APE, with SFWF contributing only 3% of the WTGs. As a result, other reasonably foreseeable offshore wind projects would add over 30 times the visible WTGs over the number of WTGs that the SFWF would introduce by itself (SWCA 2021). Even without the SFWF or the full build-out of all other reasonably foreseeable offshore wind projects, the introduction of offshore WTGs would result in long-term cumulative visual impacts to cultural resources, where sea views that are important to the historic setting or feeling and NRHP eligibility of the historic property are significantly altered by WTGs.

Conclusions

Under the No Action alternative, BOEM would not approve the COP; Project construction and installation, O&M, and conceptual decommissioning would not occur; and potential impacts on cultural resources associated with the Project would not occur. However, ongoing and future activities would have continuing temporary to long-term impacts on cultural resources, primarily through construction-related activities.

BOEM anticipates that the range of impacts for reasonably foreseeable offshore wind activities would be **negligible to major**, depending on the scale and extent of impacts and the unique characteristics of the resource. Examples of individual resources are paleolandforms, terrestrial archaeological sites, historic standing structures, and TCPs. Impacts vary widely because the impacts are dependent on the unique characteristics of the individual resources. As described in Appendix E Attachment 3, BOEM anticipates that the range of impacts for ongoing activities and reasonably foreseeable activities other than offshore wind would be **negligible to major**, for similar reasons.

Considering all IPFs together, BOEM anticipates that the impacts associated with future offshore wind activities in the APE combined with ongoing activities, reasonably foreseeable environmental trends, and reasonably foreseeable activities other than offshore wind would result in **minor to major** impacts because if avoided the overall effect would be small, but if not avoided the overall effect would be large and the resource would not be recoverable.

3.5.2.2.3 PROPOSED ACTION ALTERNATIVE

Construction and Installation

Marine Resources

If practicable, BOEM would require SFW to avoid potential impacts to the four identified potential shipwreck archaeological resources, which SFW has indicated may be feasible through Project design and engineering.[21] Based on the potential seabed-disturbing activities proposed, SFW has indicated that it may not be feasible to avoid impacts to all of the identified ancient submerged landform features and SFW is currently considering design and engineering options to avoid or minimize impacts to these resources. SFW anticipates that it will not be able to fully avoid five ancient submerged landforms during export cable installation (SFEC-CF-3, SFEC-CF-5, SFEC-CF-7, SFEC-CF-9, and SFEC-CF-13) (Gray & Pape Inc 2021).

The final impact level for marine resources is dependent on avoidance, minimization, or mitigation of adverse effects that would be determined in a memorandum of agreement (MOA) developed through BOEM's NHPA Section 106 review process and included as conditions of approval of the COP by BOEM[22]. Where marine resources are reliably identified and avoided, then impacts during construction of the SFWF and SFEC would be long term and negligible to minor. Where marine resources are identified as historic properties and not avoided, but adverse effects would not result in the resource becoming ineligible for the NRHP, then impacts to marine resources during construction of the SFWF and SFEC could be long term and minor to moderate. Where impacts would render a marine resource ineligible for the NRHP even with mitigation, impacts during construction would be long term and major. If Project construction results in the unanticipated discovery of previously unknown historic property requiring mitigation through the Section 106 consultation process, then the resultant physical impacts could be long term and minor to major (MMS 2007). BOEM would require a post-review discovery plan that would include stop-work and notification procedures to be followed if a cultural resource is encountered during construction and installation, O&M, and conceptual decommissioning.

For any unavoidable ancient submerged landform features corresponding to the time of human occupation, BOEM would consider additional investigations or other measures to resolve adverse effects and, as required, mitigations to be stipulated in the MOA for the Project, prepared pursuant to the NHPA Section 106 consultation process (36 CFR part 800). The MOA would contain measures to reduce, avoid, or mitigate adverse effects on unavoidable ancient submerged landform features. Implementation of an MOA and subsequent treatment plan, agreed to by all consulting parties participating in the NHPA Section 106 consultation process, would be expected to reduce the magnitude of impacts on ancient submerged landform features from moderate or major to minor or moderate. The exception is where impacts would render a marine resource ineligible for the NRHP even with mitigation of impacts, in which case the impact on the ancient submerged landform would remain major.

[21] Specific to Section 106 consultation, BOEM's archaeological guidelines define the marine APE to include the following geographic areas:

- The depth and breadth of the seabed potentially impacted by any bottom-disturbing activities
- The depth and breadth of terrestrial areas potentially impacted by any ground disturbing activities
- The viewshed from which renewable energy structures, whether located offshore or onshore, would be visible
- Any temporary or permanent construction or staging areas, both onshore and offshore

For the purposes of the marine archaeological assessment, SFW identified all areas of potential Project-related seabed disturbance to develop a preliminary APE for BOEM's consideration. In accordance with 36 CFR 800.4(a), BOEM would determine the APE for the Project following the agency's analyses and state historic preservation office consultations.

[22] Appendix A provides a discussion of BOEM's determination that the approval of the Project COP is subject to the Section 106 consultation process under the NHPA. Any mitigation measures identified through the Section 106 process would be required to be included as mitigation measures in the COP prior to its approval by BOEM. The Section 106 consultation process has been initiated and is ongoing at the time of this EIS.

Terrestrial Resources

Construction of onshore Project components (onshore SFEC, interconnection facility, and O&M facility) could affect cultural resources through physical disturbance.

The route selected for the SFEC onshore would minimize impacts to, or avoid, potential terrestrial archeological resources, to the extent practicable. Analysis shows that most of the SFEC onshore route has been previously disturbed; therefore, the risk of potentially encountering undisturbed archaeological deposits is minimized in these areas. Results of the additional Phase IB survey of potentially undisturbed, buried portions of the SFEC route and interconnection facility by EDR (2020c) resulted in the identification of no potential archaeological resources. Surveys conducted to date have not identified subsurface or aboveground cultural resources within the onshore Project components. However, should Project construction result in the discovery of previously unidentified cultural resources requiring mitigation through the Section 106 consultation process, the resultant physical impacts could be long term and minor to major (MMS 2007).

Construction of the O&M facility would not require the demolition or physical alteration of any aboveground historic properties (EDR 2019) at either the Quonset Business Park/Quonset Point or Montauk O&M facility sites; however, construction would either replace existing buildings that are not historic properties or would introduce new buildings to the active commercial waterfront.

Ground-disturbing activities proposed for the Quonset Business Park/Quonset Point O&M facility are minor surface improvements for paving and parking lots. SFW would construct slab-on-grade foundations for buildings and support structures. SFW would use existing docks and proposes no in-water work (EDR 2020a). As a result, BOEM anticipates that the Quonset Business Park/Quonset Point O&M facility would result in long-term, negligible to minor impacts to any unknown buried cultural resources, should they be discovered.

Ground-disturbing activities proposed for the Montauk O&M facility are minor surface improvements for paving and parking lots, footers for the office space and storage structures (because of the poor quality of the soil, including beach or fill land or dredged material), quayside reinforcement or rehabilitation, and initial and maintenance dredging (EDR 2020a). Additionally, because of the previous site disturbance, unstable soils, the presence of significant fill or dredged materials, and the lack of reported shipwrecks or other archaeological resources within the proposed dredging areas (Gray & Pape 2020), no archaeological survey was recommended at the Montauk Harbor site. The Montauk Harbor site possesses relatively low sensitivity for the presence of archaeological resources and Project construction is anticipated to result in long-term, negligible impacts to buried cultural resources. Alternatively, if Project construction results in discovery of previously unidentified historic property requiring mitigation through the Section 106 process, then the resultant physical impacts could be long term and minor to major (MMS 2007).

As noted in the COP, Native American tribes were involved, and would continue to be involved, in interpretation of the results. A post-review discovery plan would be implemented that would include stop-work and BOEM notification procedures to be followed if a cultural resource is encountered during installation and O&M.

Viewshed Resources

Based on a field review of the viewshed analyses, the interconnection facility would not be readily visible from historic properties because of the dense, mature evergreen and deciduous forest surrounding the site and the densely situated buildings and houses in the villages and surrounding area (EDR 2018). The COP EPMs note that the interconnection facility would be located adjacent to an existing substation on a land parcel zoned for commercial and industrial/utility use and that mature trees currently screen the land parcel. The COP EPMs also note that after construction, additional screening would be considered to further reduce potential visibility and visual impact (see Appendix G). When topography, vegetation, and structures are all included in the viewshed analysis, approximately 2% of the visual analysis area has possible visibility of the interconnection facility see (EDR 2018). Thus, visual impacts to NRHP-listed and NRHP-eligible resource settings during construction of the interconnection facility would be long term if visible and short term (if screened by vegetation), with the potential to be negligible (if fully shielded) to major (if obtrusively visible) (MMS 2007). COP analysis of field studies found no historic properties from which the interconnection could be viewed, and non-historic properties within viewing distance were found to be shielded from view. Additionally, the onshore SFEC would be buried, therefore eliminating potential visual impacts to aboveground historic properties.

The viewshed analysis for the Quonset Business Park/Quonset Point O&M facility indicates that the site would be located within, and visible within, the Quonset Business Park and Quonset Point Naval Air Station, which itself is a historic property (NRHP eligible). The Quonset Point Naval Air Station is an approximately 974-acre World War II–era naval training facility improved with industrial buildings and parking lots and currently serves as a Rhode Island Air National Guard Base (EDR 2020a). The new O&M facility would be in scale and character with the existing development and use of the property. As a result, the Quonset Business Park/Quonset Point O&M facility would not result in significant impacts on the NRHP-eligible Quonset Point Naval Air Station (EDR 2020a); the potential visual impacts to historic properties are anticipated to be long term but negligible to minor.

The viewshed analysis for the Montauk Harbor O&M facility indicates that one NRHP-listed property (Caleb Bragg Estate) and two NRHP-eligible properties (Montauk USCG Station Building and Montauk USCG Engineering/Boat Maintenance Building) are located within the APE for viewshed resources (EDR 2019c). However, the Caleb Bragg Estate is screened by vegetation from the proposed O&M facility and its integrity of setting beyond the historic property boundary is absent due to other existing non-historic development (EDR 2019). Although Montauk USCG Station Building and Montauk USCG Engineering/Boat Maintenance Building would have direct views of the O&M facility, their integrities of setting beyond each historic property are also absent due to other existing non-historic development (EDR 2019). As a result, the Montauk Harbor O&M facility would not have significant impacts on historic properties; the potential visual impacts to historic properties are anticipated to be long term but negligible.

The construction of the offshore Project components would also result in modification to the existing viewshed within the terrestrial resources analysis area because SFWF WTGs would be visible on the horizon from the shore (see Section 3.5.9 Visual Resources for further discussion). During construction and conceptual decommissioning, lighting associated with the Project would have temporary, intermittent, and localized impacts, whereas operations lighting would have longer term, continuous, and localized impacts, where not adequately obscured or diffused. Most of the historic properties within the APE for viewshed resources would have limited views because of screening by topography, vegetation, and other buildings/structures and would be located approximately 18 to 34 miles away from the SFWF work area (EDR 2021). Only historic properties with open ocean views along coastlines and raised coastal bluffs have potentially unobscured lines of sight and the potential to be prominently within the viewshed (within approximately 20 miles) of SFWF WTGs (see Figure E-10). The WTGs would have a uniform design, speed, height, and rotor diameter, which contribute to a homogeneous view of wind farms on the horizon. The color of the SFWF (less than 5% gray tone) generally blends well with the sky at the horizon and eliminates the need for daytime lights or red paint marking the blade tips. As discussed in Section 3.5.9 Visual Resources, because of FAA and USCG WTG lighting guidelines, adverse impacts to the seaward viewing experience would be potentially greater in nighttime than in daytime. For historic properties located on the waterfront, the WTGs would be a new feature in the visual setting. Because of their scale and form, WTGs are expected to begin to attract viewer attention under ideal lighting and atmospheric distances beginning under 18 miles from a historic property (EDR 2021; Sullivan et al. 2012). Based on visual simulations of the Project, WTGs would be visible in the distant background only on clear days (EDR 2020d; Jacobs 2021) beginning at 19 miles and ranging to 35 miles from historic properties (EDR 2021). As a result, an offshore wind farm with the size and design of WTGs planned for the SFWF would have the potential for moderate to major impacts to historic properties in its viewshed within approximately 20 miles, minor visual impacts beyond 20 miles, and negligible impacts beyond 25 miles (EDR 2021).

Of the 113 historic properties with potential views of the Project, and therefore determined to be in the APE for the Project, 10 would be along the coastline or bluffs with open ocean views, within approximately 20 miles of the SFWF. These 10 historic properties are anticipated to experience moderate visual impacts (daytime and nighttime) from the WTGs or OSS. The 10 historic properties are all coastline properties and include historic districts that may encompass a range of historic resources. The 10 historic properties are as follows:

- Gay Head Light
- Gay Head - Aquinnah Shops (a Historic District)
- Vineyard Sound and Moshup's Bridge TCP on Martha's Vineyard, Massachusetts
- Block Island Southeast Lighthouse National Historic Landmark
- Old Harbor Historic District
- Spring House Hotel within the Old Harbor Historic District
- Spring Street Historic District
- Capt. Mark L. Potter House within the Spring Street Historic District
- Spring House Hotel Cottage
- Vaill Cottage on Block Island, Rhode Island

BOEM remains in consultation with Native American tribes and other consulting parties under NHPA Section 106 on identified historic properties, adverse effects, and the resolution of adverse effects (per 36 CFR part 800).

Operations and Maintenance and Conceptual Decommissioning

Marine Resources

Offshore, O&M of the SFWF and offshore SFEC could impact unknown submerged marine resources. For example, vessels conducting O&M activities could inadvertently damage avoidance-buffered or unknown resources. However, SFW could conduct O&M activities on equipment in areas that previously experienced disturbance during construction. Therefore, impacts to confirmed submerged cultural resources and identified ancient submerged landform features during O&M could be long term but negligible. During conceptual decommissioning activities impacts to confirmed submerged cultural resources and identified ancient submerged landform features could be temporary and negligible to minor so long as they are avoided. For example, seafloor disturbance associated with future anchoring/mooring and jack-up vessels could be relatively similar to impacts identified for construction activities.

Terrestrial Resources

Onshore, based on surveys conducted, Project O&M would have no physical impacts to terrestrial resources. SFW could remove the onshore cables during conceptual decommissioning. Conceptual decommissioning of the SFWF and offshore SFEC would result in similar, or potentially reduced impacts, as those discussed above in construction. If conceptual decommissioning activities disturb an area larger than the area originally disturbed during construction, these activities could impact previously unknown archaeological resources. However, the likelihood of this would be low, and therefore impacts would be long term and negligible to minor.

Viewshed Resources

As discussed above, any viewshed changes associated with the onshore facilities (the interconnection and the O&M facility) would persist for the duration of the Project but result in no impact or negligible visual impacts to viewshed resources.

For offshore WTGS, if BOEM requires SFW to install Aircraft Detection Lighting System (ADLS) technology, nighttime visual impacts (and, to a lesser degree, daytime visual impacts) to historic properties would be reduced although not eliminated, adding negligible to moderate, long-term impacts during O&M. Without ADLS, visual impacts from nighttime lighting and daytime visibility of SFWF WTGs on historic properties in the viewshed resources APE would remain negligible to moderate for the duration of the Project, depending on the significance of viewshed in their historical setting and character and the scale of impact (EDR 2021; MMS 2007). O&M would not add further to these impacts; however, conceptual decommissioning would provide a remedy to previous visual impacts created by WTG construction.

Cumulative Impacts

Marine Resources

Offshore impacts would predominately be associated with changes in anchoring, cabling, structures, and accidental spills.

<u>Accidental releases</u>: The Proposed Action could incrementally contribute accidental releases of fuel, fluids, or hazardous material; sediment; and trash and debris to conditions under the No Action alternative. The risk would be increased primarily during construction but also would be present during operations and conceptual decommissioning. The contribution from the Proposed Action would be a low percentage of the overall spill risk from ongoing and future activities, as described in detail in Section 3.3.2.2. All vessels would comply with USCG requirements for the prevention and control of oil and fuel spills. Proper vessel regulations and operating procedures would minimize effects resulting from the release of debris, fuel, hazardous material or waste on marine resources (BOEM 2012). Additionally, required training and awareness of best management practices proposed for waste management and mitigation of marine debris for SFWF Project personnel would reduce the likelihood of occurrence to a very low risk. These releases, if any, would occur infrequently at discrete locations and vary widely in space and time, and for this reason, BOEM expects localized and temporary negligible Project impacts on cultural resources. Cumulatively, the Proposed Action when combined with past, present, and reasonably foreseeable activities would have minor, short-term impacts to marine resources.

<u>Anchoring, new cable emplacement/maintenance, and presence of structures</u>: Seafloor disturbance activities (temporary and long term) proposed for the Project include clearing or leveling of the seafloor, pile driving, monopile foundation (and associated cable protection) construction, vessel anchoring or mooring, export cable installation, and inter-array cable installation (preparation, trenching, burial, maintenance, replacement, etc.). SFW may elect to use a mechanical cutter, mechanical plow, or jet plow to install cable at the target burial depth; those methods would reduce the amount of seabed impact relative to mechanical dredging.

As noted for the No Action alternative, repeated or multiple impacts from a combination of reasonably foreseeable offshore projects to submerged cultural resources, or the larger submerged landforms within which they are identified, would result in cumulative impacts to these resources. Within its EPMs, SFW would prioritize the avoidance of ancient submerged landforms; however, avoidance may not be feasible everywhere, particularly along the export cable. The SFWF and SFEC are estimated to result in 913 acres of cabling-related seabed disturbance, and BOEM estimates an additional 10,131 acres of cabling-related disturbance for all other future offshore wind projects. The amount of seabed disturbance provides a relative indicator of the potential for ancient submerged landform impacts; as seabed disturbance area increases, the likelihood of unavoidable impacts to ancient submerged landscapes increases. Combined, other reasonably foreseeable offshore wind projects would result in over 90% of the cabling-related seabed disturbance, and the SFWF and SFEC would result in less than 10% of the cabling-related seabed disturbance. Therefore, other reasonably foreseeable offshore wind projects combined would result proportionately in approximately 10 times the additional impact risk to ancient submerged landforms over that of the SFWF and SFEC. Additionally, reasonably foreseeable offshore wind projects in BOEM Lease Area OCS-A 0486 surrounding the SFWF would add an estimated 102 in-water structures with foundations in the seabed. The cumulative impacts on marine resources, related to seabed disturbance associated with the Proposed Action, when combined with past, present, and reasonably foreseeable activities would be long term, localized, and minor to moderate, unless previously historic properties are identified and cannot be avoided and then impacts would be long term, localized and minor to major.

For any unavoidable ancient submerged landform features corresponding to the time of human occupation, BOEM would specify additional investigations or other measures to aid in resolving adverse effects, pursuant to its compliance responsibilities under the NHPA Section 106 process (36 CFR 800). BOEM requirements with COP approval would stipulate measures to reduce, avoid or mitigate adverse effects on unavoidable ancient submerged landform features. Implementation of these measures would be expected to reduce the magnitude of impacts on ancient submerged landform features from moderate or major to minor or moderate.

Climate change: The cumulative impacts from global climate change for the Proposed Action would be the same as those described for the No Action alternative. The overall magnitude of potential impacts resulting from climate change are uncertain but are anticipated to qualify as negligible to minor and long term.

Terrestrial Resources

Onshore impacts to terrestrial resources would predominately be associated with changes in ground disturbance. Onshore construction associated with the Proposed Action would incrementally add to land disturbance when compared to No Action alternative through the removal of 2.4 acres of undeveloped land for the interconnection facility and a small area (0.1 acre) of developed land at the selected O&M facility. These onshore activities could incrementally add to the physical disturbance of archaeological sites that could occur under the No Action alternative, should unanticipated discoveries of archaeological resources result from the Project during onshore construction. Otherwise, terrestrial surveys for the Project have identified no significant archaeological materials, and analysis shows that most of the APE for terrestrial resources has been previously disturbed; therefore, the risk of potentially encountering undisturbed archaeological deposits or previously undocumented cultural resources is negligible.

As described under marine resources, the Proposed Action could incrementally contribute construction-related accidental releases of fuel, fluids, or hazardous material; sediment; and/or trash and debris to conditions under the No Action alternative. The contribution from the Proposed Action would be a low percentage of the overall spill risk from ongoing and future activities, as described in detail in Section 3.3.2.2. These releases, if any, would occur infrequently at discrete locations and vary widely in space and time, and for this reason, BOEM expects localized and temporary, negligible Project impacts on cultural resources.

Based on above findings, the Proposed Action when combined with reasonably foreseeable onshore projects could result in short-term, negligible to minor cumulative impacts to terrestrial resources from construction and O&M land-based activities.

Climate change: See marine resources for analysis.

Viewshed Resources

Offshore impacts would predominately be associated with changes in in-water structures.

Light: The Proposed Action would incrementally add offshore lighting impacts from navigational and aviation hazard lighting systems on the WTGs and OSS. The incremental addition would include up to 15 WTGs with red aviation hazard flashing lights and up to 15 WTGs and one OSS with marine navigation lighting consisting of flashing yellow lights, compared to a future potential of up to 1,032 WTGs and OSS in the RI/MA WEA (including SFWF), as evaluated in the cumulative HRVEA. Of the potential 1,032 WTGs and OSS, up to 546 WTGs from other reasonably foreseeable projects would be visible from viewshed resources at risk of significant visual impacts from SFWF WTGs (SWCA 2021). As discussed under the No Action alternative, at-risk viewshed resources tend to be limited to those historic properties at shorelines within 20 miles from the SFWF due to screening by topography, vegetation, other buildings/structures, and WTG distance from shore. Although the visual impacts on viewshed resources from SFWF WTGs alone would be significant, as discussed above for the Proposed Action, incremental lighting impacts from the up to 15 SFWF WTGs would be approximately 3% of the cumulative total that would result from the build-out of WTGs for all reasonably foreseeable future offshore wind projects in the RI/MA WEA. Cumulatively, the Proposed Action when combined with past, present, and reasonably foreseeable activities could have intermittent, short-term to long-term, negligible to moderate impacts on viewshed resources.

Presence of structures: The Proposed Action would add up to 15 additional WTGs and one OSS to the condition of the No Action alternative within the viewshed resources APE. The Project would introduce new elements to the viewshed that could compromise the historic integrity of known historic properties. However, the Proposed Action would account for 3% (up to 15 WTGs) of the total future RI/MA WEA WTG locations potentially visible from the nearest affected historic property in the APE. Proportionately, 97% of the total (up to 546 WTGs) in the APE for viewshed resources would be associated with other future offshore wind development (EDR 2020e; SWCA 2021). Reasonably foreseeable future wind projects and the existing BIWF are considered in this cumulative impacts analysis (EDR 2021; SWCA 2021). Additionally, the Proposed Action would locate WTGs no closer than approximately 13.2 miles from the nearest offshore historic property boundary (Vineyard Sound and Moshup's Bridge TCP) and more than 19 miles from the nearest historic properties onshore, where setting and feeling are important to their NRHP eligibility (SWCA 2021). Incremental visual impacts to sensitive receptors from the Project would be long term and negligible to major, minimized with distance and obstructions. Cumulatively, the Proposed Action when combined with past, present, and reasonably foreseeable activities would result in long-term, negligible to moderate cumulative impacts on historic properties in the viewshed. Specifically, the Vineyard Sound and Moshup's Bridge TCP, Block Island Southeast Lighthouse National Historic Landmark, Old Harbor Historic District, Spring Street Historic District, Capt. Mark L. Potter House, Spring House Hotel, Spring House Hotel Cottage, Vaill Cottage, Gay Head Light, and Gay Head - Aquinnah Shops would receive moderate cumulative visual impacts to their historic settings (SWCA 2021).

Conclusions

Under the Proposed Action, the construction and installation of offshore components, as well as their O&M, would have **negligible to major** impacts on cultural resources. Major impacts would be limited to unavoidable impacts that would result in substantial loss of qualifying characteristics of a historic property for NRHP inclusion. Major impacts from the Proposed Action would result from the physical disturbance or damage of all or part of a historic property. Although these impacts could occur at the portions of ancient submerged landform features that SFW is unable to avoid during SFEC installation, the final magnitude of these impacts is expected to be minor to moderate. Measures agreed to by SFW, BOEM, and the NHPA Section 106 consulting parties to avoid, minimize, and/or mitigate adverse effects on historic properties would reduce the level of impact. The exception is where impacts would render a cultural resource ineligible for the NRHP even with mitigation of impacts, in which case the impact on the ancient submerged landform would remain major. Also, impacts to previously undiscovered historic properties identified during implementation of the Proposed Action could be major. However, BOEM would require a post-review discovery plan that would include stop-work and notification procedures to be followed if a cultural resource is encountered during construction and installation, O&M, and conceptual decommissioning. This plan would serve to reduce the level of impact to previously undiscovered historic properties to **moderate** or even lower levels of impact (minor or negligible) where possible.

The construction and installation of offshore components, as well as their O&M, would have **minor to moderate** impacts to viewshed resources, depending on whether impacts could affect the setting and/or character of a site, as at the Vineyard Sound and Moshup's Bridge TCP, Block Island Southeast Lighthouse National Historic Landmark, Old Harbor Historic District, Spring Street Historic District, Capt. Mark L. Potter House, Spring House Hotel, Spring House Hotel Cottage, Vaill Cottage, Gay Head Light, and Gay Head - Aquinnah Shops.

Consequently, BOEM expects the overall impact on cultural resources from the Proposed Action alone to be **moderate** because the overall impact would vary and can depend on whether resources are unavoidable or discovered during Project activities or have unobscured views of Project structures. Historic properties, if adversely affected, would be mitigated through the Section 106 process.

In the context of other reasonably foreseeable environmental trends and planned actions, the incremental impacts under the Proposed Action resulting from individual IPFs would range from **negligible to moderate** where historic properties remain NRHP-eligible to major where impacts make a historic property ineligible for the NRHP. Specifically for cultural resources, BOEM anticipates that the overall impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would also result in **negligible to major** impacts. BOEM made this determination because overall adverse effects to cultural resources could be mitigated through the Section 106 process; however, this might not stop the loss of NRHP eligibility for all historic properties.

3.5.2.2.4 VESSEL TRANSIT LANE ALTERNATIVE

Marine Resources

The Transit alternative would involve the same types or numbers of submerged historic and prehistoric resources at the SFWF and SFEC offshore development areas. However, the Transit alternative could decrease the risk of marine resource damage or destruction to unknown submerged cultural resources because the number of constructed WTG foundations would be reduced and associated inter-array cable trenching could also decrease, resulting in greater Project flexibility for avoiding ancient submerged landforms at the SFWF. The construction and installation of offshore components, as well as their O&M, might be able to avoid impacts to more marine sources under the Transit alternative; however, where impacts are not avoidable, this alternative would have the same potential for negligible to major impacts on these resources as the Proposed Action. Also, if previously undiscovered historic properties are identified and cannot be avoided, impacts would be long term, localized, and minor to major under the Transit alternative (the same as under the Proposed Action).

Terrestrial Resources

The onshore activities proposed under the Transit alternative are the same as those of the Proposed Action. Therefore, impacts to terrestrial resources would be negligible to moderate, the same as those of the Proposed Action. Also, if previously undiscovered historic properties are identified and cannot be avoided, impacts would be long term, localized, and minor to major.

Viewshed Resources

The Transit alternative could decrease impacts to viewshed resources because the number of constructed turbines and their viewshed would be reduced. Although slightly reduced, the layout modification and construction activities proposed under this alternative would still include the same historic properties visually impacted under the Proposed Action and the same potential for impacts to these properties. Therefore, the construction and installation of offshore components, as well as their O&M, would have negligible to major impacts to viewshed resources under the Transit alternative, similar to those of the Proposed Action.

Cumulative Impacts

Marine Resources

The layout modification and construction activities proposed under the Transit alternative, although increasing flexibility for avoiding submerged cultural resources in the SFWF, would have the same limits to avoiding ancient submerged landforms at the proposed SFEC location. The cumulative impacts associated with the Transit alternative when combined with past, present, and reasonably foreseeable activities would be short to long term, localized, and negligible to major. If previously undiscovered historic properties are identified and cannot be avoided, impacts to these resources would also be long term, localized, and minor to major.

Terrestrial Resources

The Transit alternative would not affect Project onshore activities. Therefore, impacts under the Transit alternative when combined with past, present, and reasonably foreseeable activities would be negligible to moderate (the same as the Proposed Action) unless previously undiscovered historic properties are identified and cannot be avoided. If previously undiscovered historic properties are identified and cannot be avoided, impacts to these resources would be long term, localized, and minor to major.

Viewshed Resources

The layout modification and construction activities proposed under the Transit alternative would incrementally reduce the number of WTGs for the SFWF; however, the same historic properties would continue to be adversely affected under this alternative as the Proposed Action. The cumulative visual impacts on historic properties in the APE for viewshed resources and associated with the Transit alternative when combined with past, present, and reasonably foreseeable activities would be long term and negligible to moderate.

Conclusions

Although the Transit alternative would reduce the number of WTGs and their associated inter-array cables, which would have an associated reduction in seabed and viewshed disturbance, BOEM expects that the impacts to cultural resources resulting from the Transit alternative would be similar to the Proposed Action. The construction and installation of offshore components, as well as their O&M, would have negligible to major impacts to cultural resources under either of these action alternatives. This includes if previously undiscovered historic properties are identified and cannot be avoided, where impacts would be long term, localized, and **minor to major**.

In context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that the Transit alternative's incremental impacts would be similar to the Proposed Action. The visual impacts of the Transit alternative when combined with past, present, and reasonably foreseeable activities would be negligible to moderate (the same as the Proposed Action). Similarly, if previously undiscovered historic properties are identified and cannot be avoided, impacts would be long term, localized, and **minor to major.**

3.5.2.2.5 FISHERIES HABITAT IMPACT MINIMIZATION ALTERNATIVE

Marine Resources

The Habitat alternative under either layout option would involve the same types or numbers of submerged historic and prehistoric resources at the SFWF and SFEC offshore development areas as under the Proposed Action. However, the Habitat alternative under either layout option could decrease the risk of marine resource damage or destruction to unknown submerged cultural resources because the number of constructed turbines would be reduced and associated inter-array cable trenching would also decrease, resulting in greater Project flexibility for avoiding ancient submerged landforms at the SFWF. The construction and installation of offshore components, as well as their O&M, could avoid impacts to more marine resources under the Habitat alternative. Where impacts are not avoidable, the construction and installation of offshore components, as well as their O&M, would have the same potential for negligible to major impacts on these resources as the Proposed Action. Also, if previously undiscovered historic properties are identified and cannot be avoided, impacts would be long term, localized, and minor to major under the Habitat alternative for either layout option, the same as under the Proposed Action.

Terrestrial Resources

The onshore activities proposed under the Habitat alternative for either layout option would be the same as those under the Proposed Action. Therefore, impacts to terrestrial resources would be negligible to moderate (the same as the Proposed Action). Also, if previously undiscovered historic properties are identified and cannot be avoided, impacts would be long term, localized, and minor to major.

Viewshed Resources

The Habitat alternative under either layout option could decrease impacts to viewshed resources because the number of constructed turbines and their viewshed would be reduced. Although slightly reduced, the layout modification and construction activities proposed under this alternative would still include the same historic properties visually impacted under the Proposed Action and the same potential for impacts to these properties. Therefore, the construction and installation of offshore components, as well as their O&M, would have negligible to major impacts to viewshed resources under the Transit alternative, similar to those of the Proposed Action.

Cumulative Impacts

Marine Resources

The layout modification and construction activities proposed under the Habitat alternative for either layout option, although increasing flexibility for avoiding submerged cultural resources in the SFWF, would have the same limits to avoiding ancient submerged landforms at the proposed SFEC location. The cumulative impacts associated with the Habitat alternative under either layout option when combined with past, present, and reasonably foreseeable activities would be short to long term, localized, and negligible to major. This includes if previously undiscovered historic properties are identified and cannot be avoided, where impacts would be long term, localized, and minor to major.

Terrestrial Resources

The Habitat alternative under either layout option would not affect Project onshore activities. Therefore, impacts under the Habitat alternative when combined with past, present, and reasonably foreseeable activities would be negligible to moderate (the same as the Proposed Action), unless previously undiscovered historic properties are identified and cannot be avoided; then, impacts would be long term, localized, and minor to major.

Viewshed Resources

The layout modification and construction activities proposed under the Habitat alternative for either layout option would incrementally reduce the number of WTGs for the SFWF; however, the same historic properties would continue to be adversely affected under this alternative as the Proposed Action. The cumulative visual impacts on historic properties in the APE for viewshed resources and associated with the Habitat alternative under either layout option when combined with past, present, and reasonably foreseeable activities would be long term and negligible to moderate.

Conclusions

Although the Habitat alternative under either layout option would reduce the number of WTGs and their associated inter-array cables, which would have an associated reduction in seabed and viewshed disturbance, BOEM expects that the impacts to cultural resources resulting from the Habitat alternative would be similar to the Proposed Action. The construction and installation of offshore components, as well as their O&M, would have negligible to major impacts to cultural resources under either of these action alternatives. If previously undiscovered historic properties are identified and cannot be avoided, impacts to these resources would also be long term, localized, and **minor to major**.

In the context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that the Habitat alternative’s incremental impacts would be similar to the Proposed Action. The visual impacts of the Habitat alternative under either layout option when combined with past, present, and reasonably foreseeable activities would be negligible to moderate (the same as the Proposed Action). Similarly, if previously undiscovered historic properties are identified and cannot be avoided, impacts would be long term, localized, and **minor to major**.

3.5.2.3 Action Alternative Comparison

As discussed above, the impacts associated with the Proposed Action alone do not change substantially under the other action alternatives. Although the number of WTGs and their associated inter-array cables vary slightly, BOEM expects that impacts to cultural resources would continue to range from negligible to moderate for all action alternatives, and the same historic properties identified would be adversely affected under any of the action alternatives. If previously undiscovered historic properties are identified and cannot be avoided, where impacts would be long term, localized, and **minor to major**.

In the context of reasonably foreseeable environmental trends and planned actions, all action alternatives would occur within the same overall environment (e.g., ongoing and future activities). Therefore, impacts would only vary if the alternatives’ incremental contributions differ. However, as noted above, BOEM expects that the incremental impact from any action alternative would be similar, with the level of individual impacts ranging from negligible to moderate. Therefore, the overall impact of any action alternative when combined with past, present, and reasonably foreseeable activities would be **negligible to moderate** unless previously undiscovered historic are identified and cannot be avoided; then, impacts would be long term, localized, and minor to major. However, BOEM would require a post-review discovery plan that would serve to reduce the level of impact to previously undiscovered historic properties to **moderate** or even lower levels of impact (minor to negligible) where possible.

Consequently, BOEM expects the overall impact on cultural resources from any action alternative to be moderate. The overall impact would vary and can depend on whether resources are unavoidable or discovered during Project activities or have unobscured views of Project structures; however, historic properties, if adversely affected, would be mitigated and thereby moderated through the Section 106 process. The exception is where impacts would render a cultural resource ineligible for the NRHP even with mitigation of impacts, in which case the impact on the ancient submerged landform would remain **major**.

3.5.2.4 Mitigation

BOEM could reduce potential impacts to cultural resources from construction and installation, O&M, and conceptual decommissioning activities by requiring the following conditions of COP approval:

- Avoid potential physical impacts to marine resources and identified historic properties through implementation of a required avoidance area around each, where practicable.
- If a resource is discovered after COP approval or is a marine resource that cannot be avoided by SFW, specify additional investigation or other measures to aid the resolution of adverse effects to the resource.
- If impacts on historic properties cannot be avoided, develop additional mitigation measures through execution of an MOA by BOEM and required signatories to resolve adverse effects under Section 106 of the NHPA.
- Require a post-review discovery plan that SFW would implement during Project construction and O&M to ensure that impacts to unanticipated cultural resources are considered.

If BOEM requires the avoidance and mitigation measures outlined above for cultural resources, then significant impacts to cultural resources would be further reduced; although, the range of potential impacts would still be identified as negligible to moderate or potentially major in the case of unavoidable impacts to marine resource and previously undiscovered historic properties.

Additionally, if BOEM requires the installation of ADLS technology on WTGs, then long-term, negligible to major visual impacts to historic properties would be further reduced by reducing the amount of time WTGs would be visible at night. The short-duration synchronized flashing of the ADLS would have effectively less visual impact at night than the standard continuous, medium-intensity red strobe light aircraft warning systems.

3.5.3 Demographics, Employment, and Economics

3.5.3.1 Affected Environment

In the COP, SFW does not indicate that any single state or county would be the primary recipient of the Project's economic impacts, adverse or beneficial. SFW indicates that as various regional ports could be used for fabrication, assembly, storage, or deployment of materials and crew during development, construction, and conceptual decommissioning of the Project. Table 3.5.3-1. documents the ports, communities, counties, and states that could be directly or indirectly affected by the Project. The list includes ports and communities that the COP indicates could be used for 1) fabrication, assembly, and deployment; 2) crew transfers, logistics, and storage; or 3) landing sites and the interconnection facility. The COP also indicates that the Port of Sheet Harbour in Nova Scotia, Canada, could be used for fabrication, assembly, and/or deployment. The table also lists the ports that are cited in Section 3.5.1 (Commercial Fisheries and For-Hire Recreational Fishing) as deriving a substantial amount of commercial fishing revenue from the Lease Area or along the offshore SFEC (see Table 3.5.1-12 and Table 3.5.1-16). Note that Sheet Harbor in Nova Scotia may be used as a backup port if needed for the marshalling of WTGs and possibly foundation components. However, the use of Sheet Harbor would be minimal as it relates to the overall Project construction (Ørsted 2021). Therefore, Sheet Harbor is not included in the analysis area.

Table 3.5.3-1. Ports, Communities, Counties, and States in the Analysis Area

Port/Facility Name/ Place Name	City/Town	County, State	Fabrication, Assembly, Deployment	Crew Transfer, Logistics, Storage	SFEC Site	Commercial Fishing	For-Hire Recreational Fishing
Port of New London	New London	New London, CT	X	X		X	
Stonington	Stonington	New London, CT				X	X
Fairhaven	Fairhaven	Bristol, MA				X	X
New Bedford Marine Commerce Terminal	New Bedford	Bristol, MA	X	X		X	X
Westport	Westport	Bristol, MA				X	X
Sparrow's Point	Edgemere	Baltimore, MD	X				
Paulsboro Marine Terminal	Paulsboro	Gloucester, NJ	X				
East Hampton	East Hampton	Suffolk, NY			X

3.5.3.1.1 DEMOGRAPHIC CHARACTERISTICS WITHIN THE ANALYSIS AREA

This section describes demographic characteristics and trends in the analysis area. Table 3.5.3-2 describes each potentially affected county and city/town in terms of its area in square miles, population change between 2010 and 2020, population density, and median household income. While a change in population is not itself considered an impact, population change has the potential to drive beneficial or adverse impacts to other socioeconomic variables, such as availability of housing and demand for public infrastructure and services.

Among the potentially affected counties, Suffolk County, New York, had the largest population with nearly 1.5 million residents as well as the highest population density. Population declined for four of the eight counties shown—New London County, Rhode Island, experienced the biggest loss at -3.3%, while Bristol County, Massachusetts, had the largest gain at 3.4%. Populations of listed communities in New York's Suffolk County all increased, while populations in all of the listed communities in Rhode Island declined, with the exception of Providence.

Table 3.5.3-2. Population and Median Income by City/Town and County

State/County/City or Town		Land Area (square miles)*	Population (2010)**	Population (2020)†	2010-2020 (percent change)	Population Density (population/ square mile)	Median Household Income (2019)††
Connecticut	New London County	665	274,055	264,999	-3.3%	398	$73,490
	New London	6	27,620	26,870	-2.7%	4,478	$46,298
	Stonington	39	18,545	18,566	0.1%	476	$81,667
Massachusetts	Bristol County	553	548,285	566,765	3.4%	1,025	$69,095
	New Bedford	20	95,072	95,517	0.5%	4,776	$46,321

Note: Population estimates for communities shown with the § or §§ symbol are estimates for 2019. These symbols also indicate the data source.

Figure 3.5.3-1 is a two-panel figure that shows past and forecast trends in population of the counties in the analysis area. The top panel contains population counts and the lower panel shows the forecast percentage change from the 2020 population estimate. While the available population forecasts do not use the same base year or the same set of assumptions with respect to future changes, they generally represent the best publicly available information. For three of the nine counties (Washington County, Rhode Island; Gloucester County, New Jersey; and Baltimore County, Maryland), forecasts show population increasing throughout the forecast period. Population forecasts for three counties increase initially but then flatten while still remaining greater than 2020 (Providence County, Rhode Island; Bristol County, Massachusetts; and Norfolk County, Virginia). Lastly, three counties are forecast to see population decline in the long run (New London County, Connecticut; Suffolk County, New York; and Newport County, Rhode Island).

3.5.3.1.2 ECONOMIC CHARACTERISTICS WITHIN THE ANALYSIS AREA

This section summarizes primary economic characteristics in the analysis area, including the gross domestic product (GDP) of each potentially affected county and state and state and county employment statistics. The GDP values presented in this analysis represent the market value of goods and services produced by the labor and property located within a geographical area, but they do not include the value of intermediate or used goods in the area. A focus of this analysis is the GDP for the "ocean economy," which includes economic activity dependent upon the ocean, such as commercial fishing and seafood processing, marine construction, commercial shipping and cargo handling facilities, ship and boat building, marine minerals, harbor and port authorities, passenger transportation, boat dealers, and ocean-related tourism and recreation (National Ocean Economics Program 2020).

Most analysis area counties display diverse economic activity, and many have well-developed ocean-based economic sectors. In particular, the ocean-related recreation and tourism sector plays a major role in many county economies affected by the Project (see Section 3.5.8 [Recreation and Tourism]). In addition, commercial fishing fleets are important to coastal communities by generating employment and income for vessel owners and crews as well as by creating demand for shoreside products and services to maintain vessels and process seafood products (see Section 3.5.1 [Commercial Fisheries and For-Hire Recreational Fishing]). The marine transportation sector is expanding in some coastal counties, with the major regional ports seeing increased vessel visits and undertaking upgrades to accommodate the increased utilization.

Table 3.5.3-3 summarizes trends in the annualized total GDP and ocean economy GDP of potentially affected states and counties. Among states, New York had both the largest total GDP and ocean economy GDP, and experienced the largest increase in total GDP over the 2005–2019 period and highest increase in ocean economy GDP over the 2005–2018 period. Among counties, the ocean economy GDP of both Washington County, Rhode Island, and Baltimore County, Maryland, more than doubled in size over the 2005–2018 period. The ocean economy GDP of Norfolk City (an independent city and the equivalent to a county in Virginia) was the only county in analysis area to experience a decline in it ocean economy.

Table 3.5.3-3. Annualized Total and Ocean Economy Gross Domestic Product of Potentially Affected States and Counties

State/County	Total GDP (millions of 2019 dollars)		2005–2019 Percent Change	Percentage of Analysis Area Total GDP in 2019	Ocean Economy GDP (millions of 2019 dollars)		2005–2018 Percent Change	Percentage of Analysis Area Ocean Economy GDP in 2018

Note: A detailed list of economic sectors and industries that the National Ocean Economics Program defines as the ocean economy is available at https://www.oceaneconomics.org/Market/sectors.asp.

Table 3.5.3-4 summarizes the employment characteristics of the analysis area, including the size of the labor force, the number of persons employed, and the unemployment rate in 2019. The size of the labor force in each county mirrors the county's population size, with the largest labor force present in urban areas. Among the potentially affected counties, Suffolk County, New York, had the largest labor force in 2019, with 0.78 million workers. Newport County, Rhode Island, had the smallest labor force, with 44,280 workers. The unemployment rate was low throughout the analysis area in 2019, ranging from 2.7% in Virginia to 3.9 in New York. The unemployment rate calculated as the number of unemployed persons in in the labor force over the entire analysis area was 3.4%. However, unemployment rates throughout the United States have risen substantially in recent months due to the restrictions on economic activity that have been imposed as a result of the COVID-19 pandemic.

Table 3.5.3-4. Employment Characteristics of Potentially Affected States and Counties, 2019

State/County	Estimated Size of Labor Force	Estimated number of Person Employed	Percentage of Labor Force That is Unemployed
Connecticut	**1,912,889**	**1,853,997**	**3.8%**
New London County	137,386	132,457	3.1%

3.5.3.2 Environmental Consequences

3.5.3.2.1 ISSUES, INDICATORS, AND SIGNIFICANCE CRITERIA

Table 3.5.3-5 lists the issues identified for this resource and the indicators and significance criteria used to assess impacts to demographics, employment, and economics for the final EIS. Appendix F provides additional details of the analysis, data sources, and assumptions.

Table 3.5.3-5. Issues, Indicators, and Significance Criteria Used to Assess Impacts to Demographics, Employment, and Economics

<table>
<tr><th>Issue</th><th>Impact Indicator</th><th>Significance Criteria</th></tr>
<tr><td>Development and construction expenditures and employment</td><td>Changes in GDP
Changes in full-time equivalent (FTE) jobs and income
Changes in the demand for housing
Changes in the local supply chain for offshore wind farm components</td><td rowspan="3">Negligible: No measurable impacts would occur.
Minor: Adverse impacts to the affected activity or geographic place could be avoided with EPMs and impacts would not disrupt the normal or routine functions of the affected activity or geographic place. Once the impacting agent is eliminated, the affected activity or geographic place would return to a condition with no measurable effects.
Moderate: Impacts to the affected activity or geographic place are unavoidable, but EPMs would reduce impacts substantially during the life of the Project. The affected activity or geographic place would have to adjust somewhat to account for disruptions due to impacts of the Project, or, once the impacting agent is eliminated, the affected activity or geographic place would return to a condition with no measurable effects if proper remedial action is taken.
Major: The affected activity or geographic place would experience unavoidable disruptions to a degree beyond what is normally acceptable, and, once the impacting agent is eliminated, the affected activity or geographic place could retain measurable effects indefinitely, even if remedial action is taken.</td></tr>

<tr><td>Conceptual decommissioning expenditures and employment</td><td>Changes in FTE jobs and income</td></tr>
</table>

3.5.3.2.2 NO ACTION ALTERNATIVE

The Affected Environment section provides information on existing demographics, employment, and economic trends from past and present activities. Attachment 3 in Appendix E provides additional information regarding past and present activities and associated demographics, employment, and economic impacts. Future non-Project actions include residential, commercial, and industrial development and onshore utility projects that include solar power, transmission, gas pipeline, communications tower, and land-based wind energy projects. Offshore projects other than offshore wind would support the existing marine industries and workforce. Ocean-based industries, including tourism and recreation, commercial fishing, and marine transportation, would continue to be important to the economies of many of the counties within the geographic analysis area. Attachment 3 in Appendix E also discloses future non-offshore wind activities and associated demographics, employment, and economic impacts. Impacts associated with future offshore wind activities are described below.

Future Activities (without the Proposed Action)

Employment: The assessment of impacts of future offshore wind activities on demographics, employment, and economics in the analysis area under the No Action alternative primarily focuses on the potential employment opportunities generated by these activities. As shown in in Appendix E, approximately 17 separate offshore wind development projects phases are in planning phases through 2030. Together, these wind farms could add approximately 21,000 MW of renewable energy by 2030 into the energy grid from Massachusetts to North Carolina, using the same geographic ranges of ports specified in the COP for the SFWF Project.

Table 3.5.3-6 shows projected employment from existing and future offshore wind developments within the analysis area for the years 2020–2030 under the No Action alternative. The estimates have been developed using the JEDI Offshore Wind Model[23] using the construction phases described in Tables E-4 in Appendix E.[24] Most of the direct construction-related jobs would be attributed to either the community

[23] The Jobs and Economic Development Impacts Offshore Wind Model—an interactive spreadsheet model developed and maintained by the National Renewable Energy Laboratory (2017)—was used to generate estimates of local employment and income as well as capital and operating expenditures. The model is described more completely in Appendix F.
[24] The timeline shown in the table does not extend into the future far enough to include conceptual decommissioning jobs.

hosting the regional headquarters of the project developer or the fabrication and storage ports that would be used. In general, the specific locations of the regional fabrication and storage ports for specific projects have not been announced, although it is clear that New Bedford has been selected for the Vineyard Wind project.

Table 3.5.3-6. Projected Construction and Operations Jobs in the Geographic Analysis Area under the No Action Alternative, 2020–2030

	2020	2021	2022	2023	2024	2025	2026	2027	2028	2029	2030

Source: Estimates were developed using the JEDI-OWM (National Renewable Energy Laboratory 2017).

Note: The O&M jobs shown for 2020 are estimates for the BIWF.

* Construction jobs are defined as full-time equivalents (FTEs), or 2,080-hour units of labor (one construction period job equates to one full-time job for 1 year).

BVG Associates, Ltd. (2017) analyzed the specific occupations required for offshore wind energy development in the United States. The main finding was a significant requirement for technician-level workers in production roles, particularly high-value manufacturing positions; installation and commissioning positions, vessel and offshore equipment operation, and commissioning and testing turbines, cables, and substations; and O&M roles, particularly turbine technicians. The report notes that a particular value of offshore wind jobs is that many are created in industrialized coastal areas, which have suffered from economic decline in recent years. Offshore wind can play an important part in reversing that situation.

In communities with ports that would be used for staging and fabrication of offshore wind facilities, offshore wind development could temporarily compete with the local commercial fishing industry for marine workers. This competition could exacerbate current fishing industry labor shortages. Recent studies (e.g., Johnson and Mazur 2018) show that some commercial fisheries in the New England and Mid-Atlantic regions face workforce challenges, with a lack of young people entering the industry. In addition, the increased economic activity during the construction phase of offshore wind facilities may temporarily increase competition for some onshore facilities and services, thereby resulting in higher prices for these facilities and services. With an increase in prices, some businesses in the commercial fishing industry and other marine sectors may seek facilities and services in ports not supporting offshore wind development.

<u>Port utilization and traffic</u>: Offshore wind development could also generate economic activity at ports used to support the construction and operation of offshore wind projects through port upgrades and development as well as marine transportation. These types of upgrades are described in Appendix E. Where existing ports are improved and channels are dredged for use in support of offshore wind, additional shore-based and marine workers would be hired, resulting in a trained workforce for the offshore wind industry and contributing to beneficial local and regional economic activity. Moreover, these port improvements would be beneficial to other port activity. Overall, the port investment and usage generated by offshore wind under the No Action alternative would have long-term beneficial impacts on

employment and economic activity by providing employment opportunities and supporting marine service industries such as marine construction, ship construction and servicing, and related manufacturing. See Whitney et al. (2016) for a summary of the current status of U.S. ports as well as some of the planned and implemented port expansions to further support offshore wind.

However, congestion and delays could increase fuel costs (i.e., for vessels forced to wait for port traffic to pass) and could decrease productivity for commercial shipping, fishing, and recreational vessel businesses, the income of which depends on the ability to spend time out of port. Collisions could lead to vessel damage and spills, which could have direct costs (i.e., vessel repairs and spill cleanup) as well as indirect costs from damage caused by spills. This would represent a temporary and minor adverse impact.

Land disturbance, presence of structures, new cable emplacement/maintenance, light, noise: Actions associated with onshore and offshore construction and O&M would result in temporary to long-term increases in noise, traffic, lighting, and human activity. These actions would qualify as negligible to minor because it is expected that these impacts would not disrupt normal or routine demographic characteristics, employment, or economic activity in the analysis area—or that, in the case of temporary economic activity specifically associated with construction, any such changes would generally revert to pre-construction conditions following construction completion. Detailed analysis of structure and cable impacts to commercial and for-hire recreation fishing and navigation are provided in Sections 3.5.1.2.2 (No Action Alternative) and 3.5.6.2.2 (No Action Alternative), respectively. Analysis of noise impacts to fish populations, which could indirectly affect fishing-related economic activity, is described in Section 3.4.2.2.2 (No Action Alternative). Lighting, noise, and structure impacts to recreation and tourism are described in Section 3.5.8.2.2 (No Action Alternative).

Conclusions

Under the No Action alternative, BOEM would not approve the COP; Project construction and installation, O&M, and conceptual decommissioning would not occur; and potential impacts associated with the Project would not occur. However, ongoing and future activities would have continuing temporary to long-term impacts on demographics, employment, and economic activity, primarily through new job formation associated with offshore wind development.

BOEM anticipates that the range of impacts for reasonably foreseeable offshore wind activities would be **negligible** to **minor**, and **minor beneficial**. Based on the IPFs described in Appendix E Attachment 3, BOEM anticipates that the range of impacts for ongoing activities and reasonably foreseeable activities other than offshore wind would be **minor** to **minor beneficial**. These impacts would be driven primarily by the continued operation of existing marine industries, especially commercial fishing, recreation/tourism, and shipping; increased pressure for environmental protection of coastal resources; the need for port maintenance and upgrades; and the risks of storm damage and sea level rise.

Considering all the IPFs together, BOEM anticipates that the impacts associated with future offshore wind activities in the geographic analysis area combined with ongoing activities, reasonably foreseeable environmental trends, and reasonably foreseeable activities other than offshore wind would result in **minor beneficial** impacts, as effects would represent a small improvement to the geographic analysis area's diverse economy.

3.5.3.2.3 PROPOSED ACTION ALTERNATIVE

Construction and Installation

The impact of the Project capital expenditures (CapEx) on GDP would be minor and beneficial for the analysis area.[25] As indicated in Table F-10 in Appendix F, local CapEx for development and construction of the SFWF are expected to inject between $182.4 and $246.8 million into the regional economy, including taxes, over a 3-year period beginning in 2021, or $60.8 to $82.3 million on an annual basis. The range of estimates depends primarily on installed capacity of the wind farm, which could be as low as 90 MW or as high as 180 MW. When compared to the analysis area, this level of spending represents less than 0.006% of the area's total GDP. Even if 100% of the larger of the two local CapEx amounts was spent in a single year entirely within Rhode Island (the smallest of the analysis area's state economies), it would account for less than 0.4% of that state's annual GDP. If that growth in GDP had been injected into Rhode Island's economy in 2018, the annual GDP growth rate would have increased from 0.77% to 1.18%. Therefore, the impact of the Project on the GDP of states within the analysis area would be beneficial but minor and temporary.

The impact of the Project CapEx on local full-time equivalent (FTE) jobs and income would be beneficial. Table F-12 in Appendix F indicates that depending on the total Project capacity, local full-time equivalent (FTE) jobs in the analysis area from direct spending by SFW over the 3-year development and construction period would range from 331 to 432, and indirect FTE jobs in the supply chain would range from 538 to 704. In addition, between 357 and 475 induced FTE jobs are expected. In total, an estimated 1,226 to 1,611 FTE jobs would be created during Project construction. These estimates of the number of jobs created are presented in job-years, which does not account for the timing or the duration of the work. In other words, these job-years would likely be spread over multiple years, which means that fewer people would likely be working at a given time than the numbers presented. As described in Table G-1 in Appendix G, where possible, local workers would be hired to meet labor needs for Project construction.

Economic benefits are also expected to accrue to ports that undertake improvements to support Project development. Additional shore-based and marine workers would be hired, resulting in a trained workforce for the offshore wind industry and contributing to beneficial local and regional economic activity. Moreover, port improvements would support and enhance other port activities. These beneficial impacts to local employment and economic activity would range from minor to moderate.

The adverse or beneficial economic impacts of Project construction activities on other sectors in the ocean economy aside from marine construction and transportation would be temporary and negligible to moderate. With respect to the ocean-related recreation and tourism sector, all construction activities would be conducted such that public recreation would not be precluded from use (see Section 3.5.8 [Recreation and Tourism]). SFW would establish a construction schedule to minimize economic impacts to local communities during the summer tourist season. Construction and installation of the Project would have temporary minor to moderate adverse economic impacts on commercial fisheries and for-hire recreational fishing because of increased congestion in ports, reduced fishing access, damage to or loss of fishing gear, and decreased catch of target species (see Section 3.5.1 [Commercial Fisheries and For-Hire Recreational Fishing]). As described in Section 3.5.1.2.3, the largest impacts in terms of exposed revenue as a percentage of total commercial fishing revenue in the Mid-Atlantic regions would be in the ports of New Shoreham (3.6%), Little Compton (3.4%), and Tiverton (2.2%). The communities in which these

[25] The Jobs and Economic Development Impacts Offshore Wind Model (JEDI-OWM) —an interactive spreadsheet model developed and maintained by the National Renewable Energy Laboratory (2017)—was used to generate estimates of capital and operating expenditures, together with estimates of local employment and income noting that the JEDI-OWM defines local as occurring within the state in which the development and construction project is based. The JEDI-OWM is described in greater detail in Appendix F.

ports are located have a low to medium dependence on commercial fishing. The annual exposed revenue across all affected ports represents approximately 0.17% of the total commercial fishing revenue of these ports. Section 3.5.1.2.3 notes that revenue exposure estimates should not be interpreted as measures of actual economic impact. The actual economic impact would depend on many factors, including the potential for fishing vessel operators to find suitable alternative fishing locations and continue to earn revenue. Considering the estimated low revenue of risk across ports, together with the small number of vessels that depend heavily on the Lease Area, the impacts to other fishing industry sectors, including seafood processors and distributors and shoreside support services, are expected to be temporary and moderate.

In communities with ports that would be used for staging and fabrication of the Project, Project-related construction activities could temporarily compete with the local commercial fishing industry for marine workers. As described in Section 3.5.3.2.1, some commercial fisheries in the New England and Mid-Atlantic regions face workforce challenges, with a lack of young people entering the industry. The competition for marine workers during Project construction may also result in higher prices for certain local shoreside support services. With an increase in service prices, some businesses in the commercial fishing industry and other marine sectors may seek services in ports not supporting Project construction.

Project construction would have a negligible impact on population-related variables such as availability of housing and demand for public infrastructure and services. Workers involved in offshore installation of WTGs, the OSS, the inter-array cable, and the offshore SFEC would all be housed on-board vessels and would be expected to work for several weeks at sea before returning to shore. These conditions imply that offshore crews would have little incentive to relocate to a port city. In ports selected for fabrication and assembly, non-local workers could need temporary housing depending on the ports selected. Local hiring practices by SFW contractors for these jobs could mitigate temporary, local increases in demand for housing and public infrastructure and services.

The Project would have a temporary and minor beneficial impact on the local supply chain for offshore wind farm components. Because of the specialized nature of many offshore wind components, a single project is unexpected to spur major investment in manufacturing facilities.

Operations and Maintenance

O&M occupations would consist of wind technicians, plant managers, water transportation workers, and engineers. As described in Table G-1 in Appendix G, where possible, local workers would be hired to meet labor needs for Project O&M. Section 3.2.1.5 of the COP states the O&M activities would be based in either Quonset Point in North Kingstown, Rhode Island, or in Montauk/East Hampton, New York. As summarized in Table F-12 in Appendix F, results from the Jobs and Economic Development Impacts Offshore Wind Model indicate that local operating expenditures (OpEx) and employment resulting from the Project would create an estimated 47 to 96 FTE jobs annually along with $4 million to $8 million in local annual income. If it is assumed that as many as 50 of the OpEx-related jobs are located in Suffolk County, New York, they would represent less than 0.01% of total employment in the county. Similarly, if 50 of the OpEx-related jobs were located in Quonset Point, they would represent less than 0.08% of the total employment in Washington County, Rhode Island. Thus, the impacts of OpEx employment and income would be beneficial and long term but minor.

In addition to local employment and income, BOEM estimates that the SFWF would provide the U.S. Treasury an annual operating fee of approximately $432,000 (Stillings 2019). The actual value of the fee would depend on various factors, such as annual average wholesale electric power price and the wind farm's capacity factor.

The adverse or beneficial economic impacts of Project O&M activities on sectors in the ocean economy are expected to be long term but negligible to moderate. Economic benefits to ports would be minor, as port use would be limited to vessel traffic associated with routine Project O&M. Operation of onshore Project components would have negligible adverse economic impacts to the ocean-related recreation and tourism sector because onshore maintenance requirements are infrequent (see Section 3.5.8 [Recreation and Tourism]). It is anticipated that ocean beaches could experience a temporary increase in curiosity visits as well as a decrease in visits from users who do not appreciate seeing the WTGs while recreating. All adverse economic impacts to commercial fisheries and for-hire recreational fishing during Project O&M would be minor to moderate (see Section 3.5.1 [Commercial Fisheries and For-Hire Recreational Fishing]). As described in Section 3.5.1.2.3, the largest impacts in terms of exposed revenue as a percentage of total commercial fishing revenue in the Mid-Atlantic regions would be in the ports of Little Compton (1.3%) and Westport (0.8%). The communities in which these ports are located have a low to medium dependence on commercial fishing. The annual exposed revenue across all affected ports represents about 0.02% of the total commercial fishing revenue of these ports. Section 3.5.1.2.3 notes that revenue exposure estimates should not be interpreted as measures of actual economic impact. The actual economic impact would depend on many factors, including the potential for continued fishing to occur in the SFWF and for fishing vessel operators to find suitable alternative fishing locations. The “reef effect” of WTG foundations and associated scour protection would have minor to moderate beneficial economic impacts to for-hire recreational fishing, depending on the extent to which the foundations attract targeted species.

Conceptual Decommissioning

As with the Project CapEx, expenditures and employment for conceptual decommissioning of the offshore infrastructure—estimated to take an additional 2 years to complete after the 25-year Project duration—are not expected to substantially change the existing trends of employment and economic activity in the region. As described in Appendix F, conceptual decommissioning costs are expected to range from $110.8 to $136.3 million (see Appendix F for assumptions and data source). Because these costs are primarily labor and contracting costs, a relatively high percentage of these expenditures would accrue to local economies. Thus, conceptual decommissioning would have a temporary, minor beneficial impact on employment and income in the analysis area.

Conceptual decommissioning of the SFWF and offshore SFEC would have similar impacts on commercial fisheries and for-hire recreational fishing as construction. Removal of structures that act as artificial reefs would result in loss of any beneficial fishing impacts that could have occurred during O&M.

Cumulative Impacts

<u>Employment</u>: BOEM anticipates that the Proposed Action would result in minor beneficial incremental impacts employment due to new hiring and economic activity. Offshore wind development would provide a regional market and ongoing demand for workers skilled in the professions and trades needed for construction, installation, maintenance, and repair of offshore wind facilities. Construction activities related to future offshore wind projects are expected to create an average of approximately 13,000 FTE job-years from 2020 through 2030, including direct, indirect, and induced jobs. It is estimated that the Project would account for approximately 4% of those job-years. By 2030, O&M activities related to future offshore wind projects are expected to create on average approximately 4,374 annual FTE jobs if direct, indirect, and induced jobs are included, with the Project accounting for about up to 2% of those jobs depending on the installed capacity of the project. Therefore, when considered in combination with past, present, and other reasonably foreseeable projects, the Project would have long-term, minor beneficial impacts for demographics, employment, and economics.

Port utilization and traffic: Port upgrades and vessel activity associated with the Proposed Action could result in minor beneficial and minor adverse incremental impacts through an increase in economic and employment opportunities, as well as reduced port access, increased delays and congestion, or increased collision risk. Where existing ports are improved and channels are dredged for use in support of offshore wind, additional shore-based and marine workers would be hired, resulting in a trained workforce for the offshore wind industry and contributing to beneficial local and regional economic activity. Therefore, when considered in combination with past, present, and other reasonably foreseeable projects, the Project would have temporary minor adverse impacts and long-term, minor beneficial impacts for demographics, employment, and economics.

Land disturbance, presence of structures, new cable emplacement/maintenance, light, noise: The Proposed Action would contribute negligible to minor incremental onshore and offshore impacts, including new structures, lighting, and noise sources, to the No Action alternative. The effects of these actions are addressed in other final EIS sections. Analysis of structure impacts to commercial and for-hire recreation fishing and navigation are provided in Sections 3.5.1.2.3 (Proposed Action Alternative) and 3.5.6.2.3 (Proposed Action Alternative). Analysis of noise impacts to fish populations, which could indirectly affect fishing-related economic activity, is described in 3.4.2.2.3 (Proposed Action Alternative). Lighting, noise, and structure impacts to recreation and tourism are described in Section 3.5.8.2.3 (Proposed Action Alternative). Overall, effects from these IPFs would be limited in duration and magnitude. Therefore, the Proposed Action when combined with other past, present, and reasonably foreseeable activities would also result in negligible to minor adverse impacts to demographics, employment, and economics.

Conclusions

Project construction and installation and conceptual decommissioning would generate new revenue and jobs to the regional economy. Economic benefits from Project O&M would be much lower than those produced during construction and conceptual decommissioning, but could also result in limited employment and income. BOEM anticipates the impacts resulting from the Proposed Action alone would range from **negligible to minor** adverse and **minor beneficial** to **moderate beneficial**. Therefore, BOEM expects the overall impact from the Proposed Action alone to be **minor beneficial** because the effect that would occur to routine demographic characteristics, employment, or economic activity in the geographic analysis area would be small. In the case of temporary economic activity specifically associated with construction, any such changes would generally revert to pre-construction conditions following construction completion.

Considering all the IPFs together, BOEM anticipates that the overall impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would result in **minor adverse** and **minor beneficial** impacts to demographics, employment, and economics. BOEM made this conclusion as the effect to routine demographic characteristics, employment, or economic activity in the geographic analysis area would be small.

3.5.3.2.4 VESSEL TRANSIT LANE ALTERNATIVE

Under the Transit alternative, the Project would have slightly smaller beneficial economic impacts during the Project construction phase because elimination of turbines would result in lower construction expenditures and employment.

During Project O&M, the Transit alternative would also have less of an adverse economic impact on commercial fisheries relative to the Proposed Action due to the lower navigation complexity of the Transit alternative. All other construction and installation, O&M, and conceptual decommissioning impacts on demographics, employment, and economics would be similar to the Proposed Action: negligible to minor adverse and minor beneficial to moderate beneficial.

Cumulative Impacts

The Transit alternative would contribute less to beneficial economic impacts due to fewer construction-related jobs. This alternative would also contribute fewer adverse impacts for commercial fisheries, due to a reduced number of WTGs. However, as noted above, the Transit alternative would otherwise result in incremental impacts to demographics, employment, and economics at quantities and durations similar to, or slightly reduced from, the Proposed Action. Therefore, the cumulative impacts to demographics, employment, and economics would be similar to the Proposed Action: negligible to minor and minor beneficial.

Conclusions

Although the Transit alternative would reduce the number of WTGs and their associated inter-array cables, BOEM expects that the impacts resulting from the alternative alone would be similar to the Proposed Action and range from **negligible to minor** adverse and **minor beneficial** to **moderate beneficial** because the effect to routine demographic characteristics, employment, or economic activity in the geographic analysis area would be small.

In context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that the Transit alternative's incremental impacts would be similar to the Proposed Action (with individual IPFs leading to impacts ranging from **negligible to minor and minor beneficial**). The overall impacts of the Transit alternative when combined with past, present, and reasonably foreseeable activities would therefore be the same level (with the same rationale) as under the Proposed Action: **minor** adverse and **minor beneficial**.

3.5.3.2.5 FISHERIES HABITAT IMPACT MINIMIZATION ALTERNATIVE

Under the Habitat alternative for either option layout, several of the proposed WTGs and associated inter-array cables would be eliminated. Consequently, this alternative would have slightly smaller beneficial economic impacts during the Project construction phase as compared to the Proposed Action because elimination of turbines would result in lower construction expenditures and employment. All other impacts on demographics, employment, and economics in the analysis area would be similar to the Proposed Action. Therefore, impacts would not be measurably different than under the Proposed Action: negligible to minor adverse and minor beneficial to moderate beneficial.

Cumulative Impacts

It is presumed that the Habitat alternative under either layout option would reduce the total number of WTGs, which would result in a marginal reduction in construction-related offshore wind farm employment. These reductions would most often be seen in the duration of employment rather than in the number of employed persons. Therefore, cumulative demographic effects would be only marginally less than the impact under the Proposed Action (i.e., negligible to minor and minor beneficial).

Conclusions

Although the Habitat alternative under either layout option would reduce the number of WTGs and their associated inter-array cables, which would have an associated reduction in associated vessel and equipment use and air emissions, BOEM expects that the impacts resulting from the alternative alone would be similar to the Proposed Action and range from **negligible to minor** adverse and **minor beneficial** to **moderate beneficial** because the effect to routine demographic characteristics, employment, or economic activity in the geographic analysis area would be small.

In context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that the Habitat alternative's incremental impacts would be similar to the Proposed Action (with individual IPFs leading to impacts ranging from **negligible** to **minor** and **minor beneficial**). The overall impacts of the Habitat alternative under either layout option when combined with past, present, and reasonably foreseeable activities would therefore be the same level (with the same rationale) as under the Proposed Action: **minor** adverse and **minor beneficial**.

3.5.3.3 Action Alternative Comparison

As discussed above, the impacts associated with Proposed Action alone do not change substantially under other evaluated action alternatives. Although the number of WTGs and their associated inter-array cables varies slightly, BOEM expects that impacts would range from **negligible to minor** adverse and **minor beneficial** to **moderate beneficial** for all action alternatives because the effect to routine demographic characteristics, employment, or economic activity in the geographic analysis area would be small.

In context of reasonably foreseeable environmental trends and planned actions, all action alternatives would occur within the same overall environment (e.g., ongoing and future activities). Therefore, impacts would only vary if the alternatives' incremental contributions differ. However, as noted above, BOEM expects that the incremental impact from any action alternative would be similar, with the level of individual impacts ranging from **negligible** to **minor** and **minor beneficial**. Therefore, the overall impact of any action alternative when combined with past, present, and reasonably foreseeable activities would be **minor** adverse and **minor beneficial**. These impacts would not disrupt normal or routine demographic characteristics, employment, or economic activity in the geographic analysis area—or that, in the case of temporary economic activity specifically associated with construction, any such changes would generally revert to pre-construction conditions following construction completion.

3.5.3.4 Mitigation

No potential additional mitigation measures for demographics, employment, and economics are identified in Appendix G.

3.5.4 Environmental Justice

3.5.4.1 Affected Environment

Executive Order 12898 (Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations) requires that "each Federal agency shall make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations, low-income populations, Native American tribes, and indigenous peoples" (EPA 2019).[26] Table 3.5.4-1 describes selected environmental justice characteristics of the cities/towns, counties, and states where potentially affected ports or landing sites are located. The environmental justice characteristics of possible cities/towns supporting Project activities that Section 3.5.1 (Commercial Fisheries and For-Hire Recreational Fishing) identified as major fishing ports (see Section 3.5.1) are shown in their own section of the table.

[26] The term *indigenous peoples* includes state-recognized tribes; indigenous and tribal community-based organizations; individual members of federally recognized tribes, including those living on a different reservation or living outside Native American country; individual members of state-recognized tribes; Native Hawaiians; Native Pacific Islanders; and individual Native Americans (EPA 2020a).

Table 3.5.4-1. Environmental Justice Characteristics of Cities/Towns, Counties, and States in the Analysis Area

* Three of the five census block groups included in the zone around Montauk are also included in the zone around Hither Hills, whereas 15 of the 22 census block groups in the zone around Hither Hills are also included in the zone around Beach Lane.

† Fifteen of the 20 census block groups in the zone around Beach Lane are also included in the zone around Hither Hills.

¶ Population composition corresponds to the demographic makeup of a community, including race, marital status, age, and ability to speak English. A high rating indicates a more vulnerable population.

‡‡ Poverty is expressed as those receiving assistance, families below the poverty line, and individuals older than 65 and younger than 18 in poverty. A high rating indicates a high rate of poverty and a more vulnerable population.

§§ Personal disruption captures unemployment status, educational attainment, poverty, and marital status. A high rating indicates less personal capacity to adapt to changes and thus a more vulnerable population.

Five-km zones were drawn around potentially affected ports or landing sites. These zones encompass most onshore Project activities during construction and installation, O&M, and conceptual decommissioning that could impact local residents. Zones were identified as areas of potential environmental justice concern if 1) the minority population exceeds 50%, or 2) the minority or low-income population is meaningfully greater than the minority or low-income population percentage in a reference population. For the purpose of this analysis, the reference population is the population of the county or state in which a 5-km zone is located. Appendix F describes the methodology used to calculate whether a minority or low-income population is meaningfully greater than the reference population. Minority and low-income populations were identified using the EPA's EJSCREEN tool (EPA 2020b). Within that tool, minority status determination is based on identifying individuals who are non-white or who are white but have Hispanic ethnicity; low-income status determination is based on identifying individuals for whom the ratio of household income to the poverty level in the previous 12 months was less than two.

Table 3.5.4-2 and Table 3.5.4-3 show the census block groups in the 5-km zones of the analysis area that are areas of potential environmental justice concern according to the above definition. Of the estimated 533 census block groups in the analysis area, approximately 41% were determined to be areas of potential environmental justice concern because of the concentrations of minority populations, whereas approximately 40% had concentrations of low-income populations. Three of the ports (New Bedford, Providence, and New London) accounted for 90% of the minority census blocks and 85% of the low-income census blocks. Figures F-1 through F-6 in Appendix F show the locations of these census block groups.

Data are not available to identify the at-sea and shoreside participants in the potentially affected commercial and for-hire recreational fisheries who are members of minority or low-income populations. However, studies (e.g., National Guestworker Alliance 2016; New American Economy 2017) suggest that certain workers in the United States commercial fishing industry, such as factory floor seafood processor workers and fishing vessel deckhands, are often members of minority and/or low-income groups. Some of these industry participants who are members of minority and/or low-income groups likely reside in communities other than those listed in Table 3.5.1-4. Due to increasing real estate values and tax burdens in many northeastern coastal communities (e.g., see Jimenez 2021), a large number of workers in the fishing industry, especially those with low incomes, may reside in distant communities and have little direct connection to the ports where fishing vessels are based and where fish are landed and processed. Consequently, the fishing industries in communities in Table 3.5.1-4 with a low population composition and poverty rating can still have a high proportion of minority and low-income individuals and have little direct connection to the ports where fishing vessels are based or where fish are landed and processed.

Guidance provided by the Council on Environmental Quality (CEQ) indicates that potential impacts on the social or cultural practices of Native American tribes as a result of impacts to the natural or physical environment should be assessed as potential environmental justice impacts (CEQ 1997). The connection of Native American tribes to marine fisheries within the current project areas has been established in academic literature (Chaves 2014; Trigger 1978). During government-to-government consultations with BOEM, representatives from federally recognized tribes expressed concerns about a variety of potential impacts to culturally significant environmental and physical resources (see Appendix A).

Representatives from federally recognized tribes shared with BOEM the deep cultural and spiritual connection their tribal members have to the natural environment and wildlife within and around the Proposed Action, including the now submerged and buried landforms on the OCS previously occupied by their ancestors, which contain the remains of their settlements as well as burials. The representatives expressed concerns about potential negative impacts to culturally significant species such as NARW, fish and shellfish communities that have sustained their people for millennia, and potential water quality impacts that could affect future generations. Representatives from the federally recognized tribes also expressed concerns about potential visual impacts to sacred landscape features and sacred spaces from the presence of renewable energy infrastructure.

Potential impacts to the following environmental and physical resources that are considered culturally significant to the consulted tribes are assessed in the final EIS: water quality (Section 3.3.2), shellfish (Section 3.4.2), finfish (Section 3.4.2), marine mammals (Section 3.4.5), benthic communities (Section 3.4.2), tourism (Section 3.5.8), and historic properties (Section 3.5.2).

Table 3.5.4-2. Census Block Groups in the Analysis Area That Are Areas of Potential Environmental Justice Concern Due to Minority Populations*

3.5.4.2 Environmental Consequences

3.5.4.2.1 ISSUES, INDICATORS, AND SIGNIFICANCE CRITERIA

Table 3.5.4-4 lists the issues identified for environmental justice and the indicators and significance criteria used to assess impacts for the final EIS.

Table 3.5.4-4. Issues, Indicators, and Significance Criteria Used to Assess Impacts to Environmental Justice

Issue	Impact Indicator	Significance Criteria
Potential public health and safety impacts	Qualitative assessment of impacts to minority and low-income populations from Project impacts that could affect public health and safety, including air quality, water quality, noise, and land use impacts	Negligible: No measurable impacts would occur. Minor to moderate: Adverse impacts to the affected environmental justice population could be avoided with EPMs or would be unavoidable but not disproportionately high and adverse. Major: The affected environmental justice population would experience disproportionately high and adverse effects due to 1) impacts on the natural or physical environment; 2) impacts that appreciably exceed or are expected to appreciably exceed those on the general population or other appropriate comparison group; or 3) impacts that occur or would occur in a minority or low-income population, or Native American tribe affected by cumulative or multiple adverse exposures from environmental hazards
Potential job and income losses due to disruption of commercial fisheries or for-hire recreational fishing*	Qualitative assessment of economic impacts to minority and low-income populations due to Project impacts to commercial fisheries and for-hire recreational fishing	
Potential underrepresentation of minority or low-income populations in the public participation process	Qualitative assessment of impacts on the natural or physical environment	

* This analysis does not assess economic impacts to minority or low-income populations that could occur as a result of employment and income changes in sectors of the ocean economy other than the commercial fishing and for-hire recreational fishing industries. As discussed in Section 3.5.3.2.3 (Demographics, Employment, and Economics), Project construction and installation would support new employment and economic activity in the marine construction and transportation sectors. As described in Table G-1 in Appendix G, where possible, local workers would be hired to meet labor needs for Project construction. These employment and income benefits are expected to be no greater for minority or low-income populations than those experienced by non-minority or non-low-income members of the general population who also reside in the analysis area. Section 3.5.3.2.3 also notes that the adverse or beneficial economic impacts of Project construction activities on other sectors in the ocean economy aside from marine construction and transportation and would be temporary and negligible to moderate. The adverse or beneficial economic impacts of Project O&M activities on sectors in the ocean economy are also expected to be negligible to moderate but long term.

3.5.4.2.2 NO ACTION ALTERNATIVE

The Affected Environment section provides information on existing environmental justice populations occurring in the geographic analysis area. Attachment 3 in Appendix E provides additional information regarding past and present activities that could affect environmental justice populations. Attachment 3 in Appendix E also discloses future non-offshore wind activities that could affect environmental justice populations. Impacts to environmental justice populations associated with future offshore wind activities are described below.

Future Activities (without the Proposed Action)

Air emissions and noise: During construction of future wind development activities, there could be temporary, minor to moderate impacts to air quality, and neighboring or adjacent land to reasonably foreseeable projects could temporarily be disturbed by project–related noise and dust. See Section 3.5.5 (Land Use and Coastal Infrastructure) and Section 3.3.1 (Air Quality) for additional details. State and local agencies would be responsible for managing actions to help minimize and avoid noise, air quality, and other impacts on nearby neighborhoods during construction. Therefore, offshore wind energy construction is expected to have temporary, minor to moderate air quality and noise impacts on environmental justice populations.

Despite the potential for increased air emissions during construction of new offshore wind energy projects, replacing the need for fossil fuel power generation, would have a net beneficial impact on air quality. The reduction in air emissions could produce measurable benefits in terms of lower health costs and loss of life. See Section 3.3.1 (Air Quality) for additional details. Members of minority and low-income populations tend to be more burdened with adverse health conditions that can increase susceptibility to the harmful health effects of exposure to environmental pollution, including the fine particulate matter air pollution from fossil fuel–fired power plants (EPA 2016; Thind et al. 2019). Therefore, the air quality improvements from offshore wind energy development would have a long-term beneficial impact on environmental justice populations. Similarly, future offshore wind project GHG emissions during construction would be negligible (14,161 tons of CO_2) as compared to aggregate global emissions, and these projects may beneficially contribute to a broader combination of actions to reduce future impacts from climate change over the long term.

By reducing fossil fuel power plant GHG emissions future offshore wind projects may also beneficially contribute to a broader combination of actions to reduce future impacts from climate change over the long term. See Section 3.3.1 (Air Quality) for additional details. People who live in poverty may be particularly vulnerable to the adverse economic impacts of climate change because they have fewer financial resources to cope with these effects (EPA 2017). Therefore, the reduction in GHG emissions resulting from offshore wind energy development would have a long-term beneficial impact on environmental justice populations.

Accidental releases and discharges: Future offshore wind activities would affect water quality via increased potential turbidity and sedimentation and accidental spills. See Section 3.3.2 (Water Quality) for additional details. However, offshore wind energy development would comply with all regulatory requirements for water quality protection. Therefore, environmental justice populations in the analysis area are expected to experience long-term but minor adverse water quality impacts as a result of future offshore wind activities.

Vessel traffic, presence of structures, new cable emplacement/maintenance, light: An analysis of vessel traffic, structure, cable, and other impacts to commercial fisheries and for-hire recreational fishing that could result from future offshore wind energy development is provided in Section 3.5.1 (Commercial Fisheries and For-Hire Recreational Fishing). Onshore and offshore lighting and structure impacts to recreation and tourism, as described in Section 3.5.8 (Recreation and Tourism), could also affect for-hire recreational fisheries. Many lower level workers employed in the commercial fishing and for-hire recreational fishing industries, such as factory floor seafood processor workers and fishing vessel deckhands, are members of minority and/or low-income groups. To the extent that the impacts of future offshore wind activities result in declines in the economic performance of commercial and for-hire recreational fisheries, members of environmental justice populations could be disproportionately affected, especially if employment in the seafood processing industry declines. However, WTG spacing and orientation measures, offshore cable burial, financial compensation programs for fishing interests, and other mitigation measures implemented by offshore wind developers, together with the ability of fishing vessel operators to adjust transit and fishing locations to avoid conflicts with construction and O&M activities related to offshore wind energy development, would help ensure that fishing businesses could continue to operate with minimal disruption. Therefore, adverse impacts to minority and low-income populations engaged in commercial fisheries and for-hire recreational fishing would be minor to moderate.

In addition, the temporary to long-term adverse impacts of future offshore wind activities on recreational fisheries could impact low-income residents who disproportionately rely on these fisheries as a food source. Similarly, future offshore wind activities could have adverse impacts on the subsistence fisheries of tribal and indigenous peoples in the analysis area. However, most recreational fishing in the analysis area occurs close to shore (see Section 3.5.8 [Recreation and Tourism]). In addition, historically, much of the fishing by the region's tribal and indigenous peoples was concentrated in the nearshore marine and estuarine environment (Bennett 1955). Recent BOEM consultation with Native American tribes in adjacent lease areas to the Project indicate that tribal subsistence fisheries continue to occur predominately in inshore areas (BOEM 2020). Consequently, future development occurring further offshore, such as offshore wind projects, are expected to have a negligible to minor impact on the recreational and subsistence fishing activities of environmental justice populations.

Land disturbance: As noted in Section 3.5.2 (Cultural Resources), cable emplacement resulting from future offshore wind energy development could damage submerged ancient landforms that may have cultural significance to tribal and indigenous peoples in the analysis area as part of ancient and ongoing tribal practices. Disturbance and destruction of even a portion of an identified submerged landform could degrade or even eliminate the value of these resources as potential repositories of archaeological knowledge and cultural significance to tribes. If these landforms are disturbed during offshore cable emplacement, the impact on the cultural resource would be permanent, resulting in a disproportionately large and adverse impact on the affected tribes. However, the results of submerged cultural resources surveys could be used to design future offshore wind activities so as to avoid impacting known submerged cultural resources or minimize impacts to varying degrees. Moreover, BOEM would work with tribes and consulting parties to develop project-specific treatment plans.

Conclusions

Under the No Action alternative, BOEM would not approve the COP; Project construction and installation, O&M, and conceptual decommissioning would not occur; and potential impacts on environmental justice populations associated with the Project would not occur. However, ongoing and future activities would have temporary to long-term impacts on environmental justice populations, primarily through public health and safety impacts associated with air emissions, noise, and water quality changes; potential job and income losses due to disruption of commercial fisheries or for-hire recreational fishing; and damage to submerged ancient landforms that may have cultural significance to tribal and indigenous peoples.

BOEM anticipates that the adverse impacts to environmental justice populations from reasonably foreseeable offshore wind activities would be long term and **minor** to **moderate**. These ratings reflect impacts on minority and low-income communities from cable emplacement, construction-phase noise and vessel traffic, and the long-term presence of offshore structures, which could affect marine-dependent businesses. Construction-related port activities could have impacts on environmental justice communities near ports through air emissions, traffic, or noise. This rating also reflects potential impacts on Tribes resulting from long-term impacts on culturally important ocean views and permanent impacts on submerged ancient landforms or other resources of importance to the values and practices of certain Native American Tribes. The air quality improvements from offshore wind energy development would have a long-term beneficial impact on environmental justice populations. As described in Appendix E Attachment 3, BOEM anticipates that the range of impacts for ongoing activities and reasonably foreseeable activities other than offshore wind would be **minor** to **moderate**.

Considering all the IPFs together, BOEM anticipates that the impacts associated with future offshore wind activities in the geographic analysis area combined with ongoing activities, reasonably foreseeable environmental trends, and reasonably foreseeable activities other than offshore wind would result in **minor** to **moderate** adverse impacts to environmental justice populations because most adverse impacts could be avoided with EPMs or would be unavoidable but not disproportionately high and adverse. In addition, beneficial effects to environmental justice populations may result from reductions in air emissions if offshore wind displaces energy generation using fossil fuels.

3.5.4.2.3 PROPOSED ACTION ALTERNATIVE

Construction and Installation

Environmental justice impacts in the final EIS are based on adverse impacts that would occur to air quality, water quality, land use and coastal infrastructure, commercial fisheries and for-hire recreational fishing, and cultural resources that are disproportionately borne by environmental justice populations. Adverse impacts to air quality during Project construction were characterized as minor to moderate, regional in extent, and short term (see Section 3.3.1 [Air Quality]). Similarly, no major adverse impacts to water quality identified during Project construction, with the potential exception of a fuel or oil spill (see Section 3.3.2 [Water Quality]). These potential spills could occur in or near concentrations of minority or low-income populations in East Hampton, New York (Figures F-1 and F-3); however, Table G-1 in Appendix G includes EPMs to avoid or minimize air emissions and potential spill impacts on water quality. SFW would develop an SPCC plan and HDD inadvertent release plan to protect nearby surface waters. Therefore, impacts to minority and low-income populations associated with changes in air or water quality during Project construction would be temporary and minor to moderate, as <u>potentially</u> disproportionately high and adverse impacts would be avoided with EPMs. As described in Section 3.5.5 (Land Use and Coastal Infrastructure), land use and coastal infrastructure affected by construction of offshore Project components would include chosen port facilities. As identified in Table 3.5.4-4, concentrations of minority or low-income populations have been identified near several ports that could support Project construction. These populations could experience short-term adverse effects as a result of noise, vibration, and vehicular traffic associated with construction-related port activities. Table 3.5.4-4 also shows concentrations of minority or low-income populations near the proposed landing sites and onshore SFEC routes. These populations could also experience short-term adverse effects through construction noise, vibration, and dust, together with intermittent delays in travel along affected roads. SFW would employ EPMs (see Table G-1 in Appendix G) to minimize noise and traffic impacts related to Project construction. Therefore, impacts to minority and low-income populations associated with noise, vibration, and vehicular traffic during Project construction would be temporary and minor to moderate, as potentially disproportionately high and adverse impacts would be avoided with EPMs.

As noted in Section 3.5.1 (Commercial Fisheries and For-Hire Recreational Fishing), some individual operators of commercial fishing or for-hire recreational fishing businesses could experience adverse economic impacts during Project construction as a result of increased port congestion, reduced fishing access, damage to or loss of fishing gear, and decreases in target species' abundance or availability. These impacts would be temporary and minor, but it is conceivable that certain workers engaged in commercial fisheries and for-hire recreational fishing, such as fishing vessel deckhands and factory floor seafood processor workers, would be more vulnerable to job or income losses should Project construction disrupt fishing activities. As described in Section 3.5.4.1, many of these workers are members of minority and/or low-income groups. However, SFW's communication plans with the fishing industry and its financial compensation program for damage to or loss of fishing gear, together with the ability of many fishing vessel operators to adjust transit and fishing locations to avoid conflicts with construction activities, would help ensure that fishing businesses could continue to operate with minimal disruption. Therefore, adverse impacts to minority and low-income individuals engaged in commercial fisheries and for-hire recreational fishing would be temporary and minor to moderate during Project construction, as <u>potentially</u> disproportionately high and adverse impacts would be avoided with EPMs.

Members of environmental justice populations for whom recreational and subsistence fisheries are an important food source are not expected to lose access to fishing areas on the shoreline or close to shore during construction of the offshore SFEC and the Project's onshore components. As described in Section 3.5.8 (Recreation and Tourism), construction staging areas would be located such that public parking, beach access, and access to campsites would be maintained. Additionally, SFW would inform all mariners, including commercial and recreational fishermen, and recreational boaters of construction activities and vessel movements (see Table G-1 in Appendix G). If the O&M facility is located in the Port of Montauk, initial construction dredging would occur, but only within a previously dredged footprint. The impact of this dredging on invertebrate and fish populations would be negligible (see Section 3.4.2 [Benthic Habitat, Essential Fish Habitat, Invertebrates, and Finfish]). Therefore, potential adverse impacts to environmental justice populations from reduced recreational and subsistence fishing opportunities caused by dredging are considered negligible.

As described in Section 3.5.2 (Cultural Resources), cable emplacement during Project construction could damage submerged ancient landforms that may have cultural significance to tribal and indigenous peoples in the analysis area as part of ancient and ongoing tribal practices. Disturbance and destruction of even a portion of an identified submerged landform could degrade or even eliminate the value of these resources as potential repositories of archaeological knowledge and cultural significance to tribes. If these landforms are disturbed during offshore cable emplacement, the impact on the cultural resource would be permanent, resulting in a disproportionately large and adverse impact on the affected tribes. BOEM remains in consultation with Native American tribes and other consulting parties under NHPA Section 106 on identified cultural resources, adverse effects, and the resolution of adverse effects (per 36 CFR part 800).

Operations and Maintenance and Conceptual Decommissioning

As described in the respective resource analysis sections, O&M would include the same permit requirements and controls as described for construction activities and would lead to the same types of minor adverse impacts to air quality (Section 3.3.1 [Air Quality]), water quality (Section 3.3.2 [Water Quality]), and land use and coastal infrastructure (Section 3.5.5 [Land Use and Coastal Infrastructure]). SFW would employ EPMs (see Table G-1 in Appendix G) to minimize air, water, and land use impacts related to Project construction Therefore, adverse impacts to minority and low-income populations would be long term and minor to moderate during Project O&M, as potentially disproportionately high and adverse impacts would be avoided with EPMs.

During operations, the Project would have a long-term, minor beneficial health impact on populations in the analysis area, including environmental justice populations, due to reduced fossil fuel power plant air emissions. See Section 3.3.1 [Air Quality] in Appendix H for additional details. Given that environmental justice populations tend to be more burdened with adverse health conditions that can increase susceptibility to the harmful effects of air pollution, the beneficial health impacts of reducing emissions may be greater than those experienced by non-minority or non-low-income members of the general population who also reside in the affected area.

As noted in Section 3.5.1 (Commercial Fisheries and For-Hire Recreational Fishing), some individual operators of commercial fishing or for-hire recreational fishing businesses could experience long-term, minor to moderate adverse economic impacts during Project O&M as a result of reduced fishing access, damage to or loss of fishing gear, and decreases in target species abundance or availability. It is conceivable that certain workers engaged in commercial fisheries and for-hire recreational fishing, such as fishing vessel deckhands and factory floor seafood processor workers, would be more vulnerable to job or income losses should Project O&M disrupt fishing activities. As described in Section 3.5.4.1, many of these workers are members of minority and/or low-income populations. However, SFW's communication plans with the fishing industry and its financial compensation program for damage to or loss of fishing gear, together with the ability of many fishing vessel operators to adjust transit and fishing locations to avoid conflicts with operation activities, would help ensure that fishing businesses could continue to operate with minimal disruption. Therefore, adverse impacts to minority and low-income populations engaged in commercial fisheries and for-hire recreational fishing would be long term and minor to moderate during Project O&M. as potentially disproportionately high and adverse impacts would be avoided with EPMs.

As previously noted, members of environmental justice populations for whom recreational and subsistence fisheries are an important food source generally fish close to shore and are not likely to travel and fish within the SFWF. Therefore, adverse impacts to these individuals during Project O&M would be long term but negligible to minor. If the O&M facility is located in the Port of Montauk, maintenance dredging would occur, but only within a previously dredged footprint. The impact of this dredging on invertebrate and fish populations would be negligible (see Section 3.4.2 [Benthic Habitat, Essential Fish Habitat, Invertebrates, and Finfish]). Therefore, potential adverse impacts to environmental justice populations from reduced recreational and subsistence fishing opportunities caused by dredging are considered negligible.

As described in Section 3.5.2 (Cultural Resources), O&M of the SFWF and offshore SFEC could impact unknown submerged marine cultural resources. For example, vessels conducting O&M activities could inadvertently damage avoidance-buffered or unknown resources. However, SFW could conduct O&M activities on equipment in areas that previously experienced disturbance during construction, thereby reducing impacts to submerged marine cultural resources to long term but negligible. Therefore, impacts to tribal and indigenous peoples due to potential disturbance of these cultural resources is expected to be negligible.

Conceptual decommissioning of the SFWF and offshore SFEC would have similar impacts on minority and low-income populations as impacts from construction.

Cumulative Impacts

Air emissions and noise: The Proposed Action would increase exposure to noise and air pollution by environmental justice populations beyond conditions under the No Action alternative. This would be a negligible incremental impact and would cease when construction is complete. As noted in Section 3.5.4.2.2, to the extent that increases in air or noise pollution occur as a result of ongoing and future non-offshore activities, environmental justice communities or individuals could experience adverse environmental and health effects. State and local agencies would be responsible for minimizing and avoiding noise and air quality impacts on nearby neighborhoods, including those neighborhoods in which environmental justice populations reside.

Despite the potential for increased air emissions during construction of new offshore wind energy projects, replacing the need for fossil fuel power generation would have a net beneficial impact on air quality. Environmental justice populations tend to be more burdened with adverse health conditions that can increase susceptibility to the harmful effects of air pollution, and they may be particularly vulnerable to the adverse economic impacts of climate change because they have fewer financial resources to cope with these effects. Therefore, the beneficial impacts of reducing air emissions, including GHG emissions, may be greater than those experienced by non-minority or non-low-income members of the general population who also reside in the region.

Accidental releases and discharges: The Proposed Action could increase water impacts to environmental justice populations. However, it is expected that onshore and offshore development, including the Proposed Action, would comply with all regulatory requirements for water quality protection. Therefore, when combined with past, present, and other reasonably foreseeable projects, the Project would have minor to moderate adverse water quality impacts on environmental justice populations.

Vessel traffic, presence of structures, new cable emplacement/maintenance, light: The Proposed Action would contribute negligible to moderate incremental onshore and offshore impacts, including new structures and cables, lighting, and vessel traffic, to conditions under the No Action alternative. The effects of these actions are addressed in other final EIS sections. An analysis of structure, cable, and vessel traffic impacts to commercial and for-hire recreation fishing is provided in Section 3.5.1 (Commercial Fisheries and For-Hire Recreational Fishing). Lighting, noise, and structure impacts to recreational and tourism activities, including recreational fishing, are described in Section 3.5.8 (Recreation and Tourism).

To the extent that Project impacts, together with the impacts of ongoing and other future onshore and offshore activities, result in declines in the economic performance of commercial and for-hire recreational fisheries, members of environmental justice populations could be disproportionately affected, especially if employment in the seafood processing industry declines. However, financial compensation policies implemented by offshore wind developers, together with the ability of some fishing vessel operators to adjust transit and fishing locations to avoid conflicts with construction and O&M activities related to offshore wind energy development, would help ensure that fishing businesses could continue to operate with minimal disruption. Therefore, the Proposed Action when combined with past, present, and reasonably foreseeable activities would result in minor to moderate adverse impacts to members of environmental justice populations employed in commercial fisheries and for-hire recreational fishing.

In addition, to the extent that the Project, together with ongoing and other future onshore and offshore activities, result in adverse impacts on recreational and subsistence fisheries, environmental justice populations could be disproportionately affected. However, most recreational and subsistence fishing in the analysis area occurs close to shore. Consequently, the Proposed Action would result in a minor to moderate incremental adverse impact to members of environmental justice populations engaged in recreational and subsistence fishing.

<u>Land disturbance</u>: The combined cable emplacement impacts on submerged marine cultural resources from ongoing and future onshore and offshore activities, including the Project, could have major disproportionate impacts on Native American tribes that trace their ancestry to these resources. However, the results of submerged cultural resources surveys could be used to design future offshore wind activities so as to avoid impacting known submerged cultural resources or minimize impacts to varying degrees. Moreover, BOEM would work with tribes and consulting parties to develop project-specific treatment plans.

Conclusions

Project construction and installation, O&M, and conceptual decommissioning would have temporary to long-term, **negligible to moderate** impacts on environmental justice populations, primarily through public health and safety impacts associated with air emissions, noise, and water quality changes; potential job and income losses due to disruption of commercial fisheries or for-hire recreational fishing; and damage to submerged ancient landforms that may have cultural significance to tribal and indigenous peoples. BOEM expects the overall impact on environmental justice populations from the Proposed Action alone due to these factors to be **minor** to **moderate,** as adverse impacts could be avoided with EPMs or would be unavoidable but not disproportionately high and adverse.

Considering all the IPFs together, BOEM anticipates that the overall impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would result in **minor** to **moderate** adverse impacts to environmental justice populations because adverse impacts could be avoided with EPMs or would be unavoidable but not disproportionately high and adverse. In addition, **minor** beneficial effects to environmental justice populations may result from reductions in air emissions if offshore wind displaces energy generation using fossil fuels.

3.5.4.2.4 VESSEL TRANSIT LANE ALTERNATIVE

The Transit alternative could result in decreased impacts to air and water quality and reduced noise levels in the analysis area during Project construction if less trenching, vessel traffic, or time is needed to install a reduced number of WTGs and their associated inter-array cables. Overall, however, the work areas and construction timing windows for the SFWF and offshore SFEC would be similar to those of the Proposed

Action. Moreover, the reduction in the number of WTGs under this alternative is not expected to affect the selection of port facilities that would support construction. Therefore, the construction phase of this alternative would result in short-term, minor to moderate adverse impacts on air and water quality and noise levels. The same environmental justice populations identified under the Proposed Action would be affected, and the level of adverse impacts on air and water quality and noise levels experienced by these populations during the O&M phase of this alternative would also not be measurably different than under the Proposed Action.

As discussed in Section 3.5.1 (Commercial Fisheries and For-Hire Recreational Fishing), the establishment of a vessel transit lane could simplify navigation through the SFWF and potentially reduce conflicts between the Project and businesses involved in commercial fisheries and for-hire recreational fishing. As a result, the Transit alternative would be less disruptive to fishing activities in the SFWF in comparison to the Proposed Action. Therefore, the Transit alternative would have a lower adverse impact on members of minority and/or low-income populations who are employed in commercial fisheries and for-hire recreational fishing, albeit still expected to be minor to moderate.

As with the Proposed Action, the Transit alternative may not be able to avoid impacts on all submerged marine landforms of cultural significance to Native Americans, but BOEM would consult with Native American tribes and other consulting parties under NHPA Section 106 on identified cultural resources, adverse effects, and the resolution of adverse effects (per 36 CFR part 800).

Cumulative Impacts

The Transit alternative would incrementally add sources of air, water quality, and noise pollution at quantities and durations similar to, or slightly reduced from, the Proposed Action. Offshore, the Transit alternative would have a lower adverse impact on members of minority and/or low-income populations who are employed in commercial fisheries and for-hire recreational fishing. Considering all the IPFs together, BOEM anticipates that the overall impacts associated with the Transit alternative when combined with past, present, and reasonably foreseeable activities would result in minor to moderate adverse impacts to environmental justice populations because adverse impacts could be avoided with EPMs or would be unavoidable but not disproportionately high and adverse. In addition, minor beneficial effects to environmental justice populations may result from reductions in air emissions if offshore wind displaces energy generation using fossil fuels.

Conclusions

Although the Transit alternative would reduce the number of WTGs and their associated inter-array cables, which would have an associated reduction in associated vessel and equipment use and air emissions, BOEM expects the overall impacts to environmental justice populations resulting from the alternative alone would be similar to the Proposed Action: **minor** to **moderate**.

In context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that the Transit alternative's incremental impacts to environmental justice populations would be similar to the Proposed Action. The overall adverse impact to environmental justice populations of the Transit alternative when combined with past, present, and reasonably foreseeable activities would therefore be the same level as under the Proposed Action: **minor** to **moderate** adverse and **minor** beneficial.

3.5.4.2.5 FISHERIES HABITAT IMPACT MINIMIZATION ALTERNATIVE

The Habitat alternative under either layout option could result in decreased impacts to air and water quality and reduced noise levels in the analysis area during Project construction if less trenching, vessel traffic, or time is needed to install a reduced number of WTGs and their associated inter-array cables. However, the reduction in the number of WTGs under this alternative is not expected to affect the selection of port facilities that would support construction. Therefore, the construction and installation phase of this alternative would be similar to the Proposed Action and result in the short-term, minor adverse impacts on air and water quality and noise levels.

As discussed in Section 3.5.1 (Commercial Fisheries and For-Hire Recreational Fishing), the exclusion of WTG sites to reduce impacts to complex fisheries habitats could simplify navigation through the SFWF and potentially reduce conflicts between the Project and businesses involved in commercial fisheries and for-hire recreational fishing. Therefore, the Habitat alternative under either layout option would have a lower adverse impact on members of minority and/or low-income populations who are employed in commercial fisheries and for- hire recreational fishing, albeit still expected to be minor to moderate.

As with the Proposed Action, the Habitat alternative under either layout option may not be able to avoid impacts on all submerged marine landforms of cultural significance to Native Americans, but BOEM would consult with Native American tribes and other consulting parties under NHPA Section 106 on identified cultural resources, adverse effects, and the resolution of adverse effects (per 36 CFR part 800).

Cumulative Impacts

The Habitat alternative under either layout option would incrementally add sources of air, water quality, and noise pollution at quantities and durations similar to, or slightly reduced from, the Proposed Action. Offshore, the Habitat alternative under either layout option would have a lower adverse impact on members of minority and/or low-income populations who are employed in commercial fisheries and for-hire recreational fishing. Considering all the IPFs together, BOEM anticipates that the overall impacts associated with the Habitat alternative under either layout option when combined with past, present, and reasonably foreseeable activities would result in minor to moderate adverse impacts to environmental justice populations because adverse impacts could be avoided with EPMs or would be unavoidable but not disproportionately high and adverse. In addition, minor beneficial effects to environmental justice populations may result from reductions in air emissions if offshore wind displaces energy generation using fossil fuels.

Conclusions

Although the Habitat alternative under either layout option would reduce the number of WTGs and their associated inter-array cables, which would have an associated reduction in associated vessel and equipment use and air emissions, BOEM expects that the overall impacts to environmental justice populations resulting from the alternative alone would be similar to the Proposed Action: **minor** to **moderate**.

In context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that the Habitat alternative's incremental impacts would be similar to the Proposed Action. The overall adverse impacts to environmental justice populations of the Habitat alternative under either layout option when combined with past, present, and reasonably foreseeable activities would therefore be the same level as under the Proposed Action: **minor** to **moderate** adverse and **minor** beneficial.

3.5.4.3 Action Alternative Comparison

As discussed above, the impacts associated with Proposed Action alone do not change substantially under other evaluated action alternatives. Although the number of WTGs and their associated inter-array cables varies slightly, BOEM expects the overall environmental justice impacts would be **minor** to **moderate** for all action alternatives. These ratings reflect impacts on minority and low-income communities from cable emplacement, construction-phase noise and vessel traffic, and the long-term presence of offshore structures, which could affect marine-dependent businesses. Construction-related port activities could have impacts on environmental justice communities near ports through air emissions, traffic, or noise. This rating also reflects potential impacts on Tribes resulting from long-term impacts on culturally important ocean views and permanent impacts on submerged ancient landforms or other resources of importance to the values and practices of certain Native American Tribes.

In context of reasonably foreseeable environmental trends and planned actions, all action alternatives would occur within the same overall environment (e.g., ongoing and future activities). Therefore, impacts would only vary if the alternatives' incremental contributions differ. However, as noted above, BOEM expects that the incremental impact from any action alternative would be similar. Therefore, the overall impact to environmental justice populations of any action alternative when combined with past, present, and reasonably foreseeable activities would be the same: **minor** to **moderate adverse**, because most adverse impacts could be avoided with EPMs or would be unavoidable but not disproportionately high and adverse. In addition, **minor** beneficial effects to environmental justice populations may result from reductions in air emissions if offshore wind displaces energy generation using fossil fuels.

3.5.4.4 Mitigation

No potential additional mitigation measures for environmental justice are identified in Appendix G. However, mitigation measures have been proposed for impacts to resource areas that would potentially affect environmental justice populations. In Table G-1 of Appendix G, see the environmental protection measures proposed by SFW for air quality, water quality, commercial fisheries and for-hire recreational fishing, and cultural resources.

3.5.5 Land Use and Coastal Infrastructure

3.5.5.1 Affected Environment

The Town of East Hampton, one of the 10 towns in Suffolk County, on the south shore of Long Island, is bordered on the south by the Atlantic Ocean, on the north by Gardiner's Bay and Block Island Sound, and on the west by the Town of Southampton. With the exception of Shelter Island, East Hampton is the least populous of the Suffolk County towns (Suffolk County Department of Planning 2011).

East Hampton is characterized by unique hamlets, villages, and countryside; includes world-renowned beaches; and supports one of the highest concentrations of rare and endangered species in New York State (Liquori and Nagle 2005). The incorporated Village of East Hampton and a portion of the incorporated Village of Sag Harbor, as well the hamlets of Amagansett, Montauk, Springs, and Wainscott, lie within the borders of East Hampton (RKG Associates, Inc. 2017). Town land use, as a whole, largely comprises small areas of low-density residential enclaves separated by large blocks of open space; limited areas of commercial, industrial, and institutional land uses occur adjacent to area roadways (Dodson and Flinker et al. 2017). Approximately 45% of East Hampton's land area is in residential land use, with more than half of the residential acreage designated as low density. Protected open space makes up the second highest percentage of land use (31%), and vacant land the third (15%) (Liquori and Nagle 2005). A number of harbors and inlets are along the north shore: Northwest Creek, Three Mile Harbor, Accabonac Harbor, Napeague Harbor, Northwest Harbor, Hog Creek, and Lake Montauk (Dodson and Flinker 2017).

The Project considers two landing sites (see Figure 3.2-3 in the COP). The proposed Beach Lane landing site is located on a Town of East Hampton public road that provides public access to the wide, straight Atlantic beach that fronts the town from the hamlet of Wainscott on the west to the easterly end of the hamlet of Montauk on the east. The public access includes parking along Beach Lane at the terminus of the roadway; the beach access is undeveloped and does not provide restroom or picnic amenities. The landing site is proposed to occur landward of the Beach Lane public parking area and is flanked by residentially developed land to the west and open farmland to the east. Wainscott School is located approximately 1 mile northeast of the Beach Lane public access parking lot and would therefore not be affected by the onshore SFEC route.

The Hither Hills landing site is located in the hamlet of Montauk in the Town of East Hampton, immediately south of the Montauk Highway in a parking lot that is part of Hither Hills State Park. The parking lot includes three Americans with Disabilities Act parking spaces and parking for 54 additional vehicles. The lot provides trail access to the park's North Trail as well as trail access to the beach, restrooms, the Hither Hills General Store, and nearby beach campgrounds (New York State Office of Parks, Recreation and Historic Preservation 2019).

From the landing sites, installation of the onshore SFEC would occur entirely underground, with access points at strategic locations via manholes for safety and ease of maintenance (Jacobs 2021). Figures 4.6-7 and 4.6-8 in the COP show land uses adjacent to the Beach Lane and Hither Hills SFEC routes.

The interconnection facility for the Project would be located adjacent to the existing East Hampton 69-kV LIPA substation on 2.4 acres of the same parcel that houses the existing substation. The existing substation parcel is zoned for commercial industrial use and the portion of the parcel proposed for the interconnection facility is currently wooded. The interconnection facility site would include all equipment necessary to safely connect the SFEC with the NYISO transmission system (see Figure 3.2-4 in the COP).

In addition to the landing sites and interconnection facility, the Project would use various ports for construction and installation as well as for O&M. SFW has proposed an O&M facility to be located onshore in an existing port either in Montauk, East Hampton, or in Quonset Point, North Kingstown, Rhode Island.

Montauk Harbor supports the largest commercial fishing port in New York State, both in terms of the landed value of fish and the number of fishing vessels. The harbor is also an estuary supporting populations of fish and wildlife (Liquori and Nagle 2005). The Montauk dock area is a major commercial and industrial center with restaurants and shops alongside a working waterfront with zoning that supports these uses. Land uses are consistent with zoning, including a marina, boatyards, fish processing, a ferry terminal, restaurants, and some retail (Dodson and Flinker 2017). The ferry terminal provides summer service to Block Island, Martha's Vineyard, and New London, Connecticut. The USCG operates a station on Star Island in Montauk Harbor, which serves as a search and rescue and law enforcement unit. Montauk Airport is on the east side of the harbor.

Quonset Point, a port located in the town of North Kingstown, Rhode Island, is a former naval air station that is now a thriving, modern industrial park (Interface Studio 2016). The industrial park, known as Quonset Point/Davisville Business Park, is on a peninsula in Narragansett Bay. The port is a multimodal transportation area with deepwater piers used for both shipping and ship repairs, an airport with the longest runway in the state, freight and passenger rail facilities, and interstate highway connections. The availability of a variety of industrially zoned land with full-service networks provide opportunities for new industries (Maguire Group, Inc. 2008).

Port facilities in New York, Rhode Island, Massachusetts, Connecticut, New Jersey, Maryland, Virginia, and/or Nova Scotia would support offshore installation activities for the SFWF and the offshore SFEC (see Table 3.1-5 in the COP). These ports are generally industrial in character and are typically adjacent to other industrial or commercial land uses and major transportation corridors. Before construction begins, SFW would finalize mobilization plans and arrangements at port facilities to support Project activities, including logistic support for fabrication, as needed (Jacobs 2021). See Section 3.5.1 (Commercial Fisheries and For-Hire Recreational Fishing), Section 3.5.3 (Demographics, Employment, and Economics), and Section 3.5.8 (Recreation and Tourism) for discussions of recreational vessel and commercial fishing activity in these ports.

3.5.5.2 Environmental Consequences

3.5.5.2.1 ISSUES, INDICATORS, AND SIGNIFICANCE CRITERIA

Table 3.5.5-1 lists the issues identified for this resource and the indicators and significance criteria used to assess impacts for the final EIS.

Table 3.5.5-1. Issues, Indicators, and Significance Criteria Used to Assess Impacts to Land Use and Coastal Infrastructure

Issue	Impact Indicator	Significance Criteria
Public health and safety	Construction- or operation-related volume increases, traffic delays, traffic re-routes, and noise Onshore EMF	Negligible: No measurable/detectable change to area land use would occur. Minor: Impacts would be detectable but would be short term and localized. Moderate: Impacts would be detectable and broad-based, affecting a variety of land uses, but would be short term and would not result in long-term change. Major: Impacts would be detectable, long term, extensive, and result in permanent land use change.
Port improvements and operations	Changes to vehicle, vessel traffic volumes, and infrastructure demands	
Land use code and zoning	Qualitative assessment of compliance with local land use regulations	

3.5.5.2.2 NO ACTION ALTERNATIVE

The Affected Environment section provides information on existing land use and coastal infrastructure trends from past and present activities. Attachment 3 in Appendix E provides additional information regarding past and present activities and associated land use and coastal infrastructure impacts. Future non-Project actions include inlet management; beach, dune, and berm construction; breach response plans; raising and retrofitting homes; road raising; and coastal process features, disaster cleanup and remediation, and port upgrades, including onshore development or underwater improvements such as dredging in New York, Connecticut, Rhode Island, and Massachusetts, to support the offshore wind industry. Attachment 3 in Appendix E discloses future non-offshore wind activities and associated land use and coastal infrastructure impacts. These impacts are also described below.

Future Activities (without the Proposed Action)

Onshore, neighboring or adjacent land to reasonably foreseeable projects could temporarily be disturbed by future Project–related noise, vibration, and dust as well as travel delays along impacted roads. The simultaneous construction of two or more onshore development projects and/or landing sites and onshore cable routes would generate cumulative short-term impacts to land use. State and local agencies would be responsible for managing actions to help minimize and avoid noise, air quality, and other impacts on nearby neighborhoods during construction. For the reasons described in the following sections, under the No Action alternative, land disturbance would have negligible to minor, short-term adverse cumulative impacts to land use and coastal infrastructure.

<u>Accidental releases and discharges</u>: Future offshore activities could result in accidental releases of trash or water quality contaminants (see Section 3.3.2.2.2 for quantities and details). Trash and contaminant spills would be minimized by vessel compliance with USCG regulations. In the event of a spill, adjacent properties and coastal infrastructure could be temporarily restricted. The exact extent of restrictions and other impacts would depend on the locations of landfall, substations, and cable routes as well as the ports used to support future offshore wind energy projects. These impacts, however, would generally be localized and short term.

Light: Permanent aviation warning lighting on offshore wind WTGs would be visible from south-facing beaches and coastlines. Visibility would depend upon distance from shore, topography, and atmospheric conditions but would be long term. If this lighting alters visitor behavior, land use in the form of tourism, recreation, and property values may subsequently be impacted. Lighting from substations could also affect the adjacent property use and residential development. However, new substations would be constructed near existing energy infrastructure or where land development regulations, such as zoning and land use plan designations, allow such uses. Therefore, land use would not be expected to be measurably changed.

Port utilization: Various ports would be improved to support future offshore wind projects (see Appendix E). These improvements would occur within the boundaries of existing port facilities or repurposed industrial facilities, would be similar to existing activities at the existing ports, and would support state strategic plans and local land use goals for the development of waterfront infrastructure. Therefore, ports would experience long-term beneficial impacts such as greater economic activity and increased employment due to demand for vessel maintenance services and related supplies, vessel berthing, loading and unloading, warehousing and fabrication facilities for offshore wind components, and other business activity related to offshore wind. State and local agencies would be responsible for minimizing the potential adverse impacts of these future port expansions by managing port resources and traffic control to ensure continued access to ports and adjacent land uses.

Conclusions

Under the No Action alternative, BOEM would not approve the COP; Project construction and installation, O&M, and conceptual decommissioning would not occur; and potential impacts on land use and coastal infrastructure associated with the Project would not occur. However, ongoing and future activities would have continuing temporary to long-term impacts on land use and coastal infrastructure, primarily through onshore construction and port activities.

BOEM anticipates that the range of impacts for reasonably foreseeable offshore wind activities would be **negligible** to **minor**. As described in Appendix E Attachment 3, BOEM anticipates that the range of impacts for ongoing activities and reasonably foreseeable activities other than offshore wind would be **minor adverse and minor beneficial**. Accidental releases and land disturbance could have temporary adverse impacts on local land uses, but as a whole, ongoing use and development would support the region’s diverse mix of land uses and provides support for continued maintenance and improvement of coastal infrastructure.

Considering all the IPFs together, BOEM anticipates that the impacts associated with future offshore wind activities in the geographic analysis area combined with ongoing activities, reasonably foreseeable environmental trends, and reasonably foreseeable activities other than offshore wind would result in **minor** adverse **and minor beneficial** impacts because the overall effect would be small, localized, and short term.

3.5.5.2.3 PROPOSED ACTION ALTERNATIVE

Construction and Installation

Land uses impacted by the construction of offshore components would include chosen port facilities used for shipping, storing, and fabricating Project components and for crew transfer, cargo logistics, and storage. SFW would use one or more ports to offload shipments of components, prepare them for installation, and load components onto vessels for delivery and installation. Selected ports could require improvements or upgrades to meet Project needs (see Table 3.1-5 in the COP). Jacobs (2021) notes that required port upgrades could include erection of buildings (up to 350,000 square feet); reinforcement of terrestrial bearing capacity (up to 1,300,000 square feet) and changes to surface materials, reinforcement, and/or rehabilitation of quayside(s) (up to 500 feet); and installation of supporting infrastructure such as lighting, electricity, water, fencing, and/or a security booth. Such upgrades, if necessary, would be conducted by individual ports or lessees operating within the confines of ports and would not be conducted by SFW.

BOEM (2016) analyzed potential impacts to ports that could require upgrades to accommodate offshore wind projects or that are in the process of completing upgrades in anticipation of increased port use associated with offshore wind projects. BOEM noted that land use and transportation impacts primarily include land-based space conflicts with current or planned uses of adjacent areas and land-side traffic delays or conflicts associated with construction. BOEM (2016) also identified potential water-based space conflicts with other uses of port waterways such as dredging, pile driving, and fill placement. The ports under consideration for construction staging are industrial in character, designated by local zoning and land use plans for heavy industrial activity, and typically adjacent to other industrial or commercial land uses and major transportation corridors.

Activities associated with offshore construction of the Project would generate noise, vibration, and vehicular traffic, and would temporarily alter views at one or more ports listed in Table 3.1-5 in the COP. Port improvements would result in combustion emissions from construction vehicles and equipment and could result in fugitive particulate emissions from soil movement. These impacts would be typical for construction in and operation of industrial ports. Noise, vibration, vehicular traffic increases, and vehicular emission generation would be short term. Space use conflicts would also be short term and would be minimized through siting for minimal displacement and coordination with both waterway users and the USCG (BOEM 2016). Potential land-side transportation impacts would be minimized through construction hour restrictions, improvements such as road widening and signalization, and appropriate route selection (BOEM 2016). Activity and development from the Project would not occur at levels above those typically experienced or expected at these facilities and would not hinder other nearby land use or use of coastal infrastructure. Overall, construction and installation of offshore components would have minor, beneficial impacts to land use and coastal infrastructure by supporting designated uses at ports and supporting port improvements and/or redevelopment. Improvements such as road widening and signalization would provide transportation flow benefits over the long term. Section 3.5.3 Demographics, Employment, and Economics provides additional detail regarding potential economic impacts of the Project’s use of the listed ports.

Construction of the chosen landing site and onshore SFEC route would temporarily disturb neighboring land uses through temporary increases in construction noise, vibration and dust, and intermittent delays in travel along impacted roads. Sheet pile installation for sea to shore transition HDD operations would occur over approximately 2 days, would occur during the daytime hours (7:00 a.m. to 8:30 p.m.), and would be largely generated by an excavator, crane, and sheet pile driver. Noise generated by these activities would comply with the Town of East Hampton noise code but would exceed the NYSDEC noise guidelines, requiring implementation of noise BMPs such as notifying nearby residences of the days and times that sheet piling would occur; installing the perimeter sound wall prior to sheet pile driving, if construction logistics allow; and using quieter methods (i.e., push-in piling) to install sheet piling as geological conditions allow.

Construction and installation of the Project’s onshore components would require construction staging in parking lots adjacent to or near the landing sites, reducing public parking available at Beach Lane or Hither Hills State Park during construction. These disturbances would be short term, with timing projected to occur between September and May (see COP Table 1.5-1). Construction along public roadways would be completed in a matter of days or weeks. At the landing site, the Project would make the physical connection between the offshore SFEC and the onshore SFEC in one underground concrete transition vault. The only long-term visible components of the cable system would be the manhole covers (Jacobs 2021).

Onshore construction and installation would include trench excavation and placement of the onshore SFEC within existing paved roads and the railroad ROW. SFW would abide by local construction ordinances. Construction would occur primarily during normal daylight hours except for certain activities associated with cable installation at the chosen landing site (Jacobs 2021) that could require nighttime activity to meet rapid construction timelines. SFW would work with the Town of East Hampton to develop a detailed plan that includes traffic and other control measures prior to beginning major construction. The traffic plan with East Hampton would identify appropriate alternative routes that would accommodate projected traffic loading during construction activities. BOEM assumes that the Project would avoid permanent disruption to existing underground utilities, such as water, sewer, and electrical lines. However, depending on the exact placement of the onshore SFEC cable, the physical size and location of the cable could hamper future installation of public utilities such as water, sewer, and storm water lines, which are typically placed beneath roadway travel lanes. Construction noise would approach or exceed the NYSDEC noise guideline limit for construction activities at receptors immediately adjacent to the road or railroad ROWs. BMPs (see Table G-1 in Appendix G) would be implemented to minimize construction noise such as replacing back-up alarms with strobes, assuring that equipment is functioning properly and is equipped with mufflers, locating especially noisy equipment as far from sensitive locations as possible, using quieter construction equipment, using path noise controls such as portable enclosures, limiting the period of time when construction occurs, and maintaining strong communication with the public. Vehicular and construction equipment emissions would be similar to those described for offshore development. The potential impacts from construction and diesel-generating equipment would be reduced through mitigation measures related to fuel-efficient engines, as outlined in Section 3.2.1, Air Quality. As a result, and considering the described traffic, construction and installation of the Project would have a moderate adverse impact to land use and coastal infrastructure.

The interconnection facility would be constructed adjacent to the existing East Hampton substation, in an area zoned for commercial industrial use. Installation of the interconnection facility could increase visibility of the existing substation to nearby residents along Horseshoe Drive (Jacobs 2021). The visual impacts of the interconnection facility would be minimized through the installation of vegetation to provide year-round screening from nearby Horseshoe Drive, appropriate substation siting, low-profile design, and minimal lighting, all of which would be directed downward (EDR 2018). As designed, the interconnection facility would generate sound below existing, ambient sound levels (VHB 2020). According to federal, state, and local noise standards, there would be no impact and no need for mitigation as a result of the operation of the interconnection facility. The interconnection facility, therefore, would have a negligible adverse impact to land use and no impacts to coastal infrastructure.

The Project would include an O&M facility to be located onshore at either Lake Montauk, East Hampton or in Quonset Point, North Kingstown, Rhode Island. The O&M facility could use existing buildings or require renovation or new construction of buildings and installation of a stationary land-based crane and floating dock. If the Lake Montauk location is selected, modification would be required for the in-water portions of the site, including maintenance repairs to the existing bulkhead and both initial and maintenance dredging to support the crew transfer vessels (BOEM 2021). To allow for suitable depths for navigation and berthing, a dredge footprint of up to 1,500 square feet would be required, with annual maintenance dredging of up to 40,500 cubic feet over a 10-year period. Dredged materials would be loaded into scows that, once full, would be transported to the adjacent beach west of the Montauk Harbor entrance, where sediment would be pumped to shore and used as nourishment material. Other potential in-water work would include maintenance repairs to the existing bulkhead. A floating dock would also be installed through pile installation to support berthing a single crew transfer vessel. One additional pile would be installed to provide safe berthing conditions (i.e., mooring dolphin). These actions could result moderate, short-term adverse land use and coastal infrastructure impacts due to disruption of access, noise, and dust typically associated with construction.

Operations and Maintenance and Conceptual Decommissioning

O&M would require daily activity at the O&M facility and periodic activity at the port chosen for O&M installation. Activity would also occur at other ports, if needed. The O&M facility would include offices, a warehouse, training facilities, repair facilities, and a floating dock, which are consistent with the range of land uses associated with the ports listed in Table 3.1-5 in the COP. The increased activity within any of the listed port areas zoned for business and industrial uses would reinforce the designated land use and provide a source of investment in the coastal infrastructure. O&M activities would be limited to temporary, periodic use of vehicles and equipment; associated impacts would be minor and would not affect land uses over those that typically occur at port facilities. Activities at ports, as described under construction and installation, would be consistent with the existing and designated uses at other ports. O&M of offshore components would therefore have minor, beneficial impacts to land use and coastal infrastructure by supporting designated uses at ports and supporting port improvements and/or redevelopment that would benefit port uses beyond those necessary for the Project.

Once installed, the onshore SFEC would be underground and would not change adjacent land uses or affect coastal infrastructure. Modeling results for onshore EMF indicate that maximum emissions would not exceed 4.7 mG at 3.28 feet aboveground and 50 feet from the duct bank line, which is below the New York Public Service Commission EMF limits of 200 mG. The maximum calculated magnetic field level at the sea-to-shore transition is 0.3 mG at an HDD depth of 62 feet, 1.8 mG at an HDD depth of 22 feet, and 11 mG at an HDD depth of 7 feet (Exponent 2018). Because these modeled values are well below the reported human health reference levels of 2,000 mG and 9,040 mG for the general population (Institute of Electrical and Electronics Engineers 2006; International Commission on Non-ionizing Radiation Protection 2010), onshore EMF adverse impacts would be long term but negligible. The SFEC would be installed at least 30 feet (9.1 m) below the current profile of the beach (Jacobs 2021). SFW has also designed the Project to account for site-specific oceanographic and meteorological conditions within the analysis area; therefore, potential for beach erosion to expose the SFEC at the sea to shore transition zone would be long term but negligible.

O&M activities would include periodic inspections and repairs at the interconnection facility and cable access manholes, which would require minimal use of worker vehicles and construction equipment. Periodic maintenance and repairs would have temporary impacts on access to adjacent land uses. The onshore SFEC would therefore have negligible impacts on land use and coastal infrastructure.

Impacts during conceptual decommissioning would be similar to the impacts during construction and installation. The activity generated at listed ports would continue to be consistent with existing and designated port uses. For onshore decommissioning, any removal of the underground, onshore cables (if not decommissioned in place) could result in temporary construction disturbances and delays along the affected roads and near the landing sites. The length and extent of these delays would be similar to those experienced during installation. If conceptual decommissioning occurs outside of the June to August peak tourist season, conceptual decommissioning of the onshore components of the Project would result in negligible impacts to land use, whereas conceptual decommissioning of the offshore components would result in beneficial impacts to port land use through supported port activities and expanded port infrastructure that would be available to other users into the future.

Cumulative Impacts

Onshore construction associated with the Proposed Action would add noise and land disturbance through the removal of 2.4 acres of land for the interconnection facility and a small area (0.1 acre) of land at the selected O&M facility to conditions under the No Action alternative. The Proposed Action would also introduce lighting at the interconnection facility, although lighting would be minimal. These actions would result in localized, short-term, minor incremental impacts on land use and coastal infrastructure. If SFW chooses the Hither Hills SFEC route, construction activities could coincide with the projected East Hampton Railroad Station improvements and could increase traffic delays; result in additional traffic rerouting; and increase short-term, construction-related vehicular and equipment emissions that would impact area residents. The FIMP Project to control beach erosion and provide hurricane protection would also extend to Montauk Point, approximately 10 miles east of Hither Hills State Park. Activities associated with the FIMP Project could overlap with the proposed cable landing and onshore SFEC route initiation at Hither Hills State Park. Longer delays at roadways and extended construction windows could result from the overlapping projects. No other onshore development projects would be adjacent to (and none would use roads impacted by) the Project landing sites and onshore SFEC. BOEM assumes that other projects would occur near existing energy infrastructure or where land development regulations, such as zoning and land use plan designations, allow such uses. State and local agencies would also be responsible for minimizing and avoiding noise, air quality, and other impacts on nearby neighborhoods during construction. Therefore, cumulative impacts associated with the Project when combined with past, present, and reasonably foreseeable future activities would be temporary, localized, and minor.

Offshore impacts would predominately be associated with changes in lighting, port use, and spills.

<u>Accidental releases and discharges</u>: The Proposed Action could result in accidental release of contaminants, trash/debris, or invasive species that could add to releases from other reasonably foreseeable projects. However, the potential volumes of oils, lubricants, and diesel spilled would be minimal and would result in localized, short-term, negligible incremental impacts on land use and coastal infrastructure. The Project and other reasonably foreseeable projects would be expected to comply with any applicable permit requirements to implement erosion, storm water, and spill controls to minimize, reduce, or avoid impacts on water and air quality. As a result, the Proposed Action when combined with past, present, and other reasonably foreseeable projects would result in adverse, short-term, and negligible cumulative impacts on land use and coastal infrastructure.

<u>Light</u>: The Proposed Action would add permanent lighting for up to 15 WTGs and one OSS. Although this lighting would be visible, in part, from south-facing beaches and coastlines, this represents a negligible (less than a 1%) incremental increase over total estimated WTG and OSS foundations providing long-term lighting under the No Action alternative if all projected offshore wind projects are constructed. BOEM estimates a maximum cumulative total of 2,301 offshore WTGs and OSS foundations for the Proposed Action plus all other future offshore wind projects. Therefore, the cumulative impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would be similar to those impacts described under the No Action alternative and would be negligible.

<u>Port utilization</u>: Port upgrades and vessel activity associated with the Proposed Action could result in minor beneficial and minor adverse incremental impacts through an increase in economic and employment opportunities, as well as reduced port access, increased delays and congestion, or increased collision risk. Project port activity and upgrades (via dredging and in-water work) could also coincide with other forecasted projects. Quonset Point is scheduled to undergo remediation at the former NIKE Battery PR-58 and Disaster Village Training Area in 2021. No specific non-Project improvements are proposed for Montauk Harbor, but the New York State Energy Research Development Authority issued an offshore wind master plan that notes Montauk Harbor as having the potential to be used or developed into facilities capable of supporting offshore wind projects (New York State Energy Research Development Authority 2017).

Port activities could be delayed or area transportation routes could experience longer delays as result of the overlap in construction activities. All activities would, however, be in accordance with land use goals and plans. Construction and operation improvements associated with the Project and other offshore wind energy would occur within the boundaries of existing port facilities or repurposed industrial facilities, would be similar to existing activities at the existing ports, and would support state strategic plans and local land use goals for development of waterfront infrastructure as well as economic opportunities (see Section 3.5.3.2.3 [Proposed Action Alternative]). State and local agencies would also be responsible for minimizing the impacts of these future development plans by ensuring continued access to ports and adjacent land uses and minimization or avoidance of noise, air quality, and other impacts on nearby neighborhoods. Therefore, when considered in combination with past, present, and other reasonably foreseeable projects, the Project would have temporary negligible adverse impacts and long-term, minor beneficial impacts.

Conclusions

Project construction and installation and conceptual decommissioning would temporarily generate noise, vibration, and vehicular traffic. Impacts during O&M would be expected to be similar, but in lower duration and extent. BOEM anticipates the adverse impacts resulting from the Proposed Action alone would range from **negligible** to **moderate**, due to land disturbance activities. Project O&M would also generate long-term, **minor beneficial** impacts by supporting designated uses at ports and supporting port improvements and/or redevelopment. Therefore, BOEM expects the overall impact on land use and coastal infrastructure from the Proposed Action alone to be **minor** adverse and **minor beneficial**, as the overall adverse effect due to land disturbance would be small, localized, and short term. Beneficial impacts could also result from port utilization.

In the context of other reasonably foreseeable environmental trends and planned actions, the incremental impacts under the Proposed Action resulting from individual IPFs would range from **negligible** to **minor** and **minor beneficial**, for similar reasons as above. Considering all the IPFs together, BOEM anticipates that the overall impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would result in **minor** impacts and **minor beneficial** impacts to land use and coastal infrastructure. BOEM made this call because the overall adverse effect would be small and the resource would be expected to recover completely. Beneficial impacts could also result from port utilization.

3.5.5.2.4 VESSEL TRANSIT LANE ALTERNATIVE

This alternative would not impact land use and coastal infrastructure. Therefore, the impacts of this alternative would be the same as those of the Proposed Action. Adverse impacts would be negligible to moderate and both short term and long term; minor beneficial impacts would be long term.

Cumulative Impacts

If the Transit alternative is implemented, economic activity at port facilities and underused industrial sites could increase. These cumulative impacts resulting from the Transit alternative would be consistent with established state and local land use goals and when combined with past, present, and reasonably foreseeable future development could generate beneficial impacts not measurably different from the Proposed Action: negligible to minor and minor beneficial.

Conclusions

Although the Transit alternative would reduce the number of WTGs and their associated inter-array cables, these changes would not measurably affect land use and coastal infrastructure. Therefore, BOEM expects that the impacts resulting from the alternative alone would be similar to the Proposed Action and range from **negligible** to **moderate**. Project O&M would also generate long-term, **minor beneficial** impacts by supporting designated uses at ports and supporting port improvements and/or redevelopment.

In context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that the Transit alternative's incremental impacts would be similar to the Proposed Action (with individual IPFs leading to impacts ranging from **negligible to minor and minor beneficial**). The overall impacts of the Transit alternative when combined with past, present, and reasonably foreseeable activities would therefore be the same level (with similar rationale) as under the Proposed Action: **minor** adverse and **minor beneficial**.

3.5.5.2.5 FISHERIES HABITAT IMPACT MINIMIZATION ALTERNATIVE

The Habitat alternative under either layout option would not impact land use and coastal infrastructure. Therefore, the impacts of this alternative would be the same as those of the Proposed Action. Adverse impacts would be negligible to moderate and both short term and long term; minor beneficial impacts would be long term.

Cumulative Impacts

The Habitat alternative under either layout option would not affect Project onshore activities; therefore, cumulative effects to land use and coastal infrastructure would be the same as those described under the Proposed Action: negligible to minor and minor beneficial.

Conclusions

Although the Habitat alternative under either layout option would reduce the number of WTGs and their associated inter-array cables, these changes would not measurably affect land use and coastal infrastructure. Therefore, BOEM expects that the impacts resulting from the alternative alone would be similar to the Proposed Action and range from **negligible** to **moderate**. Project O&M would also generate long-term, **minor beneficial** impacts by supporting designated uses at ports and supporting port improvements and/or redevelopment.

In context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that the Habitat alternative's incremental impacts would be similar to the Proposed Action (with individual IPFs leading to impacts ranging from **negligible** to **minor** and **minor beneficial**). The overall impacts of the Habitat alternative under either layout option when combined with past, present, and reasonably foreseeable activities would therefore be the same level as under the Proposed Action: **minor** adverse and **minor beneficial**.

3.5.5.3 Action Alternative Comparison

As discussed above, the impacts associated with Proposed Action alone do not change substantially under other evaluated action alternatives. Although the number of WTGs and their associated inter-array cables varies slightly, BOEM expects that land use and coastal infrastructure impacts would range from **negligible** to **moderate and minor beneficial** for all action alternatives. The main drivers for this impact rating are the beneficial impacts of port utilization and minor impacts of land disturbance.

In context of reasonably foreseeable environmental trends and planned actions, all action alternatives would occur within the same overall environment (e.g., ongoing and future activities). Therefore, impacts would only vary if the alternatives' incremental contributions differ. However, as noted above, BOEM expects that the incremental impact from any action alternative would be similar, with the level of individual impacts ranging from **negligible to minor and minor beneficial**. Therefore, the overall impact of any action alternative when combined with past, present, and reasonably foreseeable activities would be **minor** adverse and **minor beneficial**, as the overall adverse effect due to land disturbance would be small, localized, and short term. Beneficial impacts could also result from port utilization.

3.5.5.4 Mitigation

No potential additional mitigation measures for land use and coastal infrastructure are identified in Appendix G.

3.5.6 Navigation and Vessel Traffic

The reader is referred to Table 2.3.1-1 and Appendix H for a discussion of current conditions and potential impacts to navigation and vessel traffic from implementation of the Proposed Action and other considered alternatives.

3.5.7 Other Uses (marine, military use, aviation, offshore energy)

3.5.7.1 Affected Environment

<u>Marine mineral resources and dredged material disposal</u>: BOEM's Marine Mineral Program manages non-energy minerals (primarily sand and gravel) in federal waters of the OCS and leases access to these resources to target shoreline erosion, beach renourishment, and restoration projects. At this time, there are no active or requested BOEM leases near the Project. The closest active BOEM lease is offshore of New Jersey, approximately 162 miles from the Project (BOEM 2018a). One USACE borrow area (7A) is located offshore the town of Wainscott, in the vicinity of the SFEC.

The EPA designates and manages dredged material disposal sites, and USACE permits the disposal of material in the sites. One active disposal site is located in the analysis area approximately 3 miles east of Block Island, Rhode Island, and 10 miles northwest of the SFWF. No inactive or closed disposal sites are located in the geographic analysis area.

Increased shoreline erosion and coastal damage from storms has led to increased demand for sand resources in recent years. Although this increased demand is expected to continue, BOEM does not anticipate overlap between marine mineral leases and the Proposed Action.

<u>Military and national security uses</u>: The U.S. Navy, the USCG, and other military entities have numerous facilities in the region. Major onshore regional facilities include Naval Station Newport, the Naval Submarine Base New London, the Northeast Range Complex/Narragansett Bay Operation Area, Joint Base Cape Cod, and numerous USCG stations (Epsilon Associates, Inc. 2018). Onshore and offshore military use areas could have designated surface and subsurface boundaries and special use airspace. The Project is entirely within the Navy's Narragansett Operating Area in which national defense training exercises and system qualification tests are routinely conducted (MARCO 2019). This operating area extends approximately 100 miles south and 200 miles east of the Project. The Project is approximately 10 miles north of a Military Special Use Airspace (FK Facility Narragansett Bay) and 20 miles northeast of the closest submarine transit lanes. A U.S. Department of Defense assessment of compatibility of offshore wind development with military assets and activities determined that potential conflicts exist in the area surrounding the Project and could require site-specific mitigation measures (OCM 2019).

Military and national security interests are expected to continue to use the onshore and offshore areas in the analysis area at similar levels in the foreseeable future.

<u>Aviation and air traffic</u>: Numerous public and private airports serve portions of New York, Rhode Island, and Massachusetts in the region surrounding the Project. Major airports serving the region include Boston Logan International Airport, located approximately 100 miles northeast of the Project; T.F. Green Airport in Providence, Rhode Island, located approximately 50 miles north of the Project; and Montauk Airport in Montauk, New York, approximately 30 miles west of the SFWF and 9 miles north of the offshore SFEC.

The closest public airports to the Project are Nantucket Memorial Airport, approximately 55 miles east on Nantucket; Martha's Vineyard Airport, approximately 32 miles northeast on Martha's Vineyard; and Block Island State Airport, approximately 20 miles west on Block Island.

Air traffic is expected to continue at current levels in and around the Project.

Offshore energy uses: The OCS near the Project is currently experiencing active leasing and exploration in support of offshore wind energy development. Appendix E provides a list of known and anticipated offshore wind project and wind energy leases exist in the area that could lead to additional wind farm development. BOEM anticipates that developers may continue to propose offshore wind energy projects near the Project. The trend in increased wind farm development is anticipated to continue on the OCS. Several tidal energy projects have been implemented in the region and several are in the planning stages. Tidal energy projects are typically located in the nearshore environment where landforms constrict tidal water passage, thereby increasing the velocity of tidal currents. No such landforms exist in the analysis area, so tidal projects are not discussed further in this section.

Undersea cables: At least seven undersea cables are buried in the seabed west of the Lease Area that the offshore SFEC would cross. These cables deliver telecommunications signals between North America and Europe. Other than cables for other offshore wind projects, BOEM has not identified any publicly noticed plans for additional submarine cables or pipelines; therefore, no new cable installation is expected.

Radar systems: Several radar systems supporting commercial air traffic control, national defense, weather forecasting, and ocean condition observation operate near the Project (Epsilon Associates, Inc. 2018). In all, nine radar systems are within operational "line of site" of the SFWF, eight of which are high-frequency radars used to measure ocean currents and one airport surveillance radar (ASR) at Warwick RI (Colburn et al. 2020).

The high-frequency SeaSonde radars are operated by the Integrated Ocean Observing System. SeaSonde radar stations are located on the southern shore of Martha's Vineyard (three stations); on the southern shore of Nantucket (two stations); on the southeastern shore of Block Island (one station); on Montauk Point, Long Island (one station); and on the mainland shore at Misquamicut, Rhode Island (one station) (Integrated Ocean Observing System 2018).

The closest air traffic control radar system operates at Boston Logan International Airport and provides flight control for 165,000 square miles of airspace that includes airports in Connecticut, Vermont, Massachusetts, Rhode Island, Maine, New Hampshire, New York State, and Pennsylvania (FAA 2018). The Precision Acquisition Vehicle Entry/Phased Array Warning System installation at Joint Base Cape Cod supports national defense in the regions surrounding the Project. The nearest Next-Generation Radar weather system is located approximately 60 miles north of the Project. Additionally, the FAA operates a Terminal Doppler Weather Radar installation at Boston Logan International Airport.

These radar systems would continue to provide weather, navigational, and national security support to the region. The number of radars and their coverage area is anticipated to remain at current levels for the foreseeable future.

Scientific research and surveys: Regular fisheries management and ecosystem monitoring surveys conducted by or in coordination with the NEFSC would overlap offshore wind lease areas in the New England region and south into the Mid-Atlantic region. Surveys include 1) the NEFSC Bottom Trawl Survey, a more than 50-year multispecies stock assessment tool using a bottom trawl; 2) the NEFSC Sea Scallop/Integrated Habitat Survey, a sea scallop stock assessment and habitat characterization tool, using a bottom dredge and camera tow; 3) the NEFSC Surfclam/Ocean Quahog Survey, a stock assessment tool for both species using a bottom dredge; 4) the NEFSC Ecosystem Monitoring Program, a more than 40-

year shelf ecosystem monitoring program using plankton tows and conductivity, temperature, and depth units; 5) NOAA's Atlantic Marine Assessment Program for Protected Species aerial and shipboard survey; and 6) North Atlantic Right Whale Sighting Advisory System aerial survey (BOEM 2021). As future wind development continues, alternative platforms, sampling designs, and sampling methodologies could be needed to maintain surveys conducted in or near the Project.

3.5.7.2 Environmental Consequences

3.5.7.2.1 ISSUES, INDICATORS, AND SIGNIFICANCE CRITERIA

Table 3.5.7-1 lists the issues identified for this resource and the indicators and significance criteria used to assess impacts for the final EIS.

Table 3.5.7-1. Issues, Indicators, and Significance Criteria Used to Assess Impacts to Other Marine Uses

Issue	Impact Indicator	Significance Criteria
Reduction in the military's ability to access and use the site due to construction vessel traffic and WTG installation	Level of interruption to military exercises	Negligible: No measurable impacts would occur. Minor: Adverse impacts to the affected activity could be avoided with EPMs, and impacts would not disrupt the normal or routine functions of the affected activity. Once the Project is decommissioned, the affected activity would return to a condition with no measurable effects. Moderate: Impacts to the affected activity are unavoidable, but EPMs would reduce impacts substantially during the life of the Project. The affected activity would have to adjust somewhat to account for disruptions due to impacts of the Project, or, once the Project is decommissioned, the affected activity would return to a condition with no measurable effects if proper remedial action is taken. Major: The affected activity would experience unavoidable disruptions to a degree beyond what is normally acceptable, and, once the Project is decommissioned, the affected activity could retain measurable effects indefinitely, even if remedial action is taken.
Reduced availability of offshore energy (oil/gas) production at the site	Acreage of oil and gas activities excluded due to WTGs or offshore SFEC	
Reduced access to sand and minerals on the OCS	Acreage of mineral extraction area excluded due to WTGs or offshore SFEC	
Risk to aviation traffic	Qualitative assessment of risk to approach flight vectors to regional airports	
Impact to land-based radar (air traffic control, NOAA weather, high-frequency ocean observation radar)	Qualitative assessment of potential for radar shadow	
Impacts to other renewable energy projects, particularly if there is overlap in ports to be used; transit lane orientation	Qualitative assessment of potential for exclusion of other renewable energy projects	
Impact to any proposed/approved pipelines; electricity/telecom transmission lines	Qualitative assessment of potential for exclusion of or damage to other undersea cables	
Impacts to scientific research and surveys	Qualitative assessment of potential for reduced or eliminated survey opportunities	
Impact to dredged material ocean disposal sites	Project overlap with ocean disposal sites	

3.5.7.2.2 NO ACTION ALTERNATIVE

The Affected Environment section provides information on existing other use trends from past and present activities. Attachment 3 in Appendix E provides additional information regarding past and present activities and associated impacts to other uses. Future non-Project actions include cable trenching, port expansion, and increased vessel traffic. Attachment 3 in Appendix E discloses future non-offshore wind activities and associated other uses impacts. Impacts associated with future offshore wind activities are described below.

Future Projects

Marine Mineral Resources and Dredged Material Disposal

Presence of structures and new cable emplacement/maintenance: The demand for sand resources is anticipated to grow with increasing trends in coastal erosion, storm events, and sea level rise. The geographic analysis area contains a large area of available sand and mineral resources (over 4 million cubic yards of sand available for authorized use [USACE 2020]). Future offshore wind project infrastructures, including WTGs and transmission cables, could prevent future marine mineral extraction activities where project footprints overlap with extraction areas. However, mineral extraction typically occurs within 8 miles of the shoreline, limiting adverse impacts to cable routes. Additionally, future projects would avoid identified borrow areas by consulting with the BOEM Marine Minerals Program and USACE before approving offshore wind cable routes. Therefore, the combined adverse impacts on sand and mineral extraction are anticipated to be negligible under the No Action alternative.

Military and National Security

Presence of structures: Installation of up to 1,294 structures in the RI/MA WEA, which currently supports only five offshore wind turbines associated with the BIWF, as well as several meteorological buoys (see Appendix E), would impact military and national security vessels primarily through risk of allision and collision with stationary structures and other vessels. Vessels could directly allide with WTG foundations. Vessel traffic would increase during Project construction, and once the WTGs are operational, the artificial reef effect created by offshore structures could attract commercial and recreational fishing vessels. This would increase the risk of vessel collisions and increase navigation complexity, leading to potential use conflicts. In general, risks to military and national security vessels would increase over time as additional wind energy facilities are built.

Military and national security vessels could allide with WTG structures. However, deep-draft military vessels are not anticipated to transit outside of navigation channels unless necessary for SAR (of people or marine mammals) or nontypical operations. Allision risks for smaller vessels moving within or near offshore wind structures would be higher. However, these risks would be minimized by projects adhering to structural lighting requirements according to the USCG and BOEM, which would provide lighting at sea level. Additionally, allision would be further mitigated by following a fixed 1 × 1–nm WTG layout proposed by offshore wind leaseholders to facilitate safe navigation through the offshore wind energy lease areas (Brostrom et al. 2019).

Additionally, risk of collision with recreational fishing vessels could indirectly increase as a result of the artificial reef effect around the offshore wind facility structures. New artificial reef effects could attract recreational fishing vessels farther offshore than currently occurs, adding to existing vessel traffic and subsequently increasing the risk of collision with military and national security vessels. Furthermore, an increase in recreational vessels in and around offshore wind projects could increase the demand for USCG SAR operations (of people or marine mammals).

In addition to allision or collision risks, military and national security vessels may be impacted by offshore wind energy structures by the need to change routes and navigate around both project footprints and project associated vessels, particularly during the construction periods between 2021 and 2030. Furthermore, military and national security vessels may experience congestion and delays in port due to the increase in offshore wind facility vessels.

Military and national security aircraft would be impacted by the presence of tall equipment necessary for offshore wind facility construction, such as stationary lift vessels and cranes, which would increase navigational complexity in the area. Warning area W-105A measures approximately 23,000 square miles, with approximately 4% (approximately 1,000 square miles) overlaying the geographic analysis area (BOEM 2021). Military and national security operations conducted within W-105A would be impacted during construction and operation periods. However, it is assumed all offshore wind energy project operators would coordinate with relevant agencies during the COP development process to identify and minimize conflicts with military and national security operations.

Measures mitigating risks would include operational protocol to stop WTG rotation during SAR aircraft operations and implementation of FAA and BOEM recommended navigational lighting and marking to reduce the risk of aircraft collisions. Wind energy structures would be visible on military and national security vessel and aircraft radar. Nonetheless, the presence and layout of large numbers of WTGs could make it more difficult for SAR aircraft to perform operations (of people or marine mammals), leading to less effective search patterns or earlier abandonment of searches. This could result in otherwise avoidable loss of life due to maritime incidents.

Navigational hazards would gradually be eliminated when structures are removed during conceptual decommissioning. Based on coordinating efforts and the anticipated mitigating measures discussed above, the overall impacts to military and national security uses are anticipated to be minor to moderate under the No Action alternative.

Traffic: Increased vessel traffic due to construction and conceptual decommissioning of future offshore wind facilities could lead to course changes of military and national security vessels, congestion and delays at ports, and increased traffic along vessel transit routes. Vessel activity could peak in 2024 with as many as 379 vessels involved in construction of reasonably foreseeable projects. While construction periods of various wind energy facilities may be staggered, some overlap would result in a cumulative impact to traffic loads.

Aviation and Air Traffic

Presence of structures: Future offshore wind development could add up to 1,294 structures to the offshore environment in the RI/MA WEA. WTGs could have maximum blade tip height of 853 feet above mean sea level. As these structures are built, aircraft navigation patters and complexity would incrementally increase. These changes could compress lower altitude aviation activity into more limited airspace above the offshore wind energy lease areas leading to airspace conflicts or congestion, and increasing collision risks for low-flying aircraft.

All existing stationary structures would have navigation marking and lighting in accordance with FAA, USCG, and BOEM guidance to minimize collision risks.

Open airspace around the lease areas would still exist, however, after all foreseeable future offshore wind energy projects are built. BOEM assumes that offshore wind project operators would coordinate with aviation interests throughout the planning, construction, operations, and conceptual decommissioning process to avoid or minimize impacts on aviation activities and air traffic. For this reason, cumulative adverse impacts to aviation and airports are anticipated to be minor.

Offshore Energy Uses

Construction and operation of offshore energy projects are expected between 2021 and 2030. This use is not carried forward for standalone cumulative analysis because the impact of offshore wind is already evaluated as part of all other IPFs.

Undersea Cables

Presence of structures: Up to 1,294 structures along with 4,247 miles of cables are expected to be installed between 2021 and 2030 in the RI/MA WEA as part of future offshore wind energy project infrastructure. The presence of future offshore wind energy structures could preclude future submarine cable placement within any given development footprint, requiring future cables to route around these areas. However, the placement and presence of these cables would not prohibit the placement of additional cables and pipelines. Following standard industry procedures, cables and pipelines can be crossed without adverse impact. The risk of allision to cable maintenance vessels could increase as more offshore wind energy projects are constructed. However, given the infrequency of required maintenance at any given location along a cable route, this risk is expected to be low. Impacts on submarine cables would be eliminated during conceptual decommissioning of offshore wind farms if export cables associated with those projects are removed. Under the No Action alternative, minor cumulative adverse impacts to cables in the area would be anticipated.

Radar

Presence of structures: WTGs that are near or in direct line-of-site to land-based radar system can interfere with the radar signal causing shadows or clutter in the received signal. Construction of 1,294 structures in the RI/MA WEA could lead to long-term, minor cumulative impacts to radar systems. However, these structures would be sited at such a distance from existing and proposed land-based radar systems to minimize interference to most radar systems.

BOEM assumes that all offshore wind developments in the geographic analysis area would use the developer agreed up 1 × 1–nm spacing in fixed east–west rows and north–south columns (Baird 2020), and will evaluate each of those individual projects in their respective NEPA analyses. This arrangement would reduce, but not eliminate, navigational complexity and space use conflicts during the operation phases of the projects. Navigational complexity in the area would increase during construction as offshore wind foundations are installed, would remain constant during simultaneous operations, and would decrease as projects are decommissioned and structures are removed. The Final Massachusetts and Rhode Island Port Access Route Study (USCG 2020) concludes that general mitigation measures, such as properly trained radar operators, properly installed and adjusted vessel equipment, marked wind turbines, and the use of AIS all enable safe navigation with minimal loss of radar detection. Following the layout recommendations in the Final Massachusetts and Rhode Island Port Access Route Study would improve safety, but it would not remove the risk of allisions or collisions with WTGs during SAR operations (of people or marine mammals) particularly in challenging weather or visibility conditions (USCG 2020).

Scientific Research and Surveys

Presence of structures: If construction of all projected future offshore wind facilities occurs along the Atlantic coast, these developments would add up to 2,547 structures between 2021 and 2030 that could have a maximum blade tip height of up to 853 feet above mean sea level. Collectively, these developments would prevent NMFS from continuing ongoing scientific research surveys or protected species surveys under current vessel capacities and could reduce future opportunities for NMFS' scientific research in the area. This EIS incorporates, by reference, the detailed analysis of potential impacts to scientific research and surveys provided in the Vineyard Wind final EIS in Section 3.12.2.5, Scientific Research and Surveys (BOEM 2021). In summary, offshore wind facilities actuate impacts on scientific surveys and advice by preclusion of NOAA survey vessels and aircraft from sampling in survey strata and impacts on the random-stratified statistical design that is the basis for assessments, advice, and analyses. NOAA has determined survey activities within offshore wind facilities are outside of safety and operational limits. Survey vessels would be required to navigate around offshore wind projects to access survey locations, leading to a decrease in operational efficiency. The height of turbines would affect aerial survey design and protocols, requiring flight altitudes and transects to change. Scientific survey and protected species survey operations would therefore be reduced or eliminated as offshore wind facilities are constructed (BOEM 2021). Offshore wind facilities will disrupt survey sampling statistical designs, such as random stratified sampling. Impacts to the statistical design of region-wide surveys violate the assumptions of probabilistic sampling methods. Development of new survey technologies, changes in survey methodologies, and required calibrations could help to mitigate losses in accuracy and precision of current practices due to the impacts of wind development on survey strata.

Other offshore wind projects could also require implementation of mitigation and monitoring measures identified in records of decision. Identification and analysis of specific measures are speculative at this time; however, these measures could further impact NMFS's ongoing scientific research surveys or protected species surveys because of the increased vessel activity and/or in-water structures from these other projects.

BOEM is committed to working with NOAA toward a long-term regional solution to account for changes in survey methodologies as a result of offshore wind farms.

Overall, the No Action alternative would have major effects on NMFS' scientific research and protected species surveys, potentially leading to impacts on fishery participants and communities; as well as potential major impacts on monitoring and assessment activities associated with recovery and conservation programs for protected species.

Conclusions

Under the No Action alternative, BOEM would not approve the COP; Project construction and installation, O&M, and conceptual decommissioning would not occur; and potential impacts on other uses associated with the Project would not occur. However, ongoing and future activities would have continuing temporary to long-term impacts on other uses due to the presence of structures that introduce navigational complexities and vessel traffic.

BOEM anticipates that the impact to other marine uses from the combination of most ongoing activities and reasonably foreseeable activities other than offshore wind would be **negligible** because BOEM anticipates that any issues with aviation routes or radar systems would be resolved through coordination with the DOD or FAA, as well as through implementation of navigational marking of structures according to FAA, USCG, and BOEM requirements and guidelines. Impacts on scientific research and surveys are anticipated to be **moderate** for scientific research and surveys due to the impacts of ongoing offshore wind activities (BIWF) and fishing (static gear) (Weinberg 2020) as well as potential impacts from climate change and fishing. BOEM anticipates that the impacts to reasonably foreseeable offshore wind activities would be **major**, primarily because of the potential impacts to NMFS survey efforts.

Considering all the IPFs together, BOEM anticipates that the impacts associated with future offshore wind activities in the geographic analysis area combined with ongoing activities, reasonably foreseeable environmental trends, and reasonably foreseeable activities other than offshore wind would result in **negligible** to **minor** adverse impacts for most uses, as the overall effect would be small. However, the overall effect would be notable and **moderate** adverse for radar systems due to WTG interference, and **major** adverse for scientific research and surveys and USCG SAR activities (of people or marine mammals). The presence of stationary structures could prevent or hamper continued NMFS scientific research surveys using current vessel capacities and monitoring protocols or reduce opportunities for other NMFS scientific research studies in the area. Coordinators of large vessel survey operations or operations deploying mobile survey gear have determined that activities within offshore wind facilities would not be within current safety and operational limits. In addition, changes in required flight altitudes due to the proposed WTG height would affect aerial survey design and protocols. BOEM acknowledges that NOAA's Office of Marine and Aviation Operations endorses the restriction of large vessel operations to greater than 1 nm from wind installations due to safety and operational challenges.

The No Action alternative would forgo the fisheries monitoring that SFW has committed to voluntarily perform. Therefore, the results of this monitoring would not be available to provide an understanding of the effects of offshore wind development; benefit future management of finfish, invertebrates, and EFH; or inform planning of other offshore developments. However, other ongoing and future surveys could still provide similar data to support similar goals.

3.5.7.2.3 PROPOSED ACTION ALTERNATIVE

Construction and Installation

Marine mineral resources and dredged material disposal: There are no BOEM OCS sand and mineral lease areas and no identified sand resource blocks within the SFWF and offshore SFEC; therefore, the Project would have no impacts on these marine mineral resources. Similarly, because Project activities would not overlap any active dredged material disposal sites, the Project would have no impact on dredged material disposal. However, SFW has requested a buffer area between USACE borrow area 7A and the offshore SFEC. This buffer zone could result in long-term, minor adverse impacts to the USACE's ability to extract sand from the borrow area.

Military and national security uses: Access by military vessels to the SFWF and SFEC would be limited during installation; however, USCG search and rescue activities would still occur. The Proposed Action layout would ensure two lines of orientation for USCG helicopters to conduct search and rescue operations. The U.S. Department of Defense concluded that the Proposed Action would have minor but acceptable adverse impacts on their operations (OCM 2019). Therefore, the Project would have minor adverse impacts on military operations and national security.

Aviation and air traffic: The Proposed Action would add 15 WTGs with maximum blade tip heights of up to 853 feet above mean sea level to the geographic analysis area. The addition of these structures would increase navigational complexity and could change aircraft navigation patterns for aircraft flying at low altitudes and for airports in the vicinity, increasing collision risks for some aircraft during the Proposed Action's operational timeframe. However, more than 90% of existing air traffic in the analysis area would occur at altitudes that would not be impacted by the presence of WTGs (BOEM 2021).

WTGs would be marked with appropriate lighting to meet FAA warning guidelines and would be visible on the radar systems of low-flying aircrafts, similar to other large-scale sea surface activity. Therefore, impacts to air traffic would be negligible, long term, and adverse. Similarly, WTG components located at staging ports could result in issuance of notices to airmen, causing some aircraft to reroute. WTG components would be in staging ports for brief periods leading to short-term adverse impacts. This is anticipated to lead to negligible adverse impacts to air traffic.

Offshore energy uses: Because renewable energy projects occur within individual lease areas, there would be no opportunity for the SFWF to directly overlap or substantially interfere with other renewable energy projects. However, overlapping construction time frames could lead to increased navigation risk or impacts to construction ports. Such impacts are not anticipated to affect construction timelines or alter the layouts of other renewable energy projects. For this reason, adverse impacts to other renewable energy projects are deemed negligible.

Undersea cables: The installation of the SFEC would cross at least seven undersea telecom cables, three active and four inactive (see COP Figure 4.6-10). Because SFW would use standard techniques during installation to prevent damage to cables, adverse impacts would be minor. Cables installed in the future would be able to cross the SFEC using standard protection techniques; therefore, adverse impacts on future cables would be negligible.

Land-based radar systems: No radar screening analysis has been conducted for the Project; however, because the Project would be installed more than 15 miles from shore, in an area of the OCS very similar to where the Vineyard Wind Energy Project is planned, the radar screening analysis conducted by Vineyard Wind provides an acceptable surrogate. Based on that analysis, BOEM concluded the Project would have only negligible adverse impacts to radar (Epsilon Associates, Inc. 2018).

The Project would, however, adversely impact North American Aerospace Defense Command's air defense mission by causing interference with the Falmouth ASR-8, as identified by the DOD Clearinghouse. To address these concerns, BOEM plans to include approval conditions in the COP requiring 30- to 60-day advanced notification to the North American Aerospace Defense Command ahead of Project completion and when the Project is complete and operational for RAM scheduling, funding of RAM execution, and curtailment for national security or defense purposes, as described in the leasing agreement. Any other impacts on radar systems are anticipated to be mitigated by overlapping coverage and radar optimization. The FAA would evaluate potential impacts on radar systems, as well as mitigation measures, when SFW refiles Form 7460-1 for individual WTGs located within U.S. territorial waters. SFW's marine coordinator would remain on duty for the life of the Proposed Action to liaise with military, national security, civilian, and private interests to reduce potential radar conflicts.

Scientific research and surveys: Scientific research and protected species surveys could be affected from the construction of the SFWF and SFEC. Some vessels or low-flying aircraft could be required to alter course to avoid WTGs and NOAA policy advises survey vessels to remain at least 1 mile from fixed structures if possible (Gabriel 2019). Specifically, the coordinators of large vessel survey operations and operations deploying mobile survey gear regard survey activities within offshore wind facilities to exceed current safety and operational limits. In consequence, NOAA has concluded that survey operations would be curtailed within offshore wind facility areas, if not eliminated, under current vessel capacities and monitoring protocols. However, the substrate in the SFWF is substantially rock and cobble, making it suboptimal for survey and commercial trawling because equipment may become entangled. In fact, commercial fishing effort is substantially less in the SFWF than in surrounding habitat (Northeast Ocean Data Portal 2018). Also, although vessels or aircraft could be required to make minor course adjustments to avoid collisions, they would not be completely blocked from access to areas between the WTGs. Nevertheless, NMFS scientific research and protected species surveys could be curtailed within the Lease Area, and NMFS believes that construction of the SFWF and the survey adjustments needed will constitute a major, long-term impact on those surveys.

Operations and Maintenance and Conceptual Decommissioning

Impacts during O&M and conceptual decommissioning of the Project are anticipated to be less than or similar to those described for construction.

Cumulative Impacts

Marine Mineral Resources and Dredged Material Disposal

Presence of structures and new cable emplacement/maintenance: Because the Project would have no impacts on marine mineral resources or on dredged material disposal, other than long-term, minor adverse impacts to the USACE's ability to extract sand from borrow area 7A, the Project would only add negligible adverse incremental impacts to the conditions under the No Action alternative. Under the No Action alternative, it is expected that the demand for sand resources will grow based on current trends. However, there is a large area of available sand and mineral resources on the OCS (e.g., over 4 million cubic yards of sand available for authorized use [BOEM 2018b]) and future projects would avoid identified borrow areas by consulting with the BOEM Marine Minerals Program and USACE before approving offshore wind cable routes. Therefore, the cumulative impact for the Proposed Action when combined with past, present, and reasonably foreseeable projects would be long term and negligible.

Military and National Security Uses

Presence of structures: The Proposed Action would result in short-term and long-term, minor to moderate incremental impacts to military and national security through the installation of 16 structures (15 WTGs and one OSS), along with stationary lift vessels and cranes during construction, to conditions under the No Action alternative, for a total of 1,310 structures within the RI/MA WEA. Project structures could support artificial reef effects, which may also increase traffic and activity near the WTGs for recreational fishing or sightseeing vessels. These structures would increase the short-term and long-term risks of allision for military and national security vessels, as well as search and rescue vessels. However, deep-draft military vessels are not anticipated to transit outside of navigation channels unless needed for search and rescue. Potential allision risks if these vessels lost power would be minimized through the Proposed Action's 1 ×1–nm WTG spacing. BOEM also anticipates that coordination with military and national security interests would be ongoing during construction and installation, O&M, and conceptual decommissioning.

Changing navigation patterns could also concentrate vessels within and around the outsides of the RI and MA Lease Areas, potentially causing space use conflicts in these areas or reducing the effectiveness of SAR operations (of people or marine mammals). While the addition of Project structures and associated construction vessels would also increase navigational complexity or alter navigation patterns for military and national security aircraft operating in the region, Project structures would be marked as a navigational hazard per FAA, BOEM, and USCG guidelines and WTGs would be visible on military and national security vessel and aircraft radar. The Proposed Action would implement a 1 × 1–nm spacing, consistent with all other projects in the RI/MA WEA.

Proposed Action structures represents no more than a 2% increase over total estimated WTG and OSS foundations across the geographic analysis area under the No Action alternative. BOEM estimates a cumulative total of 1,310 offshore WTGs and OSS foundations for the Proposed Action plus all other future offshore wind projects in the RI/MA WEA. Therefore, the cumulative impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would consist predominately of impacts described under the No Action alternative, which would represent a long-term, minor to moderate impact on military and national security uses.

Traffic: As described in Section 3.5.6.2.3 (Proposed Action Alternative), the Proposed Action would require 13 construction vessels per construction day over the 2-year construction period. This vessel activity would increase the risk of collisions, allisions, and spills. However, the Proposed Action represents a small proportion (4%) of the total vessels potentially present. Therefore, the Proposed Action would result in negligible incremental impacts to military and national security uses.

BOEM estimates a peak of 379 vessels due to offshore wind project construction over a 10-year time frame. Although the number of construction vessels (reaching a maximum in 2024) would represent a large portion of the traffic in the region, most vessels would remain in the MWA, with fewer vessels transporting materials back and forth from ports. With multiple offshore wind projects under construction, traffic would also be spread among multiple ports to ensure sufficient capacity exists at each port and in each waterway. Additionally, BOEM also anticipates that coordination with military and national security interests would be ongoing during construction and installation, O&M, and conceptual decommissioning activity. Therefore, cumulative impacts associated with the Project when combined with past, present, and reasonably foreseeable future activities would be long term and minor.

Aviation and Air Traffic

Presence of structures: Because WTGs are the tallest features expected to be constructed on the OCS, development of additional offshore wind farms is the only expected activity to cumulatively affect air traffic. The Proposed Action would result in long-term, negligible incremental impacts to aviation and air traffic through the installation of 16 structures (15 WTGs and one OSS) to conditions under the No Action alternative. These structures would also increase navigational complexity and navigation patterns for low-flying aircraft. BOEM estimates that these impacts would occur for no more than 10% of air traffic, but affected pilots could be required to alter routes to avoid constructed WTGs. Siting of the Project more than 15 miles offshore would place the Project outside typical approach routes to nearby airports. All existing stationary structures would have navigation marking and lighting in accordance with FAA, USCG, and BOEM guidelines to minimize collision risks. WTGs would also be visible on aircraft radar.

Proposed Action structures represents no more than a 2% increase over total estimated WTG and OSS foundations across the geographic analysis area under the No Action alternative. BOEM estimates a cumulative total of 1,310 offshore WTGs and OSS foundations for the Proposed Action plus all other future offshore wind projects in the RI/MA WEA. Therefore, the cumulative impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would consist predominately of impacts described under the No Action alternative, which would represent a long-term, minor impact on aviation and air traffic uses.

Undersea Cables

Presence of structures: The Proposed Action would result in long-term, negligible incremental impacts to existing undersea cables through the installation of 16 structures (15 WTGs and one OSS) and 82.5–86.9 miles of cable to conditions under the No Action alternative. BOEM estimates a cumulative total of 1,310 offshore WTGs and OSS foundations and up to 4,334 miles of cable for the Proposed Action plus all other future offshore wind projects in the RI/MA WEA. Placement of these project components would not preclude the placement of additional cables and pipelines. Following standard industry procedures, cables and pipelines can be crossed without adverse impact. Cable maintenance vessels transiting through or working within the geographic analysis area would be at risk of allisions with Project structures, but required navigational hazard marking and implementation of a 1 × 1–nm spacing would minimize this risk, as would the relatively infrequent need for maintenance activities. For the same reasons, the cumulative effects associated with the Proposed Action and past, present, and reasonably foreseeable activities would result in long-term but negligible impacts on undersea cables.

Radar

Presence of structures: The Proposed Action would result in long-term, negligible incremental impacts to land-based radar through the installation of 16 structures (15 WTGs and one OSS) to conditions under the No Action alternative. These structures would increase the long-term risk of radar interference or clutter, but existing radars are sited at such a distance to minimize interference. BOEM's (2020) study of radar interference concludes that SeaSonde radars appear to be the most heavily-impacted radar by offshore wind projects because of their prevalence. However, as noted in Section 3.5.7.2.2 (No Action Alternative), the Final Massachusetts and Rhode Island Port Access Route Study (USCG 2020) concludes that general mitigation measures, such as properly trained radar operators, properly installed and adjusted vessel equipment, marked wind turbines, and the use of AIS, all enable safe navigation with minimal loss of radar detection. BOEM would include approval conditions in the COP regarding notification to North American Aerospace Defense Command of RAM scheduling, funding of RAM execution, and curtailment for national security or defense purposes, as needed.

Therefore, the Proposed Action and past, present, and reasonably foreseeable activities would result in long-term and moderate cumulative impacts on radar systems.

Scientific Research and Surveys

Presence of structures: The Proposed Action would result in long-term major incremental impacts to NMFS' scientific research and surveys through the installation of 16 structures (15 WTGs and one OSS) to conditions under the No Action alternative. These structures would result in adverse impacts to NMFS' scientific research and protected species surveys due to 1) WTG blade tip height that would exceed the survey altitude for current surveying methodologies, and 2) Lease Area geographic overlap with ongoing NMFS's Northeast Fisheries Science Center fishery resource monitoring surveys. Research and monitoring proposed by the lessees and/or conducted by other scientific institutions would continue in offshore wind facilities. This final EIS incorporates, by reference, the detailed analysis of potential impacts to scientific research and surveys provided in the Vineyard Wind final EIS (BOEM 2021).

Proposed Action structures represents no more than a 1% increase over total estimated 2,547 WTG and OSS foundations under the No Action alternative that could be present along the Atlantic coast if all projected future offshore wind facilities are constructed. BOEM estimates a cumulative total of 2,563 offshore WTGs and OSS foundations for the Proposed Action plus all other future offshore wind projects. Therefore, the cumulative impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would consist predominately of impacts described under the No Action alternative, which would represent a long-term, major impact on NMFS's scientific research and protected species surveys and the resulting stock assessments.

Conclusions

Project construction and installation, O&M, and conceptual decommissioning would affect ongoing military, aviation, and scientific research studies occurring in the analysis area. Similar impacts from Project O&M would occur, although at lesser extent and duration for some uses. BOEM anticipates the impacts resulting from the Proposed Action alone would range from **negligible** to **major**, as described below by topic.

- Marine mineral resources and dredging: Potential impacts would be **minor** due to limited mineral extraction and consultation with the BOEM Marine Minerals Program and the USACE before approving offshore wind cable routes.
- Military and national security uses: Potential **minor** impacts on military and national security uses would primarily be caused by installation of WTGs in the geographic analysis area, resulting in increased navigational complexity and associated risks.
- Aviation and air traffic: Potential **negligible** impacts on aviation and air traffic would primarily be caused by installation of WTGs in the geographic analysis area due to potential changed in navigational patterns.
- Undersea cables: Potential impacts on cables would be **negligible** due to the limited number of existing submarine cables and use of standard techniques to avoid impacts.
- Radar: Potential impacts on radar systems would be localized, long-term, and **negligible**. Although presence of WTGs has the potential to cause interference with radar systems, ground-based radar systems are located a sufficient distance that radar interference is not anticipated, and mitigation would not be required.
- Scientific research and surveys: Potential impacts on scientific research and surveys would generally be **major**, particularly pertaining to NOAA and NMFS surveys supporting commercial fisheries and protected species research programs. Presence of structures would exclude certain areas within the WDA occupied by project components (e.g., WTG foundations, cable routes) from potential vessel and aerial sampling, and by impacting survey gear performance, efficiency, and availability.

In the context of other reasonably foreseeable environmental trends and planned actions, the incremental impacts under the Proposed Action resulting from individual IPFs would range from **negligible** to **major**. Considering all the IPFs together, BOEM anticipates that the overall impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would range from **negligible** to **minor** adverse impacts for most uses (since the impact would be small), to **moderate** adverse for some military uses and radar systems (since potential conflicts could be addressed through established processes), and **major** adverse for NMFS's scientific research and surveys and SAR operations (of people or marine mammals). The main drivers for the major impact ratings are installation of structures, primarily WTGs, that would hinder survey efforts. NOAA and NMFS scientific research and surveys would qualify as major because entities conducting surveys and scientific research would have to make significant investments to change methodologies to account for unsampleable areas, with potential long-term and irreversible impacts on fisheries and protected species research as a whole as well as the commercial fisheries community. There could be impacts on other types of surveys, and increased opportunities to study impacts of offshore wind development on a variety of resources.

3.5.7.2.4 VESSEL TRANSIT LANE ALTERNATIVE

The Transit alternative would lead to the same types of impacts on other uses from construction and installation, O&M, and conceptual decommissioning activities as described for the Proposed Action. However, construction of this alternative would install fewer WTGs and associated inter-array cables, which would slightly reduce the construction impact footprint and installation period. Therefore, this alternative would result in negligible to moderate impacts to ongoing military, aviation, and scientific research studies occurring in the analysis area.

Cumulative Impacts

The Transit alternative would add resource impacts at quantities and durations similar to, or slightly reduced from, the Proposed Action, driven by the continued presence of offshore structures—primarily WTGs—in the Lease Area.

The transit lanes could reduce cumulative impacts related to allision and collision risk throughout the lease areas (USCG 2020). Conversely, allisions and collisions could increase if commercial and recreational fishing and boating occurs within, or congregates alongside, the transit lanes. Implementing transit lanes could allow easier access for scientific research and survey activity within the transit lanes; however, these activities would still be impacted by the presence of offshore structures. Therefore, the overall cumulative impacts of this alternative when combined with past, present, and reasonably foreseeable activities would range from negligible to minor adverse impacts for most uses (since the impact would be small), to moderate adverse for some military uses and radar systems (since potential conflicts could be addressed through established processes), and major adverse for NMFS's scientific research and surveys and SAR operations (of people or marine mammals).

Conclusions

Although the Transit alternative would reduce the number of WTGs and their associated inter-array cables, which would have an associated reduction in associated vessel and equipment use and air emissions, BOEM expects that the impacts resulting from the alternative alone would be similar to the Proposed Action and range from **negligible** to **major**.

In context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that the Transit alternative's incremental impacts would be similar to the Proposed Action (with individual IPFs leading to impacts ranging from **negligible** to **major**. The overall impacts of the Transit alternative when combined with past, present, and reasonably foreseeable activities would therefore be the same level as under the Proposed Action: **negligible** to **minor** adverse impacts for most uses (since the impact would be small), to **moderate** adverse for some military uses and radar systems (since potential conflicts could be addressed through established processes), and **major** adverse for NMFS's scientific research and surveys and SAR operations (of people or marine mammals).

3.5.7.2.5 FISHERIES HABITAT IMPACT MINIMIZATION ALTERNATIVE

The Habitat alternative under either layout option would result in a reduction in the number of turbines and associated inter-array cable. Impacts to marine mineral resources and dredged material disposal, military and national security uses, aviation and air traffic, offshore energy uses, undersea cables, land-based radar, and scientific research and surveys from construction and installation, O&M, and conceptual decommissioning of the SFWF, SFEC, and Montauk O&M facility would be reduced, but not measurably, to the Proposed Action. Therefore, the Habitat alternative under either layout option is anticipated to result in negligible to moderate adverse impacts.

Cumulative Impacts

The Habitat alternative under either layout option is similar to the Proposed Action except that it has a reduced number of turbines and associated inter-array cables. Therefore, the Habitat alternative under either layout option would add resource impacts at quantities and durations similar to, or slightly reduced from, the Proposed Action, driven by the continued presence of offshore structures—primarily WTGs—in the Lease Area. As such, the overall cumulative impacts of this alternative when combined with past, present, and reasonably foreseeable activities would range from negligible to minor adverse impacts for most uses (since the impact would be small), to moderate adverse for some military uses and radar systems (since potential conflicts could be addressed through established processes), and major adverse for NMFS's scientific research and surveys and SAR operations (of people or marine mammals).

Fisheries Habitat Impact Minimization Alternative Conclusions

Although the Habitat alternative under either layout option would reduce the number of WTGs and their associated inter-array cables, which would have an associated reduction in associated vessel and equipment use and air emissions, BOEM expects that the impacts resulting from the alternative alone would be similar to the Proposed Action and range from **negligible** to **major**.

In context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that the Habitat alternative's incremental impacts would be similar to the Proposed Action (with individual IPFs leading to impacts ranging from **negligible** to **major**). The overall impacts of the Habitat alternative under either layout option when combined with past, present, and reasonably foreseeable activities would therefore be the same level as under the Proposed Action: **negligible** to **minor** adverse impacts for most uses (since the impact would be small), to **moderate** adverse for some military uses and radar systems (since potential conflicts could be addressed through established processes), and **major** adverse for NMFS's scientific research and surveys and SAR operations (of people or marine mammals).

3.5.7.3 Action Alternative Comparison

As discussed above, the impacts associated with Proposed Action alone do not change substantially under other evaluated action alternatives. Although the number of WTGs and their associated inter-array cables varies slightly, BOEM expects that impacts to other uses would range from **negligible** to **major** for all action alternatives.

In context of reasonably foreseeable environmental trends and planned actions, all action alternatives would occur within the same overall environment (e.g., ongoing and future activities). Therefore, impacts would only vary if the alternatives' incremental contributions differ. However, as noted above, BOEM expects that the incremental impact from any action alternative would be similar, with the level of individual impacts ranging from **negligible** to **major**. Therefore, the overall impact of any action alternative when combined with past, present, and reasonably foreseeable activities would be **negligible** to **minor** adverse impacts for most uses (since the impact would be small), to **moderate** adverse for some military uses and radar systems (since potential conflicts could be addressed through established processes), and **major** adverse for NMFS's scientific research and surveys and SAR operations (of people or marine mammals). The main drivers for the major impact rating are installation of structures, primarily WTGs, that would hinder survey efforts.

3.5.7.4 Mitigation

Implementation of the regional Federal Survey Mitigation Program to address adverse impacts from Atlantic offshore wind energy development on recurring scientific research and protected species surveys may not significantly reduce the expected major impacts on NOAA scientific surveys from the Project in the short term but should lessen long-term impacts.

3.5.8 Recreation and Tourism

The reader is referred to Table 2.3.1-1 and Section 3.5.8 of Appendix H for a discussion of current conditions and potential impacts to recreation and tourism, including private recreational fishing, from implementation of the Proposed Action and other considered alternatives.

3.5.9 Visual Resources

3.5.9.1 Affected Environment

This Visual Resources section addresses non-historic visual resources. Historic visual resources are addressed in the Cultural Resources section (Section 3.5.2).

Coastal Massachusetts, Rhode Island, and Connecticut have a wide range of visual characteristics, with communities and landscapes ranging from large cities to small towns, suburbs, rural areas, and wildlife preserves (EDR 2020). Daytime and nighttime skies are characterized by clear conditions, clouds, fog, and haze. The scenic quality of the coastal environment is important to the identity, attraction, and economic health of many of the coastal communities (EDR 2020). The visual qualities of historic coastal towns, which include marine activities within small-scale harbors, and the ability to view birds and marine life, are important community characteristics (EDR 2018, 2020). The characteristic onshore landscape includes high to moderate quality scenery elements, as follows: landforms, comprising a ridge (elevation 182 feet), dunes, and scenic sea coast; waterbodies, including ponds and the Atlantic Ocean; vegetation, including dune grasses, forest, coastal scrub, and residential plantings; structures, including residential buildings, fences, roads, parking; and cultural resource elements, including the East Hampton Scenic Areas of Statewide Significance (New York State Department of State, Division of Coastal Resources 2010). The onshore landscape includes Wainscott, Georgica, Hook, Lily and Town Ponds, surrounding upland landscapes, and 7 miles of Atlantic beaches.

The characteristic seascape of the SFWF and offshore SFEC (see Figure C-31 in Appendix C) comprises views of open ocean from recreational and commercial boating (offshore) and views from the mainland and islands (onshore). Because of the proximity of the Atlantic Ocean and the views associated with the shoreline, coastal New England has been extensively developed for water-based recreation and tourism (EDR 2020) and commercial and industrial uses. Recreational and commercial vessels and activities contribute to the visual character of the seascape.

3.5.9.2 Environmental Consequences

3.5.9.2.1 ISSUES, INDICATORS, AND SIGNIFICANCE CRITERIA

Table 3.5.9-1 lists the issues identified for this resource and the indicators and significance criteria used to assess impacts for the final EIS.

Table 3.5.9-1. Issues, Indicators, and Significance Criteria Used to Assess Impacts to Visual Resources

Issue	Impact Indicator	Significance Criteria
Change in scenic quality of the landscape and seascape	Visual contrast and dominance of Project component structures and activities onshore and offshore visible in the viewshed	Negligible: The landscape or seascape character appears to be intact. Very low levels of change that do not attract viewer attention and/or atmospheric conditions obscure visibility of Project components. Project activities are not readily evident with no or minimal overall contrast and are often indistinct or not obvious. The scale of Project components is very small to small in comparison with the existing visual environment. Minor: The landscape or seascape character appears to be noticeably altered. Low levels of change that may be seen but do not attract the viewer's attention and/or atmospheric conditions begin to obscure visibility of Project components but are discernible. Project activities may be evident but do not attract attention with weak contrast, which may be visible or evident. The scale of Project components are small in comparison with the existing visual environment. Moderate: The existing landscape or seascape character appears substantially altered. Moderate levels of change that may attract attention but do not dominate the view. Project activities are evident and begin to attract attention with moderate contrast and are clearly visible or noticeable. The scale of Project components are moderate in comparison with the existing visual environment. Motion of wind turbines begins to be the focus of attention in offshore views. Major: The existing landscape or seascape character appears severely altered. Major levels of change with strong contrast that dominates the view and are the major focus of viewer attention and cannot be overlooked. The scale of Project components are large in comparison with the existing visual environment.
Change seen and perceived as Project facilities by people/ sensitive viewers	Luminance and illuminance from Project component lighting sources onshore and offshore visible in the viewshed	

3.5.9.2.2 NO ACTION ALTERNATIVE

The Affected Environment section provides information on existing visual resource trends from past and present activities. Attachment 3 in Appendix E provides additional information regarding past and present activities and associated visual impacts. Future non-Project actions include offshore wind facility development and onshore communications tower updates and replacements, development projects, and port upgrades. Attachment 3 in Appendix E also discloses future non-offshore wind activities and associated visual impacts. Impacts associated with future offshore wind activities are described below.

Future Projects

Offshore

Presence of structures: Proposed or anticipated future wind facility projects would consist of up to 1,294 WTGs and associated OSS in the visual geographic analysis area (see Attachment 4 in Appendix E). The combined visual effects of the WTGs and associated infrastructure when visible from viewing areas would create long-term, minor to major visual impacts if future projects are fully implemented. The degree of the perceivable contrast, dominance, and scale of WTGs and an OSS along the horizontal plane of the ocean depends on the viewer's proximity and orientation to the wind energy projects and will either increase or decrease as natural lighting angles and atmospheric conditions change throughout the day. Under clear conditions and depending on lighting angles, projects built within BOEM leases that are within 12 miles of viewing areas would have major visual impacts, viewing areas within 12 to 24 miles would have moderate to major impacts, and viewing areas within 24 to 30 miles would have minor impacts. Viewing areas that exceed 30 miles from projects would have negligible visual impacts due to distance, curvature of the Earth, and the influence of atmospheric conditions, which would decrease the ability of the viewer to discern or perceive projects at that distance.

Light: Development of offshore wind lease areas would increase the amount of offshore light sources associated with construction and installation, O&M, and conceptual decommissioning during the life of future projects. Lighting associated with night construction and conceptual decommissioning for future projects would be localized and temporary. Construction and conceptual decommissioning for each future project within BOEM lease areas are also assumed to be staggered; therefore, the lease areas would not have light sources across the entirety of the geographic analysis area at one time. However, light sources, depending on quantity, intensity, and location, could be visible from unobstructed sensitive onshore and offshore viewing locations based on viewer distance.

FAA hazard lighting systems would be used for the duration of Project O&M for each reasonably foreseeable offshore wind project (1,294 structures). The amassing of these WTGs and associated synchronized flashing strobe lights affixed with a minimum of three red flashing lights at the mid-section of each tower and two at the top of each WTG nacelle within the lease areas would have long-term, minor to major impacts on sensitive onshore and offshore viewing locations based on viewer distance and angle of view, and assuming no obstructions. Similar to structures discussed above, atmospheric and environmental factors such as haze and fog would also influence visibility and perceivability of hazard lighting from sensitive viewing locations.

Field observations associated with visibility of FAA hazard lighting for the BIWF off the coast of Rhode Island were conducted in May 2019 (HDR 2019). The BIWF project consists of five WTGs with a blade tip height of approximately 600 feet. Observations of FAA nighttime lighting visibility under clear sky conditions in open water identified that FAA hazard lighting may be visible to the naked eye at a distance of 26.8 miles from the viewer (HDR 2019). The BIWF report also concludes that daytime visibility of WTGs from land and water viewing locations is strongly dependent on weather conditions and distance (HDR 2019).

The implementation of an ADLS (or a similar system) would activate the hazard lighting system in response to detection of nearby aircraft. Implementation of an ADLS may be required by BOEM as a mitigation measure and condition of COP approval. The synchronized flashing of the ADLS if implemented would result in shorter duration night sky impacts on the surrounding landscape. The shorter duration synchronized flashing of the ADLS is anticipated to have reduced visual impacts at night as compared to the standard continuous, medium-intensity red strobe FAA warning system due to the duration of activation. Based on recent studies associated with the SFWF, activation of the ADLS if implemented, would occur for 3 hours and 49 minutes per year, or on average, from 2 minutes to 46 minutes per month as compared to standard continuous FAA hazard lighting (EDR 2020a). It is anticipated that the reduced time of FAA hazard lighting resulting from an implemented ADLS would reduce duration of the potential impacts of nighttime aviation lighting to less than 1% of the normal operating time that would occur without using the ADLS.

Because of the variable distances from visually sensitive viewing locations (EDR 2020b), other reasonably foreseeable offshore wind projects would have minor to major long-term cumulative effects on non-historic visually sensitive viewing areas. As also discussed in Section 3.5.8 Recreation and Tourism, the recreational and commercial boating community would experience major adverse effects in foreground views. Onshore viewers would experience minor to major effects from nighttime lighting associated with construction and O&M. After conceptual decommissioning, the minor to major impacts associated with O&M would cease.

Onshore

Future port upgrade planning projects could require port modifications and expansions, although specific locations and design have not been determined (see Appendix E, Table E-8). However, any improvements to existing port facilities and the development of new port facilities are anticipated to occur within areas of current port development. Therefore, the addition of additional structures, infrastructure, and night lighting sources associated with port expansion would have long-term, negligible to moderate impacts to sensitive onshore and offshore daytime and nighttime visually sensitive viewing areas, depending on the final location of port upgrade locations.

Conclusions

Under the No Action alternative, BOEM would not approve the COP; Project construction and installation, O&M, and conceptual decommissioning would not occur; and potential impacts on non-historic visual resources associated with the Project would not occur. However, ongoing and future activities would have continuing temporary to long-term impacts on non-historic visual resources, primarily through construction and O&M of WTGs and related lighting schemes.

BOEM anticipates that the range of impacts for reasonably foreseeable offshore wind activities would be **minor** to **major**. BOEM anticipates that the range of impacts for ongoing activities and reasonably foreseeable activities other than offshore wind would be **minor** to **major**.

Considering all the IPFs together, BOEM anticipates that the impacts associated with future offshore wind activities in the geographic analysis area combined with ongoing activities, reasonably foreseeable environmental trends, and reasonably foreseeable activities other than offshore wind would result in **moderate** adverse impacts because the overall effect would be notable, but the resource would be expected to recover completely after conceptual decommissioning.

3.5.9.2.3 PROPOSED ACTION ALTERNATIVE

Construction and Installation

Analysis area residents and visitors would experience observable changes to the characteristic background landscape and/or seascape during Project construction, including the presence of lighting, structural features, vessels, heavy equipment, vehicles, and personnel for the time period of construction. The onshore components of the Project include the interconnection facility, onshore SFEC routes, sea-to-shore transition vault (i.e., manhole), and O&M facility (located in Quonset Point, Rhode Island, or Montauk Harbor, New York); see Section 2.1.1.3, Construction and Installation, for further information.

Offshore, the increase and concentration in vessel activity during WTG construction, installation, and transport activities along with the addition of navigational marking and lighting would create short-term to long-term, moderate to major impacts to visually sensitive viewing areas. Similarly, during the installation of offshore cable systems, vessels and equipment would be concentrated and visible within the Lease Area. As cable system construction activities transition onshore, temporary vegetation clearing and surface disturbance would occur. Construction of the interconnection facility would involve temporary staging areas and vehicle traffic. The Project-related offshore and onshore construction activity would create short-term minor to moderate impacts to visually sensitive viewing areas.

Operations and Maintenance and Conceptual Decommissioning

Visual impacts from the onshore and offshore Project components would persist for the life of the Project. Because of the similarity of the existing adjacent East Hampton substation's visual features and screening by mature vegetation throughout the area, the operation of the onshore interconnection facility would cause negligible to minor long-term adverse visual impacts. Nighttime impacts caused by the onshore interconnection facility lighting would be minor because of their low-profile design, which would be directed downward.

The Quonset Point O&M facility would include two approximately 30-foot-tall structures to house office space (approximately 1,000 square feet) and storage space (approximately 11,000 square feet) with one 60-foot-tall crane that would be in use at the quayside and would be set among existing modern Air National Guard Base structures and activities. These new structures for Quonset Point would be similar to existing industrial infrastructure that have large repetitive vertical and horizontal geometric, rectangular elements and are anticipated to result in negligible to minor adverse visual impacts. The Montauk O&M facility would include similar structures for office space (1,000 square feet) and storage space (6,600 square feet) with one 60-foot-tall crane set among other similar active harbor structures and operations (EDR 2019). The structures for Montauk Point would include either reuse of the existing structures or replacement in kind of the existing structures, which have large repetitive vertical and horizontal geometric, rectangular elements and are anticipated to result in negligible long-term adverse visual impacts.

Visual impacts of offshore vessel and onshore vehicle traffic during the O&M phase would be temporary and negligible because of the low volumes of traffic. Visual impacts from vessel traffic during conceptual decommissioning would be similar to construction impacts.

The offshore components of the Project include the WTGs and the OSS, which would be visible from the visually sensitive areas in New York, Connecticut, Rhode Island, and Massachusetts. Based on visual simulations, the WTGs would be visible on the horizon from shore (unobstructed view) within the analysis area. The WTGs (and OSS) would be painted RAL 9010 Pure White or RAL 7035 Light Grey to blend into the horizon. The effects of sun lighting, shade, and shadows would cause backlit contrasts and higher impacts for onshore and offshore views from the northeast, north, and northwest. The color contrast varies due to sun angles and atmospheric clarity shifting from white WTGs against a blue or gray backdrop to a dark gray WTG against a light gray backdrop. Distance between the viewer and the WTGs, as noted in Table 3.5.9-1, along with the curvature of the Earth affects how much of the WTG is visible from sensitive viewing locations and influences its visible scale and dominance.

The 15 WTGs and one OSS would appear generally low on the horizon because of distance and the curvature of the Earth and would be located behind and partially screened or buffered by other lease area WTGs, as viewed from the northern and eastern onshore communities and sensitive viewing locations. The SFWF WTGs would be more visually apparent as viewed from the western communities and sensitive viewing locations (e.g., Block Island, Rhode Island) due to less screening from other lease areas under the foreseeable development scenario. The scale of the 15 WTGs would become less perceivable as the distance from sensitive viewing locations is increased. Atmospheric and environmental factors such as haze, sun angle, time of day, cloud cover, fog, sea spray, and wave action would also influence visibility and perceivability from sensitive viewing locations. The combined visual effect of the reasonably foreseeable WTGs in the geographic analysis area when visible from sensitive viewing areas would create long-term, minor to major visual impacts once future projects are fully implemented (see Table 3.5.9-2).

As a result, O&M would cause long-term, negligible to major visual impacts to visually sensitive viewing areas (see Table 3.5.9-2) for the life of the Project. Visual impacts from conceptual decommissioning of the WTGs and OSS would be similar to construction impacts. Long-term, moderate to major visual impacts would occur at night when aviation and navigation lighting are visible from shore that focus viewers' attention to linear, repetitive, and concentrated areas of dark skies.

Table 3.5.9-2. Summary of Impacts by Viewing Area

Viewpoint Location	Viewpoint Name	Viewer Type	Aesthetic Resource	Distance (miles)	Landscape Similarity Zone	Overall Impact
Viewpoints within 12 miles						
30	Atlantic Ocean	Tourists, fishing community	Atlantic Ocean	8.6	Open Water	Major
Viewpoints between 12 and 18 miles						
29	Nomans Land	No access	Nomans Land Island National Wildlife Refuge	15.9	Shoreline Bluffs	Minor
29	Nomans Land Sunset	No access	Nomans Land Island National Wildlife Refuge	15.9	Shoreline Bluffs	Moderate
Viewpoints between18 and 24 miles						
4	Fred Benson Beach	Resident, tourist	Crescent Beach, State Scenic Area, Rhode Island Historic District, Town Beach	20.7	Shoreline Beach	Minor
4B	New Shoreham Beach	Resident, tourist	Lakeside Drive Shore Fishing Access	20.6	Shoreline Beach	Minor
4C	Block Island Ferry	Resident, tourist, through traveler, fishing community	Block Island Sound	19.8	Open Water	Minor
5B	Southeast Lighthouse	Resident, tourist	National Register Historic Site, Mohegan Bluffs Scenic Area	19.4	Maintained Recreational Area	Minor
5B	Southeast Lighthouse Construction View	Resident, tourist	National Register Historic Site, Mohegan Bluffs Scenic Area	19.4	Maintained Recreational Area	Minor
5N	Southeast Lighthouse Night	Resident, tourist	National Register Historic Site, Mohegan Bluffs Scenic Area	19.4	Maintained Recreational Area	Major
6	Point Judith Lighthouse	Resident, tourist, fishing community	National Register Historic Site, Point Judith State Scenic Area	23.6	Maintained Recreational Area	Negligible
6N	Point Judith Lighthouse Night	Resident, tourist, fishing community	National Register Historic Site, Point Judith State Scenic Area	23.6	Maintained Recreational Area	Moderate
18	Cuttyhunk Island	Resident, tourist	The Elizabeth Islands, Buzzards Bay	22.7	Coastal Scrub/Scrub Forest	Moderate
19	Aquinnah Overlook	Resident, tourist	Gay Head - Aquinnah Shops Area State Historic Area, Gay Head West Tisbury Unit State Scenic Area	20.4	Shoreline Bluffs	Minor
19	Aquinnah Overlook Sunset	Resident, tourist	Gay Head - Aquinnah Shops Area State Historic Area, Gay Head West Tisbury Unit State Scenic Area	20.4	Shoreline Bluffs	Moderate
19N	Aquinnah Overlook Nighttime	Resident, tourist	Gay Head - Aquinnah Shops Area State Historic Area, Gay Head West Tisbury Unit State Scenic Area	20.4	Shoreline Bluffs	Major
20A	Moshup Beach	Resident, tourist	Gay Head West Tisbury State Scenic Area, Moshup Beach	20.1	Coastal Dunes	Moderate

Viewpoint Location	Viewpoint Name	Viewer Type	Aesthetic Resource	Distance (miles)	Landscape Similarity Zone	Overall Impact
20A	Moshup Beach Sunset	Resident, tourist	Gay Head West Tisbury State Scenic Area, Moshup Beach	20.1	Coastal Dunes	Moderate
21	Gay Head Lighthouse	Resident, tourist	Gay Head Lighthouse, Gay Head West Tisbury Unit State Scenic Area	20.4	Maintained Recreation Area	Negligible
22	Philbin Beach	Resident, tourist	Gay Head West Tisbury Unit State Scenic Area, Philbin Beach	20.2	Shoreline Beach	Minor
22	Philbin Beach Sunset	Resident, tourist	Gay Head West Tisbury Unit State Scenic Area, Philbin Beach	20.2	Shoreline Beach	Minor
25	Lucy Vincent Beach	Resident, tourist	Gay Head West Tisbury Unit State Scenic Area, Lucy Vincent Beach	23.8	Coastal Dunes	Negligible
25	Lucy Vincent Beach Sunset	Resident, tourist	Gay Head West Tisbury Unit State Scenic Area, Lucy Vincent Beach	23.8	Coastal Dunes	Moderate
Viewpoints between 24 and 30 miles						
2A	Trustom Pond National Wildlife Refuge	Resident, tourist	Trustom Pond/Matunuk State Scenic Area, Trustom Pond National Wildlife Refuge	27.9	Salt Pond/ Tidal Marsh	Negligible
7	Scarborough Beach	Resident, tourist	Scarborough State Beach	24.8	Shoreline Beach	Negligible
9	Narragansett Beach	Resident, tourist	Narragansett Town Beach	26.9	Shoreline Beach	Negligible
10	Beavertail Lighthouse	Resident, tourist	National Register Historic Site, Beavertail Point Scenic Area, Rhode Island Historic District, Beavertail State Park	26.3	Maintained Recreation Areas, Coastal Bluff	Negligible
11	Brenton Point State Park	Resident, tourist	Newport/Ocean Drive State Scenic Area, Brenton Point State Park, Rhode Island Historic District	25.5	Maintained Recreation Areas	Negligible
11N	Brenton Point State Park Nighttime	Resident, tourist	Newport/Ocean Drive State Scenic Area, Brenton Point State Park, Rhode Island Historic District	25.5	Maintained Recreation Areas	Moderate
12	Newport Cliff Walk	Resident, tourist	Newport/Ocean Drive State Scenic Area, Brenton Point State Park, Rhode Island Historic District	24.8	Maintained Recreation Areas, Shoreline Residential	Minor
14	Sachuest Beach (Second Beach)	Resident, tourist	Second Beach, Narragansett Bay	26.7	Shoreline Beach	Negligible
14A	Hanging Rock (Norman Bird Sanctuary)	Resident, tourist	Norman Bird Sanctuary, Paradise Avenue and Associated Roads State Scenic Byway, Second Beach	26.7	Coastal Scrub/Scrub Forest	Moderate
14B	Sachuest Point National Wildlife Refuge	Resident, tourist	Sachuest Point National Wildlife Refuge, Sachuest Point State Scenic Area	25.6	Coastal Scrub//Scrub Forest	Negligible

Viewpoint Location	Viewpoint Name	Viewer Type	Aesthetic Resource	Distance (miles)	Landscape Similarity Zone	Overall Impact
15	South Shore Beach	Resident, tourist	Narragansett Bay, Little Compton Agricultural Lands State Scenic Area, South Shore Beach	27	Shoreline Beach	Negligible
17	Gooseberry Island	Resident, tourist	Horseneck Beach State Reservation, Westport South Dartmouth Unit State Scenic Area, Buzzards Bay	26.2	Coastal Scrub/Scrub Forest	Moderate
17	Gooseberry Island Sunset	Resident, tourist	Horseneck Beach State Reservation, Westport South Dartmouth Unit State Scenic Area, Buzzards Bay	26.2	Coastal Scrub/Scrub Forest	Moderate
24	Peaked Hill Reservation	Resident, tourist	Identified by the Wampanoag of Gay Head	24.2	Forest	Minor
24	Peaked Hill Reservation Sunset	Resident, tourist	Identified by the Wampanoag of Gay Head	24.2	Forest	Moderate
Viewpoints beyond 30 miles						
1D	Montauk Point State Park	Resident, tourist, fishing community	Montauk Point State Park, National Register Historic Site, Scenic Area of Statewide Significance	35.3	Maintained Recreation Areas	Negligible
1N	Montauk Point State Park Nighttime	Resident, tourist	Montauk Point State Park, National Register Historic Site, Scenic Area of Statewide Significance	35.3	Maintained Recreation Areas	Negligible
2	Watch Hill Lighthouse	Resident, tourist	Rhode Island Historic District, State Scenic Area		Maintained Recreation Areas, Shoreline Residential	Negligible
26A	Nobska Lighthouse	Resident, tourist	National Register of Historic Places, Church Street/Nobska Point State Historic District, Nobska Beach Association Beach		Maintained Recreation Areas	Negligible
26A	Nobska Lighthouse Sunset	Resident, tourist	National Register of Historic Places, Church Street/Nobska Point State Historic District, Nobska Beach Association Beach		Maintained Recreation Areas	Negligible
27	South Beach State Park	Resident, tourist	South Beach State Park		Shoreline Beach	Negligible
27	South Beach State Park Sunset	Resident, tourist	South Beach State Park		Shoreline Beach	Minor

Cumulative Impacts

Offshore

Offshore impacts would be predominately associated with changes in above-water structures and lighting.

Presence of structures: Construction activities would incrementally add up to 15 additional WTGs and one OSS to the No Action alternative; an increase in the number of WTGs in the geographic analysis area by less than 1%. As a result, proportionately over 90% of the WTGs in the geographic analysis area would be associated with other future offshore wind development (EDR 2020b). Additionally, the Proposed Action would locate WTGs no closer than approximately 16 miles from Nomans Land, Massachusetts; 19 miles from Block Island, Rhode Island; more than 20 miles from Martha's Vineyard, Massachusetts; more than 35 miles from Montauk Point, New York; and more than 23 miles from mainland Massachusetts and Rhode Island. When combined with other past, present, and reasonably foreseeable projects, the Proposed Action would therefore result in long-term and minor to major adverse cumulative visual impacts from sensitive viewing locations.

Light: Construction related activities would incrementally add navigational safety lighting used by offshore vessels to the No Action alternative. Additionally, construction of up to 15 WTGs and one OSS would also incrementally add navigation and aviation lighting to the No Action alternative. New lighting from the Proposed Action would increase in-water structures with lighting impacts from past, present, and reasonably foreseeable future projects by no more than 1%. Nighttime vessel and construction area lighting during construction of the Proposed Action would be limited in duration and cease when construction is complete. Atmospheric and environmental conditions would influence visibility and perceivability from sensitive viewing locations. Cumulatively, when combined with other past, present, and reasonably foreseeable projects, the Proposed Action could result in long-term, minor to major adverse visual impacts on non-historic sensitive viewing locations.

Onshore

Onshore construction and installation would incrementally add an O&M facility and an interconnection facility to the No Action alternative. These new onshore structures and night lighting sources would be constructed in existing industrial areas, would use or replace existing structures, and would be expected to result in negligible to moderate visual impacts to sensitive receptors. Similarly, future port upgrades required to service the offshore wind industry would also be expected to result in similar negligible to moderate visual impacts to sensitive receptors. Therefore, the Proposed Action when combined with past, present, and reasonably foreseeable activities would result in long-term, negligible to moderate adverse cumulative impacts to daytime and nighttime visually sensitive viewing areas from structures and night lighting sources.

Conclusions

Project construction and installation, O&M, and conceptual decommissioning would introduce visible structures and navigation and aviation lighting to the geographic analysis area. BOEM anticipates the impacts resulting from the Proposed Action alone would range from **negligible** to **major** and short term to long term. However, BOEM expects the overall impact on non-historic visual resources from the Proposed Action alone to be **moderate**, as the overall effect would be notable but the resource would be expected to return to pre-project conditions after conceptual decommissioning.

In the context of other reasonably foreseeable environmental trends and planned actions, the incremental impacts under the Proposed Action resulting from individual IPFs would range from **negligible** to **moderate**. BOEM anticipates that the overall impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would result in **minor** to **moderate** impacts to non-historic visual resources. BOEM made this call because the overall effect would be notable but the resource would be expected to return to pre-project conditions after conceptual decommissioning.

3.5.9.2.4 VESSEL TRANSIT LANE ALTERNATIVE

The Transit alternative would not affect Project onshore activities; therefore, effects would be the same as the Proposed Action: negligible to major. Offshore, this alternative could result in decreased visual impacts related to nighttime aviation and navigation lighting because there would be fewer WTGs. All other visual impacts related to construction and installation, O&M, and conceptual decommissioning of onshore and nearshore components would be similar to the Proposed Action and result in similar short- and long-term, negligible to major adverse visual impacts to daytime and nighttime viewers.

Cumulative Impacts

The Transit alternative would not affect Project onshore activities. Offshore, the Transit alternative would incrementally add sources of visual impacts (structures, lighting) to the geographic analysis area at quantities and durations similar to the Proposed Action. Therefore, the overall cumulative impacts of the Transit alternative on visual resources when combined with past, present, and reasonably foreseeable activities would have long-term, negligible to major impacts.

If the Transit alternative is implemented, the WTGs associated with other reasonably foreseeable offshore wind projects may need to be relocated or eliminated within lease areas to avoid the informal or undesignated transit lanes. If these shifts result in WTG reductions that further reduce views of structures and/or nighttime lighting, these effects could decrease visual impacts relative to the Proposed Action.

Conclusions

Although the Transit alternative would reduce the number of WTGs visible in the seascape, which would have an associated reduction in visible structures with navigation and aviation lighting, BOEM expects that the impacts resulting from the alternative alone would be similar to the Proposed Action and range from **negligible** to **major**.

In context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that the Transit alternative's incremental impacts would be similar to the Proposed Action (with individual impacts ranging from **negligible** to **moderate**). The overall impacts of the Transit alternative when combined with past, present, and reasonably foreseeable activities would therefore be the same level as under the Proposed Action: **minor** to **moderate**.

3.5.9.2.5 FISHERIES HABITAT IMPACT MINIMIZATION ALTERNATIVE

This alternative under either layout option would not affect Project onshore activities; therefore, effects would be the same as the Proposed Action: negligible to major.

Offshore, this alternative could result in decreased visual impacts related to nighttime navigation lighting because there would be fewer WTGs and associated nighttime lighting. All other visual impacts related to construction and installation, O&M, and conceptual decommissioning of onshore and nearshore components would be similar to the Proposed Action and would result in similar short- and long-term, negligible to major adverse visual impacts to daytime and nighttime viewers.

Cumulative Impacts

This alternative under either layout option would not affect Project onshore activities. Offshore, this alternative would incrementally add sources of visual impacts (structures, lighting) at quantities and durations similar to the Proposed Action. Therefore, the overall cumulative impacts of the alternative on visual resources when combined with past, present, and reasonably foreseeable activities would have long-term, negligible to major impacts.

Conclusions

Although the Habitat alternative under either layout option would reduce the number of WTGs visible in the seascape, which would have an associated reduction in visible structures with navigation and aviation lighting, BOEM expects that the impacts resulting from the alternative alone would be similar to the Proposed Action and range from **negligible** to **major**.

In the context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that the Habitat alternative's incremental impacts would be similar to the Proposed Action (with individual impacts ranging from **negligible** to **moderate**). The overall impacts of the Habitat alternative under either layout option when combined with past, present, and reasonably foreseeable activities would therefore be the same level as under the Proposed Action: **minor** to **moderate**.

3.5.9.3 Action Alternative Comparison

As discussed above, the impacts associated with Proposed Action alone do not change substantially under other evaluated action alternatives, although some variation in impacts is acknowledged due to fewer WTGs being constructed. Although the number of WTGs varies slightly, BOEM expects that non-historic visual impacts would range from **negligible** to **major** for all action alternatives.

In context of reasonably foreseeable environmental trends and planned actions, all action alternatives would occur within the same overall environment (e.g., ongoing and future activities). Therefore, impacts would only vary if the alternatives' incremental contributions differ, as they do here. However, as noted above, BOEM expects that the incremental impact from any action alternative would be similar, with the level of individual impacts ranging from **negligible** to **moderate**. Therefore, the overall impact of any action alternative when combined with past, present, and reasonably foreseeable activities would be **moderate**.

3.5.9.4 Mitigation

BOEM could require installation of an ADLS as a mitigation measure. The use of ADLS technology would reduce long-term, negligible to major adverse visual impacts to non-historic properties from nighttime lighting to negligible or minor because the short-duration synchronized flashing of the ADLS would have substantially fewer visual impacts at night than the standard continuous, medium-intensity red strobe light aircraft warning systems due to the short duration of activation, as discussed in Section 3.5.9.2.2 (No Action Alternative).

CHAPTER 4. REQUIRED DISCLOSURES

4.1 UNAVOIDABLE ADVERSE IMPACTS

Table 4.1.1-1 summarizes unavoidable adverse impacts for each analyzed resource, subject to applicable EPMs (see Table G-1 in Appendix G). Table 4.1.1-1 does not include potential additional mitigation measures that could avoid or further minimize or mitigate Project impacts. Please see the individual resource discussions in Chapter 3 for detailed analyses.

4.1.1 Potential Unavoidable Adverse Impacts of the Action Alternatives

Table 4.1.1-1. Potential Unavoidable Adverse Impacts of the Action Alternatives

Resource Area	Potential, Unavoidable Adverse Impact of the Action Alternatives
Air quality	Impacts from emissions from engines associated with vessel traffic, construction activities, and equipment operation
Water quality	Increase in erosion, turbidity and sediment resuspension, and inadvertent spills during construction and installation, O&M, and conceptual decommissioning
Bats	Displacement and avoidance behavior due to habitat loss and alteration, equipment noise, and vessel traffic Individual mortality due to collisions with operating WTGs
Benthic habitat, EFH, invertebrates, and finfish	Increase in suspended sediments and resulting effects due to seafloor disturbance Habitat quality impacts including reduction in habitat as a result of seafloor surface alterations Displacement, disturbance, and avoidance behavior due to habitat loss and alteration, equipment noise, vessel traffic, increased turbidity, sediment deposition, and electromagnetic fields Individual mortality due to construction and installation, O&M, and conceptual decommissioning Conversion of soft-bottom habitat to new hard-bottom habitat
Birds	Displacement and avoidance behavior due to habitat loss and alteration, equipment noise, and vessel traffic Individual mortality due to collisions with operating WTGs
Marine mammals	Displacement, disturbance, and avoidance behavior due to habitat loss and alteration, equipment noise, vessel traffic, increased turbidity, and sediment deposition during construction and installation and O&M Temporary loss of acoustic habitat and increased potential for vessel strikes
Terrestrial and coastal habitats and fauna	Displacement and avoidance behavior from habitat loss and alteration and from equipment noise Individual mortality from collisions with vehicles or construction equipment Short-term habitat alteration and increased invasive species risk
Sea turtles	Disturbance, displacement, and avoidance behavior due to habitat loss and alteration, equipment noise, vessel traffic, increased turbidity, sediment deposition, and electromagnetic fields
Wetlands and other WOTUS	Increase in soil erosion, sedimentation, and discharges and releases from land disturbance during construction and installation, O&M, and conceptual decommissioning
Commercial fisheries and for-hire recreation fishing	Disruption to access or temporary restriction in port access or harvesting activities due to construction of offshore Project elements Disruption to harvesting activities during operations of offshore wind facility Changes in vessel transit and fishing operation patterns Changes in risk of gear entanglement or target species
Cultural resources	Impacts to unidentified or undefined submerged marine resources from Project construction and installation and O&M Impacts to terrestrial cultural resources and to the viewshed from Project construction and installation and O&M

Resource Area	Potential, Unavoidable Adverse Impact of the Action Alternatives
Demographics, employment, and economics	No unavoidable adverse impacts
Environmental justice	Changes to air quality, water quality, land use and coastal infrastructure, and commercial fisheries and for-hire recreational fishing that are disproportionately borne by minority or low-income populations from Project construction and installation, O&M, and conceptual decommissioning
Land use and coastal infrastructure	Land use disturbance due to construction as well as effects due to noise, vibration, and travel delays
Navigation and vessel traffic	Changes in vessel transit patterns
Other marine uses	Changes in access to marine mineral resource, and cable placement Disruption of scientific surveys, radar systems, military, and aviation traffic
Recreation and tourism	Disruption of coastal recreation activities during onshore construction, such as beach access Viewshed effects from the WTGs altering enjoyment of marine and coastal recreation and tourism activities Disruption to access or temporary restriction of in-water recreational activities from construction of offshore Project elements Hindrances to some types of recreational fishing from the WTGs during operation
Visual resources	Change in scenic quality of landscape and seascape

4.2 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENT OF RESOURCES

Irreversible commitments of resources are those that cannot be regained, such as the extinction of a species or the removal of mined ore. Irretrievable commitments are those that are lost for a period of time, such as the short-term loss of timber productivity in forested areas that are kept clear for a power line or a road. Table 4.2.1-1 summarizes irreversible or irretrievable effects for each analyzed resource, subject to applicable EPMs. Table 4.2.1-1 does not include potential additional mitigation measures that could avoid or further minimize or mitigate Project impacts. Chapter 3 provides a detailed discussion of effects associated with the Project.

4.2.1 Irreversible and Irretrievable Commitment of Resources by Resource Area

Table 4.2.1-1. Irreversible and Irretrievable Commitment of Resources by Resource Area

Resource Area	Irreversible Impacts	Irretrievable Impacts	Explanation
Air quality	No	No	BOEM expects air emissions to be in compliance with permits regulating air quality standards, and emissions would be temporary during construction activities. If the Proposed Action displaces fossil-fuel energy generation, overall improvement of air quality would be expected.
Water quality	No	No	BOEM does not expect activities to cause loss of or major impacts on existing inland waterbodies or wetlands. Turbidity and other water quality impacts in the marine and coastal environment would be short term, with the rare exception of a major spill.

Resource Area	Irreversible Impacts	Irretrievable Impacts	Explanation
Bats	No	No	Based on the healthy populations of bat species more susceptible to collision with operating WTGs, and assuming implementation of time-of-year restrictions for tree clearing, displacement, avoidance behavior, and individual mortality due to collisions with operating WTGs are not expected to be irreversible or irretrievable.
Benthic habitat, EFH, invertebrates, and finfish	No	No	Although local mortality could occur, BOEM does not anticipate population-level impacts. The Project could alter habitat during construction and operations but could restore the habitat after conceptual decommissioning.
Birds	No	No	Based on the healthy populations of bird species more susceptible to collision with operating WTGs, displacement, avoidance behavior, and individual mortality due to collisions with operating WTGs are not expected to be irreversible or irretrievable. Irreversible and irretrievable impacts on bird species could occur if one or more individuals of species listed under the ESA were injured or killed. However, ongoing consultation with the USFWS would identify mitigation measures that would reduce or eliminate the potential for such impacts on listed species.
Marine mammals	No	Yes	Irreversible impacts on marine mammals could occur if one or more individuals of species listed under ESA were injured or killed; however, mitigation measures would reduce or eliminate the potential for such impacts on listed species. Irretrievable impacts could occur if individuals or populations grow more slowly as a result of displacement from the Lease Area.
Terrestrial and coastal habitats and fauna	No	No	Although local mortality could occur, BOEM does not anticipate population-level impacts on other terrestrial and coastal fauna. The Project could alter habitat during construction and operations but could restore the habitat after conceptual decommissioning.
Sea turtles	No	Yes	Irreversible impacts on sea turtles could occur if one or more individuals of species listed under the ESA were injured or killed; however, mitigation measures would reduce or eliminate the potential for impacts on listed species. Irretrievable impacts could occur if individuals or populations grow more slowly as a result of displacement from the Lease Area.
Wetlands and other WOTUS	No	No	BOEM does not expect activities to cause loss of or major impacts on existing wetlands or other WOTUS.
Commercial fisheries and for-hire recreation fishing	No	Yes	Based on the anticipated duration of construction and installation and O&M, BOEM does not anticipate impacts on commercial fisheries to result in irreversible impacts. The Project could alter habitat during construction and operations, limit access to fishing areas during construction, or reduce vessel maneuverability during operations. However, the conceptual decommissioning of the Project would reverse those impacts. Irretrievable impacts could occur due to the loss of use of fishing areas at an individual level.
Cultural resources	Yes	Yes	Although unlikely, unanticipated removal or disturbance of previously unidentified cultural resources onshore and offshore could result in irreversible or irretrievable impacts.
Demographics, employment, and economics	No	No	Based on the anticipated duration of construction and installation and O&M, BOEM does not anticipate that contractor needs, housing needs, and supply requirements would lead to an irretrievable loss of workers for other projects or increase housing and supply costs.
Environmental justice	No	No	Potential environmental justice impacts, if any, would be short term and localized.
Land use and coastal infrastructure	Yes	Yes	Land use required for construction and operation activities, such as the land proposed for the interconnection facility, could result in a minor irreversible impact. Construction activities could result in a minor irretrievable impact due to the temporary loss of use of the land for otherwise typical activities. Onshore facilities may or may not be decommissioned.

Resource Area	Irreversible Impacts	Irretrievable Impacts	Explanation
Navigation and vessel traffic	No	Yes	Based on the anticipated duration of construction and installation and O&M, BOEM does not anticipate impacts on vessel traffic to result in irreversible impacts. Irretrievable impacts could occur due to changes in transit routes, which could be less efficient during the life of the Project.
Other marine uses	No	No	BOEM does not anticipate the potential impacts to be irreversible or irretrievable.
Recreation and tourism	No	No	Construction activities near the shore could result in a minor, temporary loss of use of the land for recreation and tourism purposes, but these impacts would not be irreversible or irretrievable.
Visual resources	No	Yes	Viewshed changes would persist for the life of the Project, until conceptual decommissioning is complete.

4.3 RELATIONSHIP BETWEEN THE SHORT-TERM USE OF THE HUMAN ENVIRONMENT AND THE MAINTENANCE AND ENHANCEMENT OF LONG-TERM PRODUCTIVITY

The CEQ's NEPA implementing regulations (40 CFR 1502.16) require that an EIS address the relationship between short-term use of the environment and the potential impacts of such use on the maintenance and enhancement of long-term productivity. Such impacts could occur as a result of a reduction in the flexibility to pursue other options in the future, or assignment of a specific area (land or marine) or resource to a certain use that would not allow other uses, particularly beneficial uses, to occur at a later date. An important consideration when analyzing such effects is whether the short-term environmental effects of the action would result in detrimental effects to long-term productivity of the affected areas or resources.

As assessed in Chapter 3, BOEM anticipates that most of the potential adverse effects associated with the Proposed Action would occur during construction activities, and would be temporary and minor or moderate as defined in Sections 3.3–3.5. Table 4.1.1-1 and Table 4.2.1-1 identify unavoidable, irretrievable, or irreversible impacts that would be associated with the Project. However, BOEM expects most of the marine and onshore environments to return to normal long-term productivity levels after Project conceptual decommissioning. Based on these findings, BOEM also anticipates that the Proposed Action would not result in impacts that would significantly narrow the range of future uses of the environment.

Additionally, the Project would provide several long-term benefits:

- Promotion of clean and safe development of domestic energy sources and clean energy job creation
- Promotion of renewable energy to help ensure geopolitical security; combat climate change; and provide electricity that is affordable, reliable, safe, secure, and clean
- Delivery of power to the South Fork of Suffolk County, Long Island, to contribute to New York's renewable energy requirements
- Increased habitat for certain fish species

APPENDIX A

Required Environmental Permits and Consultations

This page intentionally left blank.

CONTENTS

REQUIRED ENVIRONMENTAL PERMITS AND CONSULTATIONS

Introduction

This appendix discusses required permitting and public, agency, and Tribal involvement in the preparation of the South Fork Wind Farm and South Fork Export Cable Project environmental impact statement (EIS). This involvement included formal consultations, cooperating agency exchanges, and a public scoping comment period.

Authorizations and permits are listed in Table A-1, and cooperating or participating federal agencies are described below. The Bureau of Ocean Energy Management (BOEM) has completed the following interagency milestones to date for the Project:

- Permitting timetable: August 21, 2020
- Purpose and need: August 28, 2020
- Alternatives carried forward for evaluation: September 18, 2020

Other Federal and State Review

Table A-1 provides a discussion of other federal and state reviews required, including legal authority, jurisdiction of the agency, and the regulatory process involved.

Table A-1. Cooperating Agencies, Required Environmental Permits, and Consultations for the Project

Agency/Regulatory Authority	Cooperating Agency Status	Permit/Approval	Status
Federal			
BOEM	Lead federal agency	Construction and operations plan approval	Originally filed on June 29, 2018; updates submitted on May 24, 2019; February 2020; and May 7, 2021
U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Marine Fisheries Service	Cooperating agency	Incidental Harassment Authorization or Letter of Authorization	Filed on September 15, 2020
U.S. Department of Defense, U.S. Army Corps of Engineers	Cooperating agency	Clean Water Act (CWA) Section 404/Rivers and Harbors Act of 1899 Section 10 Individual Permit	Filed on December 23, 2020
U.S. Department of Homeland Security, U.S. Coast Guard	Cooperating agency	Private Aids to Navigation authorization	To be filed (TBF)
U.S. Department of the Interior, Bureau of Safety and Environmental Enforcement	Cooperating agency	None	Not applicable
U.S. Environmental Protection Agency	Cooperating agency	Outer Continental Shelf Air Permit	Filed on February 1, 2019
State (portions of the Project within state jurisdiction)*			
Commonwealth of Massachusetts Office of Coastal Zone Management	Cooperating agency	Concurrence with the Coastal Zone Management Program Federal Consistency Determination pursuant to the following: Coastal Zone Management Act (16 USC 1451 et seq., 15 CFR 930; 30 CFR 585.611(b), 627(b)) Massachusetts General Law (21A, Subpart 4A) Massachusetts Coastal Zone Management Program Policies (310 Code of Massachusetts Regulations 20.00 and 21.00)	Issued on June 11, 2021
State of Rhode Island Coastal Resources Management Council	Cooperating agency	Coastal Zone Management Act Consistency Certification	Issued on July 1, 2021
State of Rhode Island Department of Environmental Management	Cooperating agency	None	Not applicable
New York Department of State, Division of Coastal Resources	None	Coastal Zone Management Act (16 USC 1451 et seq.) State Executive Law Article 42, Title 19 New York Codes, Rules and Regulations (NYCRR) Part 600	Issued on May 27, 2021

Agency/Regulatory Authority	Cooperating Agency Status	Permit/Approval	Status
New York State Department of Environmental Conservation (NYSDEC)	None	State Pollutant Discharge Elimination System (SPDES) General Permit GP-0-20-001 for Stormwater Discharges from Construction Activity, pursuant to 6 NYCRR 750–757[1]	TBF
		Water quality certification pursuant to Environmental Conservation Law (ECL) Article 15 (Water Resources) Title 5 (Protection of Water) (CWA Section 401, 16 USC 1451)	TBF
		ECL Article 15 Protection of Waters Permit (excavation and fill activities) and ECL Article 25 (Tidal Wetlands). These are permits/approvals that must be filed with the NYSDEC for the Montauk operations and maintenance facility.	TBF
		The following statutory and regulatory standards apply pursuant to the ECL and its implementing regulations in 6 NYCRR for construction of the South Fork Export Cable: 1) ECL Articles 11, 13, and 25 and their implementing regulations regarding marine resources, such as fisheries and habitat; 2) ECL Article 11 and 6 NYCRR 182, relating to threatened and endangered Atlantic sturgeon; 3) ECL Article 17 and 6 NYCRR 700–706, relating to water quality; 4) ECL Article 15 and 6 NYCRR 608, regarding water quality and excavation and fill activities; and 5) ECL Article 27 and 6 NYCRR 360, et seq., relating to disposal and management of solid waste	TBF
New York State Department of Public Service	None	Certificate of Environmental Compatibility and Public Need, pursuant to Article VII of the New York Public Service Law (16 NYCRR 85–88), Article 15 (6 NYCRR 608 and 621), and Article 25 (6 NYCRR 661)	Issued on March 18, 2021
		Environmental Management and Construction Plan, pursuant to Article VII (16 NYCRR 85–88)	Filed April 21, 2021
		Section 68 Petition (permission to exercise the grants of municipal rights), pursuant to Article VII (Section 68(1))	Filed May 3, 2021
		Water Quality Certification, pursuant to Section 401 of the CWA and Implementing Regulations (6 NYCRR 701, 702, 704, 754, and 800–941)	Filed on September 14, 2018
New York State Department of Transportation - Region 10	None	Utility Work Permit - Form Perm 32, pursuant to New York State Highway Law (Article 3, design 2)	3–6 months prior to construction start
New York Office of General Services	None	New York Public Lands Law, Article 2, Section 3 responsible for the granting of easements, rights-of-way or other permissive instruments to grant permission for the use of the underwater lands.	TBF

[1] An individual SPDES permit is not expected because construction activities over 1 acre are covered under GP-0-20-001, unless they are determined to be an ineligible activity, as listed in Part 1, Subparagraph F of GP-0-20-001.

Agency/Regulatory Authority	Cooperating Agency Status	Permit/Approval	Status
Local*			
Town of East Hampton	Cooperating agency	Township of East Hampton Section 246-2 – Placement of boats, floats, moorings and anchors	TBF
Trustees of the Freeholders and Commonalty of the Town of East Hampton	Cooperating agency	None	Not applicable
Village of East Hampton	None	Coastal Erosion Permit	TBF
		Excavation/Utility Work Permit	TBF
		Design and Site Plan Application	TBF

* State and local agencies are considered cooperating agencies under the National Environmental Policy Act.

Cooperating Agencies

As part of the National Environmental Policy Act (NEPA) process, BOEM invited other federal agencies and state, Tribal, and local governments to consider becoming cooperating agencies in the preparation of the EIS. According to Council on Environmental Quality guidelines, qualified agencies and governments are those with “jurisdiction by law” or “special expertise” (40 CFR 1501.6). BOEM asked potential cooperating agencies to consider their authority and capacity to assume the responsibilities of a cooperating agency and to be aware that an agency's role in the environmental analysis neither enlarges nor diminishes the final decision-making authority of any other agency involved in the NEPA process. BOEM also provided potential cooperating agencies participating in the FAST-41 process with a written summary of expectations for cooperating agencies, including time schedules and critical action dates, milestones, responsibilities, scope, detail of cooperating agencies’ contributions, and availability of pre-decisional information.

Cooperating agency status is provided in Table A-1. More specific details regarding federal agency roles and expertise are described below.

National Marine Fisheries Service

The National Marine Fisheries Service (NMFS) is serving as a cooperating agency pursuant to 40 CFR 1501.6 because the scope of the Proposed Action and alternatives involves activities that could affect marine resources under their jurisdiction by law and special expertise. As applicable, permits and authorizations are issued pursuant to the Marine Mammal Protection Act, as amended (MMPA; 16 USC 1361 et seq.); the regulations governing the taking and importing of marine mammals (50 CFR part 216); the Endangered Species Act (ESA; 16 USC 1531 et seq.); and the regulations governing the taking, importing, and exporting of threatened and endangered species (50 CFR part 222–226). In accordance with 50 CFR part 402, NMFS also serves as the consulting agency under Section 7 of the ESA for federal agencies proposing actions that may affect marine resources listed as threatened or endangered. NMFS has additional responsibilities to conserve and manage fishery resources of the United States, which include the authority to engage in consultations with other federal agencies pursuant to the Magnuson-Stevens Fishery Conservation and Management Act (MSA) and 50 CFR part 600 when proposed actions may adversely affect essential fish habitat (EFH). MMPA is the only authorization for NMFS that requires NEPA compliance, which will be met via adoption of BOEM’s EIS and issuance of the record of decision (ROD).

NMFS has multiple roles in the NEPA process and EIS for this major federal action. First, NMFS has a responsibility to serve as a cooperating agency based on its technical expertise and legal jurisdiction over multiple trust resources. NMFS’ role is to provide expert advice regarding the action’s impact with respect to essential fish habitats, as defined in the MSA, listed threatened and endangered species and designated critical habitat listed under the ESA, marine mammals protected by the MMPA, and commercial and recreational fisheries managed under the MSA.

Second, NMFS intends to adopt the EIS in support of its authorization decision after reviewing it and determining it to be sufficient. NMFS is required to review applications for Incidental Take Authorizations (ITAs) under the MMPA, as amended (16 USC 1361 et seq.), and issue an ITA if appropriate. South Fork Wind, LLC (SFW) has submitted an application to NMFS for an ITA in conjunction with the construction and operations plan (COP), for take, as defined by the MMPA, of marine mammals incidental to Project construction and associated activities. The decision to issue an ITA under the MMPA is considered a major federal action requiring NEPA review. Therefore, NMFS has an independent responsibility to comply with NEPA. Consistent with the regulations published by the Council on Environmental Quality (40 CFR 1501.7(g)), NMFS intends to rely on the information and analyses in BOEM’s EIS to fulfill its NEPA obligations for ITA issuance, if applicable. NMFS intends to adopt the final EIS for this purpose.

Bureau of Safety and Environmental Enforcement

The Bureau of Safety and Environmental Enforcement (BSEE) is serving as a cooperating agency pursuant to 40 CFR 1501.6 because the scope of the Proposed Action and alternatives involves activities that could affect marine resources under their jurisdiction by law and special expertise.

U.S. Coast Guard

The U.S. Coast Guard is serving as a cooperating agency pursuant to 40 CFR 1501.6 because the scope of the Proposed Action and alternatives involves activities that could affect navigation and safety issues that fall under their jurisdiction by law and special expertise.

U.S. Environmental Protection Agency

The U.S. Environmental Protection Agency (EPA) is serving as a cooperating agency pursuant to 40 CFR 1501.6 because the scope of the Proposed Action and alternatives involves activities that could affect resources under their jurisdiction by law and special expertise. The EPA is responsible for issuing an Outer Continental Shelf (OCS) permit for the Project under the Clean Air Act.

U.S. Army Corps of Engineers

The U.S. Army Corps of Engineers (USACE) is serving as a cooperating agency pursuant to 40 CFR 1501.6 because the scope of the Proposed Action and alternatives involves activities that could affect resources under their jurisdiction by law and special expertise. As applicable, permits and authorizations are issued pursuant to Section 10 of the Rivers and Harbors Act of 1899 and Section 404 of the Clean Water Act. As an offshore wind energy project, the Project needs to be situated offshore in the water. The fill activities associated with the Project consist of the inter-array cable armoring at the base of the wind turbine generator (WTG) foundations, protective cable armoring for the South Fork Export Cable, dredging planned for the potential operations and maintenance facility at Montauk, and construction of a temporary cofferdam. Issuance of Section 10 or Section 404 permits requires NEPA compliance, which will be met via adoption of BOEM's EIS and issuance of the ROD.

U.S. Fish and Wildlife Service

The U.S. Fish and Wildlife Service (USFWS) is serving as a participating agency for the Project. The USFWS also serves as the consulting agency under Section 7 of the ESA for federal agencies proposing actions that may affect terrestrial resources listed as threatened or endangered.

Consultations

The following section provides a summary and status of BOEM consultations as part of the Project (ongoing, complete, and the opinion or finding of each consultation). Section 1.3.1 of the COP provides a discussion of other federal and state consultation processes being led by SFW (Jacobs Engineering Group Inc. [Jacobs] 2021).

Coastal Zone Management Act

The Coastal Zone Management Act requires that federal actions within and outside the coastal zone that have reasonably foreseeable effects on any coastal use or natural resource of the coastal zone be consistent with the enforceable policies of a state's federally approved coastal management program. On October 22, 2018, SFW submitted a federal consistency certification with the New York State Department of State –

Division of Coastal Resources, Commonwealth of Massachusetts Office of Coastal Zone Management, and the State of Rhode Island Coastal Resources Management Council per 15 CFR 930.76 Subpart E. SFW received their consistency decision as follows for each state:

- Massachusetts: July 15, 2021
- New York: May 27, 2021
- Rhode Island: July 1, 2021

The COP provides the necessary data and information under 15 CFR 930.58 (Jacobs 2021). The states' concurrence is required before BOEM could approve, or approve with conditions, the COP per 30 CFR 585.628(f) and 15 CFR 930.130(1).

Endangered Species Act

Section 7(a)(2) of the ESA of 1973, as amended (16 USC 1531 et seq.), requires that each federal agency ensure that any action authorized, funded, or carried out by the agency is not likely to jeopardize the continued existence of any endangered or threatened species or result in the destruction or adverse modification of critical habitat of those species. When the action of a federal agency could affect a protected species or its critical habitat, that agency is required to consult with either the NMFS or the USFWS, depending upon the jurisdiction of the services. Pursuant to 50 CFR 402.07, BOEM has accepted designation as the lead federal agency for the purposes of fulfilling interagency consultation under Section 7 of the ESA for listed species under the jurisdiction of NMFS and USFWS. BOEM will consult on the proposed activities considered in this EIS with both NMFS and USFWS for listed species under their respective jurisdictions. Draft biological assessments were submitted to NMFS and USFWS on January 8, 2020. BOEM completed the USFWS consultation by March 4, 2021, and the NMFS consultation on July 8, 2021.

Government-to-Government Consultation with Federally Recognized Indian Tribes

Executive Order (EO) 13175 commits federal agencies to engage in government-to-government consultation with Tribes, and Secretarial Order No. 3317 requires U.S. Department of the Interior agencies to develop and participate in meaningful consultation with federally recognized Tribes where a Tribal implication may arise. A June 29, 2018, memorandum outlines BOEM's current Tribal consultation policy (BOEM 2018). This memorandum states that "consultation is a deliberative process that aims to create effective collaboration and informed Federal decision-making" and is in keeping with the spirit and intent of the National Historic Preservation Act (NHPA) and NEPA, executive and secretarial orders, and U.S. Department of the Interior policy (BOEM 2018). BOEM implements Tribal consultation policies through formal government-to-government consultation, informal dialogue, collaboration, and engagement.

BOEM conducted government-to-government consultations with the Narragansett Indian Tribe, the Mashantucket Pequot Tribal Nation, and the Mohegan Tribe of Indians of Connecticut in an overview of planned offshore wind development projects off southern New England, including the South Fork project, in August 2018.

In October 2018, individual email invitations to participate in the scoping process for this EIS were sent to the federally recognized Narragansett Indian Tribe, Mashpee Wampanoag Tribe, Mashantucket Pequot Tribal Nation, Mohegan Tribe of Indians of Connecticut, and Shinnecock Indian Nation. Although no comments were received from the Tribes during the scoping period, the draft EIS was posted on BOEM's website for their review and comment. BOEM also conducted government-to-government consultations with the Mashpee Wampanoag Tribe in February 2019.

Between January 15 and 17, 2020, BOEM met again with the Mohegan Tribe of Indians of Connecticut, the Mashantucket Pequot Tribal Nation, and the Narragansett Indian Tribe to discuss multiple BOEM actions, including the Proposed Action. Concerns expressed by representatives from the Tribes present included possible effects on marine mammals, other marine life, and the Nantucket Sound Traditional Cultural Property (TCP). One Tribe emphasized the importance of open sea views to the east during sunrise, as well as the night sky, while others emphasized their long historical association with the sea and islands off southern New England and the critical role of fishing and shellfish gathering. All of the Tribes emphasized the importance of understanding the interconnected nature of the human world, the sea, and the living things in both worlds.

On July 21, 2020, BOEM and the BSEE conducted three separate meetings with the Mashantucket Pequot Tribal Nation, the Wampanoag Tribe of Gay Head (Aquinnah), and the Mashpee Wampanoag Tribe. These meetings generally focused on developing mitigation measures for offshore wind project impacts, funding, and best practices. Concerns expressed by representatives from the Tribes present included project effects and layout, a desire to redefine the Nantucket Sound TCP boundaries, recommendations for mitigation measures, aboriginal rights and titles, communication with developers, and cumulative effects of the present and future offshore wind projects in the area.

On July 27, 2020, BOEM held a government-to-government meeting with the Mashantucket Pequot Tribal Nation, Mashpee Wampanoag Tribe, and the Wampanoag Tribe of Gay Head (Aquinnah). Concerns voiced by the representatives from the Tribes included site avoidance, Tribal staffing, best practices, and additional Tribal involvement. This meeting concluded with some action items for BOEM, including providing additional information on marine life and electrocution risk and terrestrial and marine analysis methods, a review of previous documents, scheduling a future meeting concerning environmental studies with the National Oceanic and Atmospheric Administration (NOAA), and following up with the Advisory Council on Historic Preservation (ACHP) regarding sharing the location of marine archaeological data with consulting parties during NHPA Section 106 reviews.

On August 20, 2020, BOEM consulted with the Delaware Tribe, Mashantucket Pequot Tribal Nation, Mashpee Wampanoag Tribe, and the Wampanoag Tribe of Gay Head (Aquinnah) to discuss the impacts of offshore wind developments on marine mammals. This included an overview of the consultation process and environmental review, the BOEM Environmental Studies program and process, existing and upcoming studies related to the North Atlantic right whales, and the marine mammal analysis and findings noted in the supplemental EIS. The meeting concluded with some action items for BOEM, including to provide the above-referenced consulting parties with additional reports and to research funding options to provide tuition assistance for Tribal members interested in participating in the Protected Species Observer training certificate program.

On March 12, 2021, BOEM consulted with the Mashpee Wampanoag Tribe and the Wampanoag Tribe of Gay Head (Aquinnah) to discuss the proposed nomination of a TCP district to the National Register of Historic Places (NRHP) off the coast of Massachusetts. The TCP district proposed by the two Wampanoag Tribes would encompass the lands and waters associated with the Wampanoag culture hero Moshup, including the Nantucket Sound TCP and the Vineyard Sound-Moshup's Bridge TCP identified during consultations for the Project. The representatives from the Tribes informed BOEM that the proposed TCP district was best described as a cultural landscape: a geographic area, including both cultural and natural resources and the wildlife therein, associated with a historic event, activity, or person or exhibiting other cultural or aesthetic values. The representatives from the Tribes stated that, in their opinion, any nomination should not be limited to the activities and lands associated with Moshup but also include detailed documentation of Wampanoag history in the area, such as their participation in the whaling industry, detailing the role the Wampanoag peoples have played in the history of the region. In a subsequent meeting on April 15, 2021, BOEM informed the representative from the Wampanoag Tribe of

Gay Head (Aquinnah) that BOEM's Office of Environmental Programs, Studies Program had developed a proposal for a collaborative ethnographic and historic research project with the Wampanoag Tribe of Gay Head (Aquinnah) and Mashpee Wampanoag Tribe to collect, document, and report information that could be used by the Tribes to complete an NRHP nomination for the proposed TCP district.

On April 9, 2021, BOEM held a government-to-government consultation meeting with representatives from the Delaware Tribe of Indians, Mashantucket Pequot Tribal Nation, Mashpee Wampanoag Tribe, and the Wampanoag Tribe of Gay Head (Aquinnah). Most of the meeting focused on topics and issues applicable to all proposed offshore wind off the coast of New England, including the Project. During the meeting, representatives from the Tribes voiced concerns about potential Project-specific and cumulative impacts to water quality; marine mammals; coastal habitats; benthic communities; culturally, economically, and historically significant fisheries and shellfish populations; chemical pollutants; the financial and time burden on Tribes of participating in multiple, simultaneous offshore wind project reviews; visual impacts on TCPs; and preserving the marine and terrestrial environments for future generations, particularly the current and future ability of Tribal youth to perform sacred ceremonies and have safe havens for traditional cultural practices in the future. In addition to discussing these concerns, representatives from the Tribes also recommended that BOEM consider creating a single offshore export cable corridor for all projects off the coasts of Rhode Island and Massachusetts and requested that BOEM consult with federally recognized Tribes on all proposed offshore wind projects as a single federal action, rather than on a project-by project basis.

BOEM continues to consult with these and other Tribes on developments in offshore wind. Additional government-to-government consultations are planned for the future.

As part of COP development, SFW also conducted prior coordination with engaged Tribes, State Historic Preservation Officers, and other stakeholders identified as having potential to inform the design process (see COP Table 1.4-1).

Marine Mammal Protection Act

The MMPA was enacted to protect and conserve marine mammals and established a general moratorium on the taking and importation of marine mammals, with certain enumerated exceptions. Unless an exception applies, the act prohibits persons or vessels subject to the jurisdiction of the United States from taking any marine mammal in waters or on lands under the jurisdiction of the United States or on the high seas (16 USC 1372(a)(1), (a)(2)). Section 101(a) of the act provides the prohibitions for the incidental taking of marine mammals. The incidental take of a marine mammal falls under three categories: mortality, serious injury, or harassment (i.e., injury and/or disruption of behavioral patterns). Sections 101(a)(5)(A) and (D) of the act provide the exceptions to the prohibition on take, which give NMFS the authority to authorize the incidental but not intentional take of small numbers of marine mammals, provided certain determinations are made and statutory and regulatory procedures are met. Entities seeking to obtain authorization for the incidental take of marine mammals under NMFS jurisdiction must submit such a request (in the form of an application). Incidental take authorizations (ITA) may be issued as either 1) regulations and associated letters of authorization or 2) incidental harassment authorizations when a proposed action will not result in a potential for serious injury and/or mortality or where any such potential can be negated through required mitigation measures. NMFS also promulgated regulations to implement the provisions of the MMPA governing the taking and importing of marine mammals (50 CFR 216) and produced Office of Management and Budget (OMB)–approved application instructions (OMB Number 0648-0151) that prescribe the procedures necessary to apply for permits. All applicants must comply with these regulations and application instructions in addition to the provisions of the MMPA. Once NMFS determines an application is adequate and complete, NMFS has a corresponding duty to determine whether and how to authorize take of marine mammals incidental to the activities described in the application. To authorize the incidental take of marine mammals, NMFS evaluates the best available scientific information to determine whether the take would have a negligible impact on the affected marine mammal species or stocks and an unmitigable impact on their availability for taking for subsistence uses. NMFS must also prescribe the "means of effecting the least practicable adverse impact" on the affected species or stocks and their habitat, and on the availability of those species or stocks for subsistence uses, as well as monitoring and reporting requirements.

NMFS received an application for an ITA from SFW on September 5, 2020. As outlined above, NMFS reviews applications to determine whether to issue an authorization for the activities described in the application. The proposed incidental harassment authorization was published in the *Federal Register* on February 5, 2021 (BOEM 2021a). The public comment period was open from February 5, 2021, through March 10, 2021.

National Historic Preservation Act

The NHPA (54 USC 306108 et seq.) requires federal agencies to consider the effects of their undertakings on historic properties, to the maximum extent possible plan and act to minimize harm to National Historic Landmarks (NHLs), and afford the ACHP an opportunity to comment. BOEM has determined that approving a COP constitutes an undertaking subject to Section 106 of the NHPA and is implementing the Section 106 Process (36 CFR 800). The construction of WTGs, installation of electrical support cables, and development of staging areas are ground- or seabed-disturbing activities that could directly affect archaeological resources. The presence of WTGs could also introduce visual elements out of character with the historic setting of historic structures or landscapes; in cases where historic setting is a contributing element of historic properties' eligibility for the NRHP, the Project could affect those historic properties, including NHLs. NHLs that may be affected by the undertaking will be addressed according to Section 110(f) of the NHPA, pursuant to 36 CFR 800.10.

BOEM is using the public scoping process to fulfill the public involvement requirements under NEPA as well as to seek public involvement in its Section 106 review, pursuant to 36 CFR 800.2(d)(3).

BOEM initiated review under Section 106 of the NHPA on April 7, 2019, with letters sent to identify consulting parties for this undertaking. Letters were then sent on June 29, 2020, to initiate consultation with those parties previously identified for the undertaking. Consultation is ongoing to define the area of potential effects (APE) for the Project, to identify historic properties within the APE, and to assess effects of the undertaking on identified historic properties. BOEM held an initial consultation meeting with consulting parties on September 29, 2020, to discuss the APE and the identification of historic properties within the APE; a second consultation meeting with consulting parties on March 11, 2021, to discuss the potential effects on historic properties; and a third consultation meeting on June 29, 2021, for the discussion of adverse effects and their resolution. BOEM is developing a memorandum of agreement with consulting parties to resolve adverse effects to NRHP-listed or NRHP-eligible properties resulting from the Project, including applying special requirements (36 CFR 800.10) for protecting NHLs as necessary.

The NEPA and NHPA process will be coordinated by BOEM as the evaluation of the COP proceeds, with a summary included in the ROD for the final EIS. In accordance with the regulations for the NEPA and NHPA Section 106 processes, these will further be coordinated with the requirements of other statutes. Specifically, the Vineyard Sound and Moshup's Bridge TCP is not limited to NHPA review and would be considered further by BOEM under EO 13007 and the American Indian Religious Freedom Act. EO 13007, "Indian Sacred Sites" (61 *FR* 26771-26772), directs federal land management agencies to accommodate access to, and ceremonial use of, Indian sacred sites by Indian religious practitioners and to avoid adversely affecting the physical integrity of such sacred sites. BOEM management actions within the OCS may not directly affect Indian sacred sites; however, BOEM recognizes its undertakings could affect the physical integrity or ceremonial use of Indian sacred sites located on submerged federal lands on the OCS. As stated previously in the Government-to-Government Consultation with Federally Recognized Indian Tribes section, BOEM is also consulting with Indian Tribes on these matters in accordance with EO 13175.

Magnuson-Stevens Fishery Conservation and Management Act

Pursuant to Section 305(b) of the MSA, federal agencies are required to consult with NMFS on any action that may result in adverse effects on EFH. NMFS regulations implementing the EFH provisions of the act can be found at 50 CFR 600. As provided for in 50 CFR 600.920(b), BOEM has accepted designation as the lead agency for the purposes of fulfilling EFH consultation obligations under Section 305(b) of the act. Certain OCS activities authorized by BOEM may result in adverse effects on EFH and, therefore, require consultation with NMFS. BOEM has developed an EFH assessment (BOEM 2021b) concurrent with this EIS and transmitted that EFH assessment to NMFS on April 8, 2021. BOEM's EFH assessment determined that the Proposed Action would not adversely affect quality and quantity of EFH for several species of managed fish. BOEM and NMFS completed the EFH consultation by June 7, 2021.

Development of Environmental Impact Statement

This section provides an overview of the development of the EIS, including public scoping, cooperating agency involvement, and distribution of the EIS for public review and comment.

Scoping

On October 19, 2018, BOEM issued a notice of intent (NOI) to prepare an EIS consistent with the regulations implementing NEPA (42 USC 4321 et seq.) to assess the potential impacts of the Proposed Action and alternatives (83 *Federal Register* 53104). The notice of intent began the public scoping process for identifying issues and potential alternatives for consideration in the EIS. BOEM held three public scoping meetings near the Project to solicit feedback and identify issues and potential alternatives for consideration in the EIS. Throughout the scoping process, federal agencies; state, local, and Tribal governments; and the general public had the opportunity to help BOEM identify potential significant resources and issues, impact-producing factors, reasonable alternatives (e.g., size, geographic, seasonal, or other restrictions on construction and siting of facilities and activities), and potential mitigation measures to be analyzed in the EIS, as well as provide additional information. The formal scoping period lasted from October 19 through November 10, 2018.

BOEM accepted comment submissions on the NOI via the following mechanisms:

- Electronic submissions received via www.regulations.gov on docket number BOEM-2018-0010
- Electronic submissions received via email to a BOEM representative
- Hard copy comment letters submitted to BOEM via traditional mail
- Hard copy comment cards and/or letters received during each of the public scoping meetings
- Comments submitted verbally at each of the public scoping meetings

BOEM held three public scoping meetings at the following locations and dates:

- November 5, 2018, American Legion Post 419, Amagansett, New York
- November 7, 2018, UMASS Dartmouth SMAST East, New Bedford, Massachusetts
- November 8, 2018, Narragansett Community Center, Narragansett, Rhode Island

Summary of Scoping Comments

BOEM reviewed and considered, as appropriate, all scoping comments in the development of the draft EIS and used the comments to identify alternatives for analysis. A scoping summary report (SWCA Environmental Consultants 2019) summarizing the submissions received and the methods for analyzing them is available on BOEM's website at https://www.boem.gov/South-Fork/. In addition, all public scoping submissions received can be viewed online at http://www.regulations.gov by typing "BOEM-2018-0010" in the search field. As detailed in the scoping summary report, the resource areas or NEPA topics most referenced in the scoping comments include alternatives; commercial fisheries and for-hire recreation fishing; finfish, invertebrates, and EFH; NEPA process and engagement; and socioeconomics.

Distribution of the Draft Environmental Impact Statement for Review and Comment

On January 8, 2021, BOEM published a notice of availability for the draft EIS consistent with the regulations implementing NEPA to assess the potential impacts of the Proposed Action and alternatives (BOEM 2021c). The draft EIS was made available in electronic form for public viewing at https://www.boem.gov/South-Fork, and hard copies and/or compact discs were delivered to entities as requested. The notice of availability commenced the public review and comment period of the draft EIS. BOEM held three virtual public hearings to solicit feedback and identify issues for consideration in preparing the final EIS. Throughout the public review and comment period, federal agencies; state, local, and Tribal governments; and the general public had the opportunity to provide comments on the draft EIS in various ways, including the following:

- In hard copy form, delivered by hand or by mail, enclosed in an envelope labeled "South Fork COP EIS" and addressed to Program Manager, Office of Renewable Energy, Bureau of Ocean Energy Management, 45600 Woodland Road, Sterling, Virginia 20166. Comments must be received or postmarked no later than February 22, 2021.
- Through the regulations.gov web portal by navigating to http://www.regulations.gov and searching for docket number "BOEM-2020-0066." Click the "Comment Now!" button to the right of the document link. Enter your information and comment, then click "Submit."
- By attending one of the EIS public meetings at the locations and dates listed in the notice of availability and providing written or verbal comments.

The topics most referenced during the draft EIS comment period were commercial fisheries and recreational fishing, cumulative impacts, mitigation, marine mammals, finfish, invertebrates, and EFH.

BOEM reviewed and has considered all public submissions in the development of the final EIS except those from anonymous sources. BOEM's evaluation of public submissions focused on those comments within the submissions that were identified as substantive. EIS Appendix I describes the public comment processing methodology and definitions and also includes responses to the substantive comments received on the draft EIS. In addition, all public comment submissions received on the draft EIS can be viewed online at http://www.regulations.gov by typing "BOEM-2020-0066" in the search field.

Distribution of the Final Environmental Impact Statement for Review and Comment

The EIS is available in electronic form for public viewing at https://www.boem.gov/South-Fork/. Hard copies and/or digital versatile disks of the EIS can be requested by contacting the Program Manager, Office of Renewable Energy Programs in Sterling, Virginia. Publication of the final EIS initiates a minimum 30-day mandatory waiting period, during which BOEM is required to pause before issuing a ROD. The ROD will state clearly whether BOEM intends to approve, approve with conditions, or disapprove the COP for construction, operation, and eventual decommissioning of the Project. EIS notification lists for the Project are provided in Tables A-2 through A-4.

NOTIFICATION LIST

Table A-2. Federal Agencies

Agency	Contact	Location
Cooperating Federal Agencies		
EPA	Tim Timmermann	Boston, Massachusetts
NOAA, NMFS	Sue Tuxbury	Gloucester, Massachusetts
U.S. Coast Guard	George Detweiler	Washington, D.C.
U.S. Coast Guard	Michele DesAutels	Boston, Massachusetts
U.S. Coast Guard	Sarah Geoffrion	East Providence, Rhode Island
U.S. Department of the Interior, BSEE	Sherry Hunter	Sterling, Virginia
USACE	Robert Vietri	New York, New York
Participating Federal Agencies		
USFWS	Steve Papa	New York, New York

Table A-3. State and Local Agencies or Other Interested Parties

Agency	Contact	Location
Cooperating State and Local Agencies		
Commonwealth of Massachusetts Office of Coastal Zone Management	Robert Beori	Boston, Massachusetts
State of Rhode Island Coastal Resources Management Council	Jeff Willis	Wakefield, Rhode Island
State of Rhode Island Department of Environmental Management	Janet Coit	Providence, Rhode Island
Town of East Hampton	John Wagner	East Hampton, New York
Trustees of the Freeholders and Commonalty of the Town of East Hampton	Francis Bock	Amagansett, New York

Table A-4. Tribes and Native Organizations

Tribes and Native Organizations	State
Mashantucket Pequot Tribal Nation	Connecticut
Mashpee Wampanoag Tribe	Massachusetts
Mohegan Tribe of Indians of Connecticut	Connecticut
Narraganset Indian Tribe	Rhode Island
Shinnecock Indian Nation	New York
Wampanoag Tribe of Gay Head (Aquinnah)	Massachusetts

LIST OF PREPARERS AND REVIEWERS

Table B-1. Bureau of Ocean Energy Management Contributors

Name	Role/Resource Area
National Environmental Policy Act (NEPA) Coordinator	
Boatman, Mary	NEPA compliance
Resource Scientists and Contributors	
Baker, Arianna	Navigation and vessel traffic
Baker, Kyle	Marine mammals and sea turtles
Barnett, Connie	Cultural resources
Bedard, Justin	Government to government
Bigger, David	Birds; bats; terrestrial and coastal fauna; wetlands
Brune, Genevieve	Land use and coastal infrastructure
Carrier, Brandi	Cultural resources
Chaiken, Emma	Demographics, employment, and economics; recreation and tourism; land use and coastal infrastructure; commercial fisheries and for-hire recreational fishing;
Cody, Mary	Marine mammals; sea turtles
Draher, Jennifer	Water quality
Hesse, Jeffrey T.	Military uses
Hoffman, Willie	Cultural resources
Hooker, Brian	Benthic, finfish, invertebrates, and essential fish habitat; commercial fisheries and for-hire recreational fishing
Howson, Ursula	Benthic, finfish, invertebrates, and essential fish habitat; commercial fisheries and for-hire recreational fishing; terrestrial and coastal fauna; wetlands
Jensen, Mark	Demographics, employment, and economics; recreation and tourism; land use and coastal infrastructure; commercial fisheries and for-hire recreational fishing
McCarty, John	Visual
Morin, Michelle	Chief, Environment Branch for Renewable Energy; NEPA compliance
Stromberg, Jessica	Project coordinator
Slayton, Ian	Air quality

Table B-2. Reviewers

Name	Title	Agency
Brown, William	Chief Environmental Officer	U.S. Bureau of Ocean Energy Management (BOEM)
Giordano, Juliette	Lead Environmental Protection Specialist	Bureau of Safety and Environmental Enforcement
Melendez-Arreaga, Pedro	Solicitor	Department of Interior, Office of the Solicitor
Timmerman, Timothy	Director	Environmental Protection Agency Region 1, Office of Environmental Review
Engler, Lisa	Director	Massachusetts Office of Coastal Zone Management
Crocker, Julie	Endangered Fish Branch Chief, GARFO Protected Resources Division	National Oceanic and Atmospheric Administration (NOAA) National Marine Fisheries Service

Name	Title	Agency
Tuxbury, Susan	Fishery Biologist/Wind Program Coordinator, GARFO Habitat and Ecosystems Services Division	NOAA National Marine Fisheries Service
Coit, Janet	Director	Rhode Island Department of Environmental Management
Boyd, James	Deputy Director	Rhode Island Coastal Resource Management Council
Ciochetto, David	Principal Ocean Engineer	Rhode Island Coastal Resource Management Council
Skenyon, Justin	Principal Ocean Engineer	Rhode Island Coastal Resource Management Council
Handell, Naomi Jacek, Christine	Project Manager, USACE, New York District Regulatory Branch-Eastern Section Project Manager, USACE New England District	U.S. Army Corps of Engineers
DesAutels, Michele	District 1 Agency Point of Contact	U.S. Coast Guard

GLOSSARY

Term	Definition
affected environment	Environment as it exists today that could be impacted by the proposed Project
ancient submerged landform feature	A landform as it was in ancient times
algal blooms	Rapid growth of the population of algae, also known as algae bloom
allision	A moving ship running into a stationary ship
anthropogenic	Generated by human activity
archaeological resource	Historical place, site, building, shipwreck, or other archaeological site on the American landscape
automatic identification system	Automatic tracking system used on vessels to monitor ship movements and avoid collision
baleen whale	A cetacean with baleens (whalebones) instead of teeth
below grade	Below ground level
benthic	Related to the bottom of a body of water
benthic resources	The seafloor surface, the substrate itself, and the communities of bottom-dwelling organisms that live within these habitats
Cetacea	Order of aquatic mammals made up of whales, dolphins, porpoises, and related lifeforms
coastal habitat	Coastal areas where flora and fauna live, including salt marshes and aquatic habitats
coastal waters	Waters in nearshore areas where bottom depth is less than 98.4 feet
coastal zone	The lands and waters starting at 3 nautical miles from the land and ending at the first major land transportation route
commercial fisheries	Areas or entities raising and/or catching fish for commercial profit
commercial-scale wind energy facility	Wind energy facility usually greater than 1 megawatt that sells the produced electricity
criteria pollutant	One of six common air pollutants for which the U.S. Environmental Protection Agency sets National Ambient Air Quality Standards: carbon monoxide, lead, nitrogen dioxide, ozone, particulate matter, or sulfur dioxide
critical habitat	Geographic area containing features essential to the conservation of threated or endangered species
cultural resource	Historical districts, objects, places, sites, buildings, shipwrecks, and archeological sites on the American landscape, as well as sites of traditional, religious, or cultural significance to cultural groups, including Native American tribes
cumulative impacts	Impacts that could result from the incremental impact of a specific action, such as the proposed Project, when combined with other past, present, or reasonably foreseeable future actions or other projects; can occur from individually minor, but collectively significant actions that take place over time
demersal	Living close to the ocean floor
design envelope	The range of proposed Project characteristics defined by the applicant and used by the Bureau of Ocean Energy Management (BOEM) for purposes of environmental review and permitting
dredging	Removal of sediments and debris from the bottom of lakes, rivers, harbors, and other water bodies
duct bank	Underground structure that houses the onshore export cables, which consists of polyvinyl chloride (PVC) pipes encased in concrete
ecosystem	Community of interacting living organisms and nonliving components (such as air, water, soil)

Term	Definition
environmental protection measure (EPM)	Measure proposed in COP to avoid or minimize potential impacts
electromagnetic field	A field of force produced by electrically charged objects and containing both electric and magnetic components
endangered species	A species that is in danger of extinction in all or a significant portion of its range
Endangered Species Act–listed species	Species listed under the Endangered Species Act
ensonified	The process of filling with sound
environmental consequences	The potential impacts that the construction, operations, maintenance, and decommissioning of the proposed Project would have on the environment
environmental justice communities	Minority and low-income populations affected by the proposed Project
essential fish habitat	“Those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity” (50 Code of Federal Regulations 600)
export cables	Cables connecting the wind facility to the onshore electrical grid power
finfish	Vertebrate and cartilaginous fishery species, not including crustaceans, cephalopods, or other mollusks
for-hire commercial fishing	Commercial fishing on a for-hire vessel, i.e. a vessel on which the passengers make a contribution to a person having an interest in the vessel in exchange for carriage
for-hire recreational fishing	Fishing from a vessel carrying a passenger for hire who is engaged in recreational fishing
foundation	The bases to which the wind turbine generators and offshore substation are installed on the seabed. Three types of foundations have been considered and reviewed for the Project: jacket, monopile, or gravity-based structure. Monopile is the selected foundation type for the Project.
hard-bottom habitat	Benthic habitats comprised of hard-bottom (e.g., cobble, rock, and ledge) substrates
historic property	Prehistoric or historic district, site, building, structure, or object that is eligible for or already listed in the National Register of Historic Places. Also includes any artifacts, records, and remains (surface or subsurface) related to and located within such a resource
horizontal directional drilling	Trenchless technique for installing underground cables, pipes, and conduits using a surface-launched drilling rig
hull	Watertight frame or body of a ship
inter-array cables	Cables connecting the wind turbine generators to the electrical service platforms
interconnection facility	Substation connecting the proposed Project to the existing bulk power grid system
invertebrate	Animal with no backbone
jack-up vessel	Mobile and self-elevating platform with buoyant hull
jet plow	Method of submarine cable installation equipment that primarily uses water jets to fluidize soil, temporarily opening a channel to enable the cable to be lowered under its own weight or be pushed to the bottom of the trench via a cable depressor.
knot	Unit of speed equaling 1 nautical mile per hour
landing site	The shoreline landing site at which the offshore cable transitions to onshore
Lease Area	The entire area that Deepwater Wind New England, LLC purchased from BOEM
marine mammal	Aquatic vertebrate distinguished by the presence of mammary glands, hair, three middle ear bones, and a neocortex (a region of the brain)
marine waters	Waters in offshore areas where bottom depth is more than 98.4 feet
mechanical cutter	Method of submarine cable installation equipment that involves a cutting wheel or excavation chain to cut a narrow trench into the seabed allowing the cable to sink under its own weight or be pushed to the bottom of the trench via a cable depressor.

Term	Definition
mechanical plow	Method of submarine cable installation equipment that involves pulling a plow along the cable route to lay and bury the cable. The plow's share cuts into the soil, opening a temporary trench which is held open by the side walls of the share, while the cable is lowered to the base of the trench via a depressor. Some plows may use additional jets to fluidize the soil in front of the share.
monopile or monopile foundation	A long steel tube driven into the seabed that supports a tower
nautical mile	A unit used to measure sea distances and equivalent to approximately 1.15 miles
offshore South Fork Export Cable	Export cables located in state or marine waters
offshore substation	The interconnection point between the wind turbine generators and the export cable; the necessary electrical equipment needed to connect the inter-array cables to the offshore export cables
onshore South Fork Export Cable	Export cables located on land
operations and maintenance facilities	Would include offices, control rooms, warehouses, shop space, and pier space
outer continental shelf	All submerged land, subsoil, and seabed belonging to the United States but outside of states' jurisdiction
pile	A type of foundation akin to a pole
pile driving	Installing foundation piles by driving them into the seafloor
pinnipeds	Carnivorous, semiaquatic, fin-footed marine mammals, also known as seals
plume	Column of fluid moving through another fluid
private aids to navigation	Visual references operated and maintained by the U.S. Coast Guard, including radar transponders, lights, sound signals, buoys, and lighthouses, that support safe maritime navigation
Project	The siting and development of the South Fork Wind Farm and the South Fork Export Cable
protected species	Endangered or threatened species that receive federal protection under the Endangered Species Act of 1973 (as amended)
right-of-way	Registered easement on private land that allows access by another entity
scour protection	Protection consisting of rock and stone that would be placed around all foundations to stabilize the seabed near the foundations as well as the foundations themselves
sessile	Attached directly by the base
soft-bottom habitat	Benthic habitats include soft-bottom (i.e., unconsolidated sediments) and hard-bottom (e.g., cobble, rock, and ledge) substrates, as well as biogenic habitat (e.g., eelgrass, mussel beds, and worm tubes) created by structure-forming species
South Fork Wind Farm (SFWF)	The work area containing all proposed wind turbine generators, offshore substations, and inter-array cables
substrate	Earthy material at the bottom of a marine habitat; the natural environment that an organism lives in
suspended sediments	Very fine soil particles that remain in suspension in water for a considerable period of time without contact with the bottom. Such material remains in suspension due to the upward components of turbulence and currents, and/or by suspension.
threatened species	A species that is likely to become endangered within the foreseeable future
tidal energy project	Project related to the conversion of the energy of tides into usable energy, usually electricity
transition vault	Underground concrete transition vault that to be constructed at the landing site and inside of which offshore and shore South Fork Export Cable would be spliced together.
trawl	A large fishing net dragged by a vessel at the bottom or in the middle of sea or lake water

Term	Definition
turbidity	A measure of water clarity
vibracore	Technology/technique for collecting core samples of underwater sediments and wetland soils
viewshed	Area visible from a specific location
visual resource	The visible physical features on a landscape, including natural elements such as topography, landforms, water, vegetation, and manmade structures
wetland	Land saturated with water; marshes; swamps
wind energy	Electricity from naturally occurring wind
wind energy area	Areas with significant wind energy potential and defined by BOEM
wind turbine generator	Component that puts out electricity in a structure that converts kinetic energy from wind into electricity

Burial depth - offshore	4 feet	6 feet	X	X		X		X		X		X	X				X	X	X	
OPERATIONS AND MAINTENANCE FACILITY																				
Montauk, East Hampton, New York	One or more buildings with up to 1,000 square feet of office space and up to 6,600 square feet of storage space	One or more buildings with up to 1,000 square feet of office space and up to 6,600 square feet of storage space	X	X	X	X	X		X	X	X		X			X			X	X
Quonset Point, North Kingstown, Rhode Island (two potential locations at the same facility)	One or more buildings with up to 1,000 square feet of office space and up to 11,000 square feet of storage space	One or more buildings with up to 1,000 square feet of office space and up to 11,000 square feet of storage space	X	X	X	X	X		X	X	X		X			X			X	X

Notes: In this appendix, distances in miles are in statute miles (miles used in the traditional sense) or nautical miles (or nm) (miles used specifically for marine navigation). Statute miles are more commonly used and are referred to simply as miles, whereas nautical miles are referred to by name or by their abbreviation nm.

* Although this EIS evaluates 180 MW as the maximum design feature, it is important to note that interconnection at the East Hampton substation is currently limited to no more than 130 MW, which matches the energy production requirement of the Power Purchase Agreement with Long Island Power Authority.

Table D-2. Maximum-Case Scenario Measurements for South Fork Export Cable Seabed Footprint

Seabed Footprint	Maximum Temporary Seabed Footprint	Maximum Permanent Seabed Footprint	3.3.1 Air Quality	3.3.2 Water Quality	3.4.1 Bats	3.4.2 Benthic, Essential Fish Habitat, Invertebrates, and Finfish	3.4.3 Birds	3.4.4 Marine Mammals	3.4.5 Other Terrestrial and Coastal Habitats and Fauna	3.4.6 Sea Turtles	3.4.7 Wetlands and Other Waters of the United States	3.5.1 Commercial Fisheries and For-Hire Recreational Fishing	3.5.2 Cultural Resources	3.5.3 Demographics, Employment, and Economics	3.5.4 Environmental Justice	3.5.5 Land Use and Coastal Infrastructure	3.5.6 Navigation and Vessel Traffic	3.5.7 Other Uses (marine, military use, aviation, offshore energy)	3.5.8 Recreation and Tourism	3.5.9 Visual Resources
INTER-ARRAY CABLE

APPENDIX E

Cumulative Activities Scenario

This page intentionally left blank.

CONTENTS

Attachments

Tables

This page intentionally left blank.

CUMULATIVE ACTIVITIES SCENARIO

Cumulative impacts are the incremental effects of a proposed action on the environment when added to other past, present, or reasonably foreseeable future actions, regardless of which agency or person undertakes the actions (40 CFR 1508.7)[1].

This appendix discusses resource-specific cumulative activities that could occur if Project impacts occur in the same location and timeframe as impacts from other relevant past, present, or reasonably foreseeable future actions. The *Project* here is the construction, operations and maintenance (O&M), and conceptual decommissioning of a wind energy project located within the Bureau of Ocean Energy Management's (BOEM's) Renewable Energy Lease Area OCS-A 0517, approximately 18 statute miles southeast of Block Island, Rhode Island, and 34 statute miles east of Montauk Point, New York.

The geographic analysis area varies for each resource as shown below in Table E-1 and on Figures E-1 through E-17 in Attachment 1. BOEM anticipates that impacts could occur between the start of Project construction in 2022 and the completion of Project decommissioning approximately 2053. The geographic analysis area is defined by the impact-producing factor with the maximum geographic area of impact, for example sound during pile driving. For the mobile resources, bats, birds, finfish and invertebrates, marine mammals, and sea turtles, the species potentially impacted are those that occur within the area of impact of the Proposed Action. The geographic analysis area for these mobile resources is the general range of the species. The purpose of these analysis areas is to capture the cumulative impacts to each of those resources that are impacted by the Proposed Action.

In this appendix, distances in miles are in statute miles (miles used in the traditional sense) or nautical miles (miles used specifically for marine navigation). This appendix uses statute miles more commonly and refers to them simply as *miles*, whereas nautical miles are referred to by name.

[1] On July 16, 2020, the Council on Environmental Quality (CEQ), which is responsible for federal agency implementation of NEPA, updated the regulations for implementing the procedural provisions of NEPA (85 CFR 43304-43376). Since BOEM's NEPA review of the proposed Project began prior to the September 14, 2020, effective date of the updated regulations, this draft environmental impact statement was prepared under the previous version of the regulations (1978, as amended in 1986 and 2005).

Table E-1. Resource-Specific Geographic Analysis Areas

Resource	Geographic Analysis Area	Rationale
Physical Resources		
Air quality*	The Outer Continental Shelf (OCS) permit area (consisting of the South Fork Wind Farm [SFWF], portions of the offshore South Fork Export Cable [SFEC] and all other potentially affected areas within 25 miles of the Lease Area) and all lands within a 15.5-mile radius of potential Project on-land construction areas and port locations (Figure E-1).	The geographic analysis area encompasses the geographic region subject to U.S. Environmental Protection Agency (EPA) review as part of an OCS permit for the Project under the Clean Air Act. The geographic analysis area also considers potential air quality impacts associated with the on-land construction areas and the mustering port(s) outside of the OCS permit area. Given the generally low emissions of the sea vessels and equipment that would be used during proposed construction activities, any potential air quality impacts would likely be within a few miles of the source. BOEM selected the 15.5-mile distance to provide a reasonable buffer.
Water quality	The watersheds and groundwater basins that cross or fall within the project. The geographic analysis area for offshore water quality impacts includes coastal and marine waters within a 10-mile radius of Project components, as well as a 15.5-mile radius of waterways for ports that may be used during the Project (Figure E-2).	The onshore geographic analysis area was chosen to capture the extent of the natural network of waterbodies that could be affected by construction and operation activities of the proposed project. The offshore geographic analysis area was chosen by analyzing a worst-case scenario of an incidental oil discharge under the project, which would equate to the simultaneous release of all oils used by all project components and vessels.
Biological Resources		
Bats	The U.S. coastline from Maine to Florida (Figure E-3). Although some historic anecdotal observations of bats up to 1,212 miles offshore of North America exist, recent offshore observations of tree bats range from 10.5 to 26 miles (Hatch et al. 2013). For this reason, the geographic analysis area for bats consists of the U.S. east coast, from Maine to Florida, to capture migratory species, and extends 100 miles offshore.	The geographic analysis area was established to capture most of the movement range for migratory species. Northern long-eared bats and other cave bats do not typically occur on the OCS. Tree bats are long-distance migrants; their range includes most of the Atlantic coast from Florida to Maine. Although these species have been documented traversing the open ocean and have the potential to encounter wind turbine generators (WTGs), use of offshore habitat is thought to be limited and generally restricted to spring and fall migration. The onshore limit of the geographic scope is intended to cover most of the onshore habitat used by those species that may encounter the Project during most of their life cycles.
Benthic habitat	The maximum work area for the SFWF as well as the construction and operational footprint of the SFEC and potential O&M facilities (Figure E-4a). This includes a 10-mile radius around the Lease Area and a 330-foot buffer on either side of the SFEC.	The geographic analysis area captures the extent of benthic habitat occurring within the footprint of Project activities because benthic habitats do not move or migrate like other biological resources. This area also accounts for some transport of water masses, sediment transport, and for benthic invertebrate larval transport due to ocean currents.
Essential fish habitat, invertebrates, and finfish	The Northeast Shelf Large Marine Ecosystem (LME), which extends from the southern edge of the Scotian Shelf (in the Gulf of Maine) to Cape Hatteras, North Carolina (Figure E-4b).	This area is likely to capture the majority of the movement range for most species in this group.[†]
Birds	The United States coastline from Maine to Florida (see Figure E-3). The offshore limit is 100 miles from the Atlantic shore to capture the migratory movements of most species in this group. The onshore limit is 0.5 mile (0.8 km) inland to cover onshore habitats used by the species that may be affected by offshore components of the proposed Project as well as those species that could be affected by proposed onshore Project components.	The geographic analysis area was established to capture resident species and migratory species that winter as far south as South America and the Caribbean, and those that breed in the Arctic or along the Atlantic Coast that travel through the area.

Resource	Geographic Analysis Area	Rationale
Marine mammals	The Scotian Shelf, Northeast Shelf, and Southeast Shelf LMEs (Figure E-5).	The geographic analysis area is likely to capture most of the movement range for most species in this group.† BOEM notes that potential vessel trips from port locations in the Gulf of Mexico could occur under the Proposed Action. However, whether ports in these regions would be used or not would not be known until additional details are available when contracts are in place. Because BOEM estimates that only up to four vessel trips could occur (but are unlikely), the geographic analysis area was not extended to encompass the Gulf of Mexico.
Terrestrial and coastal habitats and faunas	All onshore Project areas, including a 1.0-mile buffer (Figure E-6).	BOEM expects the resources in this area to have small home ranges. These resources are unlikely to be affected by impacts outside their home ranges.
Sea turtles	The Northeast and Southeast Shelf LMEs (Figure E-7).	This area is likely to capture the majority of the movement range for most species in this group.†
Wetlands and other waters of the United States	The three subwatersheds that overlap the onshore Project (Figure E-8).	This area encompasses the drainage basin and network of surface waterbodies that could be affected by Project construction and O&M activities.
Socioeconomic and Cultural Resources		
Commercial fisheries and for-hire recreation fishing	Waters managed by the New England Fishery Management Council and/or the Mid-Atlantic Fisheries Management Council within the U.S. Exclusive Economic Zone (from 3 to 200 nautical miles from the coastline), plus the state waters of the Commonwealth of Massachusetts, Rhode Island and New York (from 0 to 3 nautical miles from the coastline) (Figure E-9).	The boundaries for the geographic analysis area were developed to consider impacts to federally permitted vessels operating in all fisheries in state and U.S. Exclusive Economic Zone waters.
Cultural resources	Terrestrial cultural resources: The footprint of all onshore Project components, plus the viewshed in which Project facilities could be visible (the area of potential effects for visual impacts analysis) (Figure E-10). Marine cultural resources: The SFWF and offshore SFEC, the adjacent BOEM lease areas OCS-A 0486 and OCS-A 0487, plus a 1,000-foot buffer zone extending from the edge of project components outward and overlapping with the two adjacent lease areas (Figure E-11).	This terrestrial cultural resources geographic analysis area accounts for the footprint of onshore Project development where physical impacts could occur to historic properties and the viewshed within which visibility of the Project could result in an impact on the visual setting of a historic property from construction, O&M, or conceptual decommissioning. The marine cultural resources geographic analysis area encompass offshore locations where BOEM anticipates impacts associated with construction, O&M, and conceptual decommissioning of the Project.
Demographics, employment, and economics	Suffolk County in New York; Providence, Newport, and Washington Counties in Rhode Island; Bristol County in Massachusetts; New London County in Connecticut; Gloucester County in New Jersey; Baltimore County in Maryland; and Norfolk City/County in Virginia. These counties include those with proposed onshore infrastructure, potential port cities, and counties in closest proximity to the Lease Area (Figure E-12).	These counties are the most likely to experience beneficial or negative economic impacts from the proposed Project.
Environmental justice	The same as the demographics, employment, and economics geographic analysis area (see Figure E-12).	The geographic analysis area would be the same as the socioeconomics geographic analysis area, as these counties, and environmental justice communities located within, are the most likely to experience impacts from the proposed Project.

Resource	Geographic Analysis Area	Rationale
Land use and coastal infrastructure	Town of East Hampton and the ports potentially used for Project construction, O&M, and conceptual decommissioning (Figure E-13).[‡]	These areas encompass locations where BOEM anticipates direct and indirect impacts associated with proposed onshore facilities and ports.
Navigation and vessel traffic	Coastal and marine waters within a 10-mile radius of Project components, as well as waterways for ports that may be used during the Project (Figure E-14).	These areas encompass locations where BOEM anticipates direct and indirect impacts associated with Project construction, O&M, and conceptual decommissioning.
Other Uses (marine, military use, aviation, offshore energy, scientific research and surveys)	Marine mineral extraction: Areas within 0.25 mile of the Project and footprints of other cables and wind lease areas in the RI-MA WEA. National security/military use/ aviation and air traffic/ radar systems: An area roughly bounded by Montauk, New York; Providence, Rhode Island; Provincetown, Massachusetts; and within a 10-mile buffer from wind lease areas in the RI-MA WEA (Figure E-15). Aviation and air traffic: Airspace and airports used by regional air traffic. Radar systems: Includes air space used by regional air traffic. Offshore energy: Other known wind energy project locations. Cables and pipelines: area within 1 mile of the Project and other undersea facilities and wind lease areas in the RI-MA WEA. Scientific research and surveys: Same as for finfish, invertebrates, and EFH and includes the footprint of the Proposed Action and all reasonably foreseeable projects between Maine and mid–North Carolina.	These areas encompass locations where BOEM anticipates direct and indirect impacts associated with Project construction, O&M, and conceptual decommissioning. The scientific research and surveys area encompasses the locations where scientific research and surveys are anticipated to occur.
Recreation and tourism	The geographic analysis area includes all Project components, plus a 40-mile radius from the WTG array (Figure E-16).	This geographic analysis area was selected to coincide with the April 2019 SFWF visual impact assessment visual analysis area to address Project visibility from sensitive resources and encompass all locations where BOEM anticipates direct and indirect impacts associated with Project construction, O&M, and conceptual decommissioning.
Visual resources	The area of analysis for cumulative visual impacts uses the 40-mile visual analysis area as defined in the April 2019 SFWF visual impact assessment (Figure E-17).	This geographic analysis area was selected to coincide with the April 2019 SFWF visual impact assessment visual analysis area to address Project visibility from sensitive resources and encompass all locations where BOEM anticipates direct and indirect impacts associated with Project construction, O&M, and conceptual decommissioning.

* BOEM is not proposing to model impacts at Class I areas because no federal Class I areas are located within the geographic analysis area or within the initial screening distance of 100 km from a federal Class I area for sources emitting less than 1,000 tons per year of NOx (U.S. Forest Service, National Park Service, and U.S. Fish and Wildlife Service [2010]).

† LMEs are delineated based on ecological criteria including bathymetry, hydrography, productivity, and trophic relationships among populations of marine species, and the National Oceanic and Atmospheric Administration (NOAA) uses them as the basis for ecosystem-based management.

‡ South Fork Wind, LLC plans to finalize the specific ports during the facility design report phase.

PAST, PRESENT, AND FUTURE REASONABLY FORESEEABLE ACTIVITIES AND PROJECTS

This section includes a list and description of past, present, and reasonably foreseeable projects that could contribute to cumulative impacts. Projects or actions that are considered speculative per the definition provided in 43 CFR 46.30[2] are noted in subsequent tables but excluded from the cumulative impact analysis in Chapter 3.

Cumulative projects and activities described in this section consist of 10 types of actions: 1) other offshore wind energy development activities; 2) undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); 3) tidal energy projects; 4) marine minerals use and ocean-dredged material disposal; 5) military use; 6) marine transportation; 7) fisheries use and management; 8) global climate change; 9) oil and gas activities; and 10) onshore development activities.

BOEM analyzed the possible extent of future other offshore wind energy development activities on the Atlantic Outer Continental Shelf (OCS) to determine reasonably foreseeable cumulative effects measured by installed power capacity. Since the development of the South Fork Wind Farm (SFWF) and South Fork Export Cable (SFEC) Project draft environmental impact statement (EIS), BOEM has received eight additional construction and operations plans, which provide more specific details of projects. The cumulative analysis numbers are refined to include this new information. However, the overall estimates for reasonably foreseeable activities have not changed significantly and the methodology is the same. Table E-2 is updated with the information and represents status of projects as of June 1, 2021. The methodology for developing the scenario is the same as for the Vineyard Wind project, and details of the scenario development are described in the *Vineyard Wind 1 Offshore Wind Energy Project Final Environmental Impact Statement* (BOEM 2021a).

[2] 43 CFR 46.30 – Reasonably foreseeable future actions include those federal and non-federal activities not yet undertaken, but sufficiently likely to occur, that a responsible official of ordinary prudence would take such activities into account in reaching a decision. The federal and non-federal activities that BOEM must take into account in the analysis of cumulative impacts include, but are not limited to, activities for which there are existing decisions, funding, or proposals identified by BOEM. Reasonably foreseeable future actions do not include those actions that are highly speculative or indefinite.

This page intentionally left blank.

Table E-2. Offshore Wind Activities on the U.S. Atlantic Coast (dates shown as of June 1, 2021)

Lease Number	States	Lessee/Developer Name	Project Name	Construction Date	Operations Date	Facility Description	BOEM Permitting Stage*	Power Purchase Agreement (PPA)/ Offshore Renewable Energy Certificate (OREC) Status
Active Projects (state)								
N/A (state project)	Rhode Island	Deepwater Wind, LLC (now Ørsted)	Block Island Wind Farm	2015	2016	30 MW (5 WTGs)	N/A	PPA with RI
Active Projects (federal)								
OCS-A 0483	Virginia	Virginia Electric and Power Company (dba Dominion Virginia Power)	Virginia Commercial Offshore Wind (per SAP)	2024–2025	2026	2,640 MW (205 WTGs); one met buoy	SAP approved; SAP submitted; COP in progress	No PPAs signed to date
OCS-A 0486	Rhode Island and Connecticut	Revolution Wind, LLC (Ørsted and Eversource)	Revolution Wind	2023	2023	880 MW (100 WTGs)	COP in progress; SAP approved	PPA with CT and RI
OCS-A 0487; OCS-A 0500 (portions)	New York	Ørsted and Eversource	Sunrise Wind	2024	2024	880 MW (122 WTGs)	COP submitted	OREC awarded by NYSERDA (PPA with NY)
OCS-A 0490 (portion)	Maryland	U.S. Wind Inc.	U.S. Wind (Maryland Offshore Wind Project)	2024	2024	1500 MW (125 WTGs)	COP submitted; SAP approved	OREC awarded by State of Maryland
OCS-A 0497	Virginia	Virginia Department of Mines, Minerals and Energy (Ørsted & Dominion Energy)	Coastal Virginia Offshore Wind	2021	2021	12 MW (two WTGs); one wave/current buoy	Operating	N/A (research)
OCS-A 0498 (portion)	New Jersey	Ocean Wind, LLC (Ørsted & PSEG)	Ocean Wind	2023	2024	1,100 MW (98 WTGs)	COP in progress SAP approved	PPA with NJ
OCS-A 0499	New Jersey	Atlantic Shores Offshore Wind, LLC	Atlantic Shores	2025	2026		SAP approved; COP submitted	No PPA signed to date
OCS-A 0500 (portion)	Massachusetts	Bay State Wind LLC (Ørsted & Eversource)	Bay State Wind	2026	2027	800 MW; two FLIDAR buoys; one met buoy	COP in progress SAP approved	No PPA signed to date
OCS-A 0501 (north)	Massachusetts	Vineyard Wind LLC	Vineyard Wind 1	2023	2023	800 MW (62 WTGs); two met buoys	ROD issued	PPA with MA
OCS-A 0501 (south)	Connecticut	Vineyard Wind LLC	Park City Wind	2024	2026	Up to 1,714 MW (121 WTGs)	COP in progress	PPA with CT
OCS-A 0508	North Carolina, Virginia	Avangrid Renewables, LLC	Kitty Hawk Offshore	2025	2026	Up to 60 WTGs; up to two buoys; and up to two platforms	COP in progress; SAP approved	No PPA signed to date
OCS-A 0512 (phase 1 and phase 2	New York	Equinor Wind US, LLC	Empire Wind Phase 1, Empire Wind Phase 2 (Boardwalk Wind)	2024	2025	816 MW (68 WTGs); two met buoys; one wave/ met buoy; one subsea current meter mooring	COP in progress; SAP approved	PPA with NY
OCS-A 0517	New York	South Fork Wind, LLC (Ørsted & Eversource)	South Fork Wind Farm (Proposed Action)	2023	2023	132 MW (up to 15 WTGs); one met buoy	Final EIS in progress COP received SAP approved	PPA with NY
OCS-A 0519 (portion; includes former OCS-A 0482)	Delaware, Maryland	Skipjack Offshore Energy, LLC (Ørsted)	Skipjack	2023	2023	192 MW (up to 16 WTGs); one met buoy	COP received	OREC awarded by State of Maryland (connection to PJM grid in Delaware)
OCS-A 0521 (north)	Massachusetts	Mayflower Wind Energy, LLC (Shell & EDP Renewables)	Mayflower (north)	2024	2024	Up to 804 MW (101 WTGs); one met buoy	SAP approved	PPA with MA
Future Projects (federal)								
OCS-A 0482	Delaware	GSOE I LLC (Ørsted & PSEG)	Garden State Offshore Energy	Collectively the technical capacity of this is group is 1,080 MW (90 WTGs). The remaining capacity may be used by demand from NJ or MD (see Attachment 4).			SAP approved	PPA with DE and NJ
OCS-A 0519 (remainder)	Maryland/Delaware	Skipjack Offshore Energy, LLC (Ørsted)	To be determined (TBD)				SAP approved	No PPAs signed to date

Lease Number	**States**	**Lessee/Developer Name**	**Project Name**	**Construction Date**	**Operations Date**	**Facility Description**	**BOEM Permitting Stage***	**Power Purchase Agreement (PPA)/ Offshore Renewable Energy Certificate (OREC) Status**
OCS-A 0487 (remainder)	Rhode Island	Sunrise Wind, LLC	TBD	This group is exposed to 2,500 MW of demand -for MA (1,600 MW remaining), CT (900 MW remaining), and RI (900 MW expected). Collectively the remaining technical capacity is 4,968 MW (see Attachment 4).			SAP approved	No PPAs signed to date
OCS-A 0500 (remainder)	Massachusetts	Bay State Wind LLC (Ørsted & Eversource)	Constitution Wind				SAP approved	No PPAs signed to date
OCS-A 0520	TBD (New England)	Equinor Wind US LLC	Beacon Wind				SAP submitted	No PPA signed to date
OCS-A 0521 (remainder)	Massachusetts	Mayflower Wind Energy, LLC (Shell & EDP Renewables)	TBD				TBD	No PPAs signed to date
OCS-A 0522 (portion)	Massachusetts	Vineyard Wind LLC	Liberty Wind (Vineyard Wind 2)				SAP submitted	No PPAs signed to date
OCS-A 0522 (remainder)	Massachusetts	Vineyard Wind LLC	TBD				TBD	No PPAs signed to date
OCS-A 0498 (remainder)	New Jersey	Ocean Wind, LLC (Ørsted & PSEG)	TBD	This group may support up to approximately 3,480 MW of development (290 WTGs) from NJ and NY.			SAP approved	No PPAs signed to date

Notes: NA = not applicable; TBD = to be determined.

* Under BOEM Permitting Stage, COP status is assumed to be in process, under review, or not yet commenced based on publicly available information.

Offshore Wind Energy Development Activities

Site Characterization Studies

A lessee is required to provide the results of site characterization activities with its site assessment plan (SAP) or COP. For the purposes of the cumulative effects analysis, BOEM makes the following assumptions for survey and sampling activities:

- Site characterization would occur on all existing leases.
- Site characterization would likely take place in the first 3 years following execution of a lease, based on the fact that a lessee would likely want to generate data for its COP at the earliest possible opportunity.
- Lessees would likely survey most or all of the proposed lease area during the 5-year site assessment term to collect required geophysical information for siting of a meteorological tower and/or two buoys and commercial facilities (wind turbines). The surveys may be completed in phases, with the meteorological tower and/or buoy areas likely to be surveyed first.
- Lessee would not use air guns, which are typically used for deep penetration two-dimensional or three-dimensional exploratory seismic surveys to determine the location, extent, and properties of oil and gas resources (BOEM 2016).

Table E-3 describes the typical site characterization surveys, the types of equipment and/or method used, and which resources the survey information would inform.

Table E-3. Site Characterization Survey Assumptions

Survey Type	Survey Equipment and/or Method	Resource Surveyed or Information Used to Inform
High-resolution geophysical surveys	Side-scan sonar, sub-bottom profiler, magnetometer, multi-beam echosounder	Shallow hazards, archaeological, Bathymetric charting, benthic habitat
Geotechnical/ sub-bottom sampling	Vibracores, deep borings, cone penetration tests	Geological
Biological	Grab sampling, benthic sled, underwater imagery/ sediment profile imaging	Benthic habitat
	Aerial digital imaging; visual observation from boat or airplane	Bird
	Ultrasonic detectors installed on survey vessels used for other surveys	Bat
	Visual observation from boat or airplane	Marine fauna (marine mammals and sea turtles)
	Direct sampling of fish and invertebrates	Fish

Source: BOEM (2016).

Site Assessment Activities

After SAP approval, a lessee can evaluate the meteorological conditions, such as wind resources, with the approved installation of meteorological towers and/or buoys. Site assessment activities have been approved or are in the process of being approved for multiple lease areas consisting of one to three meteorological buoys per SAP (see Table E-2). Site assessment would likely take place starting within 1 to 2 years of lease execution, because preparation of an SAP (and subsequent BOEM review) takes time. This cumulative analysis considers these site assessment activities.

Construction and Operation of Offshore Wind Facilities

Table E-2 lists all offshore wind leasing activities that BOEM considers reasonably foreseeable by lease areas and projects, their permitting stage/assessment, and anticipated timeline.

Monitoring and Mitigation

Future offshore wind projects could require monitoring or mitigation as part of BOEM approval in their records of decisions. Although specific measures are too speculative to include at this time, BOEM anticipates that measures could include actions such as passive acoustic monitoring, trawl surveys, acoustic telemetry, and gillnet or ventless trap surveys.

COMMERCIAL FISHERIES CUMULATIVE FISHERY EFFECTS ANALYSIS

Table E-4 depicts future construction schedules of offshore wind projects from Maine to North Carolina including Block Island Wind Farm, which is currently operating in state waters off Rhode Island. Also included are all of the projects that are currently in various stages of planning within BOEM's offshore leases in the U.S. Exclusive Economic Zone from Massachusetts to North Carolina. The table lists 17 future marine wind projects, all of which will require a NEPA process with an environmental impact statement or environmental assessment.[3] The project schedule and project areas shown in Table E-4 serves as the basis of the assessment of potentially affected revenue for the No Action alternative in Section 3.5.1.2.2 as well as the cumulative effects for the Proposed Action, as described in Section 3.5.1.2.3.

The following assumptions have been made with respect to lease areas and portions of lease areas that are included in the assessment, noting that unless noted in the bulleted list below, the entire lease area for a project listed in Table E-4 is included in the quantitative analysis of commercial fishing revenues at risk:

- Vineyard Wind 1 occupies only the northwestern portion of OCS-A 0501 and could affect 51% of the commercial fishing revenue generated in the lease area (NMFS 2021).
- Sunrise Wind will be built in the southeastern portion of the lease area and is assumed by the analysts that it could affect 55% of the commercial fishing revenue generated in OCS-A 0487.
- Bay State Wind occupies the only northeastern portion of OCS-A 0500 and could affect 41% of the commercial fishing revenue generated in the lease area (NMFS 2021).
- Park City Wind is built in two phases: Phase 1 could affect 65% of the revenues generated in the southwestern portion of OCS-A 0501 that was not used by Vineyard Wind; Phase 2 is assumed to comprise the remaining 35%. The southwestern portion of OCS-A 0501 comprises 49% of the commercial fisheries revenue generated in the entire lease area (NMFS 2021).
- Beacon Wind is built in the northeastern portion of OCS-A 0520 and is assumed by analysts to potentially affect 55% of the commercial fishing revenue generated from the entire lease area.
- Mayflower Wind comprises only the northwestern portion of OCS-A 0521 and could affect 56% of the commercial fishing revenue generated in the lease area (NMFS 2021).
- Liberty Wind 1 occupies the northeastern portion of OCS-A 0522 and could affect 41% of the commercial fishing revenue generated in the lease area (NMFS 2021).

[3] The U.S. Department of Energy announced a scoping process for Aqua Ventus in February 2017; however, the *Federal Register* does not include any notices that a NEPA environmental assessment has been completed. NEPA environmental assessments for Block Island and Coastal Virginia Offshore Wind have been completed.

- Ocean Wind is built in the eastern portion of OCS-A 0498. This area could affect 45% of the commercial fishing revenue in the lease area (NMFS 2021).
- Empire Wind Phase 1 is built in the northwestern portion of OCS-A 0512. This area could affect 26% of the commercial fishing revenue in the lease area (NMFS 2021).
- Empire Wind Phase 2 is built in the southeastern portion of OCS-A 0512. This area could affect 75% of the commercial fishing revenue in the lease area (NMFS 2021).
- Atlantic Shores Wind Farm in the first year of offshore construction is assumed to potentially affect 5% of the commercial fishing revenue of OCS-A 0499, based on the number of foundations listed in Table E-4. In the second year of offshore construction, the project could affect the full extent of the lease area.
- US Wind is built in the southeastern portion of OCS-A 0490. This area could affect 54% of the commercial fishing revenue in the lease area (NMFS 2021).
- Skipjack is assumed to be built in the southern portion of OCS-A 0519. This area could affect 26% of the commercial fishing revenue in the lease area (NMFS 2021).
- Dominion CVOW Commercial in OCS-A 0483 is assumed to develop 138 foundations in 2024 and the final 70 in 2025. Based on the number foundations, the analysts assume construction could affect 66% of the commercial fishing revenue in the first year, increasing in the second year to potentially affect all of the revenue in the lease area.
- Kitty Hawk in OCS-A 0508 is assumed by the analysts to potentially affect 40% of the commercial fishing revenues in the lease area.

BOEM assumes proposed offshore wind projects will include the same or similar components as the proposed Project: wind turbines, offshore and onshore cable systems, offshore substations, onshore O&M facilities, and onshore interconnection facilities. BOEM further assumes that other potential offshore wind projects will employ the same or similar construction, O&M, and conceptual decommissioning activities as the proposed Project. However, future offshore wind projects would be subject to evolving economic, environmental, and regulatory conditions. Lease areas may be split into multiple projects, expanded, or removed, and development within a particular lease area may occur in phases over long periods of time. Research currently being conducted in combination with data gathered regarding physical, biological, socioeconomic, and cultural resources during development of initial offshore wind projects in the United States could affect the design and implementation of future projects, as could advancements in technology. For the cumulative impact analysis, all proposed projects included in Table E-3 are analyzed in Chapter 3 of this EIS.

For consideration of cumulative environmental impacts from future offshore wind projects and for a list of best management practices (BMPs) that were considered in the impact analysis in Chapter 3 of this EIS, please see the Project EIS's Appendix G (Environmental Protection Measures, Mitigation, and Monitoring).

Table E-4. Future Offshore Wind Project Construction Schedule (dates shown as of June 1, 2021)

Project/Region	Number of FDN before 2021	Number of FDN 2021	Number of FDN 2022	Number of FDN 2023	Number of FDN 2024	Number of FDN 2025	Number of FDN 2026	Number of FDN 2027	Number of FDN 2028	Number of FDN 2029	Number of FDN 2030 and Beyond

Estimated O&M subtotal:	*0*	*2*	*2*	*2*	*2*	*140*	*271*	*271*	*271*	*271*	*271*
ESTIMATED ANNUAL TOTAL CONSTRUCTION:	**2**	**0**	**0**	**298**	**744**	**367**	**476**	**0**	**0**	**0**	**0**
ESTIMATED O&M TOTAL	**0**	**2**	**2**	2	300	1,044	1,411	1,887	1,887	1,887	1,887

Notes: For projects with 2-year construction schedules, and for purposes of this table, all foundations (FDN) are assumed to be installed in the first year of construction. However, a note is made in the second year cell ("cont.") to indicate any FDN installation not completed in the first year would be continued in the second year.

Incorporation by Reference of Cumulative Impacts Study and the Analyses Therein

BOEM has completed a study of impact-producing factors (IPFs) on the North Atlantic OCS to consider in an offshore wind development cumulative impacts scenario (BOEM 2019). That study is incorporated in this documented by reference. The study identifies cause-and-effect relationships between renewable energy projects and resources potentially affected by such projects. It further classifies those relationships into a manageable number of IPFs through which renewable energy projects could affect resources. It also identifies the types of actions and activities to be considered in a cumulative impacts scenario. The study identifies actions and activities that may affect the same physical, biological, economic, or cultural resources as renewable energy projects and states that such actions and activities may have the same IPFs as offshore wind projects.

The BOEM (2019a) study identifies the relationships between IPFs associated with specific past, present, and reasonably foreseeable actions and activities in the North Atlantic OCS to consider in a NEPA cumulative impacts scenario. These IPFs and their relationships were used in the EIS analysis of cumulative impacts and the application of which IPF applied to which resource was decided by BOEM. If an IPF was not associated with the SFWF Project, it was not included in the cumulative impacts analysis.

As discussed in the BOEM (2019a) study, reasonably foreseeable activities other than offshore wind projects may also affect the same resources as the proposed Project or other offshore wind projects, possibly via the same IPFs or via IPFs through which offshore wind projects do not contribute. This Appendix E lists reasonably foreseeable non-offshore wind activities that may contribute to the cumulative impacts of the proposed Project.

Undersea Transmission Lines, Gas Pipelines, and Other Submarine Cables

The following existing undersea transmission lines, gas pipelines, and other submarine cables are located near the Project:

- New Shoreham (Block Island), Rhode Island, is served by a submarine power cable from the Block Island Wind Farm to New Shoreham (Block Island).
- A submarine power cable connects Block Island to the mainland electrical grid at Narragansett, Rhode Island.
- Service to Martha’s Vineyard is provided by four electric cables from Falmouth, located in three corridors through Vineyard Sound. Two cables are located in the same corridor between Elm Road in Falmouth and West Chop; one is located between Shore Street in Falmouth and Eastville (East Chop), and one connects between Mill Road in Falmouth and West Chop.
- Two cables service Nantucket through Nantucket Sound, from Dennis Port and Hyannis Port to landfall at Jetties Beach.
- Additional submarine cables, including fiber-optic cables and trans-Atlantic cables that originate near Charlestown, Rhode Island; New York City; Long Island, near Trenton, New Jersey; and Wall, New Jersey, are located offshore New England and mid-Atlantic states, but outside the proposed Project area.
- Two natural gas pipelines are located offshore Boston, Massachusetts, in Massachusetts Bay and lead to liquid natural gas (LNG) export facilities: the Neptune pipeline and the Northeast Gateway LNG pipeline.

The offshore wind projects listed in Table E-2 that have a COP under review are presumed to include at least one identified cable route. Cable routes have not yet been announced for the remainder of the projects.

Tidal Energy Projects

The following tidal energy projects have been proposed or studied on the U.S East Coast and are in operation or considered reasonably foreseeable:

- The Bourne Tidal Test Site, located in the Cape Cod Canal near Bourne, Massachusetts, is a testing platform for tidal turbines that was installed in late 2017 by the Marine Renewable Energy Collaborative. The Bourne Tidal Test Site offers a test platform for tidal turbines (MRECo 2017, 2018).
- Cobscook Bay Tidal Project, located in Maine, is a Federal Energy Regulatory Commission-(FERC) licensed tidal project that began operations in 2012. The project owner, Ocean Power Energy Company, has informed FERC that it will not apply for relicensing, and removal and site restoration activities are anticipated to be conducted prior to its current license expiration date in January 2022 (FERC 2012a).
- Western Passage Tidal Energy Project, a proposed tidal energy site in the Western Passage, received a preliminary permit from FERC in 2016. The preliminary permit allows developers to study a project but does not authorize construction.
- The Roosevelt Island Tidal Energy (RITE) Project located in the East Channel of the East River, a tidal strait connecting the Long Island Sound with the Atlantic Ocean in the New York Harbor. In 2005, Verdant Power petitioned FERC for permission to the first U.S. commercial license for tidal power. In 2012, FERC issued a 10-year license to install up to 1 MW of power (30 turbines/10 TriFrames) at the RITE project (FERC 2012b; Verdant Power 2018).

Dredging and Port Improvement Projects

The following dredging projects have been proposed or studied between New York, New York, and Boston, Massachusetts, and are either in operation or are considered reasonably foreseeable:

- The U.S. Army Corps of Engineers (USACE) New England District partnership with Rhode Island Coastal Resources Management Council proposes a project that would dredge approximately 23,700 cubic yards of sandy material from the Point Judith Harbor Federal Navigation Project to widen the existing 15-foot-deep mean lower low water (MLLW) West Bulkhead channel by 50 feet and extend the same channel approximately 1,200 feet into the North Basin area (USACE 2018a).
- The Plymouth Harbor Federal Navigation Project in Plymouth, Massachusetts, includes maintenance dredging of approximately 385,000 cubic yards of sand and silt from approximately 75 acres of the authorized project area in order to restore the project to authorized and maintained dimensions (USACE 2018b).
- The Port of New Bedford was awarded a $15.4 million U.S. Department of Transportation Better Utilizing Investments to Leverage Development grant to improve the port's infrastructure and to help with the removal of contaminated materials. The funding will be used to extend the port's bulkhead, creating room for 60 additional commercial vessels, and additional sites for offshore wind staging (Phillips 2018).
- Proposed New Haven Harbor Improvements would include deepening the main ship channel, maneuvering area, and turning basin to -40 feet MLLW and widening the main channel and turning basin to allow larger vessels to efficiently access the Port of New Haven’s terminals. The proposed improvements would remove approximately 4.28 million cubic yards of predominately glacially deposited silts from the federal channel (USACE 2018c).

- The Nature Conservancy seeks a permit to place an artificial reef array in Narraganset Bay at 130 Shore Road in Narragansett Bay in East Providence, Rhode Island. The proposed work involves the construction of a 0.14-acre artificial reef using 91 pre-fabricated reef modules. The artificial reef array would consist of 58 Pallet Balls (4.0 × 2.9 feet) and 33 Bay Balls (3 × 2 feet). The reef modules would be transported to the project site by barge and lowered to the seafloor by crane (USACE 2019).
- The Rhode Island Coastal Resources Management Council has awarded funding for nine habitat restoration projects comprising four salt marsh restoration and enhancement projects, two projects involving restoration of fish passage, one coastal buffer project, and two projects for technical and support services related to habitat restoration (Rhode Island Coastal Resources Management Council 2018a).
- The Town of Dennis seeks a permit for the selective dredging of multiple navigation and mooring basins within multiple waterways in the towns of Dennis and Yarmouth. Suitable dredged material will be used as nourishment on multiple town-owned beaches in Dennis whereas material that is not deemed suitable for beach nourishment will be disposed of at the Cape Cod Bay Disposal Site and at the South Dennis Landfill. The town is requesting to dredge approximately 434,310 cubic yards from portions of these waterways over 10 years encompassing an area of approximately 96.03 acres (USACE 2018d).

The following port improvement projects have been proposed in Connecticut, Rhode Island, Massachusetts, and/or New Jersey, and are either in operation or are considered reasonably foreseeable:

- The Connecticut Port Authority announced a $93 million public-private partnership to upgrade the Connecticut State Pier in New London to support the offshore wind industry (Sheridan 2019). According to the Connecticut Maritime Strategy 2018 (Connecticut Port Authority 2018b), New London is the only major port between New York and Maine that does not have vertical obstruction and offshore barriers, two factors that are critical for offshore wind turbine assembly. The document includes strategic objectives to manage and redevelop the Connecticut State Pier partially to support the offshore wind industry, which could create a dramatic increase in demand for the Connecticut State Pier and regional job growth. The development partnership, announced in May 2019, includes a 3-year plan to upgrade infrastructure to meet heavy-lift requirements of Ørsted and Eversource offshore wind components (Cooper 2019). Redevelopment of the Connecticut State Pier is considered a reasonably foreseeable activity.
- In Rhode Island, South Fork Wind, LLC has committed to investing approximately $40 million in improvements at the Port of Providence, the Port of Davisville at Quonset Point, and possibly other Rhode Island ports for the Revolution Wind Project (Kuffner 2018). This investment will position Rhode Island ports to participate in construction and operation of future offshore wind projects in the region (Rhode Island Governor’s Office 2018). The Port of Davisville has added a 150-megaton mobile harbor crane, which will enable the port to handle wind turbines and heavy equipment, and enables the Port of Davisville to participate in regional offshore wind projects (Port of Davisville 2017). Further improvements at Rhode Island ports to support the offshore wind industry are considered reasonably foreseeable.
- The Massachusetts Clean Energy Center (MassCEC) has identified 18 waterfront sites in Massachusetts that may be available and suitable for use by the offshore wind industry. Potential activities at these sites include manufacturing of offshore wind transmission cables, manufacture and assembly of turbine components, substation manufacturing and assembly, O&M bases, and storage of turbine components (MassCEC 2020).

- The MassCEC manages the New Bedford Marine Commerce Terminal in New Bedford, Massachusetts. The 29-acre facility was completed in 2015 and is the first in North America designed specifically to support the construction, assembly, and deployment of offshore wind projects (MassCEC 2018). The New Bedford Port Authority Strategic Plan 2018–2023 contains goals related to expanding the New Bedford Marine Commerce Terminal to improve and expand services to the offshore wind industry, including development of North Terminal with the capacity to handle two separate offshore wind installation projects in the future (Port of New Bedford 2018). Vineyard Wind signed an 18-month lease with the Marine Commerce Terminal in October 2018 (Port of New Bedford 2020) and has supported the New Bedford Port Authority with grants to develop publicly owned facilities to support shore-based operations for offshore wind facilities (Vineyard Wind 2019).

Marine Minerals Use and Ocean Dredged Material Disposal

The closest active lease in BOEM's Marine Minerals Program for sand borrow areas for beach replenishment is located offshore New Jersey near Harvey Cedars, Surf City, Long Beach Township, Ship Bottom, and Beach Haven (Lease Number OCS-A-0505). The Lessee, Long Beach Island, Barnegat Inlet to Little Egg Harbor Inlet (Amendment) has been approved through June 29, 2018, for 12,000,000 cubic yards volume requested (BOEM 2018a).

In addition, reconnaissance and/or design-level OCS studies along the East Coast from Rhode Island to Florida have identified potential future sand resources. Sand resources identified nearest the Project include locations offshore Rhode Island (between Block Island and Charlestown), Long Island (Rockaway Beach, Long Beach, and Fire Island, New York), and Sandy Hook, New Jersey. The closest potential sand borrow location to the Project is the Manasquan Project off the coast of New Jersey, approximately 162 miles from the Project.

The EPA Region 1 is responsible for designating and managing ocean disposal sites for materials offshore in the region of the Project. The USACE issues permits for ocean disposal sites; all ocean sites are for the disposal of dredged material permitted or authorized under the Marine Protection, Research, and Sanctuaries Act (16 USC 1431 et seq. and 33 USC 1401 et seq.). There are nine active projects along the Massachusetts, Rhode Island, Connecticut and New York coasts, with the closest dredge disposal project, the Rhode Island Sound Disposal Site (RISDS) located northeast of Block Island (USACE 2018e).

Military Use

Military activities can include various vessel training exercises, submarine and antisubmarine training, and U.S. Air Force exercises. The U.S. Navy, the U.S. Coast Guard (USCG), and other military entities have numerous facilities in the region. Major onshore regional facilities include Joint Base Cape Cod, Naval Station Newport, Newport Naval Undersea Warfare Center, Naval Submarine Base New London, and USCG Academy (BOEM 2013; Epsilon Associates, Inc 2018; Rhode Island Coastal Resources Management Council 2010). The U.S. Atlantic Fleet also conducts training and testing exercises in the Narraganset Bay Operating Area, and the Newport Naval Undersea Warfare Center routinely performs testing in the area (BOEM 2013).

Marine Transportation

Marine transportation in the region is diverse and sourced from many ports and private harbors from New York to Massachusetts. Commercial vessel traffic in the region includes research, tug/barge, liquid tankers (such as those used for liquid petroleum), cargo, military and search-and-rescue vessels, and commercial fishing vessels. Recreational vessel traffic includes cruise ships, sailboats, and charter boats. A number of federal agencies, state agencies, educational institutions, and environmental non-governmental organizations participate in ongoing research offshore including oceanographic, biological, geophysical, and archaeological surveys. The Northeast Regional Planning Body anticipates that major vessel traffic routes will be relatively stable in the region for the foreseeable future, but that coastal developments and market demands that are unknown at this time could affect them (Northeast Regional Planning Body 2016). One new regional maritime highway project received funding from the Maritime Administration. A new barge service (Davisville/Brooklyn/ Newark Container-on-Barge Service) is proposed to run twice each week in state waters between Newark, New Jersey; Brooklyn, New York; and the Port of Davisville in Rhode Island, which is located on Quonset Point, one of the potential O&M locations.

National Marine Fisheries Service Activities

Research and enhancement permits may be issued for marine mammals protected by the Marine Mammal Protection Act (MMPA) and for threatened and endangered species under the ESA. NMFS is anticipated to continue issuing research permits under section 10(a)(1)(A) of the ESA to allow take of certain ESA-listed species for scientific research. Scientific research permits issued by NMFS currently authorize studies on ESA-listed species in the Atlantic Ocean, some of which occur in portions of the Lease Area. Current fisheries management and ecosystem monitoring surveys conducted by or in coordination with the Northeast Fisheries Science Center (NEFSC) could overlap with offshore wind lease areas in the New England region and south into the Mid-Atlantic region. Surveys include 1) the NEFSC Bottom Trawl Survey, a more than 50-year multispecies stock assessment tool using a bottom trawl; 2) the NEFSC Sea Scallop/Integrated Habitat Survey, a sea scallop stock assessment and habitat characterization tool, using a bottom dredge and camera tow; 3) the NEFSC Surfclam/Ocean Quahog Survey, a stock assessment tool for both species using a bottom dredge; and 4) the NEFSC Ecosystem Monitoring Program, a more than 40-year shelf ecosystem monitoring program using plankton tows and conductivity, temperature, and depth units. These surveys are anticipated to continue within the region, regardless of offshore wind development.

The regulatory process administered by the NMFS, which includes stock assessments for all marine mammals and 5-year reviews for all ESA-listed species, assists in informing decisions on take authorizations and the assessment of project-specific and cumulative impacts that consider past, present, and reasonably foreseeable future actions in biological opinions. Stock assessments completed regularly under MMPA include estimates of potential biological removal that stocks of marine mammals can sustainably absorb. MMPA take authorizations require that a proposed action have no more than a negligible impact on species or stocks, and that a proposed action impose the least practicable adverse impact on the species. MMPA authorizations are reinforced by monitoring and reporting requirements so that NMFS is kept informed of deviations from what has been approved. Biological opinions for federal and non-federal actions are similarly grounded in status reviews and conditioned to avoid jeopardy and to allow continued progress toward recovery. These processes help to ensure that, through compliance with these regulatory requirements, a proposed action would not have a measurable impact on the conservation, recovery, and management of the resource.

Directed Take Permits for Scientific Research and Enhancement

NMFS issues permits for research on protected species for scientific purposes. These scientific research permits include the authorization of directed take for activities such as capturing animals and taking measurements and biological samples to study their health, tagging animals to study their distribution and migration, photographing and counting animals to get population estimates, taking animals in poor health to an animal hospital, and filming animals. NMFS also issues permits for enhancement purposes; these permits are issued to enhance the survival or recovery of a species or stock in the wild by taking actions that increase an individual's or population's ability to recover in the wild. In waters near the Lease Area, scientific research and enhancement permits have been issued previously for satellite, acoustic, and multi-sensor tagging studies on large and small cetaceans, research on reproduction, mortality, health, and conservation issues for North Atlantic Right Whales, and research on population dynamics of harbor and gray seals. Reasonably foreseeable future impacts from scientific research and enhancement permits include physical and behavioral stressors (e.g., restraint and capture, marking, implantable and suction tagging, biological sampling).

Fisheries Use and Management

The National Marine Fisheries Service (NMFS) implements regulations to manage commercial and recreational fisheries in federal waters, including those within which the Project would be located; the State of New York, state of Rhode Island, and Commonwealth of Massachusetts regulate commercial fisheries in state waters (within 3 nautical miles of the coastline). There were no active aquaculture leases or activities within federal or state waters within the Lease Area or along the export cable route as of spring 2018 (Jacobs 2021). The project overlaps two of NMFS' eight regional councils to manage federal fisheries: Mid-Atlantic Fisheries Management Council (MAFMC) which includes New York, New Jersey, Pennsylvania, Delaware, Maryland, Virginia and North Carolina; and New England Fishery Management Council (NEFMC), which includes Maine, New Hampshire, Massachusetts, Rhode Island, and Connecticut (NEFMC 2016). The councils manage species with many fishery management plans that are frequently updated, revised, and amended and coordinate with each other to jointly manage species across jurisdictional boundaries (MAFMC 2019). Many of the fisheries managed by the councils are fished for in state waters or outside of the Mid-Atlantic region, so the council works with the Atlantic States Marine Fisheries Commission (ASMFC). ASMFC is composed of the 15 Atlantic coast states and coordinates the management of marine and anadromous resources found in the states' marine waters. In addition, the lobster and Jonah crab fisheries are cooperatively managed by the states and NMFS under the framework of the ASMFC (2019).

The fishery management plans of the Councils and ASMFC were established, in part, to manage fisheries to avoid overfishing. They accomplish this through an array of management measures, including annual catch quotas, minimum size limits, and closed areas. These various measures can further reduce (or increase) the size of landings of commercial fisheries in the Northeast and the Mid-Atlantic regions.

NOAA Fisheries also manages highly migratory species (HMS), such as tuna and sharks, that can travel long distances and cross domestic boundaries. Table E-5 summarizes other fishery management plans and actions in the region.

Table E-5. Other Fishery Management Plans

Area	Plan and Projects
Atlantic States Marine Fisheries Commission	ASMFC Five-Year Strategic Plan 2014–2018 (ASMFC 2014) Draft 2019 strategic management plan under review Management, Policy and Science Strategies for Adapting Fisheries Management to Changes in Species Abundance and Distribution Resulting from Climate Change (ASMFC 2018)
New York	Ocean Action Plan 2017–2027 – adaptive management plan (New York State Department of Environmental Conservation [NYSDEC] 2017) New York State filed a petition with the NOAA, NMFS, and the MAMFC to demand that commercial fluke allocations be revised to provide fishers with equitable access to summer flounder. New York is also reviewing other species where there is an unfair allocation, including black sea bass and bluefish, and may pursue similar actions (Governor’s Office 2018a).
Long Island Regional Development Council (LIRDC)	East Hampton Shellfish Hatchery project to consolidate the hatchery’s municipal hatchery and nursing facilities. Haskell’s seafood facility in East Quogue is proposed become a fully functioning seafood processing plant. Shinnecock Dock Revitalization to provide better processing and packing facilities for local fishermen (LIRDC 2018).
Suffolk County	Suffolk County Shellfish Aquaculture Lease Program in Peconic Bay and Gardiners Bay (limited to conveyance of shellfish cultivation); a complete review of the Lease Program is required to determine if and/or how the program should be changed and implemented in 2020 and beyond (Suffolk County 2018).

Global Climate Change

Section 7.6.1.4 of the Programmatic EIS for Alternative Energy Development and Production and Alternate Use of Activities on the Outer Continental Shelf (Minerals Management Service 2007) describes global climate change with respect to assessing renewable energy development. Climate change is predicted to affect Northeast fishery species differently (Hare et al. 2016), and the NMFS biological opinion discusses in detail the potential impacts of global climate change on protected species that occur within the proposed action area (NMFS 2013).

The Intergovernmental Panel on Climate Change (IPCC) released a special report in October 2018 that compared risks associated with an increase of global warming of 1.5 degrees Celsius (°C) and an increase of 2°C. The report found that climate-related risks depend on the rate, peak, and duration of global warming, and that an increase of 2°C was associated with greater risks associated with climatic changes such as extreme weather and drought; global sea level rise; impacts to terrestrial ecosystems; impacts to marine biodiversity, fisheries, and ecosystems and their functions and services to humans; and impacts to health, livelihoods, food security, water supply, and economic growth (IPCC 2018).

Table E-6 summarizes regional plans and policies that are in place to address climate change, and Table E-7 summarizes resiliency plans.

Table E-6. Climate Change Plans and Policies

Plans and Policies	Summary/Goal
New York	
Reforming the Energy Vision (New York State 2014)	State's energy policy to build integrated energy network; Clean energy goal to reduce greenhouse gases (GHG) 40% by 2030 and 80% by 2050.
Order Adopting a Clean Energy Standard (State of New York Public Service Commission 2016)	Requirement that 50% of New York's electricity come from renewable energy sources by 2030.
New York State Energy Plan 2015; 2017 Biennial Report to 2015 Plan (New York State Energy Research Development Authority [NYSERDA] 2015, 2017a)	Requires 40% reduction in GHG from 1990 levels; 50% electricity will come from renewable energy resources; and 600 trillion British thermal units (Btu) increase in statewide energy efficiency.
Governor Cuomo State of State Address 2017, 2018, 2021	2017: Set offshore wind energy development goal of 2,400 MW by 2030 (Governor's Office 2017a). 2018: Procurement of at least 800 MW of offshore wind power between two solicitations in 2018 and 2019; new energy efficiency target for investor-owned utilities to more than double utility energy efficiency progress by 2025; energy storage initiative to achieve 1,500 MW of storage by 2025 and up to 3,000 MW by 2030 (Governor Office 2018b, 2018c). 2021: The governor's 2021 agenda—Reimagine | Rebuild | Renew—establishes a goal of building out its renewable energy program. The agenda notes the development of two new offshore wind farms more than 20 miles off the shore of Long Island, the creation of dedicated offshore port facilities, and additional transmission capacity development.
New York State Offshore Wind Master Plan (2017) (NYSERDA 2017b)	Grants NYSERDA ability to award 25-year long-term contracts for projects ranging from approximately 200 MW to approximately 800 MW, with an ability to award larger quantities if sufficiently attractive proposals are received. Each proposer is also required to submit at least one proposal of approximately 400 MW. Bids are due in February 2019, awards are expected in spring 2019; and contracts are expected to be executed thereafter.
2020 Offshore Wind Solicitation	As noted above, NYSERDA has provisionally awarded two offshore wind projects, totaling 2,490 MW. Empire Wind 2 (1,260 MW) and Beacon Wind (1,230 MW) of Equinor Wind US LLC will generate enough clean energy to power 1.3 million homes and will be major economic drivers, supporting the following: • More than 5,200 direct jobs • Combined economic activity of $8.9 billion in labor, supplies, development, and manufacturing statewide • $47 million in workforce development and just access funding
The Climate Leadership and Community Protection Act (CLCPA), enacted on July 18, 2019, signed into law in July 2019 and effective January 1, 2020	CLCPA establishes economy-wide targets to reduce GHG emissions by 40% of 1990 levels by 2030 and 85% of 1990 levels by 2050.

Plans and Policies	Summary/Goal
Massachusetts	
Global Warming Solutions Act (GWSA) of 2008	Framework to reduce GHG emissions by requiring 25% reduction in emissions from all sectors below 1990 baseline emission level in 2020, at least 80% reduction in 2050. Full implementation of these policies is projected to result in total net reduction of 25.0 million metric tons of carbon dioxide equivalent, or 26.4% below 1990 baseline level (Commonwealth of Massachusetts 2018a).
Massachusetts Clean Energy and Climate Plan (CECP) for 2020; 2015 CECP Update	Policies that aim to reduce GHG emissions in the commonwealth across all sectors; full implementation of policies would result in reducing emissions by at least 25% below 1900 level in 2020 (Commonwealth of Massachusetts 2015).
Executive Order 569, Establishing an Integrated Climate Strategy for the Commonwealth and "Act to Promote Energy Diversity" (2016)	Calls for large procurements of offshore wind and hydroelectric resources (Commonwealth of Massachusetts 2016).
Environmental Bond Bill and An Act to Advance Clean Energy (2018)	Sets new targets for offshore wind, solar, and storage technologies; expands Renewable Portfolio Standard requirements for 2020–2029; establishes a Clean Peak Standard; and permits fuel switching in energy efficiency programs (Commonwealth of Massachusetts 2018a).
Massachusetts State Hazard Mitigation and Climate Adaption Plan 2018	Updated 2013 plan to comprehensively integrate climate change impacts and adaptation strategies with hazard mitigation planning while complying with federal requirements for state hazard mitigation plans and maintaining eligibility for federal disaster recovery and hazard mitigation funding under the Stafford Act. The plan will next be submitted to the Federal Emergency Management Agency (FEMA) for approval. In 2020, a new 2030 emissions limit and CECP for 2030 will be published (Commonwealth of Massachusetts 2018a, 2018b).
Rhode Island	
Governor's Climate Priorities (2018) Executive Order 15-17, 17-06	Increasing in-state renewable energy tenfold by 2020 (to 1,000 MWs) through new development and regional procurement (State of Rhode Island 2015a, 2017, 2018a).
Resilient Rhode Island Act (2014)	Established the Executive Climate Change Coordinating Council (EC4) and set specific GHG reduction targets; incorporates consideration of climate change impacts into the powers and duties of all state agencies (State of Rhode Island 2014).
Rhode Island Greenhouse Gas Emissions Reductions Plan (2016)	Targets for GHG reductions: 10% below 1990 levels by 2020; 45% below 1990 levels by 2035; 80% below 1990 levels by 2040 (State of Rhode Island 2016).
Energy 2035 Rhode Island State Energy Plan (2015)	Long-term comprehensive strategy for energy services across all sectors using a secure, cost-effective, and sustainable energy system; plan to increase sector fuel diversity, produce net economic benefits, and reduce GHG emissions by 45% by the year 2035 (State of Rhode Island 2015b).
Resilient Rhody (2018)	Planning document outlining climate resiliency actions; focuses on leveraging emissions reduction targets and adaptation (State of Rhode Island 2018b).

Table E-7. Resiliency Plans and Policies in the Lease Area

Plans and Policies	Summary
New York	
Part 490 of Community Risk and Resiliency Act (CRRA) of 2014	Establishes statewide science-based sea-level rise projections for coastal regions of the state. As of 2019, DEC is in the process of developing a State Flood Risk Management Guidance document for state agencies (NYSDEC n.d. [2019]).
NY Rising Community Reconstruction (NYRCR) (2018)	$20.4 million in projects on Long Island to help flood-prone communities plan and prepare for extreme weather events as they continue projects to recover from Superstorm Sandy, Hurricane Irene, and Tropical Storm Lee. Three projects were announced for Suffolk County and five for Nassau County (Governor’s Office 2018c).
Massachusetts	
Municipal Vulnerability Preparedness grant program (MVP) (2017)	Provides support for cities and towns to plan for resiliency and implement key climate change adaptation actions for resiliency. The City of New Bedford has received MVP designation as of November 1, 2018 (Commonwealth of Massachusetts 2019a).
Coastal Grant and Resilience Program	Provides financial and technical support for local efforts to increase awareness and understanding of climate impacts, identify and map vulnerabilities, conduct adaptation planning, redesign vulnerable public facilities and infrastructure, and implement non-structural approaches that enhance natural resources and provide storm damage protection (Commonwealth of Massachusetts 2019b).
Rhode Island	
Nantucket’s Coastal Resilience Plan	The plan is currently under development, and while no actions have been identified to date, potential shoreline management activities could include sediment management, construction of seawalls and similar structures, and other activities (Town and County of Nantucket 2018a, 2018b).
Shoreline Change Special Area Management Plan (Beach SAMP)	Rhode Island Coastal Resources Management Council is developing the Shoreline Change Special Area Management Plan (Beach SAMP) to improve the state’s resilience and manage the shoreline (Town and County of Nantucket 2018b) (Rhode Island Coastal Resources Management Council 2018b).

Oil and Gas Activities

The proposed Project area is located in the North Atlantic Planning Area of the OCS Oil and Gas Leasing Program (National OCS Program). On September 8, 2020, the White House issued a presidential memorandum for the Secretary of the Interior on the withdrawal of certain areas of the United States OCS from leasing disposition for 10 years, including the areas currently designated by BOEM as the South Atlantic and Straits of Florida Planning Areas (The White House 2020). The South Atlantic Planning Area includes the OCS off South Carolina, Georgia, and northern Florida. On September 25, the White House issued a similar memorandum for the Mid-Atlantic Planning Area that lies south of the northern administrative boundary of North Carolina (The White House 2020b). This withdrawal prevents consideration of these areas for any leasing for purposes of exploration, development, or production during the 10-year period beginning July 1, 2022, and ending June 30, 2032. However, at this time, there has been no decision by the Secretary of the Interior regarding future oil and gas leasing in the North Atlantic or remainder of the Mid-Atlantic Planning Areas. Existing leases in the withdrawn areas are not affected.

BOEM issues geological and geophysical (G&G) permits to obtain data for hydrocarbon exploration and production; locate and monitor marine mineral resources; aid in locating sites for alternative energy structures and pipelines; identify possible manmade, seafloor, or geological hazards; and locate potential archeological and benthic resources. G&G surveys are typically classified into categories by equipment type and survey technique.

There are currently no such permits under review for areas offshore Massachusetts and Rhode Island; areas under consideration for G&G surveys are located in federal waters offshore Delaware to Georgia (BOEM 2021b).

Several liquefied natural gas ports are located on the East Coast of the United States. Table E-8 lists existing, approved, and proposed LNG ports on the East Coast of the United States that provide (or may in the future provide) services such as natural gas export, natural gas supply to the interstate pipeline system or local distribution companies, or storage of LNG for periods of peak demand, or production of LNG for fuel and industrial use (FERC 2018).

Table E-8. Liquid Natural Gas Terminals Located in the Northeastern United States

Terminal Name	Type	Company	Jurisdiction	Distance from Project (approximate)	Status
Everett, MA	Import terminal	GDF SUEZ—DOMAC	FERC	90 miles north	Existing
Offshore Boston, MA	Import terminal	Neptune LNG	U.S. Department of Transportation Maritime Administration (MARAD)/USCG	100 miles north	Existing
Offshore Boston, MA	Import terminal, authorized to re-export delivered LNG	Excelerate Energy—Northeast Gateway	MARAD/USCG	95 miles north (Buoy B)	Existing
Cove Point, MD (Chesapeake Bay)	Import terminal	Dominion—Cove Point LNG	FERC	340 miles southwest	Existing
Elba Island, GA (Savannah River)	Import terminal	El Paso—Southern LNG	FERC	835 miles southwest	Existing
Elba Island, GA (Savannah River)	Export terminal	Southern LNG Company	FERC	835 miles southwest	Approved
Jacksonville, FL	Export terminal	Eagle LNG Partners	FERC	960 miles southwest	Proposed

Onshore Development Activities

Onshore development activities that may contribute to cumulative impacts include visible infrastructure such as onshore wind turbines and cell towers, port development, and other energy projects such as transmission and pipeline projects. Coastal development projects permitted through regional planning commissions and towns may also contribute to cumulative impacts. These may include residential, commercial, and industrial developments spurred by population growth in the region (Table E-9).

Table E-9. Existing, Approved, and Proposed Onshore Development Activities

Type	Description
Local planning documents	• Suffolk County Master Plan (Suffolk County 2015) • A City Master Plan: New Bedford 2020 (City of New Bedford 2010) • Town of North Kingstown Comprehensive Plan Update 2008 (Town of North Kingston 2008)
Onshore wind projects	• According to the U.S. Geological Survey, there are nine onshore wind projects located within the 41-mile viewshed of the project (U.S. Geological Survey 2018).
Communications towers	• There are numerous communications towers located in Suffolk County, on offshore islands, and within the viewshed of the proposed Project components. Within the recreation/tourism geographic analysis area, there are 864 communications towers, 10 of which exceed the Federal Aviation Administration height limit for marking/lighting requirements (Federal Aviation Administration 2016). • The East Hampton Town Board is replacing its aging 800-megahertz frequency emergency communication system tower to a 700-megahertz system with updated equipment. This will require the replacement of a 150-foot communication tower with a 300-foot lattice tower and the raising of a 55-foot monopole to 85 feet. This upgrade also requires replacing antennas at towers near the East Hampton Airport in Wainscott, at the Amagansett firehouse, and at the East Hampton Town Hall complex (Chinese 2018).
Development projects	• As a part of New York State’s $100 billion infrastructure project, $5.6 billion will go to transform the Long Island Railroad (LIRR) to improve system connectivity. Within Suffolk County, the following stations will receive funds for upgrades: Brentwood, Deer Park, East Hampton, Northport, Ronkonkoma, Stony Brook, Port Jefferson, and Wyandanch. The East Hampton historic LIRR station will undergo upgrades and modernizations (Metropolitan Transit Authority 2017; Governor’s Office 2017b). Additional plans for transit-oriented design (TOD) and highway improvements are planned in Suffolk County in state and county planning documents. • Fire Island Inlet to Montauk Point (FIMP) Project is a $1.2 billion project by the USACE, NYDEC, and Long Island, NY municipalities to engage in inlet management; beach, dune and berm construction; breach response plans; raising and retrofitting 4,400 homes; road-raising; groin modifications; and coastal process features. Within Suffolk County, portions of the Towns of Babylon, Islip, Brookhaven, Southampton, and East Hampton; 12 incorporated villages along Long Island’s south shore (mainland); Fire Island National Seashore; and the Poospatuck and Shinnecock Indian Reservations will be involved in this project (USACE 2018f). • The USACE is working to remediate and cleanup a former defense site (former NIKE Battery PR-58 and Disaster Village Training Area) at Quonset Development Corporation in North Kingstown, RI. A feasibility study was performed from 2014 to 2016, and the final remedial investigation/feasibility study was published in 2016. Pre-design investigations, followed by remedial designs and engineering plans, and remedial action is proposed for 2021 (USACE 2018g). • The Massachusetts Department of Environmental Protection Bureau of Air and Waste approved National Grid’s application for the construction and operation of a diesel generator and a battery electric storage system at an existing electric generating facility located at 32 Bunker Road in Nantucket, approximately 1 mile north of the coastline. The facilities are anticipated to be operational in 2019 (MassDEP 2017; Utility Dive 2018).

Type	Description

Port studies/upgrades	The USACE completed the Lake Montauk Harbor Feasibility Study in 2020. The study determined that Lake Montauk Harbor has insufficient channel and depth to support commercial fishing fleet activities. The study evaluated a range of alternative navigation improvement plans; the recommended plan consisted of deepening the existing navigation channel to -17 feet MLLW depth, creating a deposition basin immediately east of the channel at a width of 100 feet, and placing dredged material on the shoreline west of the inlet for a distance of 3,000 feet and a width of approximately 44 feet.
	Ports in New York, Connecticut, Rhode Island, and Massachusetts may require upgrades to support the offshore wind industry developing in the northeastern United States. Upgrades may include onshore developments or underwater improvements (such as dredging).
	• In December 2017, NYSERDA issued an offshore wind master plan that assessed 54 distinct waterfront sites along the New York Harbor and Hudson River and 11 distinct areas with multiple small sites along the Long Island coast. Twelve waterfront areas and five distinct areas were singled out for “potential to be used or developed into facilities capable of supporting OSW projects” (Table 26; NYSERDA 2017b). Nearly all identified sites would require some level of infrastructure upgrade (from minimal to significant) depending on OSW activities intended for the site. Particular sites of interest include Red Hook-Brooklyn, South Brooklyn Marine Terminal, and the Port of Coeymans (NYSERDA 2017b). For additional information regarding specific proposed improvements to these ports, see DockNYC 2018, Capital Region Economic Development Council 2018, American Association of Port Authorities 2016, Rulison 2018, and NYCEDC 2018.
	• The Connecticut Port Authority is currently evaluating proposals from parties to develop, finance, and manage the Connecticut State Pier in New London under a long-term operating agreement (Connecticut Port Authority 2018a). According to the Connecticut Maritime Strategy 2018 (Connecticut Port Authority 2018b), New London is the only major port between New York and Maine that does not have vertical obstruction and offshore barriers, two factors that are critical for offshore wind turbine assembly. The document includes strategic objectives to manage and redevelop the Connecticut State Pier partially to support the offshore wind industry, which could create a dramatic increase in demand for the Connecticut State Pier and regional job growth. Redevelopment of the State Pier is considered a reasonably foreseeable activity, though specific redevelopment plans are not yet available.
	• In Rhode Island, DWW has committed to investing approximately $40 million in improvements at the Port of Providence, the Port of Davisville at Quonset Point, and possibly other Rhode Island ports for the Revolution Wind Project (Kuffner 2018). The Port of Davisville has added a 150-megaton mobile harbor crane, which will enable the port to handle wind turbines and heavy equipment, and enables the Port of Davisville to participate in regional offshore wind projects (Port of Davisville 2017). Further improvements at Rhode Island ports to support the offshore wind industry are considered reasonably foreseeable.
	• The Massachusetts Clean Energy Center (MassCEC) has identified 18 waterfront sites in Massachusetts that may be available and suitable for use by the offshore wind industry. Potential activities at these sites include manufacturing of offshore wind transmission cables, manufacture and assembly of turbine components, substation manufacturing and assembly, O&M bases, and storage of turbine components (MassCEC 2017a, 2017b). The Draft New Bedford Port Authority Strategic Plan 2018 – 2023 contains goals related to expanding the New Bedford Marine Commerce Terminal to improve and expand services to the offshore wind industry (Port of New Bedford 2018; MassCEC 2018), but no new improvements were identified.
	• New York State proposed port improvements include the governor's 2021 agenda—Reimagine | Rebuild | Renew—which includes upgrades to create five dedicated port facilities for offshore wind, including the following:
	  ○ The nation's first offshore wind tower manufacturing facility, to be built at the Port of Albany
	  ○ An offshore wind turbine staging facility and O&M hub to be established at the South Brooklyn Marine Terminal
	  ○ Increasing the use of the Port of Coeymans for cutting-edge turbine foundation manufacturing
	  ○ Buttressing ongoing O&M out of Port Jefferson and Port of Montauk Harbor in Long Island

Ongoing and Future Non-Offshore Wind Activity Analysis (Part 1)

This page intentionally left blank.

BOEM developed the following tables based on their 2019 study *National Environmental Policy Act Documentation for Impact-Producing Factors in the Offshore Wind Cumulative Impacts Scenario on the North Atlantic Outer Continental Shelf* (BOEM 2019), which evaluates potential impacts associated with ongoing and future non-offshore wind activities. The content of these tables has been vetted and approved by cooperating agencies to the SFWF EIS and therefore has been included in whole for their use in impact and cumulative analyses, and for ease in reference by the reader.

Table E2-1. Summary of Activities and the Associated Impact-Producing Factors for Air Quality

Associated IPFs: Sub-IPFs	**Ongoing Activities**	**Future Non-Offshore Wind Activities Intensity/Extent**
Accidental releases: Fuel/fluids/ hazmat	Accidental releases of air toxics HAPS are due to potential chemical spills. Ongoing releases occur in low frequencies. These may lead to short-term periods of toxic pollutant emissions through surface evaporation. According to the U.S. Department of Energy, 31,000 barrels of petroleum are spilled into U.S. waters from vessels and pipelines in a typical year. Approximately 40.5 million barrels of oil were lost as a result of tanker incidents from 1970 to 2009, according to International Tanker Owners Pollution Federation Limited, which collects data on oil spills from tankers and other sources. From 1990 to1999, the average annual input to the coastal Northeast was 220,000 barrels of petroleum and offshore it was up to less than 70,000 barrels.	Accidental releases of air toxics or HAPS will be due to potential chemical spills. See Table E2-2 for a quantitative analysis of these risks. Gradually increasing vessel traffic over the next 30 years would increase the risk of accidental releases. These may lead to short-term periods of toxic pollutant emissions through evaporation. Air quality impacts will be short-term and limited to the local area at and around the accidental release location.
Air emissions: Construction and decommissioning	Air emissions originate from combustion engines and electric power generated by burning fuel. These activities are regulated under the CAA to meet set standards. Air quality has generally improved over the last 30 years; however, some areas in the Northeast have experienced a decline in air quality over the last 2 years. Some areas of the Atlantic coast remain in nonattainment for ozone, with the source of this pollution from power generation. Many of these states have made commitments toward cleaner energy goals to improve this, and offshore wind is part of these goals. Primary processes and activities that can affect the air quality impacts are expansions and modifications to existing fossil fuel power plants, onshore and offshore activities involving renewable energy facilities, and various construction activities.	The largest air quality impacts over the next 30 years will occur during the construction phase of any one project; however, projects will be required to comply with the CAA. During the limited construction and decommissioning phases, emissions may occur that are above *de minimis* thresholds and will require offsets and mitigation. Primary emission sources will be increased commercial vehicular traffic, air traffic, public vehicular traffic, and combustion emissions from construction equipment and fugitive emissions from construction-generated dust. As projects come online, power generation emissions overall will decline and the industry as a whole will have a net benefit on air quality.
Air emissions: O&M		Activities associated with operation and maintenance of onshore wind projects will have a proportionally very small contribution to emissions compared to the construction and decommissioning activities over the next 30 years. Emissions will largely be due to commercial vehicular traffic and operation of emergency diesel generators. Such activity will result in short-term, intermittent, and widely dispersed emissions and small air quality impacts.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Air emissions: Power generation emissions reductions		Many Atlantic states have committed to clean energy goals, with offshore wind being a large part of that. Other reductions include transitioning to onshore wind and solar. The No Action Alternative without implementation of other future offshore wind projects would likely result in increased air quality impacts regionally due to the need to construct and operate new energy generation facilities to meet future power demands. These facilities may consist of new natural-gas-fired power plants, coal-fired, oil-fired, or clean-coal-fired plants. These types of facilities would likely have larger and continuous emissions and result in greater regional scale impacts on air quality.
Climate change	The construction, operation, and decommissioning of offshore wind projects would produce GHG emissions (nearly all CO_2) that can contribute to climate change; however, these contributions would be minuscule compared to aggregate global emissions. CO_2 is relatively stable in the atmosphere and generally mixed uniformly throughout the troposphere and stratosphere. Hence the impact of GHG emissions does not depend upon the source location. Increasing energy production from offshore wind projects will likely decrease GHGs emissions by replacing energy from fossil fuels.	Development of future onshore wind projects will produce a small overall increase in GHG emissions over the next 30 years. However, these contributions would be very small compared to the aggregate global emissions. The impact on climate change from these activities would be very small. As more projects come online, some reduction in GHG emissions from modifications of existing fossil fuel facilities to reduce power generation. Overall, it is anticipated that there would be no cumulative impact on global warming as a result of onshore wind project activities.

Notes: % = percent; BOEM = Bureau of Ocean Energy Management; CAA = Clean Air Act; CO = carbon monoxide; draft EIS = draft environmental impact statement; EIS = environmental impact statement; GHG = greenhouse gas; HAP = hazardous air pollutant; IPF = impact producing factor; NAAQS = National Ambient Air Quality Standards; NO2 = nitrogen dioxide ; NOx = nitrogen oxides; O&M = operations and maintenance; PM2.5 = particulate matter with diameters 2.5 microns or smaller; PM10 = particulate matter with diameters 10 microns or smaller; ppb = parts per billion; SO2 = sulfur dioxide; USC = United States Code; USEPA = U.S. Environmental Protection Agency; VOC = volatile organic compounds.

Table E2-2. Summary of Activities and the Associated Impact-Producing Factors for Water Quality

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Accidental releases: Fuel/fluids/ hazmat	Accidental releases of fuels and fluids occur during vessel usage for dredge material ocean disposal, fisheries use, marine transportation, military use, survey activities, and submarine cable lines, and pipeline laying activities. According to the DOE, 31,000 barrels of petroleum are spilled into U.S. waters from vessels and pipelines in a typical year. Approximately 40.5 million barrels of oil were lost as a result of tanker incidents from 1970 to 2009, according to International Tanker Owners Pollution Federation Limited, which collects data on oil spills from tankers and other sources. From 1990 to 1999, the average annual input to the coastal Northeast was 220,000 barrels of petroleum and into the offshore was < 70,000 barrels. Impacts on water quality would be expected to brief and localized from accidental releases.	Future accidental releases from offshore vessel usage, spills, and consumption will likely continue on a similar trend. Impacts are unlikely to affect water quality.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Accidental releases: Trash and debris	Trash and debris may be accidentally discharged through fisheries use, dredged material ocean disposal, marine minerals extraction, marine transportation, navigation and traffic, survey activities, and cables, lines, and pipeline laying. Accidental releases of trash and debris are expected to be low probability events. BOEM assumes operator compliance with federal and international requirements for management of shipboard trash; such events also have a relatively limited spatial impact.	As population and vessel traffic increase gradually over the next 30 years, accidental release of trash and debris may increase. However, there does not appear to be evidence that the volumes and extents anticipated would have any effect on water quality.
Anchoring	Impacts from anchoring occur due to ongoing military use and survey, commercial, and recreational activities.	Impacts from anchoring may occur semi-regularly over the next 30 years due to offshore military operations or survey activities. These impacts would include increased seabed disturbance resulting in increased turbidity levels. All impacts would be localized, short-term, and temporary.
New cable emplacement/ maintenance	Elevated suspended sediment concentrations can occur under natural tidal conditions and increase during storms, trawling, and vessel propulsion. Survey activities, and new cable and pipeline laying activities disturb bottom sediments and cause temporary increases in suspended sediment; these disturbances would be short-term and either be limited to the emplacement corridor or localized.	Suspension of sediments may continue to occur infrequently over the next 30 years due to survey activities, and submarine cable, lines, and pipeline-laying activities. Future new cables would occasionally disturb the seafloor and cause short-term increases in turbidity and minor alterations in localized currents resulting in local short-term impacts. The FCC has two pending submarine tele-communication cable applications in the North Atlantic. If the cable routes enter the water quality geographic analysis area, short-term disturbance in the form of increased suspended sediment and turbidity would be expected.
Port utilization: Expansion	Between 1992 and 2012, global shipping traffic increased fourfold (Tournadre 2014). The U.S. OCS is no exception to this trend, and growth is expected to continue as human population increases. In addition, the general trend along the coastal region from Virginia to Maine is that port activity will increase modestly. The ability of ports to receive the increase in larger ships will require port modifications, which, along with additional vessel traffic, could have impacts on water quality through increases in suspended sediments and the potential for accidental discharges. The increased sediment suspension could be long-term depending on the vessel traffic increase. Certain types of vessel traffic have increased recently (e.g., ferry use and cruise industry) and may continue to increase in the foreseeable future.	The general trend along the coastal region from Virginia to Maine is that port activity will increase modestly over the next 30 years. Port modifications and channel deepening activities are being undertaken to accommodate the increase in vessel traffic and deeper draft vessels that transit the Panama Canal Locks. The additional traffic and larger vessels could have impacts on water quality through increases in suspended sediments and the potential for accidental discharges. Certain types of vessel traffic have increased recently (e.g., ferry use and cruise industry) and may continue to increase in the foreseeable future.
Presence of structures	The installation of onshore and offshore structures leads to alteration of local water currents. These disturbances would be local but, depending on the hydrologic conditions, have the potential to impact water quality through the formation of sediment plumes.	Impacts associated with the presence of structures includes temporary sediment disturbance during maintenance. This sediment suspension would lead to interim and localized impacts.
Discharges	Discharges impact water quality by introducing nutrients, chemicals, and sediments to the water. There are regulatory requirements related to prevention and control of discharges, the prevention and control of accidental spills, and the prevention and control of nonindigenous species.	Increased coastal development is causing increased nutrient pollution in communities. In addition, ocean disposal activity in the North and Mid-Atlantic is expected to gradually decrease or remain stable. Impacts of ocean disposal on water quality are minimized because USEPA has established dredge spoil criteria and regulate the disposal permits issued by USACE. The impact on water quality from sediment suspension during these future activities would be short-term and localized.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Land disturbance: erosion and sedimentation	Ground disturbance activities may lead to un-vegetated or otherwise unstable soils. Precipitation events could mobilize the soils into nearby surface waters, leading to potential erosion and sedimentation effects and subsequent increased turbidity.	Ground disturbance associated with construction and installation of onshore components could lead to un-vegetated or unstable soils. Precipitation events could mobilize these soils leading to erosion and sedimentation effects and turbidity. The impacts for future offshore wind through this IPF would be staggered in time and localized. The impacts would be short term and localized with an increased likelihood of impacts limited to onshore construction periods.
Land disturbance: Onshore construction	Onshore construction activities may lead to un-vegetated or otherwise unstable soils as well as soil contamination due to leaks or spills from construction equipment. Precipitation events could mobilize the soils into nearby surface waters, leading to increased turbidity and alteration of water quality.	The general trend along coastal regions is that port activity will increase modestly in the future. This increase in activity includes expansion needed to meet commercial, industrial, and recreational demand. Modifications to cargo handling equipment and conversion of some undeveloped land to meet port demand would be required to receive the increase in larger ships.

Notes: BOEM = Bureau of Ocean Energy Management; DO = dissolved oxygen; DOE = U.S. Department of Energy; EIS = Environmental Impact Statement; ESP = electrical service platform; FCC = Federal Communications Commission; gal = gallon; IPF = impact-producing factors; NASA = National Aeronautics and Space Administration; OCS = Outer Continental Shelf; OECC = Offshore Export Cable Corridor; USACE = U.S. Army Corps of Engineers; USCG = U.S. Coast Guard; USEPA = Environmental Protection Agency; WDA = Wind Development Area; WTG = wind turbine generator.

Table E2-3. Summary of Activities and the Associated Impact-Producing Factors for Birds

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Accidental releases: Fuel/fluids/ hazmat	See Table E2-2 for a quantitative analysis of these risks. Ongoing releases are frequent/chronic. Ingestion of hydrocarbons can lead to morbidity and mortality due to decreased hematological function, dehydration, drowning, hypothermia, starvation, and weight loss (Briggs et al. 1997, Haney et al. 2017, Paruk et al. 2016). Additionally, even small exposures that result in feather oiling can lead to sublethal effects that include changes in flight efficiencies and result in increased energy expenditure during daily and seasonal activities including chick provisioning, commuting, courtship, foraging, long-distance migration, predator evasion, and territory defense (Maggini et al. 2017). These impacts rarely result in population-level impacts.	See Table E2-2 for a quantitative analysis of these risks. Gradually increasing vessel traffic over the next 30 years would increase the potential risk of accidental releases and associated impacts, including mortality, decreased fitness, and health effects on individuals. Impacts are unlikely to affect populations.
Accidental releases: Trash and debris	Trash and debris are accidentally discharged through onshore sources; fisheries use; dredged material ocean disposal; marine minerals extraction; marine transportation, navigation, and traffic; survey activities; and cables, lines, and pipeline laying on an ongoing basis. In a study from 2010, students at sea collected more than 520,000 bits of plastic debris per square mile. In addition, many fragments come from consumer products blown out of landfills or tossed out as litter. (Law et al. 2010). Birds may accidentally ingest trash mistaken for prey. Mortality is typically a result of blockages caused by both hard and soft plastic debris (Roman et al. 2019).	As population and vessel traffic increase gradually over the next 30 years, accidental release of trash and debris may increase. This may result in increased injury or mortality of individuals. However, there does not appear to be evidence that the volumes and extents would have any impact on bird populations.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Light: Vessels	Ocean vessels have an array of lights including navigational lights, deck lights, and interior lights. Such lights can attract some birds. The impact is localized and temporary. This attraction would not be expected to result in an increased risk of collision with vessels. Population-level impacts would not be expected.	Gradually increasing vessel traffic over the next 30 years would increase the potential for bird and vessel interactions. While birds may be attracted to vessel lights, this attraction would not be expected to result in increased risk of collision with vessels. No population-level impacts would be expected.
Light: Structures	Buoys, towers, and onshore structures with lights can attract birds. Onshore structures like houses and ports emit a great deal more light than offshore buoys and towers. This attraction has the potential to result in an increased risk of collision with lighted structures (Huppop et al. 2006). Light from structures is widespread and permanent near the coast, but minimal offshore.	Light from onshore structures is expected to gradually increase in proportion with human population growth along the coast. This increase is expected to be widespread and permanent near the coast, but minimal offshore.
New cable emplacement/ maintenance	Cable emplacement and maintenance activities disturb bottom sediments and cause temporary increases in suspended sediment; these disturbances will be temporary and generally limited to the emplacement corridor. Infrequent cable maintenance activities disturb the seafloor and cause temporary increases in suspended sediment; these disturbances will be temporary and limited to the emplacement corridor. Suspended sediment could impair the vision of diving birds that are foraging in the water column (Cook and Burton 2010). However, given the localized nature of the potential impacts, individuals would be expected to successfully forage in nearby areas not affected by increased sedimentation and no biologically significant impacts on individuals or populations would be expected.	Future new cables, would occasionally disturb the seafloor and cause temporary increases in suspended sediment, resulting in localized, short-term impacts. The FCC has two pending submarine telecommunications cable applications in the North Atlantic. Impacts would be temporary and localized, with no biologically significant impacts on individuals or populations.
Noise: Aircraft	Aircraft routinely travel in the geographic analysis area for birds. With the possible exception of rescue operations and survey aircraft, no ongoing aircraft flights would occur at altitudes that would elicit a response from birds. If flights are at a sufficiently low altitude, birds may flush, resulting in non-biologically significant increased energy expenditure. Disturbance, if any, would be localized and temporary and impacts would be expected to dissipate once the aircraft has left the area.	Aircraft noise is likely to continue to increase as commercial air traffic increases; however, very few flights would be expected to be at a sufficiently low altitude to elicit a response from birds. If flights are at a sufficiently low altitude, birds may flush, resulting in non-biologically significant increased energy expenditure. Disturbance, if any, would be localized and temporary and impacts would be expected to dissipate once the aircraft has left the area.
Noise: G&G	Infrequent site characterization surveys and scientific surveys produce high-intensity impulsive noise around sites of investigation. These activities could result in diving birds leaving the local area. Non-diving birds would be unaffected. Any displacement would only be temporary during non-migratory periods, but impacts could be greater if displacement were to occur in preferred feeding areas during seasonal migration periods.	Same as ongoing activities, with the addition of possible future oil and gas surveys.
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water could result in intermittent, temporary, localized impacts on diving birds due to displacement from foraging areas if birds are present in the vicinity of pile-driving activity. The extent of these impacts depends on pile size, hammer energy, and local acoustic conditions. No biologically significant impacts on individuals or populations would be expected.	No future activities were identified within the geographic analysis area for birds other than ongoing activities.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Noise: Onshore construction	Onshore construction is routinely used in generic infrastructure projects. Equipment could cause displacement. Any displacement would only be temporary and no individual fitness or population-level impacts would be expected.	Onshore construction will continue at current trends. Some behavior responses could range from escape behavior to mild annoyance, but no individual injury or mortality would be expected.
Noise: Vessels	Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. Sub-surface noise from vessels could disturb diving birds foraging for prey below the surface. The consequence to birds would be similar to noise from G&G but likely less because noise levels are lower.	No future activities were identified within the geographic analysis area for birds other than ongoing activities.
Presence of structures: Entanglement, gear loss, gear damage	Each year, 2,551 seabirds die annually from interactions with U.S. commercial fisheries on the Atlantic (Sigourney et al. 2019). Even more die due to abandoned commercial fishing gear (nets). In addition, recreational fishing gear (hooks and lines) is periodically lost on existing buoys, pilings, hard protection, and other structures and has the potential to entangle birds.	No future activities were identified within the geographic analysis area for birds other than ongoing activities.
Presence of structures: Fish aggregation	Structures, including tower foundations, scour protection around foundations, and various hard protections atop cables create uncommon relief in a mostly flat seascape. Structure-oriented fishes are attracted to these objects. These impacts are local and can be short-term to permanent. These fish aggregations can provide localized, short-term to permanent, beneficial impacts to some bird species because it could increase prey species availability.	New cables, installed incrementally in the geographic analysis area for birds over the next 20 to 30 years, would likely require hard protection atop portions of the cables (see New cable emplacement/maintenance row). Any new towers, buoys, or piers would also create uncommon relief in a mostly flat seascape. Structure-oriented fishes could be attracted to these locations. Abundance of certain fishes may increase. These impacts are expected to be local and may be short-term to permanent. These fish aggregations can provide localized, short-term to permanent beneficial impacts on some bird species due to increased prey species availability.
Presence of structures: Migration disturbances	A few structures may be scattered about the offshore geographic analysis area for birds, such as navigation and weather buoys and light towers (NOAA 2020). Migrating birds can easily fly around or over these sparsely distributed structures.	The infrequent installation of future new structures in the marine or onshore environment over the next 30 years would not be expected to result in migration disturbances.
Presence of structures: Turbine strikes, displacement, and attraction	A few structures may be in the offshore geographic analysis area for birds, such as navigation and weather buoys, turbines, and light towers (NOAA 2020). Given the limited number of structures currently in the geographic analysis area, individual- and population-level impacts due to displacement from current foraging habitat would not be expected. Stationary structures in the offshore environment would not be expected to pose a collision risk to birds. Some birds like cormorants and gulls may be attracted to these structures and opportunistically roost on these structures.	The installation of future new structures in the marine or onshore environment over the next 30 years would not be expected to result in an increase in collision risk or to result in displacement. Some potential for attraction and opportunistic roosting exists, but would be expected to be limited given the anticipated number of structures.
Traffic: Aircraft	General aviation accounts for approximately two bird strikes per 100,000 flights (Dolbeer et al. 2019). Additionally, aircraft are used for scientific and academic surveys in marine environments.	Bird fatalities associated with general aviation would be expected to increase with the current trend in commercial air travel. Aircraft will continue to be used to conduct scientific research studies as well as wildlife monitoring and pre-construction surveys. These flights would be well below the 100,000 flights and no bird strikes would be expected to occur.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Land disturbance: Onshore construction	Onshore construction activity will continue at current trends. There is some potential for indirect impacts associated with habitat loss and fragmentation.	Future non-offshore wind development would continue to occur at the current rate. This development has the potential to result in habitat loss, but would not be expected to result in injury or mortality of individuals.
Climate change: Warming and sea level rise, storm severity/frequency	Increased storm frequency and severity during the breeding season can reduce productivity of bird nesting colonies and kill adults, eggs, and chicks.	No future activities were identified within the geographic analysis area for birds other than ongoing activities.
Climate change: Ocean acidification	Increasing ocean acidification may affect prey species upon which some birds feed and could lead to shifts in prey distribution and abundance. Intensity of impacts on birds is speculative.	No future activities were identified within the geographic analysis area for birds other than ongoing activities.
Climate change: Warming and sea level rise, altered habitat/ecology	Climate change, influenced in part by GHG emissions, is expected to continue to contribute to a gradual warming of ocean waters over the next 30 years, influencing the distribution of bird prey resources.	No future activities were identified within the geographic analysis area for birds other than ongoing activities.
Climate change: Warming and sea level rise, altered migration patterns	Birds rely on cues from the weather to start migration. Wind direction and speed influence the amount of energy used during migration. For nocturnal migrants, wind assistance is projected to increase across eastern portions of the continent (0.32 m/s; 9.6%) during spring migration by 2091, and wind assistance is projected to decrease within eastern portions of the continent (0.17 m/s; 6.6%) during autumn migration (La Sorte et al. 2018).	No future activities were identified within the geographic analysis area for birds other than ongoing activities.
Climate change: Warming and sea level rise, property/ infrastructure damage	This sub-IPF would have no impacts on birds.	No future activities were identified within the geographic analysis area for birds other than ongoing activities.
Climate change: Warming and sea level rise, protective measures (barriers, seawalls)	The proliferation of coastline protections have the potential to result in long-term, high-consequence, impacts on bird nesting habitat.	No future activities were identified within the geographic analysis area for birds other than ongoing activities.
Climate change: Warming and sea level rise, increased disease frequency	Climate change, influenced in part by GHG emissions, is expected to continue to contribute to a gradual warming of ocean waters over the next 30 years, influencing the frequencies and distributions of various diseases of birds.	No future activities were identified within the geographic analysis area for birds other than ongoing activities.

Notes: ADLS = Aircraft Detection Light System; BMP = best management practice; BOEM = Bureau of Ocean Energy Management; EIS = environmental impact statement; ESP = electrical service platform; FAA = Federal Aviation Administration; FCC = Federal Communications Commission; G&G = Geological and Geophysical; GHG = greenhouse gas; IPF = impact-producing factors; m/s = meter per second; NOAA = National Oceanic and Atmospheric Administration; OCS = outer continental shelf; ROW = right-of-way; USCG = U.S. Coast Guard; WDA = wind development area; WTG = wind turbine generator.

Table E2-4. Summary of Activities and the Associated Impact-Producing Factors for Bats

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded and would result in high-intensity, low-exposure level, long-term, but localized intermittent risk to bats in nearshore waters. Direct impacts are not expected to occur as recent research has shown that bats may be less sensitive to temporary threshold shifts than other terrestrial mammals (Simmons et al. 2016). Indirect impacts (i.e., displacement from potentially suitable habitats) could occur as a result of construction activities, which could generate noise sufficient to cause avoidance behavior (Schaub et al. 2008). Construction activity would be temporary and highly localized.	Similar to ongoing activities, noise associated with pile driving activities would be limited to nearshore waters, and these high-intensity, but low-exposure risks would not be expected to result in direct impacts. Some indirect impacts (i.e., displacement from potentially suitable foraging habitats) could occur as a result of construction activities, which could generate noise sufficient to cause avoidance behavior (Schaub et al. 2008). Construction activity would be temporary and highly localized and no population-level effects would be expected.
Noise: Construction	Onshore construction occurs regularly for generic infrastructure projects in the bats geographic analysis area. There is a potential for displacement caused by equipment if construction occurs at night (Schaub et al. 2008). Any displacement would only be temporary. No individual or population level impacts would be expected. Some bats roosting in the vicinity of construction activities may be disturbed during construction, but would be expected to move to a different roost farther from construction noise. This would not be expected to result in any impacts as frequent roost switching is a common component of a bat's life history (Hann et al. 2017; Whitaker 1998).	Onshore construction is expected to continue at current trends. Some behavioral responses and avoidance of construction areas may occur (Schaub et al. 2008). However, no injury or mortality would be expected.
Presence of structures: Migration disturbances	There may be few structures scattered throughout the offshore bats geographic analysis area, such as navigation and weather buoys and light towers (NOAA 2020). Migrating bats can easily fly around or over these sparsely distributed structures, and no migration disturbance would be expected. Bat use of offshore areas is very limited and generally restricted to spring and fall migration. Very few bats would be expected to encounter structures on the OCS and no population-level effects would be expected.	The infrequent installation of future new structures in the marine environment of the next 30 years is expected to continue. As described under Ongoing Activities, These structures would not be expected to cause disturbance to migrating tree bats in the marine environment.
Presence of structures: Turbine strikes	There may be few structures in the offshore bats geographic analysis area, such as navigation and weather buoys, turbines, and light towers (NOAA 2020). Migrating tree bats can easily fly around or over these sparsely distributed structures, and no strikes would be expected.	The infrequent installation of future new structures in the marine environment of the next 30 years is expected to continue. As described under Ongoing Activities, these structures would not be expected to result in increased collision risk to migrating tree bats in the marine environment.
Land disturbance: onshore construction	Onshore construction activities are expected to continue at current trends. Potential direct effects on individuals may occur if construction activities include tree removal when bats are potentially present. Injury or mortality may occur if trees being removed are occupied by bats at the time of removal. While there is some potential for indirect impacts associated with habitat loss, no individual or population-level effects would be expected.	Future non-offshore wind development would continue to occur at the current rate. This development has the potential to result in habitat loss and could result in injury or mortality of individuals.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Climate change: Warming and sea level rise, storm severity/frequency	Storms during breeding and roosting season can reduce productivity and increase mortality. Intensity of this impact is speculative.	No future activities were identified within the bats geographic analysis area other than ongoing activities.
Climate change: Ocean acidification; Warming and sea level rise, altered habitat/ecology; Warming and sea level rise, altered migration patterns; Warming and sea level rise, property/ infrastructure damage; Warming and sea level rise, protective measures (barriers, sea walls); Warming and sea level rise, storm severity/frequency, sediment erosion, deposition	These sub-IPFs would have no impacts on bats.	No future activities were identified within the bats geographic analysis area other than ongoing activities.
Climate change: Warming and sea level rise, increased disease frequency	Disease can weaken, lower reproductive output, and/or kill individuals. Some tropical diseases will move northward. Extent and intensity of this impact is highly speculative.	No future activities were identified within the bats geographic analysis area other than ongoing activities.

Notes: EIS = Environmental Impact Statement; ESP = electrical service platform; IPF = impact-producing factors; NOAA = National Oceanic and Atmospheric Administration; OCS = outer continental shelf; ROW = right-of-way; WTG = wind turbine generator.

ATTACHMENT 3

Ongoing and Future Non-Offshore Wind Activity Analysis (Part 2)

This page intentionally left blank.

BOEM developed the following tables based on their 2019 study *National Environmental Policy Act Documentation for Impact-Producing Factors in the Offshore Wind Cumulative Impacts Scenario on the North Atlantic Outer Continental Shelf* (BOEM 2019), which evaluates potential impacts associated with ongoing and future non-offshore wind activities. The content of these tables has been vetted by cooperating agencies to the SFWF EIS and therefore has been included in whole for their use in impact and cumulative analyses, and for ease in reference by the reader.

Table E3-1. Summary of Activities and the Associated Impact-Producing Factors for Terrestrial and Coastal Fauna

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Land disturbance: Erosion and sedimentation	Periodic ground-disturbing activities contribute to elevated levels of erosion and sedimentation, but usually not to a degree that affects terrestrial and coastal fauna, assuming that industry standard BMPs are implemented.	No future activities were identified within the geographic analysis area other than ongoing activities.
Land disturbance: Onshore construction	Periodic clearing of shrubs and tree saplings along existing utility ROWs causes disturbance and temporary displacement of mobile species and may cause direct injury or mortality of less-mobile species, resulting in short-term impacts that are less than noticeable. Continual development of residential, commercial, industrial, solar, transmission, gas pipeline, onshore wind turbine, and cell tower projects also causes disturbance, displacement, and potential injury and/or mortality of fauna, resulting in small temporary impacts.	No future activities were identified within the geographic analysis area other than ongoing activities.
Land disturbance: Onshore, land use changes	Periodically, undeveloped parcels are cleared and developed for human uses, permanently changing the condition of those parcels as habitat for terrestrial fauna. Continual development of residential, commercial, industrial, solar, transmission, gas pipeline, onshore wind turbine, transportation infrastructure, sewer infrastructure, and cell tower projects could permanently convert various areas.	No future activities were identified within the geographic analysis area other than ongoing activities.
Climate change: Warming and sea level rise, altered habitat/ecology	Climate change, influenced in part by greenhouse gas emissions, is altering the seasonal timing and patterns of species distributions and ecological relationships, likely causing permanent changes of unknown intensity gradually over the next 30 years.	No future activities were identified within the geographic analysis area other than ongoing activities.

Notes: BMPs = best management practices; BOEM = Bureau of Ocean Energy Management; IPF = impact-producing factors; ROW = right-of-way; WMA = wildlife management area.

Table E3-2. Summary of Activities and the Associated Impact-Producing Factors for Coastal Habitats

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Accidental releases: Fuel/fluids/ hazmat	See Table E2-2 for a discussion of ongoing accidental releases. Accidental releases of fuel/fluids/hazmat have the potential to cause habitat contamination and harm to the species that build biogenic coastal habitats (e.g., eelgrass, oysters, mussels, slipper limpets, salt marsh cordgrass) from releases and/or cleanup activities. Only a portion of the ongoing releases contact coastal habitats in the geographic analysis area. Impacts are small, localized, and temporary.	See Attachment 2 for a discussion of accidental releases.
Accidental releases: Trash and debris	Ongoing releases of trash and debris occur from onshore sources, fisheries use, dredged material ocean disposal, marine minerals extraction, marine transportation, navigation and traffic, survey activities and cables, lines and pipeline laying. As population and vessel traffic increase, accidental releases of trash and debris may increase. Such materials may be obvious when they come to rest on shorelines; however, there does not appear to be evidence that the volumes and extents would have any detectable impact on coastal habitats.	No future activities were identified within the geographic analysis area for coastal habitats other than ongoing activities.
Anchoring	Vessel anchoring related to ongoing military, survey, commercial, and recreational activities will continue to cause temporary to permanent impacts in the immediate area where anchors and chains meet the seafloor. These impacts include increased turbidity levels and potential for direct contact to cause physical damage to coastal habitats. All impacts are localized; turbidity is short-term and temporary; physical damage can be permanent if it occurs in eelgrass beds or hard bottom.	No future activities were identified within the geographic analysis area for coastal habitats other than ongoing activities.
EMF	EMFs continuously emanate from existing telecommunication and electrical power transmission cables. New cables generating EMFs are infrequently installed in the analysis area. The extent of impacts is likely less than 50 feet from the cable, and the intensity of impacts on coastal habitats is likely undetectable.	No future activities were identified within the geographic analysis area for coastal habitats other than ongoing activities.
Light: Vessels	Navigation lights and deck lights on vessels would be a source of ongoing light. The extent of impacts is limited to the immediate vicinity of the lights, and the intensity of impacts on coastal habitats is likely undetectable.	Light is expected to continue to increase gradually with increasing vessel traffic over the next 30 years. The extent of impacts would likely be limited to the immediate vicinity of the lights, and the intensity of impacts on coastal habitats would likely be undetectable.
Light: Structures	Ongoing lights from navigational aids and other structures onshore and nearshore. The extent of impacts is likely limited to the immediate vicinity of the lights, and the intensity of impacts on coastal habitats is likely undetectable.	No future activities were identified within the geographic analysis area for coastal habitats other than ongoing activities.
New cable emplacement/ maintenance	Ongoing cable maintenance activities infrequently disturb bottom sediments; these disturbances are local and limited to the emplacement corridor (see the Sediment deposition and burial IPF).	No future activities were identified within the geographic analysis area other than ongoing activities.
Noise: Onshore/offshore construction	Ongoing noise from construction occurs frequently near shores of populated areas in New England and the mid-Atlantic, but infrequently offshore. Noise from construction near shore is expected to gradually increase over the next 30 years in line with human population growth along the coast of the geographic analysis area. The intensity and extent of noise from construction is difficult to generalize, but impacts are local and temporary.	No future activities were identified within the analysis area other than ongoing activities.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Noise: G&G	Site characterization surveys and scientific surveys are ongoing. The intensity and extent of the resulting impacts are difficult to generalize, but are local and temporary.	Site characterization surveys, scientific surveys, and exploratory oil and gas surveys are anticipated to occur infrequently over the next 30 years. Site characterization surveys typically use sub-bottom profiler technologies that generate less-intense sound waves similar to common deep-water echosounders. The intensity and extent of the resulting impacts are difficult to generalize, but are likely local and temporary.
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water and/or through the seabed can reach coastal habitats. The extent depends on pile size, hammer energy, and local acoustic conditions.	No future activities were identified within the analysis area other than ongoing activities.
Noise: Cable laying/trenching	Rare but ongoing trenching for pipeline and cable laying activities emits noise; cable burial via jet embedment also causes similar noise impacts. These disturbances are temporary, local, and extend only a short distance beyond the emplacement corridor. Impacts of trenching noise on coastal habitats are discountable compared to the impacts of the physical disturbance and sediment suspension.	New or expanded submarine cables and pipelines may occur in the geographic analysis area infrequently over the next 30 years. These disturbances would be temporary, local, and extend only a short distance beyond the emplacement corridor. Impacts of trenching noise on coastal habitats are discountable compared to the impacts of the physical disturbance and sediment suspension.
Presence of structures: Habitat conversion	Various structures, including pilings, piers, towers, riprap, buoys, and various means of hard protection, are periodically added to the seascape, creating uncommon relief in a mostly flat seascape and converting previously existing habitat (whether hard-bottom or soft-bottom) to a type of hard habitat, although it differs from the typical hard-bottom habitat in the analysis area, namely, coarse substrates in a sand matrix. The new habitat may or may not function similarly to hard-bottom habitat typical in the region (Kerckhof et al. 2019; HDR 2019). Soft bottom is the dominant habitat type on the OCS, and structures do not meaningfully reduce the amount of soft-bottom habitat available (Guida et al. 2017; Greene et al. 2010). Structures can also create an artificial reef effect, attracting a different community of organisms.	Any new cable or pipeline installed in the geographic analysis area would likely require hard protection atop portions of the route (see cells to the left). Such protection is anticipated to increase incrementally over the next 30 years. Where cables would be buried deeply enough that protection would not be used, presence of the cable would have no impact on coastal habitats.
Presence of structures: Transmission cable infrastructure	Various means of hard protection atop existing cables can create uncommon hard-bottom habitat. Where cables are buried deeply enough that protection is not used, presence of the cable has no impact on coastal habitats.	See above.
Land disturbance: Erosion and sedimentation	Ongoing development of onshore properties, especially shoreline parcels, periodically causes short-term erosion and sedimentation of coastal habitats.	No future activities were identified within the geographic analysis area other than ongoing activities.
Land disturbance: Onshore construction	Ongoing development of onshore properties, especially shoreline parcels, periodically causes short-term to permanent degradation of onshore coastal habitats.	No future activities were identified within the geographic analysis area other than ongoing activities.

Associated IPFs: Sub-IPFs	**Ongoing Activities**	**Future Non-Offshore Wind Activities Intensity/Extent**
Land disturbance: Onshore, land use changes	Ongoing development of onshore properties, especially shoreline parcels, periodically causes the conversion of onshore coastal habitats to developed space.	No future activities were identified within the geographic analysis area other than ongoing activities.
Seabed profile alterations	Ongoing sediment dredging for navigation purposes results in localized, short-term impacts on coastal habitats through this IPF. Dredging typically occurs only in sandy or silty habitats, which are abundant in the analysis area and are quick to recover from disturbance. Therefore, such impacts, while locally intense, have little effect on the general character of coastal habitats.	No future activities were identified within the geographic analysis area other than ongoing activities.
Sediment deposition and burial	Ongoing sediment dredging for navigation purposes results in fine sediment deposition within coastal habitats. Ongoing cable maintenance activities also infrequently disturb bottom sediments; these disturbances are local, limited to the emplacement corridor. No dredged material disposal sites were identified within the geographic analysis area.	No future activities were identified within the geographic analysis area other than ongoing activities.
Climate change: Ocean acidification	Ongoing CO_2 emissions causing ocean acidification may contribute to reduced growth or the decline of reefs and other habitats formed by shells.	No future activities were identified within the geographic analysis area other than ongoing activities.
Climate change: Warming and sea level rise, altered habitat/ecology	Climate change, influenced in part by ongoing greenhouse gas emissions, is expected to continue to contribute to a widespread loss of shoreline habitat from rising seas and erosion. In submerged habitats, warming is altering ecological relationships and the distributions of ecosystem engineer species, likely causing permanent changes of unknown intensity gradually over the next 3 years.	See above.

Notes: BOEM = Bureau of Ocean Energy Management; COP = Construction and Operations Plan; EIS = Environmental Impact Statement; EMF = electromagnetic field; G&G = Geological and Geophysical; IPF = impact-producing factors; OCS = Outer Continental Shelf; OECC = offshore export cable corridor; SSU = special, sensitive, and unique.

Table E3-3. Summary of Activities and the Associated Impact-Producing Factors for Benthic Resources

Associated IPFs: Sub-IFPs	**Ongoing Activities**	**Future Non-Offshore Wind Activities Intensity/Extent**
Accidental releases: Fuel/fluids/ hazmat	See Attachment 2/Table E2-2 for a discussion of ongoing accidental releases. Accidental releases of hazmat occur periodically, mostly consisting of fuels, lubricating oils, and other petroleum compounds. Because most of these materials tend to float in seawater, they rarely contact benthic resources. The chemicals with potential to sink or dissolve rapidly often dilute to non-toxic levels before they affect benthic resources. The corresponding impacts on benthic resources are rarely noticeable.	Gradually increasing vessel traffic over the next 30 years would increase the risk of accidental releases. See previous cell and Attachment 2/Table E2-2 on water quality for details.
Accidental releases: Invasive species	Invasive species are periodically released accidentally during ongoing activities, including the discharge of ballast water and bilge water from marine vessels. The impacts on benthic resources (e.g., competitive disadvantage, smothering) depend on many factors, but can be noticeable, widespread, and permanent.	No future activities were identified within the geographic analysis area other than ongoing activities.
Accidental releases: Trash and debris	Ongoing releases of trash and debris occurs from onshore sources, fisheries use, dredged material ocean disposal, marine minerals extraction, marine transportation, navigation and traffic, survey activities and cables, lines and pipeline laying. However, there does not appear to be evidence that ongoing releases have detectable impacts on benthic resources.	No future activities were identified within the geographic analysis area other than ongoing activities.

Associated IPFs: Sub-IFPs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Anchoring	Regular vessel anchoring related to ongoing military, survey, commercial, and recreational activities continues to cause temporary to permanent impacts in the immediate area where anchors and chains meet the seafloor. These impacts include increased turbidity levels and the potential for direct contact to cause injury and mortality of benthic resources, as well as physical damage to their habitats. All impacts are localized; turbidity is temporary; injury and mortality are recovered in the short term; and physical damage can be permanent if it occurs in eelgrass beds or hard bottom.	No future activities were identified within the geographic analysis area other than ongoing activities.
EMFs	EMFs continuously emanate from existing telecommunication and electrical power transmission cables. New cables generating EMFs are infrequently installed in the geographic analysis area. Some benthic species can detect EMFs, although EMFs do not appear to present a barrier to movement. The extent of impacts (behavioral changes) is likely less than 50 feet (15.2 meters) from the cable and the intensity of impacts on benthic resources is likely undetectable.	No future activities were identified within the geographic analysis area other than ongoing activities.
New cable emplacement/ maintenance	Cable maintenance activities infrequently disturb benthic resources and cause temporary increases in suspended sediment; these disturbances would be local and limited to the emplacement corridor. New cables are infrequently added near shore. Cable emplacement/maintenance activities injure and kill benthic resources, and result in temporary to long-term habitat alterations. The intensity of impacts depends on the time (season) and place (habitat type) where the activities occur. (See also the IPFs of Seabed profile alterations and Sediment deposition and burial.)	No future activities were identified within the geographic analysis area other than ongoing activities.
Noise: Onshore/offshore construction	See Table E3-4 on finfish, invertebrates, and EFH. Detectable impacts of construction noise on benthic resources rarely, if ever, overlap from multiple sources.	See Table E3-4 on finfish, invertebrates, and EFH. Detectable impacts of construction noise on benthic resources would rarely, if ever, overlap from multiple sources.
Noise: G&G	See Table E3-4 on finfish, invertebrates, and EFH. Detectable impacts of G&G noise on benthic resources rarely, if ever, overlap from multiple sources.	See Table E3-4 on finfish, invertebrates, and EFH. Detectable impacts of G&G noise on benthic resources would rarely, if ever, overlap from multiple sources.
Noise: O&M	See Table E3-4 on finfish, invertebrates, and EFH.	See Table E3-4 on finfish, invertebrates, and EFH.
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water and/or through the seabed can cause injury and/or mortality to benthic resources in a small area around each pile and can cause short-term stress and behavioral changes to individuals over a greater area. The extent depends on pile size, hammer energy, and local acoustic conditions.	No future activities were identified within the geographic analysis area other than ongoing activities.
Noise: Cable laying/trenching	Infrequent trenching activities for pipeline and cable laying, as well as other cable burial methods, emit noise. These disturbances are local, temporary, and extend only a short distance beyond the emplacement corridor. Impacts of this noise are typically less prominent than the impacts of the physical disturbance and sediment suspension.	New or expanded submarine cables and pipelines are likely to occur in the geographic analysis area. These disturbances would be infrequent over the next 30 years, local, temporary, and extend only a short distance beyond the emplacement corridor. Impacts of this noise are typically less prominent than the impacts of the physical disturbance and sediment suspension.

Associated IPFs: Sub-IFPs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Port utilization: Expansion	See Table E3-4 on finfish, invertebrates, and EFH.	See Table E3-4 on finfish, invertebrates, and EFH.
Presence of structures: Entanglement, gear loss, gear damage	Commercial and recreational fishing gear are periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures. The lost gear, moved by currents, can disturb, injure, or kill benthic resources, creating small, short-term, localized impacts.	Future new cables would present additional risk of gear loss, resulting in small, short-term, localized impacts (disturbance, injury).
Presence of structures: Hydrodynamic disturbance	See Table E3-4 on finfish, invertebrates, and EFH.	See E3-4 on finfish, invertebrates, and EFH.
Presence of structures: Fish aggregation	Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables continuously create uncommon relief in a mostly sandy seascape. Structure-oriented fishes are attracted to these locations. Increased predation upon benthic resources by structure-oriented fishes can adversely affect populations and communities of benthic resources. These impacts are local and permanent.	New cables installed in the geographic analysis area over the next 30 years would likely require hard protection atop portions of the route (see the "new cable emplacement/maintenance" row in this table). Any new towers, buoy, or piers would also create uncommon relief in a mostly flat, sandy seascape. Structure-oriented fishes could be attracted to these locations. Increased predation upon benthic resources by structure-oriented fishes could adversely affect populations and communities of benthic resources. These impacts are expected to be local and to be permanent as long as the structures remain.
Presence of structures: Habitat conversion	Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables continuously provide uncommon hard-bottom habitat. A large portion is homogeneous sandy seascape but there is some other hard and/or complex habitat. Benthic species dependent on hard-bottom habitat can benefit on a constant basis, although the new habitat can also be colonized by invasive species (e.g., certain tunicate species). Structures are periodically added, resulting in the conversion of existing soft-bottom and hard-bottom habitat to the new hard-structure habitat.	See above for quantification and timing. Any new towers, buoy, piers, or cable protection structures would create uncommon relief in a mostly sandy seascape. Benthic species dependent on hard-bottom habitat could benefit, although the new habitat could also be colonized by invasive species (e.g., certain tunicate species). Soft bottom is the dominant habitat type in the region, and species that rely on this habitat would not likely experience population-level impacts (Guida et al. 2017; Greene et al. 2010).
Presence of structures: Transmission cable infrastructure	The presence of transmission cable infrastructure, especially hard protection atop cables, causes impacts through entanglement/gear loss/damage, fish aggregation, and habitat conversion. Therefore, see those sub-IPFs within Presence of structures.	See other sub-IPFs within Presence of structures.

Associated IPFs: Sub-IFPs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Discharges	The gradually increasing amount of vessel traffic is increasing the cumulative permitted discharges from vessels. Many discharges are required to comply with permitting standards established to ensure potential impacts on the environment are minimized or mitigated. However, there does not appear to be evidence that the volumes and extents have any impact on benthic resources.	There is the potential for new ocean dumping/dredge disposal sites in the Northeast. Impacts (disturbance, reduction in fitness) of infrequent ocean disposal to benthic resources are short-term because spoils are typically recolonized naturally. In addition, the USEPA has established dredge spoil criteria and it regulates the disposal permits issued by the USACE; these discharges are required to comply with permitting standards established to ensure potential impacts on the environment are minimized or mitigated.
Regulated fishing effort	Ongoing commercial and recreational regulations for finfish and shellfish implemented and enforced by states, towns, and/or NOAA, depending on jurisdiction, affect benthic resources by modifying the nature, distribution and intensity of fishing-related impacts, including those that disturb the seafloor (trawling, dredge fishing).	No future activities were identified within the geographic analysis area other than ongoing activities.
Seabed profile alterations	Ongoing sediment dredging for navigation purposes results in localized short-term impacts (habitat alteration, injury, and mortality) on benthic resources through this IPF. Dredging typically occurs only in sandy or silty habitats, which are abundant in the geographic analysis area and are quick to recover from disturbance. Therefore, such impacts, while locally intense, have little impact on benthic resources in the geographic analysis area.	No future activities were identified within the geographic analysis area other than ongoing activities.
Sediment deposition and burial	Ongoing sediment dredging for navigation purposes results in fine sediment deposition. Ongoing cable maintenance activities also infrequently disturb bottom sediments; these disturbances are local, limited to the emplacement corridor. Sediment deposition could have adverse impacts on some benthic resources, especially eggs and larvae, including smothering and loss of fitness. Impacts may vary based on season/time of year. Where dredged materials are disposed, benthic resources are smothered. However, such areas are typically recolonized naturally in the short term. Most sediment dredging projects have time-of-year restrictions to minimize impacts on benthic resources. Most benthic resources in the geographic analysis area are adapted to the turbidity and periodic sediment deposition that occur naturally in the geographic analysis area.	The USACE and/or private ports may undertake dredging projects periodically. Where dredged materials are disposed, benthic resources are buried. However, such areas are typically recolonized naturally in the short term. Most benthic resources in the geographic analysis area are adapted to the turbidity and periodic sediment deposition that occur naturally in the geographic analysis area.
Climate change: Ocean acidification	Ongoing CO_2 emissions causing ocean acidification may contribute to reduced growth or the decline of benthic invertebrates that have calcareous shells, as well as reefs and other habitats formed by shells.	No future activities were identified within the geographic analysis area other than ongoing activities.
Climate change: Warming and sea level rise, altered habitat/ecology	Climate change, influenced in part by ongoing greenhouse gas emissions, is expected to continue to contribute to a gradual warming of ocean waters, influencing the distributions of benthic species and altering ecological relationships, likely causing permanent changes of unknown intensity gradually over the next 30 years.	See above.

Associated IPFs: Sub-IFPs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Climate change: Warming and sea level rise, altered migration patterns	See above.	See above.
Climate change: Warming and sea level rise, disease frequency	Climate change, influenced in part by ongoing greenhouse gas emissions, is expected to continue to contribute to a gradual warming of ocean waters, influencing the frequencies of various diseases of benthic species, and likely causing permanent changes of unknown intensity over the next 30 years.	See above.

Notes: BMP = best management practice; BOEM = Bureau of Ocean Energy Management; CO_2 = carbon dioxide; COP = Construction and Operations Plan; EFH = Essential Fish Habitat; EIS = Environmental Impact Statement; EMF = electromagnetic field; ESP = electrical service platform; G&G = Geological and Geophysical; hazmat = hazardous materials; IPF = impact-producing factors; met = meteorological; NA = not applicable; NOAA = National Oceanic and Atmospheric Administration; OCS = Outer Continental Shelf; OECC = Offshore Export Cable Corridor(s); USACE = U.S. Army Corps of Engineers; USEPA = U.S. Environmental Protection Agency; WTG = wind turbine generator.

Table E3-4. Summary of Activities and the Associated Impact-Producing Factors for Finfish, Invertebrates, and Essential Fish Habitat

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Accidental releases: Fuel/fluids/ hazmat	See Attachment 2/Table E2-2 for a quantitative analysis of these risks. Ongoing releases are frequent/chronic. Impacts, including mortality, decreased fitness, and contamination of habitat, are localized and temporary, and rarely affect populations.	See Attachment 2/Table E2-2 for a quantitative analysis of these risks. Gradually increasing vessel traffic over the next 30 years would increase the risk of accidental releases. Impacts are unlikely to affect populations.
Accidental releases: Invasive species	Invasive species are periodically released accidentally during ongoing activities, including the discharge of ballast water and bilge water from marine vessels. The impacts on finfish, invertebrates, and EFH depend on many factors, but can be widespread and permanent.	No future activities were identified within the geographic analysis area for this resource other than ongoing activities.
Anchoring	Vessel anchoring related to ongoing military use, and survey, commercial, and recreational activities continues to cause temporary to permanent impacts in the immediate area where anchors and chains meet the seafloor. Impacts on finfish, invertebrates, and EFH are greatest for sensitive EFH (e.g., eelgrass, hard bottom) and sessile or slow-moving species (e.g., corals, sponges, and sedentary shellfish).	Impacts from anchoring may occur on a semi-regular basis over the next 30 years due to offshore military operations, survey activities, commercial vessel traffic, and/or recreational vessel traffic. These impacts would include increased turbidity levels and potential for direct contact causing mortality of benthic species and, possibly, degradation of sensitive habitats. All impacts would be localized; turbidity would be temporary; impacts from direct contact would be recovered in the short term. Degradation of sensitive habitats such as certain types of hard bottom (e.g., boulder piles), if it occurs, could be long-term.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
EMF	EMF emanates continuously from installed telecommunication and electrical power transmission cables. Biologically significant impacts on finfish, invertebrates, and EFH have not been documented for AC cables (CSA Ocean Sciences, Inc. and Exponent 2019 and see Thomsen et al. 2015), but behavioral impacts have been documented for benthic species (skates and lobster) near operating DC cables (Hutchison et al. 2018). The impacts are localized and affect the animals only while they are within the EMF. There is no evidence to indicate that EMF from undersea AC power cables negatively affects commercially and recreationally important fish species within the southern New England area (CSA Ocean Sciences, Inc. and Exponent 2019).	During operation, future new cables would produce EMF. (See cell to the left.) Submarine power cables in the geographic analysis area for this resource are assumed to be installed with appropriate shielding and burial depth to reduce potential EMF to low levels. EMF of any two sources would not overlap (even for multiple cables within a single OECC). Although the EMF would exist as long as a cable was in operation, impacts, on finfish, invertebrates, and EFH would likely be difficult to detect.
Light: Vessels	Marine vessels have an array of lights including navigational lights and deck lights. There is little downward-focused lighting, and therefore only a small fraction of the emitted light enters the water. Light can attract finfish and invertebrates, potentially affecting distributions in a highly localized area. Light may also disrupt natural cycles, e.g., spawning, possibly leading to short-term impacts.	See cell to the left.
Light: Structures	Offshore buoys and towers emit light, and onshore structures, including buildings and ports, emit a great deal more on an ongoing basis. Light can attract finfish and invertebrates, potentially affecting distributions in a highly localized area. Light may also disrupt natural cycles, e.g., spawning, possibly leading to short-term impacts. Light from structures is widespread and permanent near the coast, but minimal offshore.	Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast, but minimal offshore.
New cable emplacement/ maintenance	Infrequent cable maintenance activities disturb the seafloor and cause temporary increases in suspended sediment; these disturbances are local, limited to the cable corridor. New cables are infrequently added near shore. Cable emplacement/ maintenance activities disturb, displace, and injure finfish and invertebrates and result in temporary to long-term habitat alterations. The intensity of impacts depends on the time (season) and place (habitat type) where the activities occur. (See also the IPF of Sediment deposition and burial.)	Future new cables would occasionally disturb the seafloor and cause temporary increases in suspended sediment, resulting in local short-term impacts. The FCC has two pending submarine telecommunication cable applications in the North Atlantic. If the cable routes enter the geographic analysis area for this resource, short-term disturbance would be expected. The intensity of impacts would depend on the time (season) and place (habitat type) where the activities would occur.
Noise: Aircraft	Noise from aircraft reaches the sea surface on a regular basis. However, there is not likely to be any impact of aircraft noise on finfish, invertebrates, and EFH, as very little of the aircraft noise propagates through the water.	Aircraft noise is likely to continue to increase as commercial air traffic increases. However, there is not likely to be any impact of aircraft noise on finfish, invertebrates, and EFH.
Noise: Onshore/offshore construction	Noise from construction occurs frequently in near shores of populated areas in New England and the mid-Atlantic but infrequently offshore. The intensity and extent of noise from construction is difficult to generalize, but impacts are local and temporary. See also sub-IPF for Noise: Pile driving.	Noise from construction near shores is expected to gradually increase in line with human population growth along the coast of the geographic analysis area for this resource.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Noise: G&G	Ongoing site characterization surveys and scientific surveys produce noise around sites of investigation. These activities can disturb finfish and invertebrates in the immediate vicinity of the investigation and can cause temporary behavioral changes. The extent depends on equipment used, noise levels, and local acoustic conditions.	Site characterization surveys, scientific surveys, and exploratory oil and gas surveys are anticipated to occur infrequently over the next 30 years. Seismic surveys used in oil and gas exploration create high-intensity impulsive noise to penetrate deep into the seabed, potentially resulting in injury or mortality to finfish and invertebrates in a small area around each sound source and short-term stress and behavioral changes to individuals over a greater area. Site characterization surveys typically use sub-bottom profiler technologies that generate less-intense sound waves more similar to common deep-water echosounders. The intensity and extent of the resulting impacts are difficult to generalize, but are likely local and temporary.
Noise: O&M	Some finfish and invertebrates may be able to hear the continuous underwater noise of operational WTGs. As measured at the Block Island Wind Farm, this low frequency noise barley exceeds ambient levels at 164 feet (50 meters) from the WTG base. Based on the results of Thomsen et al. (2015), sound pressure levels would be expected to be at or below ambient levels at relatively short distances (approximately 164 feet [50 meters]) from WTG foundations. These low levels of elevated noise likely have little to no impact. Noise is also created by operations and maintenance of marine minerals extraction and commercial fisheries, each of which has small local impacts.	New or expanded marine minerals extraction and commercial fisheries may intermittently increase noise during their operations and maintenance over the next 30 years. Impacts would likely be small and local.
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water and/or through the seabed can cause injury and/or mortality to finfish and invertebrates in a small area around each pile, and can cause short-term stress and behavioral changes to individuals over a greater area. Eggs, embryos, and larvae of finfish and invertebrates could also experience developmental abnormalities or mortality resulting from this noise, although thresholds of exposure are not known (Weilgart 2018, Hawkins and Popper 2017). Potentially injurious noise could also be considered as rendering EFH temporarily unavailable or unsuitable for the duration of the noise. The extent depends on pile size, hammer energy, and local acoustic conditions.	No future activities were identified within the geographic analysis area for this resource other than ongoing activities.
Noise: Cable laying/ trenching	Infrequent trenching activities for pipeline and cable laying, as well as other cable burial methods, emit noise. These disturbances are temporary, local, and extend only a short distance beyond the emplacement corridor. Impacts of this noise are typically less prominent than the impacts of the physical disturbance and sediment suspension.	New or expanded submarine cables and pipelines are likely to occur in the geographic analysis area for this resource. These disturbances would be infrequent over the next 30 years, temporary, local, and extend only a short distance beyond the emplacement corridor. Impacts of this noise are typically less prominent than the impacts of the physical disturbance and sediment suspension.
Noise: Vessels	While ongoing vessel noise may have some effect on behavior, it is likely limited to brief startle and temporary stress responses. Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, and scientific and academic research vessels.	See cell to the left.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also going through continual upgrades and maintenance, including dredging. Port utilization is expected to increase over the next 30 years.	Between 1992 and 2012, global shipping traffic increased fourfold (Tournadre 2014). The U.S. OCS is no exception to this trend, and growth is expected to continue as human population increases. Certain types of vessel traffic have increased recently (e.g. ferry use and cruise industry) and may continue to increase in the foreseeable future. In addition, the general trend along the coast from Virginia to Maine is that port activity will increase modestly. The ability of ports to receive the increase may require port modifications, leading to local impacts. Future channel deepening activities will likely be undertaken. Existing ports have already affected finfish, invertebrates, and EFH, and future port projects would implement BMPs to minimize impacts. Although the degree of impacts on EFH would likely be undetectable outside the immediate vicinity of the ports, adverse impacts on EFH for certain species and/or life stages may lead to impacts on finfish and invertebrates beyond the vicinity of the port.
Presence of structures: Entanglement, gear loss, gear damage	Commercial and recreational fishing gear is periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures. The lost gear, moved by currents, can disturb habitats and potentially harm individuals, creating small, localized, short-term impacts.	No future activities were identified within the geographic analysis area for this resource other than ongoing activities.
Presence of structures: Hydrodynamic disturbance	Manmade structures, especially tall vertical structures such as foundations for towers of various purposes, continuously alter local water flow at a fine scale. Water flow typically returns to background levels within a relatively short distance from the structure. Therefore, impacts on finfish, invertebrates, and EFH are typically undetectable. Indirect impacts of structures influencing primary productivity and higher trophic levels are possible but are not well understood. New structures are periodically added.	Tall vertical structures can increase seabed scour and sediment suspension. Impacts would likely be highly localized and difficult to detect. Indirect impacts of structures influencing primary productivity and higher trophic levels are possible but are not well understood.
Presence of structures: Fish aggregation	Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables create uncommon relief in a mostly sandy seascape. Structure-oriented fishes are attracted to these locations. These impacts are local and often permanent. Fish aggregation may be considered adverse, beneficial, or neutral.	New cables, installed incrementally in the geographic analysis area for this resource over the next 20 to 30 years, would likely require hard protection atop portions of the route (see the New cable emplacement/ maintenance IPF). Any new towers, buoys, or piers would also create uncommon relief in a mostly sandy seascape. Structure-oriented fishes could be attracted to these locations. Abundance of certain fishes may increase. These impacts are local and may be permanent.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Presence of structures: Habitat conversion	Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables create uncommon relief in a mostly sandy seascape. A large portion is homogeneous sandy seascape but there is some other hard and/or complex habitat. Structure-oriented species thus benefit on a constant basis; however, the diversity may decline over time as early colonizers are replaced by successional communities dominated by blue mussels and anemones (Degraer et al. 2019 [Chapter 7]). Structures are periodically added, resulting in the conversion of existing soft-bottom and hard-bottom habitat to the new hard-structure habitat.	New cable, installed incrementally in the analysis area over the next 20 to 30 years, would likely require hard protection atop portions of the route (see New cable emplacement/ maintenance). Any new towers, buoys, or piers would also create uncommon relief in a mostly sandy seascape. Structure-oriented species would benefit (Claisse et al. 2014, Smith et al. 2016); however, the diversity may decline over time as early colonizers are replaced by successional communities dominated by blue mussels and anemones (Degraer et al. 2019 [Chapter 7]). Soft bottom is the dominant habitat type from Cape Hatteras to the Gulf of Maine (over 60 million acres), and species that rely on this habitat would not likely experience population-level impacts (Guida et al. 2017; Greene et al. 2010).
Presence of structures: Migration disturbances	Human structures in the marine environment, e.g., shipwrecks, artificial reefs, and oil platforms, can attract finfish and invertebrates that approach the structures during their migrations. This could slow migrations. However, temperature is expected to be a bigger driver of habitat occupation and species movement than structure is (Moser and Shepherd 2009; Fabrizio et al. 2014; Secor et al. 2018). There is no evidence to suggest that structures pose a barrier to migratory animals.	The infrequent installation of future new structures in the marine environment over the next 30 years may attract finfish and invertebrates that approach the structures during their migrations. This could tend to slow migrations. However, temperature is expected to be a bigger driver of habitat occupation and species movement (Moser and Shepherd 2009; Fabrizio et al. 2014; Secor et al. 2018). Migratory animals would likely be able to proceed from structures unimpeded.
Presence of structures: Transmission cable infrastructure	See other sub-IPFs within the Presence of structures IPF. See Table E3-2 on Coastal Habitats.	See other sub-IPFs within the Presence of structures IPF. See Table E3-2 on Coastal Habitats.
Regulated fishing effort	Regulated fishing effort results in the removal of a substantial amount of the annually produced biomass of commercially regulated finfish and invertebrates and can also influence bycatch of non-regulated species. Ongoing commercial and recreational regulations for finfish and shellfish implemented and enforced by states, municipalities, and/or NOAA, depending on jurisdiction, affect finfish, invertebrates, and EFH by modifying the nature, distribution and intensity of fishing-related impacts, including those that disturb the seafloor (trawling, dredge fishing).	No future activities were identified within the geographic analysis area for this resource other than ongoing activities.
Seabed profile alterations	Ongoing sediment dredging for navigation purposes results in localized short-term impacts (habitat alteration, change in complexity) on finfish, invertebrates, and EFH through this IPF. Dredging is most likely in sand wave areas where typical jet plowing is insufficient to meet target cable burial depth. Sand waves that are dredged would likely be redeposited in like-sediment areas. Any particular sand wave may not recover to the same height and width as pre-disturbance; however, the habitat function would largely recover post-disturbance. Therefore, seabed profile alterations, while locally intense, have little impact on finfish, invertebrates, and EFH on a regional (Cape Hatteras to Gulf of Maine) scale.	No future activities were identified within the geographic analysis area for this resource other than ongoing activities.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Sediment deposition and burial	Ongoing sediment dredging for navigation purposes results in fine sediment deposition. Ongoing cable maintenance activities also infrequently disturb bottom sediments; these disturbances are local, limited to the emplacement corridor. Sediment deposition could have negative impacts on eggs and larvae, particularly demersal eggs such as longfin squid, which are known to have high rates of egg mortality if egg masses are exposed to abrasion or burial. Impacts may vary based on season/time of year.	No future activities were identified within the geographic analysis area for this resource other than ongoing activities.
Climate change: Ocean acidification	Continuous carbon dioxide emissions causing ocean acidification may contribute to reduced growth or the decline of invertebrates that have calcareous shells over the course of the next 30 years.	No future activities were identified within the geographic analysis area for this resource other than ongoing activities.
Climate change: Warming and sea level rise, altered habitat/ ecology	Climate change, influenced in part by greenhouse gas emissions, is expected to continue to contribute to a gradual warming of ocean waters over the next 30 years, influencing the distributions of finfish, invertebrates, and EFH. This sub-IPF has been shown to affect the distribution of fish in the northeast United States, with several species shifting their centers of biomass either northward or to deeper waters (Hare et al. 2016).	See above.
Climate change: Warming and sea level rise, altered migration patterns	See above.	See above.
Climate change: Warming and sea level rise, disease frequency	Climate change, influenced in part by greenhouse gas emissions, is expected to continue to contribute to a gradual warming of ocean waters over the next 30 years, influencing the frequencies of various diseases of finfish and invertebrates.	See above.

Notes: °C = degrees Celsius; AC = alternating current; BMP = best management practice; BOEM = Bureau of Ocean Energy Management; COP = Construction and Operations Plan; DC = direct current; EFH = essential fish habitat; EMF = electromagnetic field; EIS = Environmental Impact Statement; ESP = electrical service platform; FCC = Federal Communications Commission; G&G = Geological and Geophysical; GW = gigawatts; IPF = impact-producing factors; met = meteorological; NA = not applicable; NOAA = National Oceanic and Atmospheric Administration; O&M = operations and maintenance; OCS = Outer Continental Shelf; OECC = Offshore Export Cable Corridor(s); USACE = United States Army Corps of Engineers; WDA = Wind Development Area; WTG = wind turbine generator.

Table E3-5. Summary of Activities and the Associated Impact-Producing Factors for Marine Mammals

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Accidental releases: Fuel/fluids/hazmat	See Attachment 2/Table E2-2 for a quantitative analysis of these risks. Ongoing releases are frequent/chronic. Marine mammal exposure to aquatic contaminants and inhalation of fumes from oil spills can result in mortality or sublethal effects on the individual fitness, including adrenal effects, hematological effects, liver effects lung disease, poor body condition, skin lesions, and several other health affects attributed to oil exposure (Kellar et al. 2017; Mazet et al. 2001; Mohr et al. 2008, Smith et al. 2017; Sullivan et al. 2019; Takeshida et al. 2017). Additionally, accidental releases may result in impacts on marine mammals due to effects to prey species (Table E3-4).	See Attachment 2/Table E2-2 for a quantitative analysis of these risks. Gradually increasing vessel traffic over the next 30 years would increase the risk of accidental releases. Marine mammal exposure to aquatic contaminants and inhalation of fumes from oil spills can result in mortality or sublethal effects on the individual fitness, including adrenal effects, hematological effects, liver effects lung disease, poor body condition, skin lesions, and several other health affects attributed to oil exposure (Kellar et al. 2017; Mazet et al. 2001; Mohr et al. 2008, Smith et al. 2017; Sullivan et al. 2019; Takeshida et al. 2017). Additionally, accidental releases may result in impacts on marine mammals due to effects to prey species (Table E3-4).
Accidental releases: Trash and debris	Trash and debris may be accidentally discharged through fisheries use, dredged material ocean disposal, marine minerals extraction, marine transportation, navigation and traffic, survey activities and cables, lines and pipeline laying, and debris carried in river outflows or windblown from onshore. Accidental releases of trash and debris are expected to be low quantity, local, and low-impact events. Worldwide 62 of 123 (50.4%) marine mammal species have been documented ingesting marine litter (Werner et al. 2016). Stranding data indicate potential debris induced mortality rates of 0 to 22%. Mortality has been documented in cases of debris interactions, as well as blockage of the digestive track, disease, injury, and malnutrition (Baulch and Perry 2014). However, it is difficult to link physiological effects to individuals to population level impacts (Browne et al. 2015).	As population and vessel traffic increase gradually over the next 30 years, accidental release of trash and debris may increase. Trash and debris may continue to be accidentally released through fisheries use and other offshore and onshore activities. There may also be a long-term risk from exposure to plastics and other debris in the ocean. Worldwide 62 of 123 (50.4%) of marine mammal species have been documented ingesting marine litter (Werner et al. 2016). Mortality has been documented in cases of debris interacts, as well as blockage of the digestive track, disease, injury, and malnutrition (Baulch and Perry 2014).
EMF	EMFs emanate constantly from installed telecommunication and electrical power transmission cables. Marine mammals appear to have a detection threshold for magnetic intensity gradients (i.e., changes in magnetic field levels with distance) of 0.1% of the earth's magnetic field or about 0.05 μT (Kirschvink 1990) and are thus likely to be very sensitive to **minor** changes in magnetic fields (Walker et al. 2003). There is a potential for animals to react to local variations of the geomagnetic field caused by power cable EMFs. Depending on the magnitude and persistence of the confounding magnetic field, such an effect could cause a trivial temporary change in swim direction or a longer detour during the animal's migration (Gill et al. 2005). Such an effect on marine mammals is more likely to occur with direct current cables than with AC cables (Normandeau et al. 2011). However, there are numerous transmission cables installed across the seafloor and no impacts on marine mammals have been demonstrated from this source of EMF.	During operation, future new cables would produce EMF. Submarine power cables in the marine mammal geographic analysis area are assumed to be installed with appropriate shielding and burial depth to reduce potential EMF to low levels. EMF of any two sources would not overlap. Although the EMF would exist as long as a cable was in operation, impacts, if any, would likely be difficult to detect, if they occur at all. Marine mammals have the potential to react to submarine cable EMF, however, no effects from the numerous submarine cables have been observed. Further, this IPF would be limited to extremely small portions of the areas used by migrating marine mammals. As such, exposure to this IPF would be low, and as a result impacts on marine mammals would not be expected.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
New cable emplacement/ maintenance	Cable maintenance activities disturb bottom sediments and cause temporary increases in suspended sediment; these disturbances will be local and generally limited to the emplacement corridor. Data are not available regarding marine mammal avoidance of localized turbidity plumes; however, Todd et al. (2015) suggest that since some marine mammals often live in turbid waters and some species of mysticetes and sirenians employ feeding methods that create sediment plumes, some species of marine mammals have a tolerance for increased turbidity. Similarly, McConnell et al. (1999) documented movements and foraging of grey seals in the North Sea. One tracked individual was blind in both eyes, but otherwise healthy. Despite being blind, observed movements were typical of the other study individuals, indicating that visual cues are not essential for grey seal foraging and movement (McConnell et al. 1999). If elevated turbidity caused any behavioral responses such as avoiding the turbidity zone or changes in foraging behavior, such behaviors would be temporary, and any impacts would be temporary and short-term. Turbidity associated with increased sedimentation may result in temporary, short-term impacts on marine mammal prey species (Table E3-4).	The FCC has two pending submarine telecommunication cable application in the North Atlantic. The impact on water quality from accidental sediment suspension during cable emplacement is temporary and short-term. If elevated turbidity caused any behavioral responses such as avoidance of the turbidity zone or changes in foraging behavior, such behaviors would be temporary, and any negative impacts would be temporary and short-term. Turbidity associated with increased sedimentation may result in temporary, short-term impacts on some marine mammal prey species (Table E3-4).
Noise: Aircraft	Aircraft routinely travel in the marine mammal geographic analysis area. With the possible exception of rescue operations, no ongoing aircraft flights would occur at altitudes that would elicit a response from marine mammals. If flights are at a sufficiently low altitude, marine mammals may respond with behavioral changes, including short surface durations, abrupt dives, and percussive behaviors (i.e. breaching and tail slapping) (Patenaude et al. 2002). These brief responses would be expected to dissipate once the aircraft has left the area. Similarly, aircraft have the potential to disturb hauled out seals if aircraft overflights occur within 2,000 feet (610 meters) of a haul out area (Efroymson et al. 2000). However, this disturbance would be temporary, short-term, and result in minimal energy expenditure. These brief responses would be expected to dissipate once the aircraft has left the area.	Future low altitude aircraft activities such as survey activities and navy training operations could result short-term responses of marine mammals to aircraft noise. If flights are at a sufficiently low altitude, marine mammals may respond with a behavior changes, including short surface durations, abrupt dives, and percussive behaviors (i.e. breaching and tail slapping) (Patenaude et al. 2002). These brief responses would be expected to dissipate once the aircraft has left the area.
Noise: G&G	Infrequent site characterization surveys and scientific surveys produce high-intensity impulsive noise around sites of investigation. These activities have the potential to result in high intensity, high consequence impacts, including auditory injuries, stress, disturbance, and behavioral responses, if present within the ensonified area (NOAA 2018). Survey protocols and underwater noise mitigation procedures are typically implemented to decrease the potential for any marine mammal to be within the area where sound levels are above relevant harassment thresholds associated with an operating sound source to reduce the potential for behavioral responses and injury (PTS/TTS) close to the sound source. The magnitude of effects, if any, is intrinsically related to many factors, including: acoustic signal characteristics, behavioral state (e.g., migrating), biological condition, distance from the source, duration and level of the sound exposure, as well as environmental and physical conditions that affect acoustic propagation (NOAA 2018).	Same as ongoing activities, with the addition of possible future oil and gas exploration surveys.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Noise: Turbines	Marine mammals would be able to hear the continuous underwater noise of operational WTGs. As measured at the Block Island Wind Facility, this low frequency noise barely exceeds ambient levels at 164 feet (50 meters) from the WTG base. Based on the results of Thomsen et al. (2015) and Kraus et al. (2016), sound pressure levels would be expected to be at or below ambient levels at relatively short distances from the WTG foundations.	This sub-IPF does not apply to future non-offshore wind development.
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water and/or through the seabed can result in high-intensity, low-exposure level, long-term, but localized intermittent risk to marine mammals. Impacts would be localized in nearshore waters. Pile driving activities may negatively affect marine mammals during foraging, orientation, migration, predator detection, social interactions, or other activities (Southall et al. 2007). Noise exposure associated with pile-driving activities can interfere with these functions, and have the potential to cause a range of responses, including insignificant behavioral changes, avoidance of the ensonified area, PTS, harassment, and ear injury, depending on the intensity and duration of the exposure. BOEM assumes that all ongoing and potential future activities will be conducted in accordance with a project-specific IHA to minimize impacts on marine mammals.	No future activities were identified within the marine mammal geographic analysis area other than ongoing activities.
Noise: Cable laying/trenching	N/A	Cable laying impacts resulting from future non-offshore wind activities would be identical to those described for future offshore wind projects.
Noise: Vessels	Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, scientific and academic research vessels, as well as other construction vessels. The frequency range for vessel noise falls within marine mammals' known range of hearing and would be audible. Noise from vessels presents a long-term and widespread impact on marine mammals across in most oceanic regions. While vessel noise may have some effect on marine mammal behavior, it would be expected to be limited to brief startle and temporary stress response. Results from studies on acoustic impacts from vessel noise on odontocetes indicate that small vessels at a speed of 5 knots in shallow coastal water can reduce the communication range for bottlenose dolphins within 164 feet (50 meters) of the vessel by 26% (Jensen et al. 2009). Pilot whales in a quieter, deep-water habitat could experience a 50% reduction in communication range from a similar size boat and speed (Jensen et al. 2009). Since lower frequencies propagate farther away from the sound source compared to higher frequencies, low frequency cetaceans are at a greater risk of experiencing Level B Harassment produced by vessel traffic.	Any offshore projects that require the use of ocean vessels could result in long term but infrequent impacts on marine mammals, including temporary startle responses, masking of biologically relevant sounds, physiological stress, and behavioral changes. However, BOEM expects that these brief responses of individuals to passing vessels would be unlikely given the patchy distribution of marine mammals and no stock or population level effects would be expected.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also going through continual upgrades and maintenance. Port expansion activities are localized to nearshore habitats, and are expected to result in temporary, short-term impacts, if any, on marine mammals. Vessel noise may affect marine mammals, but response would be expect to be temporary and short-term (see Vessels: Noise sub-IPF above). The impacts on water quality from sediment suspension during port expansion activities is temporary, short-term, and would be similar to those described under the New cable emplacement/maintenance IPF above.	Between 1992 and 2012, global shipping traffic increased fourfold (Tournadre 2014). The U.S. OCS is no exception to this trend, and growth is expected to continue as human population increases. In addition, the general trend along the coastal region from Virginia to Maine is that port activity will increase modestly. The ability of ports to receive the increase in larger ships will require port modifications. Future channel deepening activities are being undertaken to accommodate deeper draft vessels for the Panama Canal Locks. The additional traffic and larger vessels could have impacts on water quality through increases in suspended sediments and the potential for accidental discharges. The increased sediment suspension could be long-term depending on the vessel traffic increase. Certain types of vessel traffic have increased recently (e.g. ferry use and cruise industry) and may continue to increase in the foreseeable future. Additional impacts associated with the increased risk of vessel strike could also occur (see the Traffic: Vessel collisions sub-IPF below).
Presence of structures: Entanglement or ingestion of lost fishing gear	There are more than 130 artificial reefs in the Mid-Atlantic region. This sub-IPF may result in long-term, high intensity impacts, but with low exposure due to localized and geographic spacing of artificial reefs, long-term. Currently bridge foundations and the Block Island Wind Facility may be considered artificial reefs and may have higher levels of recreational fishing, which increases the chances of marine mammals encountering lost fishing gear, resulting in possible ingestions, entanglement, injury, or death of individuals (Moore and van der Hoop 2012), if present nearshore where these structures are located. There are very few, if any, areas within the OCS geographic analysis area for marine mammals that would serve to concentrate recreational fishing and increase the likelihood that marine mammals would encounter lost fishing gear.	No future activities were identified within the marine mammal geographic analysis area other than ongoing activities.
Presence of structures: Habitat conversion and prey aggregation	There are more than 130 artificial reefs in the Mid-Atlantic region. Hard-bottom (scour control and rock mattresses) and vertical structures (bridge foundations and Block Inland Wind Facility WTGs) in a soft-bottom habitat can create artificial reefs, thus inducing the ‘reef’ effect (Taormina et al. 2018; NMFS 2015). The reef effect is usually considered a beneficial impact, associated with higher densities and biomass of fish and decapod crustaceans (Taormina et al. 2018), providing a potential increase in available forage items and shelter for seals and small odontocetes compared to the surrounding soft-bottoms.	The presence of structures associated with non-offshore wind development in near shore coastal waters have the potential to provide habitat for seals and small odontocetes as well as preferred prey species. This "reef effect" has the potential to result in long term, low-intensity benefits. Bridge foundations will continue to provide foraging opportunities for seals and small odontocetes with measurable benefits to some individuals. Hard-bottom (scour control and rock mattresses used to bury the offshore export cables) and vertical structures (i.e., WTG and ESP foundations) in a soft-bottom habitat can create artificial reefs, thus inducing the “reef effect” (Taormina et al. 2018; Causon and Gill 2018). The reef effect is usually considered a beneficial impact, associated with higher densities and biomass of fish and decapod crustaceans (Taormina et al. 2018), providing a potential increase in available forage items and shelter for marine mammals compared to the surrounding soft-bottoms.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Presence of structures: Avoidance/ displacement	No ongoing activities in the marine mammal geographic analysis area beyond offshore wind facilities are measurably contributing to this sub-IPF. There may be some impacts resulting from the existing Block Island Wind Facility, but given that there are only 5 WTGs, no measurable impacts are occurring.	Not contemplated for non-offshore wind facility sources.
Presence of structures: Behavioral disruption - breeding and migration	No ongoing activities in the marine mammal geographic analysis area beyond offshore wind facilities are measurably contributing to this sub-IPF.	Not contemplated for non-offshore wind facility sources.
Presence of structures: Displacement into higher risk areas (Vessels and Fishing)	No ongoing activities in the marine mammal geographic analysis area beyond offshore wind facilities are measurably contributing to this sub-IPF.	Not contemplated for non-offshore wind facility sources.
Traffic: Vessel collisions	Current activities that are contributing to this sub-IPF include port traffic levels, fairways, traffic separation schemes, commercial vessel traffic, recreational and fishing activity, and scientific and academic vessel traffic. Vessel strike is relatively common with cetaceans (Kraus et al. 2005) and one of the primary causes of death to NARWs with as many as 75% of known anthropogenic mortalities of NARWs likely resulting from collisions with large ships along the US and Canadian eastern seaboard (Kite-Powell et al. 2007). Marine mammals are more vulnerable to vessel strike when they are within the draft of the vessel and when they are beneath the surface and not detectable by visual observers. Some conditions that make marine mammals less detectable include weather conditions with poor visibility (e.g., fog, rain, and wave height) or nighttime operations. Vessels operating at speeds exceeding 10 knots have been associated with the highest risk for vessel strikes of NARWs (Vanderlaan and Taggart 2007). Reported vessel collisions with whales show that serious injury rarely occurs at speeds below 10 knots (Laist et al. 2001). Data show that the probability of a vessel strike increases with the velocity of a vessel (Pace and Silber 2005; Vanderlaan and Taggart 2007).	Vessel traffic associated with non-offshore wind development has the potential to result in an increased collision risk. While these impacts would be high consequence, the patchy distribution of marine mammals makes stock or population-level effects unlikely (Navy 2018).
Climate change: Warming and sea level rise, storm severity/ frequency	Increased storm frequency could result in increased energetic costs for marine mammals and reduced fitness, particularly for juveniles, calves and pups.	No future activities were identified within the geographic analysis area for marine mammals other than ongoing activities.
Climate change: Ocean acidification	This sub-IPF has the potential to lead to long-term, high-consequence impacts on marine ecosystems by contributing to reduced growth or the decline of invertebrates that have calcareous shells.	No future activities were identified within the marine mammal geographic analysis area other than ongoing activities.
Climate change: Warming and sea level rise, altered habitat/ecology	This sub-IPF has the potential to lead to long-term, high-consequence impacts on marine mammals as a result of changes in distribution, reduced breeding, and/or foraging habitat availability, and disruptions in migration.	No future activities were identified within the marine mammal geographic analysis area other than ongoing activities.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Climate change: Warming and sea level rise, altered migration patterns	This sub-IPF has the potential to lead to long-term, high-consequence impacts on marine mammal habitat use and migratory patterns. For example, the NARW appears to be migrating differently and feeding in different areas in response to changes in prey densities related to climate change (Record et al. 2019; MacLeod 2009; Nunny and Simmonds 2019.)	No future activities were identified within the marine mammal geographic analysis area other than ongoing activities.
Climate change: Warming and sea level rise, increased disease frequency	Climate change, influenced in part by greenhouse gas emissions, is expected to continue to contribute to a gradual warming of ocean waters, influencing the frequencies of various diseases of marine mammals, such as Phocine distemper. Climate change is clearly influencing infectious disease dynamics in the marine environment; however, no studies have shown a definitive causal relationship between any components of climate change and increases in infectious disease among marine mammals. This is due in large part to a lack of sufficient data and to the likely indirect nature of climate change's impact on these diseases. Climate change could affect the incidence or prevalence of infection, the frequency or magnitude of epizootics, and/or the severity or presence of clinical disease in infected individuals. There are a number of potential proposed mechanisms by which this might occur (see summary in Burge et al. 2014 Climate Change Influences on Marine Infectious Diseases: Implications for Management and Society).	No future activities were identified within the marine mammal geographic analysis area other than ongoing activities.
Climate change: Warming and sea level rise, storm severity/frequency, sediment erosion, deposition	Increased storm frequency could result in increased energetic costs for marine mammals, reduced fitness, particularly for juveniles, calves and pups. Erosion could impact seal haul outs reducing their habitat availability, especially as things like sea walls are added, blocking seals access to shore.	No future activities were identified within the marine mammal geographic analysis area other than ongoing activities.

Notes: μPa = micropascal; μT = microtesla; AC = alternating current; BA = Biological Assessment; BOEM = Bureau of Ocean Energy Management; BMP = best management practice; BSW = Bay State Wind; CFR = Code of Federal Regulations; COP = Construction and Operations Plan; dB = decibel; dB RMS = decibel root mean square; DP = dynamic positioning; EIS = Environmental Impact Statement; EMF = electromagnetic field; FCC = Federal Communications Commission; G&G = Geological and Geophysical; hazmat = hazardous material; HRG = High Resolution Geophysical; Hz = hertz; IHA = Incidental Harassment Authorization; IPF = impact-producing factors; met = meteorological; MW = megawatt; NARW = North Atlantic right whale; OCS = Outer Continental Shelf; OECC = Offshore Export Cable Corridor; PAM = passive acoustic monitoring; PSO = protected species observer; PTS = permanent threshold shift; SOV = service operations vessel; TTS = temporary threshold shift; USCG = U.S. Coast Guard; WDA = Wind Development Area; WTG = wind turbine generator.

Table E3-6. Summary of Activities and the Associated Impact-Producing Factors for Sea Turtles

Associated IPF: Sub-IPFs	**Ongoing Activities**	**Future Non-Offshore Wind Activities Intensity/Extent**
Accidental releases: Fuel/fluids/hazmat	See Attachment 2/Table E2-2 for a quantitative analysis of these risks. Ongoing releases are frequent and chronic. Sea turtle exposure to aquatic contaminants and inhalation of fumes from oil spills can result in mortality (Shigenaka et al. 2010) or sublethal effects on individual fitness, including adrenal effects, dehydration, hematological effects, increased disease incidence, liver effects, poor body condition, skin effects, skeletomuscular effects, and several other health effects that can be attributed to oil exposure (Camacho et al. 2013; Bembenek-Bailey et al. 2019; Mitchelmore et al. 2017; Shigenaka et al. 2010; Vargo et al. 1986). Additionally, accidental releases may result in impacts on sea turtles due to effects on prey species (Table E3-4).	See Attachment 2/Table E2-2 for a quantitative analysis of these risks. Gradually increasing vessel traffic over the next 30 years would increase the risk of accidental releases. Sea turtle exposure to aquatic contaminants and inhalation of fumes from oil spills can result in mortality (Shigenaka 2010; Wallace et al. 2010) or sublethal effects on individual fitness, including adrenal effects, dehydration, hematological effects, increased disease incidence, liver effects, poor body condition, skin effects, skeletomuscular effects, and several other health effects that can be attributed to oil exposure (Camacho et al. 2013; Bembenek-Bailey et al. 2019; Mitchelmore et al. 2017; Shigenaka et al. 2010; Vargo et al. 1986). Additionally, accidental releases may result in impacts on sea turtles due to effects on prey species (Table E3-4).
Accidental releases: Trash and debris	Trash and debris may be accidentally discharged through fisheries use, dredged material ocean disposal, marine minerals extraction, marine transportation, navigation and traffic, survey activities, cables, lines, and pipeline laying, as well as debris carried in river outflows or windblown from onshore. Accidental releases of trash and debris are expected to be low quantity, local, and low-impact events. Direct ingestion of plastic fragments is well documented and has been observed in all species of sea turtles (Bugoni et al. 2001; Hoarau et al. 2014; Nelms et al. 2016; Schuylar et al. 2014). In addition to plastic debris, ingestion of tar, paper, Styrofoam™, wood, reed, feathers, hooks, lines, and net fragments have also been documented (Thomás et al. 2002). Ingestion can also occur when individuals mistake debris for potential prey items (Gregory 2009; Hoarau et al. 2014; Thomás et al. 2002). Potential ingestion of marine debris varies among species and life history stages due to differing feeding strategies (Nelms et al. 2016). Ingestion of plastics and other marine debris can result in both lethal and sublethal impacts on sea turtles, with sublethal effects more difficult to detect (Gall and Thompson 2015; Hoarau et al. 2014; Nelms et al. 2016; Schuyler et al. 2014). Long-term sublethal effects may include dietary dilution, chemical contamination, depressed immune system function, poor body condition, as well as reduced growth rates, fecundity, and reproductive success. However, these effects are cryptic and clear causal links are difficult to identify (Nelms et al. 2016).	Trash and debris may be accidentally discharged through fisheries use, dredged material ocean disposal, marine minerals extraction, marine transportation, navigation and traffic, survey activities and cables, lines and pipeline laying, and debris carried in river outflows or windblown from onshore. Accidental releases of trash and debris are expected to be low quantity, local, and low-impact events. Direct and indirect ingestion of plastic fragments and other marine debris is well documented and has been observed in all species of sea turtles (Bugoni et al. 2001; Gregory 2009; Hoarau et al. 2014; Nelms et al. 2016; Schuylar et al. 2014; Thomás et al. 2002). Ingestion can result in both lethal and sublethal impacts on sea turtles, with sublethal effects more difficult to detect (Gall and Thompson 2015; Hoarau et al. 2014; Nelms et al. 2016; Schuyler et al. 2014). However, these effects are cryptic and clear causal links are difficult to identify (Nelms et al. 2016).

Associated IPF: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
EMF	EMFs emanate constantly from installed telecommunication and electrical power transmission cables. Sea turtles appear to have a detection threshold of magnetosensitivity and behavioral responses to field intensities ranging from 0.0047 to 4000 µT for loggerhead turtles, and 29.3 to 200 µT for green turtles, with other species likely similar due to anatomical, behavioral, and life history similarities (Normandeau et al. 2011). Juvenile or adult sea turtles foraging on benthic organisms may be able to detect magnetic fields while they are foraging on the bottom near the cables and up to potentially 82 feet (25 meters) in the water column above the cable. Juvenile and adult sea turtles may detect the EMF over relatively small areas near cables (e.g., when resting on the bottom or foraging on benthic organisms near cables or concrete mattresses). There are no data on impacts on sea turtles from EMFs generated by underwater cables, although anthropogenic magnetic fields can influence migratory deviations (Luschi et al. 2007; Snoek et al. 2016). However, any potential impacts from AC cables on turtle navigation or orientation would likely be undetectable under natural conditions, and thus would be insignificant (Normandeau et al. 2011).	During operations, future new cables would produce EMF. Submarine power cables in the geographic analysis area for sea turtles are assumed to be installed with appropriate shielding and burial depth to reduce potential EMF to low levels. (Section 5.2.7 of BOEM's 2007 Final Programmatic Environmental Impact Statement for Alternative Energy Development and Production and Alternate Use of Facilities on the Outer Continental Shelf.) EMF of any two sources would not overlap. Although the EMF would exist as long as a cable was in operation, impacts, if any, would likely be difficult to detect, if they occur at all. Further, this IPF would be limited to extremely small portions of the areas used by resident or migrating sea turtles. As such, exposure to this IPF would be low, and as a result, impacts on sea turtles would not be expected.
Light: Vessels	Ocean vessels such as ongoing commercial vessel traffic, recreational and fishing activity, scientific and academic research traffic have an array of lights including navigational, deck lights, and interior lights. Such lights have some limited potential to attract sea turtles, although the impacts, if any, are expected to be localized and temporary.	Construction, operations, and decommissioning vessels associated with non-offshore wind activities produce temporary and localized light sources that could result in the attraction or avoidance behavior of sea turtles. These short-term impacts are expected to be of low intensity and occur infrequently.
Light: Structures	Artificial lighting on nesting beaches or in nearshore habitats has the potential to result in disorientation to nesting females and hatchling turtles. Artificial lighting on the OCS does not appear to have the same potential for effects. Decades of oil and gas platform operation in the Gulf of Mexico, that can have considerably more lighting than offshore WTGs, has not resulted in any known impacts on sea turtles (BOEM 2019).	Non-offshore wind activities would not be expected to appreciably contribute to this sub-IPF. As such, no impact on sea turtles would be expected.
New cable emplacement/ maintenance	Cable maintenance activities disturb bottom sediments and cause temporary increases in suspended sediment; these disturbances will be local and generally limited to the emplacement corridor. Data are not available regarding effects of suspended sediments on adult and juvenile sea turtles, although elevated suspended sediments may cause individuals to alter normal movements and behaviors. However, these changes are expected to be too small to be detected (NOAA 2020). Sea turtles would be expected to swim away from the sediment plume. Elevated turbidity is most likely to affect sea turtles if a plume causes a barrier to normal behaviors, but no impacts would be expected due to swimming through the plume (NOAA 2020). Turbidity associated with increased sedimentation may result in short-term, temporary impacts on sea turtle prey species (Table E3-4).	The FCC has two pending submarine telecommunication cable application in the North Atlantic. The impact on water quality from accidental sediment suspension during cable emplacement is short-term and temporary. If elevated turbidity caused any behavioral responses such as avoidance of the turbidity zone or changes in foraging behavior, such behaviors would be temporary, and any impacts would be short-term and temporary. Turbidity associated with increased sedimentation may result in short-term, temporary impacts on some sea turtle prey species (Table E3-4).

Associated IPF: Sub-IPFs	**Ongoing Activities**	**Future Non-Offshore Wind Activities Intensity/Extent**
Noise: Aircraft	Aircraft routinely travel in the geographic analysis area for sea turtles. With the possible exception of rescue operations, no ongoing aircraft flights would occur at altitudes that would elicit a response from sea turtles. If flights are at a sufficiently low altitude, sea turtles may respond with a startle response (diving or swimming away), altered submergence patterns, and a temporary stress response (National Science Foundation [NSF] and U.S. Geological Survey [USGS] 2011; Samuel et al. 2005). These brief responses would be expected to dissipate once the aircraft has left the area.	Future low altitude aircraft activities such as survey activities and navy training operations could result in short-term responses of sea turtles to aircraft noise. If flights are at a sufficiently low altitude, sea turtles may respond with a startle response (diving or swimming away), altered submergence patterns, and a temporary stress response (NSF and USGS 2011; Samuel et al. 2005). These brief responses would be expected to dissipate once the aircraft has left the area.
Noise: G&G	Infrequent site characterization surveys and scientific surveys produce high-intensity impulsive noise around sites of investigation. These activities have the potential to result in some impacts including potential auditory injuries, short-term disturbance, behavioral responses, and short-term displacement of feeding or migrating sea turtles, if present within the ensonified area (NSF and USGS 2011). The potential for PTS and TTS is considered possible in proximity to G&G surveys using air guns, but impacts are unlikely as turtles would be expected to avoid such exposure and survey vessels would pass quickly (NSF and USGS 2011). No significant impacts would be expected at the population level.	Same as ongoing activities, with the addition of possible future oil and gas exploration surveys.
Noise: Turbines	Available evidence suggests that typical underwater noise levels from operating WTGs would be below current cumulative injury and behavioral effect thresholds for sea turtles. Operating turbines were determined to produce underwater noise on the order of 110 to 125 dB RMS, occasionally reaching as high as 128 dB RMS in the 10-Hz to 8-kHz range (Tougaard et al. 2020). As measured at the Block Island Wind Facility, low-frequency operational noise barely exceeds ambient levels at 164 feet (50 meters) from the WTG base (Miller and Potty 2017). Operational noise impacts would be expected to be negligible.	This sub-IPF does not apply to future non-offshore wind development.
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water and/or through the seabed can result in high intensity, low exposure levels, and long-term, but localized intermittent risk to sea turtles. Impacts, potentially including behavioral responses, masking, TTS, and PTS, would be localized in nearshore waters. Data regarding threshold levels for impacts on sea turtles from sound exposure during pile driving are very limited, and no regulatory threshold criteria have been established for sea turtles. Based on current literature, the following thresholds are used to assess impacts to turtles: Potential mortal injury: 210 dB cumulative SPL or greater than 207 dB peak SPL (Popper et al. 2014) Potential mortal injury: 204 dB_{SEL}, 232 dB_{PEAK} (PTS), 189 dB_{SEL}, 226 dB_{PEAK} (TTS) (Navy 2017) Behavioral harassment: 175 dB referenced to 1 μPa RMS (Navy 2017)	No future activities were identified within the geographic analysis area for sea turtles other than ongoing activities.
Noise: Cable laying/trenching	N/A	Cable laying impacts resulting from future non-offshore wind activities would be identical to those described for future offshore wind projects.

Associated IPF: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Noise: Vessels	The frequency range for vessel noise (10 to 1000 Hz; MMS 2007) overlaps with sea turtles' known hearing range (less than 1000 Hz with maximum sensitivity between 200 to 700 Hz; Bartol 1994) and would therefore be audible. However, Hazel et al. (2007) suggest that sea turtles' ability to detect approaching vessels is primarily vision-dependent, not acoustic. Sea turtles may respond to vessel approach and/or noise with a startle response (diving or swimming away) and a temporary stress response (NSF and USGS 2011). Samuel et al. (2005) indicated that vessel noise could have an effect on sea turtle behavior, especially their submergence patterns.	See Section 3.4.6. Any offshore projects that require the use of ocean vessels could result in long-term but infrequent impacts on sea turtles, including temporary startle responses, masking of biologically relevant sounds, physiological stress, and behavioral changes, especially their submergence patterns (NSF and USGS 2011; Samuel et al. 2005). However, BOEM expects that these brief responses of individuals to passing vessels would be unlikely given the patchy distribution of sea turtles and no stock or population level effects would be expected.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also going through continual upgrades and maintenance. Port expansion activities are localized to nearshore habitats, and are expected to result in short-term, temporary impacts, if any, on sea turtles. Vessel noise may affect sea turtles, but response would be expected to be short-term and temporary (see the Vessels: Noise sub-IPF above). The impact on water quality from sediment suspension during port expansion activities is short-term, temporary, and would be similar to those described under the New cable emplacement/maintenance IPF above.	Between 1992 and 2012, global shipping traffic increased fourfold (Tournadre 2014). The U.S. OCS is no exception to this trend, and growth is expected to continue as human population increases. In addition, the general trend along the coastal region from Virginia to Maine is that port activity will increase modestly. The ability of ports to receive the increase in larger ships will require port modifications. Future channel deepening activities are being undertaken to accommodate deeper draft vessels for the Panama Canal Locks. The additional traffic and larger vessels could have impacts on water quality through increases in suspended sediments and the potential for accidental discharges. The increased sediment suspension could be long-term depending on the vessel traffic increase. Certain types of vessel traffic have increased recently (e.g., ferry use and cruise industry) and may continue to increase in the foreseeable future. Additional impacts associated with the increased risk of vessel strikes could also occur (see the Traffic: Vessel collisions sub-IPF below).
Presence of structures: Entanglement or ingestion of lost fishing gear	The Mid-Atlantic region has more than 130 artificial reefs. Currently bridge foundations and the Block Island Wind Facility may be considered artificial reefs and may have higher levels of recreational fishing, which increases the chances of sea turtles encountering lost fishing gear, resulting in possible ingestions, entanglement, injury, or death of individuals (Berreiros and Raykov 2014; Gregory 2009; Vegter et al. 2014) if present where these structures are located. At the scale of the OCS geographic analysis area for sea turtles, there are very few areas that would serve to concentrate recreational fishing and increase the likelihood that sea turtles would encounter lost fishing gear.	No future activities were identified within the geographic analysis area for sea turtles other than ongoing activities.
Presence of structures: Habitat conversion and prey aggregation	The Mid-Atlantic region has more than 130 artificial reefs. Hard-bottom (scour control and rock mattresses) and vertical structures (bridge foundations and Block Inland Wind Facility WTGs) in a soft-bottom habitat can create artificial reefs, thus inducing the reef effect (Taormina et al. 2018; NMFS 2015). The reef effect is usually considered a beneficial impact, associated with higher densities and biomass of fish and decapod crustaceans (Taormina et al. 2018), providing a potential increase in available forage items and shelter for sea turtles compared to the surrounding soft-bottoms.	The presence of structures associated with non-offshore wind development in near-shore coastal waters has the potential to provide habitat for sea turtles as well as preferred prey species. This reef effect has the potential to result in long-term, low-intensity beneficial impacts. Bridge foundations will continue to provide foraging opportunities for sea turtles with measurable benefits to some individuals.

Associated IPF: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Presence of structures: Avoidance/ displacement	No ongoing activities in the geographic analysis area for sea turtles beyond offshore wind facilities are measurably contributing to this sub-IPF. There may be some impacts resulting from the existing Block Island Wind Facility, but given that there are only 5 WTGs, no measurable impacts are occurring.	Not contemplated for non-offshore wind facility sources.
Presence of structures: Behavioral disruption - breeding and migration	No ongoing activities in the geographic analysis area for sea turtles beyond offshore wind facilities are measurably contributing to this sub-IPF.	Not contemplated for non-offshore wind facility sources.
Presence of structures: Displacement into higher risk areas (Vessels and Fishing)	No ongoing activities in the geographic analysis area for sea turtles beyond offshore wind facilities are measurably contributing to this sub-IPF.	Not contemplated for non-offshore wind facility sources.
Traffic: Vessel collisions	Current activities contributing to this sub-IPF include port traffic levels, fairways, traffic separation schemes, commercial vessel traffic, recreational and fishing activity, and scientific and academic vessel traffic. Propeller and collision injuries from boats and ships are common in sea turtles. Vessel strike is an increasing concern for sea turtles, especially in the southeastern United States, where development along the coasts is likely to result in increased recreational boat traffic. In the United States, the percentage of strandings of loggerhead sea turtles that were attributed to vessel strikes increased from approximately 10% in the 1980s to a record high of 20.5% in 2004 (NMFS and USFWS 2007). Sea turtles are most susceptible to vessel collisions in coastal waters, where they forage from May through November. Vessel speed may exceed 10 knots in such waters, and evidence suggests that they cannot reliably avoid being struck by vessels exceeding 2 knots (Hazel et al. 2007).	Vessel traffic associated with non-offshore wind development has the potential to result in an increased collision risk. While these impacts would be high consequence, the patchy distribution of sea turtles makes stock or population-level effects unlikely (Navy 2018).
Climate change: Warming and sea level rise, storm severity/frequency	Increased storm frequency could lead to long-term, high-consequence impacts on sea turtle onshore beach nesting habitat, including changes to nesting periods, changes in sex ratios of nestlings, drowned nests, as well as loss or degradation of nesting beaches. Offshore impacts, including sedimentation of near-shore hard bottom habitats have the potential to result in long-term, high consequence changes to foraging habitat availability for green turtles.	No future activities were identified within the geographic analysis area for sea turtles other than ongoing activities.
Climate change: Ocean acidification	This sub-IPF has the potential to lead to long-term, high-consequence impacts on marine ecosystems by contributing to reduced growth or the decline of invertebrates that have calcareous shells.	No future activities were identified within the geographic analysis area for sea turtles other than ongoing activities.
Climate change: Warming and sea level rise, altered habitat/ecology	This sub-IPF has the potential to lead to long-term, high-consequence impacts on sea turtles by influencing distributions of sea turtles and/or prey resources. This sub-IPF has the potential to lead to long-term, high-consequence impacts on sea turtle breeding, foraging, and sheltering habitat use.	No future activities were identified within the geographic analysis area for sea turtles other than ongoing activities.

Associated IPF: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Climate change: Warming and sea level rise, altered migration patterns	This sub-IPF has the potential to lead to long-term, high-consequence impacts on sea turtle habitat use and migratory patterns.	No future activities were identified within the geographic analysis area for sea turtles other than ongoing activities.
Climate change: Warming and sea level rise, disease frequency	Climate change, influenced in part by greenhouse gas emissions, is expected to continue to contribute to a gradual warming of ocean waters, influencing the frequencies of various diseases of sea turtles such as fibropapillomatosis.	No future activities were identified within the geographic analysis area for sea turtles other than ongoing activities.
Climate change: Warming and sea level rise, protective measures (barriers, sea walls)	The proliferation of coastline protections have the potential to result in long-term, high-consequence impacts on sea turtle nesting by eliminating or precluding access to potentially suitable nesting habitat or access to potentially suitable habitat.	No future activities were identified within the geographic analysis area for sea turtles other than ongoing activities.
Climate change: Warming and sea level rise, storm severity, frequency, sediment erosion, deposition	Sediment erosion and/or deposition in coastal waters have the potential to result in long-term, high-consequence impacts on green sea turtle foraging habitat. Additionally, sediment erosion has the potential to result in the degradation or loss of potentially suitable nesting habitat.	No future activities were identified within the geographic analysis area for sea turtles other than ongoing activities.

Notes: µPa = micropascal; µT = microtesla; AC = alternating current; ADLS = Aircraft Detection Light System; AIS = Automatic Identification System; BMP = best management practice; BOEM = Bureau of Ocean Energy Management; BSW = Bay State Wind; CFR = Code of Federal Regulations; COP = Construction and Operations Plan; dB = decibel; dB re 1 µPa = decibels relative to one micropascal; dB RMS = decibel root mean square; DC = direct current; DP = dynamic positioning; DPS = distinct population segment; EMF = electromagnetic field; ESP = electrical service platform; FAA = Federal Aviation Administration; FCC = Federal Communications Commission; G&G = Geological and Geophysical; HRG = high resolution geophysical; Hz = hertz; IHA = Incidental Harassment Authorization; IPF = impact-producing factors; MCT = Marine Commerce Terminal; met = meteorological; NARW = North Atlantic right whale; NEPA = National Environmental Policy Act; NMFS = National Marine Fisheries Service; NRA = Navigational Risk Assessment; OCS = Outer Continental Shelf; OECC = Offshore Export Cable Corridor; PAM = passive acoustic monitoring; PSO = protected species observer; PTS = permanent threshold shift; RMS = root mean square; SEIS = Supplemental EIS; SOV = service operations vessel; SPL = sound pressure level; TTS = temporary threshold shift; USACE = U.S. Army Corps of Engineers; USCG = US Coast Guard; WDA = Wind Development Area; WTG = wind turbine generator.

Table E3-7. Summary of Activities and the Associated Impact-Producing Factors for Demographics, Employment, and Economics

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Energy generation/ security	In 2017, Massachusetts energy production totaled 125.2 trillion Btu, of which 72.4 trillion Btu was from renewable sources, including geothermal, hydroelectric, wind, solar, and biomass (U.S. Energy Information Administration 2018).	Ongoing development of onshore solar and wind energy would provide diversified, small-scale energy generation. State and regional energy markets would require additional peaker plants and energy storage to meet the electricity needs when utility scale renewables are not producing.
Light: Structures	Offshore buoys and towers emit low-intensity light, while onshore structures, including houses and ports, emit substantially more light on an ongoing basis.	Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast, but minimal offshore.
Light: Vessels	Ocean vessels have an array of lights including navigational lights and deck lights.	Anticipated modest growth in vessel traffic would result in some growth in the nighttime traffic of vessels with lighting.
New cable emplacement/ maintenance	Infrequent cable maintenance activities disturb the seafloor and cause temporary increases in suspended sediment; these disturbances would be local and limited to emplacement corridors. In the geographic analysis area for demographics, employment, and economics there are six existing power cables.	The FCC has two pending submarine telecommunication cable applications in the North Atlantic. Future new cables would disturb the seafloor and cause temporary increases in suspended sediment resulting in infrequent, localized, short-term impacts over the next 30 years.
Noise: O&M	Limited to South Fork Wind Project	Not applicable
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. These disturbances are temporary, local, and extend only a short distance beyond the work area.	No future activities were identified within the geographic analysis area for demographics, employment, and economics other than ongoing activities.
Noise: Cable laying/trenching	Infrequent trenching for pipeline and cable laying activities emit noise. These disturbances are temporary, local, and extend only a short distance beyond the emplacement corridor. Impacts of trenching noise are typically less prominent than the impacts of the physical disturbance and sediment suspension.	Periodic trenching would be needed over the next 30 years for repair or new installation of underground infrastructure.
Noise: Vessels	Vessel noise occurs offshore and more frequently near ports and docks. Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. Vessel noise is anticipated to continue at or near current levels.	Planned new barge route and dredging disposal sites would generate vessel noise when implemented. The number and location of such routes are uncertain.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also going through continual upgrades and maintenance. The Marine Commerce Terminal at the Port of New Bedford was upgraded by the port specifically to support the construction of offshore wind energy facilities.	Ports would need to perform maintenance and upgrade facilities over the next 30 years to ensure that they can still receive the projected future volume of vessels visiting their ports, and to be able to host larger deep-draft vessels as they continue to increase in size.
Port utilization: Maintenance/ dredging	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. As ports expand, maintenance dredging of shipping channels is expected to increase.	Ports would need to perform maintenance and upgrades over the next 30 years to ensure that they can still receive the projected future volume of vessels visiting their ports, and to be able to host larger deep-draft vessels as they continue to increase in size.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Presence of structures: Allisions	An allision occurs when a moving vessel strikes a stationary object. The stationary object can be a buoy, a port feature, or another anchored vessel. The likelihood of allisions is expected to continue at or near current levels.	Vessel allisions with non-offshore wind stationary objects should not increase meaningfully without a substantial increase in vessel congestion.
Presence of structures: Entanglement, gear loss, gear damage	Commercial and recreational fishing gear is periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures. Such loss and damage are direct costs for gear owners, and are expected to continue at or near current levels.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Fish aggregation	Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables create uncommon relief in a mostly flat seascape. Structure-oriented fishes are attracted to these locations, which may be known as fish aggregating devices (FADs). Recreational and commercial fishing can occur near the FADs, although recreational fishing is more popular, because commercial mobile fishing gear is more likely to snag on FADs.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Habitat conversion	Structures, including foundations, scour protection around foundations, and various means of hard protection atop cables create uncommon relief in a mostly flat seascape. Structure-oriented species thus benefit on a constant basis.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Navigation hazard	Vessels need to navigate around structures to avoid allisions, especially in nearshore areas. This navigation becomes more complex when multiple vessels must navigate around a structure, because vessels need to avoid both the structure and each other.	Vessel traffic, overall, is not expected to meaningfully increase over the next 30 years. The presence of navigation hazards is expected to continue at or near current levels.
Presence of structures: Space use conflicts	Current structures do not result in space use conflicts.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Viewshed	No existing offshore structures are within the viewshed of the WDA except buoys.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Transmission cable infrastructure	The existing offshore cable infrastructure supports the economy by transmitting electric power and communications between mainland and islands. Additional communication cables run between the U.S. East Coast and European countries along the eastern Atlantic.	: No known proposed structures not associated with offshore wind development are reasonably foreseeable.
Traffic: Vessels	Study area ports and marine traffic related to shipping, fishing, and recreation are important to the region's economy. No substantial changes are anticipated to existing vessel traffic volumes.	New vessel traffic near the study area would be generated by proposed barge routes and dredging demolition sites over the next 30 years. Marine commerce and related industries would continue to be important to the study area economy.
Traffic: Vessel collisions	The region's substantial marine traffic may result in occasional vessel collisions, which would result in costs to the vessels involved. The likelihood of collisions is expected to continue at or near current rates.	No substantial changes anticipated.

Associated IPFs: Sub-IPFs	**Ongoing Activities**	**Future Non-Offshore Wind Activities Intensity/Extent**
Land disturbance: Onshore construction	Onshore development activities support local population growth, employment, and economies. Disturbances can cause temporary, localized traffic delays and restricted access to adjacent properties. The rate of onshore land disturbance is expected to continue at or near current rates.	Onshore development projects would be ongoing in accordance with local government land use plans and regulations.
Climate change	Climate models predict climate change if current trends continue. Climate change has adverse implications for demographics and economic health of coastal communities, due in part to the costs of resultant damage to property and infrastructure, fisheries and other natural resources, increased disease frequency, and sedimentation, among other factors.	Onshore projects that reduce air emissions could contribute to the effort to limit climate change. Onshore solar and wind energy projects, although producing less energy than potential offshore wind developments, would also provide incremental reductions.
Regulated fishing effort	Commercial and recreational regulations for finfish and shellfish implemented and enforced by NOAA Fisheries and coastal states affect how commercial and for-hire recreational fisheries operate. Commercial and recreational for-hire fisheries are managed by FMPs, which are established to manage fisheries to avoid overfishing through catch quotas, special management areas, and closed area regulations. These can reduce or increase the size of available landings to commercial and for-hire recreational fisheries.	Reasonably foreseeable fishery management actions include measures to reduce the risk of interactions between fishing gear and the North Atlantic right whale by 60% (McCreary and Brooks 2019). This will likely have a significant impact on fishing effort in the lobster and Jonah crab fisheries in the geographic analysis area for this resource. See No Action alternative for additional fishery management actions that will affect commercial fisheries and for-hire recreational fishing.

Notes: ADLS = Aircraft Detection Light System; BOEM = Bureau of Ocean Energy Management; Btu = British thermal unit; EIS = Environmental Impact Statement; ESP = electrical service platform; FADs = fish aggregating devices; FCC = Federal Communications Commission; FMPs = fishery management plans; G&G = Geological and Geophysical; GW = gigawatts; IPF = impact-producing factors; MA = Massachusetts; NA = not applicable; NOAA = National Oceanic and Atmospheric Administration; O&M = operations and maintenance; OECC = Offshore Export Cable Corridor(s); RI = Rhode Island; SAR = search and rescue; SEIS = Supplemental Environmental Impact Statement; USCG = United States Coast Guard; WDA = Wind Development Area; WTG = wind turbine generator.

Table E3-8. Summary of Activities and the Associated Impact-Producing Factors for Environmental Justice

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Air emissions: Construction/ decommissioning	Ongoing population growth and new development within the analysis area is likely to increase traffic with resulting increase in emissions from motor vehicles. Some new industrial development may result in emissions-producing uses. At the same time, many industrial waterfront areas near environmental justice communities are losing industrial uses, and converting to more commercial or residential uses.	New development may include emissions-producing industry and new development that would increase emissions from motor vehicles. Some historically industrial waterfront locations will continue to lose industrial uses, with no new industrial development to replace it. Cities such as New Bedford are promoting start-up space and commercial uses to re-use industrial space.
Air emissions: Operations and maintenance	Ongoing population growth and new development within the analysis area is likely to increase traffic with resulting increase in emissions from motor vehicles. Some new industrial development may result in emissions-producing uses. At the same time, many industrial waterfront areas near environmental justice communities are losing industrial uses, and converting to more commercial or residential uses.	New development may include emissions-producing industry and new development that would increase emissions from motor vehicles. Some historically industrial waterfront locations will continue to lose industrial uses, with no new industrial development to replace it. Cities such as New Bedford are promoting start-up space and commercial uses to re-use industrial space.
Light: Structures	Offshore buoys and towers emit low-intensity light, while onshore structures, including houses and ports, emit substantially more light on an ongoing basis.	Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast, but minimal offshore.
New cable emplacement/ maintenance	Infrequent cable maintenance activities disturb the seafloor and cause temporary increases in suspended sediment; these disturbances would be local and limited to emplacement corridors.	The FCC has two pending submarine telecommunication cable applications in the North Atlantic. Future new cables would disturb the seafloor and cause temporary increases in suspended sediment, resulting in infrequent, localized, short-term impacts over the next 30 years.
Noise: Operations and maintenance	Offshore operations and maintenance of existing wind energy projects generates negligible amounts of noise.	There are no reasonably foreseeable offshore facilities that would generate noise from operations/maintenance.
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. These disturbances are temporary, local, and extend only a short distance beyond the work area.	No future activities were identified within the analysis area other than ongoing activities.
Noise: Trenching	Infrequent trenching for pipeline and cable laying activities emits noise. These disturbances are temporary, local, and extend only a short distance beyond the emplacement corridor. Impacts of trenching noise are typically less prominent than the impacts of the physical disturbance and sediment suspension.	Periodic trenching would be needed over the next 30 years for repair or new installation of underground infrastructure.
Noise: Vessels	Vessel noise occurs offshore and more frequently near ports and docks. Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. Vessel noise is anticipated to continue at or near current levels.	Planned new barge route and dredging disposal sites would generate vessel noise when implemented. The number and location of such routes are uncertain.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also going through continual upgrades and maintenance. The MCT at the Port of New Bedford is a completed facility developed by the port specifically to support the construction of offshore wind facilities.	Ports would need to perform maintenance and upgrade facilities to ensure that they can still receive the projected future volume of vessels visiting their ports, and to be able to host larger deep-draft vessels as they continue to increase in size.
Presence of structures: Entanglement, gear loss/ damage	Commercial and recreational fishing gear is periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures. Such loss and damage are direct costs for gear owners, and are expected to continue at or near current levels.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Navigation hazard	Vessels need to navigate around structures to avoid allisions, especially in nearshore areas. This navigation becomes more complex when multiple vessels must navigate around a structure, because vessels need to avoid both the structure, and each other.	Vessel traffic is generally not expected to meaningfully increase over the next 30 years. The presence of navigation hazards is expected to continue at or near current levels.
Presence of structures: Space use conflicts	Current structures do not result in space use conflicts.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Viewshed	There are no existing offshore structures within the viewshed of the WDA except buoys.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Transmission cable infrastructure	Seven subsea cable corridors cross cumulative lease areas.	Existing cable operation and maintenance activities would continue within the analysis area.
Traffic: Vessels	Study area ports and marine traffic related to shipping, fishing and recreation are important to the region's economy. No substantial changes are anticipated to existing vessel traffic volumes.	New vessel traffic near the study area would be generated by proposed barge routes and dredging demolition sites over the next 30 years. Marine commerce and related industries would continue to be important to the study area employment.
Land disturbance: Erosion and sedimentation	Potential erosion and sedimentation from development and construction is controlled by local and state development regulations.	New development activities would be subject to erosion and sedimentation regulations.
Land disturbance: Onshore construction	Onshore development supports local population growth, employment, and economics.	Onshore development would continue in accordance with local government land use plans and regulations.
Land disturbance: Onshore, land use changes	Onshore development would result in changes in land use in accordance with local government land use plans and regulations.	Development of onshore solar and wind energy would provide diversified, small-scale energy generation.
Climate change	Climate models predict climate change if current trends continue. Climate change has adverse implications for demographics and the economic health of coastal communities, due in part to the costs of resultant damage to property and infrastructure, fisheries, and other natural resources; increased disease frequency; and sedimentation, among other factors.	Onshore projects that reduce air emissions could contribute to the effort to limit climate change. Onshore solar and wind energy projects, although producing less energy than potential offshore wind developments, would also provide incremental reductions.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Regulated fishing effort	Commercial and recreational regulations for finfish and shellfish implemented and enforced by NOAA Fisheries and coastal states affect how commercial and for-hire recreational fisheries operate. Commercial and recreational for-hire fisheries are managed by FMPs, which are established to manage fisheries to avoid overfishing through catch quotas, special management areas, and closed area regulations. These can reduce or increase the size of available landings to commercial and for-hire recreational fisheries.	Reasonably foreseeable fishery management actions include measures to reduce the risk of interactions between fishing gear and the North Atlantic right whale by 60% (McCreary and Brooks 2019). This will likely have a significant impact on the fishing effort in the lobster and Jonah crab fisheries in the geographic analysis area for this resource. See No Action alternative for additional fishery management actions that will affect commercial fisheries and for-hire recreational fishing.

Table E3-9. Summary of Activities and the Associated Impact-Producing Factors for Cultural Resources

Associated IPF: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Accidental releases: Fuel/fluids/hazmat	See Attachment 2/Table E2-2 for water quality for a quantitative analysis of these risks. Accidental releases of fuel/fluids/hazmat occur during vessel use for recreational, fisheries, marine transportation, or military purposes, and other ongoing activities. Both released fluids and cleanup activities that require the removal of contaminated soils and/or seafloor sediments can cause impacts on cultural resources because resources are impacted during by the released chemicals as well as the ensuing cleanup activities.	Gradually increasing vessel traffic over the next 30 years would increase the risk of accidental releases within the geographic analysis area for cultural resources, increasing the frequency of small releases. Although the majority of anticipated accidental releases would be small, resulting in small-scale impacts on cultural resources, a single, large-scale accidental release such as an oil spill, could have significant impacts on marine and coastal cultural resources. A large-scale release would require extensive cleanup activities to remove contaminated materials resulting in damage to or the complete removal of terrestrial and marine cultural resources. In addition, the accidentally released materials in deep water settings could settle on seafloor cultural resources such as wreck sites, accelerating their decomposition and/or covering them and making them inaccessible/unrecognizable to researchers, resulting in a significant loss of historic information. As a result, although considered unlikely, a large-scale accidental release and associated cleanup could result in permanent, geographically extensive, and large-scale impacts on cultural resources.

Associated IPF: Sub-IPFs	**Ongoing Activities**	**Future Non-Offshore Wind Activities Intensity/Extent**
Accidental releases: Trash and debris	Accidental releases of trash and debris occur during vessel use for recreational, fisheries, marine transportation, or military purposes and other ongoing activities. While the released trash and debris can directly affect cultural resources, the majority of impacts associated with accidental releases occur during cleanup activities, especially if soil or sediment removed during cleanup affect known and undiscovered archaeological resources. In addition, the presence of large amounts of trash on shorelines or the ocean surface can impact the cultural value of TCPs for stakeholders. State and federal laws prohibiting large releases of trash would limit the size of any individual release and ongoing local, state, and federal efforts to clean up trash on beaches and waterways would continue to mitigate the effects of small-scale accidental releases of trash.	Future activities with the potential to result in accidental releases include construction and operations of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications). Accidental releases would continue at current rates along the northeast Atlantic coast.
Anchoring	The use of vessel anchoring and gear (i.e., wire ropes, cables, chain, sweep on the seafloor) that disturbs the seafloor, such as bottom trawls and anchors, by military, recreational, industrial, and commercial vessels can impact cultural resources by physically damaging maritime archaeological resources such as shipwrecks and debris fields.	Future activities with the potential to result in anchoring/gear utilization include construction and operations of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); military use; marine transportation; fisheries use and management; and oil and gas activities. These activities are likely to continue to occur at current rates along the entire coast of the eastern United States.
Gear utilization: Dredging	Activities associated with dredge operations and activities could damage marine archaeological resources. Ongoing activities identified by BOEM with the potential to result in dredging impacts include construction and operation of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); tidal energy projects; marine minerals use and ocean-dredged material disposal; military use; marine transportation; fisheries use and management; and oil and gas activities.	Dredging activities would gradually increase through time as new offshore infrastructure is built, such as gas pipelines and electrical lines, and as ports and harbors are expanded or maintained.
Light: Vessels	Light associated with military, commercial, or construction vessel traffic can temporarily affect coastal historic structures and TCP resources when the addition of intrusive, modern lighting changes the physical environment ("setting") of cultural resources. The impacts of construction and operations lighting would be limited to cultural resources on the shoreline for which a nighttime sky is a contributing element to historic integrity. This excludes resources that are closed at night, such as historic buildings, lighthouses, and battlefields, and resources that generate their own nighttime light, such as historic districts. Offshore construction activities that require increased vessel traffic, construction vessels stationed offshore, and construction area lighting for prolonged periods can cause more sustained and significant visual impacts on coastal historic structure and TCP resources.	Future activities with the potential to result in vessel lighting impacts include construction and operation of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); marine minerals use and ocean-dredged material disposal; military use; marine transportation; fisheries use and management; and oil and gas activities. Light pollution from vessel traffic would continue at the current intensity along the northeast coast, with a slight increase due to population increase and development over time.
Light: Structures	The construction of new structures that introduce new light sources into the setting of historic architectural properties or TCPs can result in impacts, particularly if the historic and/or cultural significance of the resource is associated with uninterrupted nighttime skies or periods of darkness. Any tall structure (commercial building, radio antenna, large satellite dishes, etc.) requiring nighttime hazard lighting to prevent aircraft collision can cause these types of impacts.	Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast, but minimal offshore.

Associated IPF: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Port utilization: Expansion	Major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also going through continual upgrades and maintenance. The MCT was upgraded by the Port of New Bedford specifically to support the construction of offshore wind facilities. Expansion of port facilities can introduce large, modern port infrastructure into the viewsheds of nearby historic properties, impacting their setting and historic significance.	Future activities with the potential to result in port expansion impacts include construction and operation of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); tidal energy projects; marine minerals use and ocean-dredged material disposal; military use; marine transportation; fisheries use and management; and oil and gas activities. Port expansion would continue at current levels, which reflect efforts to capture business associated with the offshore wind industry (irrespective of specific projects).
Presence of structures	The only existing offshore structures within the viewshed of the geographic analysis area are minor features such as buoys.	Non-offshore wind structures that could be viewed would be limited to meteorological towers. Marine activity would also occur within the marine viewshed of the geographic analysis area.
New cable emplacement/ maintenance	Current offshore construction activity is limited to subsea fiber optic and electrical transmission cables, including six existing power cables in the geographic analysis area.	Future activities with the potential to result in seafloor disturbances similar to offshore impacts include construction and operation of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); tidal energy projects; marine minerals use and ocean-dredged material disposal; military use; and oil and gas activities. Such activities could cause impacts on submerged archaeological resources including shipwrecks and formerly subaerially exposed pre-contact Native American archaeological sites.
Land disturbance: Onshore construction	Onshore construction activities can impact archaeological resources by damaging and/or removing resources.	Future activities that could result in terrestrial land disturbance impacts include onshore residential, commercial, industrial, and military development activities in central Cape Cod, particularly those proximate to OECRs and interconnection facilities. Onshore construction would continue at current rates.
Climate change: Warming and sea level rise, storm severity/frequency	Sea level rise and increased storm severity and frequency would result in impacts on archaeological, architectural, and TCP resources. Increased storm frequency and severity would also result in damage to and/or destruction of architectural properties. Sea level rise would increase erosion-related impacts on archaeological and architectural resources, while sea level rise would inundate archaeological, architectural, and TCP resources.	Sea level rise and storm severity/frequency would increase due to the effects of climate change.
Climate change: Warming and sea level rise, altered habitat/ecology	Altered habitat/ecology related to warming seas and sea level rise would impact the ability of Native Americans and other communities to use maritime TCPs for traditional fishing, shell fishing, and fowling activities.	The rate of change to habitats/ecology would increase as a result of climate change.
Climate change: Warming and sea level rise, altered migration patterns	Altered migration patterns related to warming seas and sea level rise would impact the ability of Native Americans and other communities to use maritime TCPs for traditional fishing, shell fishing, and fowling activities.	The rate of change to migratory animal patterns would increase as a result of climate change.

Associated IPF: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Climate change: Warming and sea level rise, property/ infrastructure damage	Sea level rise and increased storm severity and frequency would result in impacts on archaeological, architectural, and TCP resources. Increased storm frequency and severity would result in damage to and/or destruction of architectural properties. Sea level rise would increase erosion-related impacts on archaeological and architectural resources while sea level rise would inundate archaeological, architectural, and TCP resources.	The rate of property and infrastructure damage would increase as a result of climate change.
Climate change: Warming and sea level rise, protective measures (barriers, sea walls)	The installation of protective measures such as barriers and sea walls would impact archaeological resources during associated ground-disturbing activities. Construction of these modern protective structures would alter the viewsheds from historic properties and/or TCPs, resulting in impacts on the historic and/or cultural significance of resources.	The installation of coastal protective measures would increase as a result of climate change.
Climate change: Warming and sea level rise, storm severity/frequency, sediment erosion, deposition	Sea level rise and increased storm severity and frequency would result in impacts on archaeological, architectural, and TCP resources. Increased storm frequency and severity would result in damage to and/or destruction of architectural properties. Sea level rise would increase erosion related impacts on archaeological and architectural resources while sea level rise would inundate archaeological, architectural, and TCP resources.	Sea level rise and storm severity/frequency would increase due to the effects of climate change.

Notes: ADLS = Aircraft Detection Light System; BMP = best management practice; BOEM = Bureau of Ocean Energy Management; hazmat = hazardous materials; ESP = electrical service platform; IFP = impact-producing factors; MCT = New Bedford Marine Commerce Terminal; MHC = Massachusetts Historical Commission; NEPA = National Environmental Policy Act; NHL = National Historic Landmark; NHPA = National Historic Preservation Act; NRHP = National Register of Historic Places; OCS = Outer Continental Shelf; OECC = Offshore Export Cable Corridor; OECR = Onshore Export Cable Route; RI and MA Lease Areas = Rhode Island and Massachusetts Lease Areas; SHPO = state historic preservation office; TCP = Traditional Cultural Property; WDA = Wind Development Area; WTG = wind turbine generator.

Table E3-10. Summary of Activities and the Associated Impact-Producing Factors for Recreation and Tourism

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Anchoring	Anchoring occurs due to ongoing military, survey, commercial, and recreational activities.	Impacts from anchoring would continue, and may increase due to offshore military operations, survey activities, commercial vessel traffic, and/or recreational vessel traffic. Modest growth in vessel traffic could increase the temporary, localized impacts of navigational hazards, increased turbidity levels, and potential for direct contact causing mortality of benthic resources.
Light: Vessels	Ocean vessels have an array of lights including navigational lights and deck lights.	Anticipated modest growth in vessel traffic would result in some growth in the nighttime traffic of vessels with lighting.
Light: Structures	Offshore buoys and towers emit low-intensity light. Onshore structures, including houses and ports, emit substantially more light on an ongoing basis.	Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast, but minimal offshore.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
New cable emplacement/ maintenance	Infrequent cable maintenance activities disturb the seafloor and cause temporary increases in suspended sediment; these disturbances would be local and limited to emplacement corridors.	Cable maintenance or replacement of existing cables in the geographic analysis area would occur infrequently, and would generate short-term disturbances.
Noise: O&M	Limited to Block Island Wind Farm	Not applicable
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. These disturbances are temporary, local, and extend only a short distance beyond the work area.	No future activities were identified within the recreation and tourism geographic analysis area other than ongoing activities.
Noise: Cable laying/trenching	Offshore trenching occurs periodically in connection with cable installation or sand and gravel mining.	No future activities were identified within the recreation and tourism geographic analysis area other than ongoing activities.
Noise: Vessels	Vessel noise occurs offshore and more frequently near ports and docks. Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. Vessel noise is anticipated to continue at or near current levels.	Planned new barge routes and dredging disposal sites would generate vessel noise when implemented. The number and location of such routes are uncertain.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also going through continual upgrades and maintenance. The Marine Commerce Terminal at the Port of New Bedford was upgraded by the port specifically to support the construction of offshore wind energy facilities.	Ports would need to perform maintenance and upgrade facilities over the next 30 years to ensure that they can still receive the projected future volume of vessels visiting their ports, and to be able to host larger deep-draft vessels as they continue to increase in size.
Port utilization: Maintenance/ dredging	No major ports are within the geographic analysis area. Periodic maintenance is necessary for harbors within the analysis area.	Ongoing maintenance and dredging of harbors within the geographic analysis area will continue as needed. No specific projects are known.
Presence of structures: Allisions	An allision occurs when a moving vessel strikes a stationary object. The stationary object can be a buoy, a port feature, or another anchored vessel. The likelihood of allisions is expected to continue at or near current levels.	Vessel allisions with non-offshore wind stationary objects should not increase meaningfully without a substantial increase in vessel congestion.
Presence of structures: Entanglement, gear loss, gear damage	Commercial and recreational fishing gear is periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures.	No future activities were identified within the recreation and tourism geographic analysis area other than ongoing activities.
Presence of structures: Fish aggregation	Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables create uncommon relief in a mostly flat seascape. Structure-oriented fishes are attracted to these locations. Recreational and commercial fishing can occur near these aggregation locations, although recreational fishing is more popular, because commercial mobile fishing gear is more likely to snag on structures.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Habitat conversion	Structures, including foundations, scour protection around foundations, and various means of hard protection atop cables create uncommon relief in a mostly flat seascape. Structure-oriented species thus benefit on a constant basis.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Presence of structures: Navigation hazard	Vessels need to navigate around structures to avoid allisions, especially in nearshore areas. This navigation becomes more complex when multiple vessels must navigate around a structure, because vessels need to avoid both the structure and each other.	Vessel traffic, overall, is not expected to meaningfully increase over the next 30 years. The presence of navigation hazards is expected to continue at or near current levels.
Presence of structures: Space use conflicts	Current structures do not result in space use conflicts.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Viewshed	The only existing offshore structures within the viewshed of the Project are minor features such as buoys.	Non-offshore wind structures that could be viewed in conjunction with the offshore components of the Project would be limited to meteorological towers. Marine activity would also occur within the marine viewshed.
Traffic: Vessels	Study area ports and marine traffic related to shipping, fishing, and recreation are important to the region's economy. No substantial changes are anticipated to existing vessel traffic volumes.	New vessel traffic near the study area would be generated by proposed barge routes and dredging demolition sites over the next 30 years. Marine commerce and related industries would continue to be important to the study area economy.
Traffic: Vessel collisions	The region's substantial marine traffic may result in occasional vessel collisions, which would result in costs to the vessels involved. The likelihood of collisions is expected to continue at or near current rates.	An increased risk of collisions is not anticipated from future activities.

Notes: ADLS = Aircraft Detection Light System; EFH = essential fish habitat; ESP = electrical service platform; FAA = Federal Aviation Administration; IPF = impact-producing factors; MW = megawatts; OECC = Offshore Export Cable Corridor; RI and MA = Rhode Island and Massachusetts; SEIS = Supplemental EIS; USCG = U.S. Coast Guard; WDA = Wind Development Area; WTG = wind turbine generator.

Table E3-11. Summary of Activities and the Associated Impact-Producing Factors for Commercial Fisheries and For-Hire Recreational Fishing

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Anchoring	Impacts from anchoring occur due to ongoing military, survey, commercial, and recreational activities. The short-term, localized impact to this resource is the presence of a navigational hazard (anchored vessel) to fishing vessels.	Impacts from anchoring may occur on a semi-regular basis over the next 30 years due to offshore military operations, survey activities, commercial vessel traffic, and/or recreational vessel traffic. Anchoring could pose a temporary (hours to days), localized (within a few hundred meters of anchored vessel) navigational hazard to fishing vessels.
New cable emplacement/ maintenance	New cable emplacement and infrequent cable maintenance activities disturb the seafloor, increase suspended sediment, and cause temporary displacement of fishing vessels. These disturbances would be local and limited to the emplacement corridor.	Future new cables and cable maintenance would occasionally disturb the seafloor and cause temporary displacement in fishing vessels and increases in suspended sediment resulting in local, short-term impacts. The FCC has two pending submarine tele-communication cable applications in the North Atlantic. If the cable routes enter the geographic analysis area for this resource, short-term disruption of fishing activities would be expected.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Noise: Construction, trenching, operations and maintenance	Noise from construction occurs frequently in coastal habitats in populated areas in New England and the Mid-Atlantic, but infrequently offshore. The intensity and extent of noise from construction is difficult to generalize, but impacts are local and temporary. Infrequent offshore trenching could occur in connection with cable installation. These disturbances are temporary, local, and extend only a short distance beyond the emplacement corridor. Low levels of elevated noise from operational WTGs likely have low to no impacts on fish and no impacts at a fishery level. Noise is also created by operations and maintenance of marine minerals extraction, which has small, local impacts on fish, but likely no impacts at a fishery level.	Noise from construction near shore is expected to gradually increase in line with human population growth along the coast of the geographic analysis area for this resource. Noise from dredging and sand and gravel mining could occur. New or expanded marine minerals extraction may increase noise during their operations and maintenance over the next 30 years. Impacts from construction, operations, and maintenance would likely be small and local on fish, and not seen at a fishery level. Periodic trenching would be needed for repair or new installation of underground infrastructure. These disturbances would be temporary, local, and extend only a short distance beyond the emplacement corridor. Impacts of trenching noise on commercial fish species are typically less prominent than the impacts of the physical disturbance and sediment suspension. Therefore, fishery-level impacts are unlikely.
Noise: G&G	Ongoing site characterization surveys and scientific surveys produce noise around sites of investigation. These activities can disturb fish and invertebrates in the immediate vicinity of the investigation and can cause temporary behavioral changes. The extent depends on equipment used, noise levels, and local acoustic conditions.	Site characterization surveys, scientific surveys, and exploratory oil and gas surveys are anticipated to occur infrequently over the next 30 years. Seismic surveys used in oil and gas exploration create high-intensity impulsive noise to penetrate deep into the seabed, potentially resulting in injury or mortality to finfish and invertebrates in a small area around each sound source and short-term stress and behavioral changes to individuals over a greater area. Site characterization surveys typically use sub-bottom profiler technologies that generate less-intense sound waves more similar to common deep-water echosounders. The intensity and extent of the resulting impacts are difficult to generalize, but are likely local and temporary.
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when ports or marinas, piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water and/or through the seabed can cause injury and/or mortality to finfish and invertebrates in a small area around each pile, and can cause short-term stress and behavioral changes to individuals over a greater area, leading to temporary local impacts on commercial fisheries and for-hire recreational fishing. The extent depends on pile size, hammer energy, and local acoustic conditions.	No future activities were identified within the analysis area other than ongoing activities.
Noise: Vessels	Vessel noise is anticipated to continue at levels similar to current levels. While vessel noise may have some impact on behavior, it is likely limited to brief startle and temporary stress responses. Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, and scientific and academic research vessels.	Planned new barge route and dredging disposal sites would generate vessel noise when implemented.

Associated IPFs: Sub-IPFs	**Ongoing Activities**	**Future Non-Offshore Wind Activities Intensity/Extent**
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also going through continual upgrades and maintenance, including dredging. Port utilization is expected to increase over the next 30 years.	Ports would need to perform maintenance and upgrades to ensure that they can still receive the projected future volume of vessels visiting their ports, and to be able to host larger deep-draft vessels as they continue to increase in size. Port utilization is expected to increase over the next 30 years, with increased activity during construction. The ability of ports to receive the increase in vessel traffic may require port modifications, such as channel deepening, leading to local impacts on fish populations. Port expansions could also increase vessel traffic and competition for dockside services, which could affect fishing vessels.
Presence of structures: Navigation hazard and allisions	Structures within and near the cumulative lease areas that pose potential navigation hazards include the Block Island Wind Farm WTGs, buoys, and shoreline developments such as docks and ports. An allision occurs when a moving vessel strikes a stationary object. The stationary object can be a buoy, a port feature, or another anchored vessel. Two types of allisions occur: drift and powered. A drift allision generally occurs when a vessel is powered down due to operator choice or power failure. A powered allision generally occurs when an operator fails to adequately control their vessel movements, or is distracted.	No known reasonably foreseeable structures are proposed to be located in the geographic analysis area that could affect commercial fisheries. Vessel allisions with non-offshore wind stationary objects should not increase meaningfully without a substantial increase in vessel congestion.
Presence of structures: Entanglement, gear loss, gear damage	Commercial and recreational fishing gear is periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures. The lost gear, moved by currents, can disturb habitats and potentially harm individuals, creating small, localized, short-term impacts on fish, but likely no impacts at a fishery level.	No future activities were identified within the analysis area other than ongoing activities.
Presence of structures: Habitat conversion and fish aggregation	Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables create uncommon relief in a mostly sandy seascape. A large portion is homogeneous sandy seascape but there is some other hard and/or complex habitat. Structures are periodically added, resulting in the conversion of existing soft-bottom and hard-bottom habitat to the new hard-structure habitat. Structure-oriented fishes are attracted to these locations. These impacts are local and can be short-term to permanent. Fish aggregation may be considered adverse, beneficial, or neither. Commercial and for-hire recreational fishing can occur near these structures. For-hire recreational fishing is more popular, as commercial mobile fishing gear risk snagging on the structures.	New cables, installed incrementally in the analysis area over the next 20 to 30 years, would likely require hard protection atop portions of the route (see New cable emplacement/maintenance IPF above). Any new towers, buoys, or piers would also create uncommon relief in a mostly flat seascape. Structure-oriented species could be attracted to these locations. Structure-oriented species would benefit (Claisse et al. 2014, Smith et al. 2016). This may lead to more and larger structure-oriented fish communities and larger predators opportunistically feeding on the communities, as well as increased private and for-hire recreational fishing opportunities. Soft bottom is the dominant habitat type in the region, and species that rely on this habitat would not likely experience population-level impacts (Guida et al. 2017; Greene et al. 2010). These impacts are expected to be local and may be long-term.
Presence of structures: Migration disturbances	Human structures in the marine environment, e.g., shipwrecks, artificial reefs, buoys, and oil platforms, can attract finfish and invertebrates that approach the structures during their migrations. This could slow species migrations. However, temperature is expected to be a bigger driver of habitat occupation and species movement than structure (Secor et al. 2018). There is no evidence to suggest that structures pose a barrier to migratory animals.	The infrequent installation of future new structures in the marine environment over the next 30 years may attract finfish and invertebrates that approach the structures during their migrations. This could tend to slow migrations. However, temperature is expected to be a bigger driver of habitat occupation and species movement (Secor et al. 2018). Migratory animals would likely be able to proceed from structures unimpeded. Therefore, fishery-level impacts are not anticipated.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Presence of structures: Space use conflicts	Current structures do not result in space use conflicts.	No known reasonably foreseeable structures are proposed for location in the geographic analysis area that could affect commercial fisheries and for-hire recreational fishing.
Presence of structures: Transmission cable infrastructure	The existing offshore cable infrastructure supports the economy by transmitting electric power and communications between mainland and islands. Seven subsea cable corridors cross cumulative lease areas. Shoreline developments are ongoing and include docks, ports, and other commercial, industrial, and residential structures.	No known proposed structures (other than those associated with offshore wind development) are reasonably foreseeable and proposed to be located in the geographic analysis area for this resource.
Traffic: Vessels and vessel collisions	No substantial changes are anticipated to the vessel traffic volumes. The study area would continue to have numerous ports and the extensive marine traffic related to shipping, fishing, and recreation would continue to be important to the region's economy. The region's substantial marine traffic may result in occasional collisions. Vessels need to navigate around structures to avoid allisions. When multiple vessels need to navigate around a structure, then navigation is more complex, as the vessels need to avoid both the structure and each other. The risk for collisions is ongoing but infrequent.	New vessel traffic in the geographic analysis area would consistently be generated by proposed barge routes and dredging demolition sites. Marine commerce and related industries would continue to be important to the regional economy.
Climate change	Impacts to commercial fisheries and for-hire recreational fishing are expected to result from climate change events such as increased magnitude or frequency of storms, shoreline changes, ocean acidification, and water temperature changes. Risks to fisheries associated with these events include habitat/distribution shifts, disease incidence, and risk of invasive species. If these risk factors result in a decrease in catch and/or an increase in fishing costs (e.g., transiting time), the profitability of businesses engaged in commercial fisheries and for-hire recreational fishing would be adversely affected. While climate change is predicted to have adverse impacts on the distribution and/or productivity of some stocks targeted by commercial fisheries and for-hire recreational fishing, other stocks may be beneficially affected. The economies of communities reliant on marine species that are vulnerable to the effects of climate change could be adversely affected. If the distribution of important stocks changes, it could affect where commercial and for-hire recreational fisheries are located. Furthermore, coastal communities with fishing businesses that have infrastructure near the shore could be adversely affected by sea level rise.	No future activities were identified within the geographic analysis area for this resource other than ongoing activities.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Regulated fishing effort	Commercial and recreational regulations for finfish and shellfish implemented and enforced by NOAA Fisheries and coastal states, affect how the commercial and for-hire recreational fisheries operate. Commercial and recreational for-hire fisheries are managed by FMPs, which are established to manage fisheries to avoid overfishing through catch quotas, special management areas, and closed area regulations. These can reduce or increase the size of available landings to commercial and for-hire recreational fisheries. For example, ongoing fishing restrictions designed to rebuild depleted stocks in the Northeast Multispecies (large-mesh) fishery will continue to reduce landings in that fishery.	Reasonably foreseeable fishery management actions include measures to reduce the risk of interactions between fishing gear and the North Atlantic right whale by 60% (McCreary and Brooks 2019). This will likely have a have a major adverse impact on fishing effort in the lobster and Jonah crab fisheries in the geographic analysis area for this resource. As discussed in Karp et al. (2019), changing climate and ocean conditions and the resultant effects on species distributions and productivity can have significant effects on management decisions, such as allocation, spatiotemporal closures, stock status determinations, and catch limits. See No Action alternative for additional fishery management actions that will affect commercial fisheries and for-hire recreational fishing.

Notes: BOEM = Bureau of Ocean Energy Management; COP = Construction and Operations Plan; EIS = Environmental Impact Statement; FMPs = fishery management plans; G&G = Geological and Geophysical; GHG = greenhouse gas; IPF = impact-producing factors; met = meteorological; NMFS = National Marine Fisheries Service; NOAA = National Oceanic and Atmospheric Administration; OCS = Outer Continental Shelf; OECC = Offshore Export Cable Corridor; RI and MA Lease Area = Rhode Island and Massachusetts Lease Areas; SAR = search and rescue; VMS = vessel monitoring system; WDA = Wind Development Area; WTG = wind turbine generator.

Table E3-12. Summary of Activities and the Associated Impact-Producing Factors for Land Use and Coastal Infrastructure

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Accidental releases: Fuel/fluids/ hazmat	Various ongoing onshore and coastal construction projects include the use of vehicles and equipment that contain fuel, fluids, and hazardous materials that could be released.	Ongoing onshore construction projects involve vehicles and equipment that use fuel, fluids, or hazardous materials could result in an accidental release. Intensity and extent would vary, depending on the size, location, and materials involved in the release.
Light: Structures	Various ongoing onshore and coastal construction projects have nighttime activities, as well as existing structures, facilities, and vehicles that would use nighttime lighting.	Ongoing onshore construction projects involving nighttime activity could generate nighttime lighting. Intensity and extent would vary, depending on the location, type, direction, and duration of nighttime lighting.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also going through continual upgrades and maintenance. The MCT at the Port of New Bedford is a completed facility developed by the port specifically to support the construction of offshore wind facilities.	Ports would need to perform maintenance and upgrade facilities to ensure that they can still receive the projected future volume of vessels visiting their ports, and to be able to host larger deep draft vessels as they continue to increase in size.
Presence of structures: Viewshed	The only existing offshore structures within the offshore viewshed of the Project are minor features such as buoys.	Non-offshore wind structures that could be viewed in conjunction with the offshore components would be limited to met towers. Marine activity would also occur within the marine viewshed.
Presence of structures: Transmission cable infrastructure	Onshore buried transmission cables are present in the area near the Project onshore and offshore improvements. Onshore activities would only occur where permitted by local land use authorities, which would avoid long-term land use conflicts.	No known proposed structures are reasonably foreseeable and proposed to be located in the geographic analysis area for land use and coastal infrastructure.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Land disturbance: Onshore construction	Onshore construction supports local population growth, employment, and economics.	Onshore development would continue in accordance with local government land use plans and regulations.
Land disturbance: Onshore, land use changes	New development or redevelopment would result in changes in land use in accordance with local government land use plans and regulations.	Ongoing and future development and redevelopment is anticipated to reinforce existing land use patterns, based on local government planning documents.

Notes: ADLS = Aircraft Detection Light System; IPF = impact-producing factors; MCT = New Bedford Marine Commerce Terminal; met = meteorological; NOAA = National Oceanic and Atmospheric Administration; ROW = right-of-way; USACE = U.S. Army Corps of Engineers; WTG = wind turbine generator.

Table E3-13. Summary of Activities and the Associated Impact-Producing Factors for Navigation and Vessel Traffic

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Anchoring	Larger commercial vessels (specifically tankers) sometimes anchor outside of major ports to transfer their cargo to smaller vessels for transport into port, an operation known as lightering. These anchors have deeper ground penetration and are under higher stresses. Smaller vessels (commercial fishing or recreational vessels) would anchor for fishing and other recreational activities. These activities cause temporary to short-term impacts on navigation in the immediate anchorage area. All vessels may anchor in an emergency scenario (such as power loss) if they lose power to prevent them from drifting and creating navigational hazards for other vessels or drifting into structures.	Lightering and anchoring operations are expected to continue at or near current levels, with the expectation of moderate increase commensurate with any increase in tankers visiting ports. Deep draft visits to major port visits are expected to increase as well, increasing the potential for an emergency need to anchor, creating navigational hazards for other vessels. Recreational activity and commercial fishing activity would likely stay largely the same related to this IPF.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also going through continual upgrades and maintenance. Impacts from these activities would be short term and could include congestion in ports, delays, and changes in port usage by some fishing or recreational vessel operators.	Ports would need to perform maintenance and perform upgrades to ensure that they can still receive the projected future volume of vessels visiting their ports, and to be able to host larger deep draft vessels as they continue to increase in size. Impacts would be short term and could include congestion in ports, delays, and changes in port usage by some fishing or recreational vessel operators.
Presence of structures: Allisions	An allision occurs when a moving vessel strikes a stationary object. The stationary object can be a buoy, a port feature, or another anchored vessel. There are two types of allisions that occur: drift and powered. A drift allision generally occurs when a vessel is powered down due to operator choice or power failure. A powered allision generally occurs when an operator fails to adequately control their vessel movements, or is distracted.	Absent other information, and because total vessel transits in the area have remained relatively stable since 2010, BOEM does not anticipate vessel traffic to greatly increase over the next 30 years. Vessel allisions with non-offshore wind stationary objects should not increase meaningfully without a substantial increase in vessel congestion.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Presence of structures: Fish aggregation	Items in the water, such as ghost fishing gear, buoys, and energy platform foundations can create an artificial reef effect, aggregating fish. Recreational and commercial fishing can occur near the artificial reefs. Recreational fishing is more popular than commercial near artificial reefs as commercial mobile fishing gear can risk snagging on the artificial reef structure.	Fishing near artificial reefs is not expected to change meaningfully over the next 30 years.
Presence of structures: Habitat conversion	Equipment in the ocean can create a substrate for mollusks to attach to, and fish eggs to settle near. This can create a reef-like habitat and benefit structure-oriented species on a constant basis.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Migration disturbances	Noise-producing activities, such as pile driving and vessel traffic, may interfere and adversely affect marine mammals during foraging, orientation, migration, response to predators, social interactions, or other activities. Marine mammals may also be sensitive to changes in magnetic field levels. The presence of structures and operation noise could cause mammals to avoid areas.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Navigation hazard	Vessels need to navigate around structures to avoid allisions. When multiple vessels need to navigate around a structure, then navigation is made more complex, as the vessels need to avoid both the structure and each other.	Absent other information, and because total vessel transits in the area have remained relatively stable since 2010, BOEM does not anticipate vessel traffic to greatly increase over the next 30 years. Even with increased port visits by deep draft vessels, this is still a relatively small adjustment when considering the whole of New England vessel traffic. The presence of navigation hazards is expected to continue at or near current levels.
Presence of structures: Space use conflicts	Currently, the offshore area is occupied by marine trade, stationary and mobile fishing, and survey activities.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Transmission cable infrastructure	See IPF for Anchoring.	See IPF for Anchoring.
New cable emplacement/ maintenance	Within the geographic analysis area for navigation and vessel traffic, existing cables may require access for maintenance activities. Infrequent cable maintenance activities may cause temporary increases in vessel traffic and navigational complexity.	The FCC has two pending submarine tele-communication cable applications in the North Atlantic. Future new cables would cause temporary increases in vessel traffic during installation or maintenance, resulting in infrequent, localized, short-term impacts over the next 30 years. Care would need to be taken by vessels that are crossing the cable routes during these activities.
Traffic: Aircraft	USCG search and rescue (SAR) helicopters are the main aircraft that may be flying at low enough heights to risk interaction with WTGs. USCG SAR aircraft need to fly low enough that they can spot objects in the water.	SAR operations could be expected to increase with any increase in vessel traffic. However, as vessel traffic volume is not expected to increase appreciably, neither should SAR operations. Draft EIS Section 3.5.6 provides a discussion of navigation impacts on fishing vessel traffic.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Traffic: Vessels	See the sub-IPF for Presence of structures: Navigation hazard.	See the sub-IPF for Presence of structures: Navigation hazard.
Traffic: Vessels, collisions	See the sub-IPF for Presence of structures: Navigation hazard.	See the sub-IPF for Presence of structures: Navigation hazard.

Table E3-14. Summary of Activities and the Associated Impact-Producing Factors for Other Uses: Military and National Security Uses

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Presence of structures: Allisions	Existing stationary facilities that present allision risks include the five offshore wind turbines associated with Block Island Wind Farm, dock facilities, meteorological buoys associated with offshore wind lease areas, and other offshore or shoreline-based structures.	No additional non-offshore wind stationary structures were identified within the geographic analysis area. Stationary structures such as private or commercial docks may be added close to the shoreline.
Presence of structures: Fish aggregation	Existing stationary facilities that act as FADs include offshore wind turbines associated with Block Island Wind Farm.	No future non-offshore wind additional stationary structures that would act as FADs were identified within the geographic analysis area.
Presence of structures: Navigation hazard	Existing stationary facilities within the geographic analysis area that present navigational hazards include the five WTGs in the Block Island Wind Farm, onshore wind turbines, communication towers, dock facilities, and other onshore and offshore commercial, industrial, and residential structures.	No future non-offshore wind stationary structures were identified within the offshore analysis area. Onshore, development activities are anticipated to continue with additional proposed communications towers and onshore commercial, industrial, and residential developments.
Presence of structures: Space use conflicts	Existing stationary facilities within the geographic analysis area that present a navigational hazard include the five WTGs in the Block Island Wind Farm, onshore wind turbines, communication towers, dock facilities, and other onshore and offshore commercial, industrial, and residential structures.	No future non-offshore wind stationary structures were identified within the offshore analysis area. Onshore, development activities are anticipated to continue with additional proposed communications towers and onshore commercial, industrial, and residential developments.
Presence of structures: Transmission cable infrastructure	Seven subsea cable corridors cross cumulative lease areas.	Submarine cables would remain in current locations with infrequent maintenance continuing along those cable routes for the foreseeable future.
Traffic: Vessels	Current vessel traffic in the region is described in draft EIS Section 3.5.6. Vessel activities associated with offshore wind in the cumulative lease areas is currently limited to site assessment surveys.	Continued vessel traffic in the region, as described in draft EIS Section 3.5.6.
Traffic: Vessels, collisions	Current vessel traffic in the region is described in draft EIS Section 3.5.6. Vessel activities associated with offshore wind in the cumulative lease areas is currently limited to site assessment surveys.	Continued vessel traffic in the region is described in draft EIS Section 3.5.6.

Table E3-15. Summary of Activities and the Associated Impact-Producing Factors for Other Uses: Aviation and Air Traffic

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Presence of structures: Navigation hazard	Existing aboveground stationary facilities within the geographic analysis area that present navigational hazards include the five WTGs in the Block Island Wind Farm, onshore wind turbines, communication towers, dock facilities, and other onshore and offshore structures exceeding 200 feet in height.	No future non-offshore wind stationary structures were identified within the offshore analysis area. Onshore development activities are anticipated to continue with additional proposed communications towers.
Presence of structures: Space use conflicts	Existing aboveground stationary facilities within the geographic analysis area that could cause space use conflicts for aircraft include the five WTGs associated with Block Island Wind Farm, onshore wind turbines, communication towers, and other onshore and offshore structures exceeding 200 feet in height.	No future non-offshore wind stationary structures were identified within the offshore analysis area. Onshore, development activities are anticipated to continue with additional proposed communications towers.

Table E3-16. Summary of Activities and the Associated Impact-Producing Factors for Other Uses: Cables and Pipelines

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Presence of structures: Allisions and navigation hazards	Structures within and near the geographic analysis area that pose potential allision hazards include the five Block Island Wind Farm WTGs, meteorological buoys associated with offshore wind lease areas, and shoreline developments such as docks, ports, and other commercial, industrial, and residential structures.	Reasonably foreseeable non-offshore wind structures that could affect submarine cables have not been identified in the geographic analysis area.
Presence of structures: Space use conflicts	Two submarine cables cross the far western portion of OCS-A 0487. These cables are associated with a larger network of submarine cables that make landfall near Charlestown, Massachusetts.	Reasonably foreseeable non-offshore wind structures have not been identified in the geographic analysis area.
Presence of structures: Transmission cable infrastructure	Seven subsea cable corridors cross cumulative lease areas.	Reasonably foreseeable non-offshore wind structures have not been identified in the geographic analysis area.

Table E3-17. Summary of Activities and the Associated Impact-Producing Factors for Other Uses: Radar Systems

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Presence of structures: Navigation hazards	Wind developments in the direct line-of-sight with, or extremely close to, radar systems can cause clutter and interference. Existing wind developments in the area include scattered onshore wind turbines, and five WTGs in the Block Island Wind Farm.	Reasonably foreseeable non-offshore wind structures proposed for construction in the lease areas that could affect radar systems have not been identified.

Table E3-18. Summary of Activities and the Associated Impact-Producing Factors for Other Uses: Scientific Research and Surveys

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Presence of structures: Navigation hazards	Stationary structures are limited in the open ocean environment of the geographic analysis area, and include met buoys associated with site assessment activities, the five Block Island Wind Farm WTGs, and the two CVOW WTGs. Other lease areas within the geographic analysis area are not yet developed, and are in various stages of permitting.	Reasonably foreseeable non-offshore wind activities would not implement stationary structures within the open ocean environment that would pose navigational hazards and raise the risk of allisions for survey vessels and collisions for survey aircraft.

Maximum-Case Scenario Estimates for Offshore Wind Projects

This page intentionally left blank.

The following tables provide maximum-case scenario estimates of potential offshore wind project impacts assuming maximum buildout, using SFWF EIS geographic analysis areas and COP-designated numbers for the SFWF and SFEC. BOEM developed these estimates based on offshore wind demand, as discussed in their 2019 study *National Environmental Policy Act Documentation for Impact-Producing Factors in the Offshore Wind Cumulative Impacts Scenario on the North Atlantic Outer Continental Shelf* (BOEM 2019). Estimates disclosed in this EIS's Chapter 3, No Action analyses were developed by summing acreage or number calculations across all lease areas noted as occurring within, or overlapping, a given geographic analysis area. This likely over-estimates some impacts in cases where lease areas only partially overlap analysis areas. However, this approach was used to provide the most conservative estimate of future offshore wind development.

This page intentionally left blank.

Table E4-1. Offshore Wind Leasing Activities on the U.S. East Coast: Projects and Assumptions (as of May 1, 2021) (part 1)

Region	Lease/Project/ Lease Remainder[1]	Status	Resource/Projects[3]						Estimated Offshore Construction Schedule[4]	Expected Turbine Size[5]	Generating Capacity (MW) (INTERNAL NOTE - FULL MW)						Generating Capacity (MW)

	TOTAL VA/NC LEASES											
	OCS Total[24, 25]:											

Notes: COP = Construction and Operations Plan, CT = Connecticut, DE = Delaware, EFH =essential fish habitat, FDR = Facility Design Report, FIR = Fabrication and Installation Report, MA = Massachusetts, MD = Maryland, MW = megawatt, NE = New England, NJ = New Jersey, nm = nautical mile, NY = New York, OSS = offshore substation, PPA = Power Purchase Agreement, RAP = Research Activities Plan, RI = Rhode Island, tpy = tons per year, WTG = wind turbine generator

1. The spacing/layout for projects/regions are as follows: NE State water projects include a single strand of WTGs and no OSSs; for projects in the RI and MA Lease Areas, a 1 × 1–nm grid spacing is assumed; for the projects in the New Jersey/New York and the Delaware/Maryland lease areas, BOEM assumes that a 1 × 1–nm grid spacing also would be utilized; for the Coastal Virginia Offshore Wind Project, the spacing is 0.7 nm; and the Dominion commercial lease area off the coast of Virginia would utilize 0.5 nm average spacing, which is less than the 1 × 1–nm spacing due to the need to attain the state's goals.
2. Because development could occur anywhere within the RI and MA Lease Areas and assumes a continuous 1 x 1–nm grid, the actual development for these projects is expected to be approximately 73% of the collective technical capacity. Under the cumulative scenario described in in this appendix (Appendix E), the total area in the RI and MA Lease Areas is greater than the area needed to meet state demand. Therefore, if a project is not constructed, BOEM assumes that another future project would be constructed to fulfill the unmetdemand.
3. This column identifies lease areas that are applicable to each resource based on the geographic analysis areas shown in Attachment 1 of this appendix.
4. The estimated construction schedule is based on information known at the time of this analysis and could be different when an applicant submits a COP. Furthermore, for this cumulative analysis BOEM assumes that construction of all the foundations would be installed during year 1 of construction and the balance of the work would be completed in year 2.
5. It is difficult to accurately predict future technology for planned but currently unscheduled offshore wind awards, including turbine spacing and capacity. For those projects with announced WTG sizes, BOEM used the assumption of an 8- or 12-MW WTG based on maximum-impact case for the resource. BOEM understands that it is feasible that in the future, turbine capacity could be greater than 12 MW. For future procurements and projects under this cumulative analysis, BOEM assumes the largest turbine that is presently commercially available, a 12-MW WTG, to evaluate potential impacts.
6. The generating capacity for the lease areas within the air quality geographic analysis area without a known project size has been assumed to be a percentage of the technical capacity (7,304 MW). The percentage (73%) has been calculated based on the amount of lease area acreage for the specific lease areas (359,146 acres [1,453 km^2]) divided by the remaining “RI and MA Lease Areas” total (491,515 acres [1,989 km^2]). The air quality geographic analysis area includes 100% of the following leases: Bay State Wind Project, part of OCS-A 0500; OCS-A 0500 and OCS-A 0487 remainder; OCS-A 0520 (Equinor Massachusetts); and OCS-A 0521 remainder.
7. The generating capacity for the lease areas within the water quality geographic analysis area without a known project size has been assumed to be a percentage of the technical capacity (7,304 MW). The percentage (63%) has been calculated based on the amount of lease area acreage for the specific lease areas (310,041 acres [1,255 km^2]) divided by the remaining “RI and MA Lease Areas” total (491,515 acres [1,989 km^2]). The water quality geographic analysis area includes the following leases: 100% of Bay State Wind Project, part of OCS-A 0500; 22% of OCS-A 0500 and OCS-A 0487 remainder; and 63% of OCS-A 0520 (Equinor Massachusetts).
8. The generating capacity for the lease areas within the benthic resources geographic analysis area without a known project size has been assumed to be a percentage of the technical capacity (7,304 MW). The percentage (63%) has been calculated based on the amount of lease area acreage for the specific lease areas (310,041 acres [1,255 km^2]) divided by the “MA/RI Lease Area” total (491,515 acres [1,989 km^2]). The benthic resources geographic analysis areas includes the following leases: 100% of the Bay State Wind Project, part of OCS-A 0500; 9% of OCS-A 0500 and OCS-A 0487 remainder; and 63% of OCS-A 0520 (Equinor Massachusetts).
9. BOEM assumes that each offshore wind development would have its own cable (both onshore and offshore) and that future projects would not utilize a regional transmission line. The length of offshore export cable for those lease areas without a known project size has been assumed to include two offshore cables totaling 120 miles (193 kilometers). The offshore export cable would be buried a minimum of 6 feet (1.8 meters) but not more than 10 feet (3.1 meters).
10. The length of inter-array cabling has been assumed for all lease areas, except the SFWF and Vineyard Wind 1 which have been calculated by the applicant, to be the average amount per foundation based on the COPs submitted to date, which is 1.48 miles (2.4 kilometers). In addition, for those lease areas that require more than one OSS, it has been assumed that an additional 6.2 miles (9.9 kilometers) of inter-link cable would be required to link the two OSSs. Inter-array cable is assumed to be buried between 4 and 6 feet.
11. The hub height for lease areas is based on worst-case scenario for the resource area.
12. The rotor diameter for lease areas is based on worst-case scenario for the resource area.
13. The total height of the turbine for lease areas is based on worst-case scenario for the resource area.
14. The number of turbines for those lease areas without a known project size has been calculated based on the generating capacity and a 12-MW turbine.
15. The estimated number of foundations is the total number of turbines plus OSSs, and it has been assumed that for every 50 turbines there would be one OSS installed. There are some exceptions to this assumption where additional relevant information is available in publicly available COPs for future projects.
16. The foundation footprint has been assumed to be 0.1 acre, which is based on the largest monopile reported (12 MW) for all lease areas other than the SFWF and Vineyard Wind 1, which have been calculated by the applicant.
17. The seabed disturbance with the addition of scour protection was calculated based on scour protection expected in submitted COPs. It is assumed that for all lease areas that a 12-MW foundation with addition of scour protection would be 1.0 acre per foundation other than SFWF and Vineyard Wind 1, which have been calculated by the applicant.
18. Offshore export cable seabed bottom disturbance is assumed to be due to installation of the export cable, the use of jack-up vessels, and the need to perform dredging.
19. For projects other than the SFWF, which has been calculated by the applicant, the offshore export cable hard protection is assumed to be similar to Vineyard Wind 1 Project, which is 0.357 acre (1.445 square meters [m^3]) per mile of offshore export cable. It is assumed that 10% of the offshore export cable would require protection.
20. Anchoring disturbance for the SFWF has been calculated by the applicant. Anchoring disturbance for other lease areas has been assumed to be a rate equal to 0.10 acres (405 m^3) per mile of offshore export cable, with the exception of Vineyard Wind 1 Project, which is 0.044 acres per mile of offshore export cable.
21. Inter-array construction seabed disturbance for the SFWF has been calculated by the applicant. Inter-array construction seabed disturbance for other lease areas has been assumed to be a rate equal to the average area per foundation, 2.4 acres (9.712 m^3) per foundation, with the exception of Vineyard Wind 1 Project, which is 2.04 acres (8.256 m^3) per foundation.

22. The inter-array operating footprint for the SFWF has been calculated by the applicant. The inter-array operating footprint for other lease areas is assumed to be a rate equal to the average amount per foundation of 1.43 acres (5.787 m^3) per foundation for all other lease areas.
23. Inter-array cable hard protection for the SFWF has been calculated by the applicant. The inter-array cable hard protection for other lease areas is assumed to be zero for all other lease areas with the exception of Vineyard Wind 1 Project, Vineyard Wind South OCS-A 5001, and Revolution Wind OCS-A 0486.
24. BOEM recognizes that the estimates presented within this cumulative analysis are likely high, conservative estimates; however, BOEM believes that this analysis is appropriately capturing the potential cumulative impacts and errs on the side of maximum impacts. Totals by lease area and by OCS may not fully sum due to rounding errors.
25. New York's demand is not double-counted, this total comes from looking at New York's state demand, not adding up the potential of the areas because that would double-count New York.

a. The construction and operations plan for the southern portion of OCA-A 0501 contemplates fully developing the remaining lease area as part of the northeast leases' 1 × 1–nm grid over two phases.

b. CO_2 estimated based on project size relative to other projects.

c. Emissions values represent 80% of the total for this development, as only 80% of the development lies within the geographic scope of direct impacts from the proposed action.

d. Emissions estimated by taking the average for each pollutant per foundation for the most advanced commercial plan, Vineyard Wind 1 (13-MW turbine), and multiplying by the number of foundations in remainder/unspecified area within air quality scope.

e. Emissions values represent 5% of the total for this development, as only 5% of the development lies within the geographic scope of direct impacts from the proposed action.

INTRODUCTION

This appendix provides information by resource, as applicable, that supplements the information provided in the South Fork Wind Farm (SFWF) and South Fork Export Cable (SFEC) Project environmental impact statement (EIS).

AVIAN AND BAT POST-CONSTRUCTION MONITORING FRAMEWORK

Introduction

South Fork Wind, LLC (SFW) is proposing the approximately 130-megawatt (MW) SFWF Project located in the Bureau of Ocean Energy Management (BOEM) Renewable Energy Lease Area OCS-A 0517 (Lease Area). The Project will consist of up to 15 wind turbine generators (WTGs) with a capacity of 6 to 12 MW per turbine, submarine cables between the WTGs, and an offshore substation. This SFWF Avian and Bat Post-Construction Monitoring Framework (hereafter the Framework) focuses solely on the offshore footprint of the Project within the Lease Area and does not apply to the offshore export cable, cable landfall, or onshore portions of the Project.

SFW has developed this Framework to outline an approach to post-construction monitoring that supports advancement of the understanding of bird and bat interactions with offshore wind farms. It addresses the monitoring options set forth in Section 3.4.3.4 of the SFW draft environmental impact statement (draft EIS) (BOEM 2021a) and Section 6.1.2 in the SFW biological assessment (BA) (BOEM 2021b) and associated U.S. Fish and Wildlife Service (USFWS) concurrence letter (dated March 4, 2021). The scope of monitoring is designed to meet federal requirements (30 CFR 585.626(b)(15) and 585.633(b)) and is scaled to the size and risk profile of the Project with a focus on species of conservation concern.

The intent of the Framework is to outline overarching monitoring objectives, proposed monitoring elements, and reporting requirements. A detailed Avian and Bat Post-Construction Monitoring Plan (Monitoring Plan), based on this Framework, will be developed in coordination with BOEM, the USFWS, and other relevant regulatory agencies. Where feasible, monitoring conducted at the SFWF will be coordinated with monitoring at other Ørsted offshore wind projects in the Northeast region to facilitate integrated analyses across a broader geographic area.

Monitoring objectives and associated methods are summarized in Table F-1. Technical approaches were selected based on offshore logistical constraints, their ability to address monitoring objectives, and the effectiveness in the marine environment. Emerging technologies, such as multi-sensor radar/camera collision detection systems, are not proposed under this Framework because they have not yet been broadly deployed offshore or demonstrated to effectively reduce uncertainties related to potential impacts on birds and bats.

Table F-1. Monitoring Objectives, General Approaches to Be Used, and Types of Data Generated

Taxa	SFWF Monitoring Objective	Approach	Duration	Data Output
Bats	Monitor occurrence of bats	Acoustics	2 years	Presence; temporal and weather patterns
Birds	Monitor occurrence of nocturnal migratory birds	Acoustics	2 years	Presence; temporal and weather patterns
Birds	Determine use by roseate terns	Radio-tags	Up to 3 years	Presence; temporal and weather patterns
Birds	Conduct behavior observations around turbines	Boat-based observers	1 year	Species, flight height, activity, avoidance behavior
Both	Document mortality	Incidental observations	Project lifetime	Incidence, identification

Bat Acoustic Monitoring

The presence of bats in the marine environment has been documented in the United States (BOEM 2013; Cryan and Brown 2007; Dowling et al. 2017; Grady and Olson 2006; Hatch et al. 2013; Johnson et al. 2011). However, there remains uncertainty regarding the extent to which bats occur offshore, particularly within offshore wind farms. Acoustic detectors are commonly used to study bat movements and migration (Johnson et al. 2011). SFW will conduct bat acoustic monitoring to assess bat activity at the SFWF, targeting key data gaps related to species presence/composition, temporal patterns of activity, and correlation with weather and atmospheric conditions.

Acoustic monitoring of bat presence will be conducted for 2 years post-construction. Two ultrasonic bat detector stations will be installed on the offshore substation, wind turbine platforms, and/or buoys in early spring or late winter (March) and removed in late fall or early winter (December) after migration, or the most appropriate period, as determined in cooperation with BOEM, the USFWS, and other relevant regulatory agencies. The detectors will record calls of both cave-hibernating bats, including the northern long-eared bat (*Myotis septentrionalis*), and migratory tree bats; the resulting information can be used to identify bats to species. All acoustic data recorded will be processed with approved software to filter out poor-quality data and identify the presence of bat calls. High-frequency calls will then be classified by an experienced acoustician to the highest resolution possible (e.g., species, genus, family).

All bat calls detected and identified will be analyzed to understand relationships with time of day, season, and weather/atmospheric conditions. The results will provide information on bat presence offshore and the conditions under which they may occur near offshore wind turbines.

Nocturnal Migratory Bird Acoustic Monitoring

Some North American breeding songbirds are known to migrate over the Atlantic OCS (Adams et al. 2015a, 2015b; Drury and Keith 1962), but there is uncertainty about the extent to which migrants use the offshore environment. Acoustic detectors are commonly used to study songbird migration (Farnsworth 2005) and have been used at offshore wind facilities (Hüppop et al. 2016), including at the Block Island Wind Farm (Stantec 2018). SFW will conduct avian acoustic monitoring to assess nocturnal migratory songbird occurrence in the SFWF, targeting key data gaps related to species presence/composition, temporal patterns of offshore activity, and correlation to weather conditions.

Acoustic monitoring for birds will be conducted for 2 years post-construction. Two acoustic detector stations will be installed at the substation and/or buoy to collect data from spring through fall during each monitoring year, capturing both migratory periods; detector stations will not be installed on wind turbines due to sound interference from turbine blades. The acoustic data will be processed through a filter and then a final species group identification will be conducted by a qualified biologist. Given the potential for large numbers of acoustic detections, the acoustic data could be sub-sampled to focus on peak migration periods, as well as nights when migration rates are expected to be high, based on factors such as weather conditions and results from NEXRAD radar data (e.g., Welcker and Vilela 2020).

Acoustic data on birds will be analyzed to determine which species are migrating through the SFWF, and identify any relationships with time of day, season, and weather/atmospheric conditions. The results will provide information on the presence of vocalizing nocturnal migrants offshore and the conditions under which they may occur near offshore wind turbines.

Motus Tracking Network and Roseate Tern Use Study

Tracking studies indicate that at least some individual Endangered Species Act (ESA)–listed roseate terns (*Sterna dougallii*) pass through the Rhode Island/Massachusetts Wind Energy Area (RI/MA WEA), within which the SFWF is located (Loring et al. 2018, 2019). However, due to limited coverage of onshore automated telemetry receiving stations and low probability of detecting tags (hereafter, Motus receivers and tags) in the offshore environment (Loring et al. 2019), there remains uncertainty related to offshore movements of roseate terns during migration in the vicinity of the SFWF. SFW will install offshore Motus receiver stations and contribute funding to a roseate tern radio-tagging effort to address this data gap. The Motus receivers will also provide opportunistic presence/absence data on other species carrying Motus tags, such as piping plover (*Charadrius melodus*), red knot (*Calidris canutus rufa*), migratory songbirds, and bats.

Movements of radio-tagged roseate terns in the vicinity of the SFWF will be monitored for up to 3 years post-construction, during spring, summer, and fall. Motus receivers will be installed at up to four locations within the SFWF to determine the presence/absence of ESA-listed species. The specific number and location of offshore receiver stations will be selected to optimize coverage and will be determined using a design tool currently being developed through a New York State Energy Research and Development Authority (NYSERDA)–funded project.[1] In addition, existing Motus receiver stations at up to two onshore locations near the SFWF (e.g., Block Island, Buzzards Bay) will be refurbished to confirm the presence and movements of radio-tagged roseate terns in waters adjacent to the SFWF (refurbishment needs will be discussed with the USFWS). Funding for up to 50 Motus tags per year will be provided to researchers working with roseate terns for up to 3 consecutive years.

Roseate tern presence/absence in the SFWF will be analyzed by comparing detections within the wind farm to coastal receiver towers. All detections will be analyzed to understand relationships with time of day, season, and weather. The results will provide data on if tagged terns occur in the SFWF.

Ship-Based Avian Point Count Surveys

While marine bird collision and displacement vulnerability has been well researched in Europe (Goodale and Milman 2016), these studies have been conducted on relatively small turbines. There is a data gap on how species that are vulnerable to collision, such as gulls, will behave around the larger SFWF turbines and if birds vulnerable to displacement will fly between turbines spaced 1 nautical mile apart. To rapidly collect data on bird behavior, SFW will use vessel-based field biologists to conduct observations of birds around the turbines using traditional behavioral study methods such as time-activity budgets. The data collected through field observation will increase understanding in the following areas: 1) avoidance and attraction to the turbines; 2) changes in flight height and speed in relation to distance from the turbines and the rotor-swept zone; and 3) general behavior of birds near turbines.

[1] https://www.briloon.org/renewable/automatedvhfguidance.

Monitoring of bird behavior around turbines in the SFWF will occur for 1 year post-construction (two surveys per seasons for a total of eight surveys). The exact number of point counts will be determined in consultation with BOEM, the USFWS, and other relevant regulatory agencies. Point count surveys will be designed to document bird movement behavior at micro- and meso-scales around turbines, including flight height, position relative to turbines, perching behavior, movement, and behavior. Observations will be made from a survey vessel, with flight height estimates potentially aided by laser rangefinders or other measuring technology.

Point count and focal-animal sampling data will be analyzed to determine the extent of interaction of different bird species with turbines. Metrics relative to turbines, such as mean closest approach and range, flight height relative to behavior, time spent in different behaviors, perching time, and other behavioral metrics, will provide quantitative information on collision and displacement vulnerability.

Documentation of Dead and Injured Birds and Bats

SFW, or its designated operator, will implement a reporting system to document dead or injured birds or bats found incidentally on vessels and project structures during construction, operation, and decommissioning. The location will be marked using a global positioning system; an Incident Reporting Form will be filled out; and digital photographs taken. Any animals detected that could be ESA-listed, will have their identity confirmed by consulting biologists and a report will be submitted to the designated staff at SFW, who will then report it to BOEM, the USFWS, and other relevant regulatory agencies. Carcasses with federal or research bands or tags will be reported to the U.S. Geological Survey Bird Band Laboratory, BOEM, and the USFWS.

Adaptive Monitoring

Adaptive monitoring is an important principle underlying SFW's post-construction monitoring Framework. Over the course of monitoring, SFW will work with BOEM, the USFWS, and other relevant regulatory agencies to determine the need for adjustments to monitoring approaches, consideration of new monitoring technologies, and/or additional periods of monitoring based on an ongoing assessment of monitoring results. Potential triggers for adaptive monitoring may include, but not be limited to, equipment failure, an unexpected impact to birds or bats identified through monitoring, or new opportunities to collaborate with adjacent project(s). The monitoring plan will include a series of potential adaptive monitoring actions, developed in coordination with BOEM, the USFWS, and other relevant regulatory agencies, to be considered as appropriate.

Reporting

SFW will submit an annual report to BOEM and the USFWS summarizing post-construction monitoring activities, preliminary results as available, and any proposed changes in the monitoring program. SFW will participate in an annual meeting with BOEM and the USFWS to discuss the report.

COMMERCIAL FISHERIES AND FOR-HIRE RECREATIONAL FISHING

Information in this section provides an overview of the commercial fisheries data used in EIS Section 3.5.1 Commercial Fisheries and For-Hire Recreational Fishing.

Overview of Commercial Fisheries Data Used in the Environmental Impact Statement Section 3.5.1

The primary source of data was summarized Vessel Trip Report (VTR) data provided by NMFS (2021a). Included were annual VTR data (2008–2019) for specific geographic areas relevant to the Project showing commercial fishing revenue, trips, and the number of unique vessels for each fishery management plan (FMP) fishery, species, gear, and port of landing.[2] These data were also used to analyze the distribution of commercial fishing revenue from the SFWF Lease Area across fishing vessels. In addition, the VTR data provided by NMFS (2021a) described the activities of for-hire recreational fishing vessels, including landings by species and the number of angler trips by port.

[2] NMFS requires all federally permitted commercial fishing vessels (with the exception of those vessels that only have a lobster permit) to submit a VTR for every fishing trip (50 CFR 648.7). The VTR data provide a broad census of fishing activity that encompasses the majority of commercial fisheries active near the SFWF and offshore SFEC. VTRs include a single fishing location (reported in latitude and longitude coordinates) for each trip. VTR location information is only an approximation of fishing activity, particularly with respect to use of mobile gear, because fishermen self-report only one set of coordinates for a fishing trip, despite the fact that one trip may include multiple gear tows that take place in many different locations across a much wider area. VTR instructions require that fishermen record the haulback position where most of the fishing occurred (NMFS 2020).

A fisherman with a vessel with a federal lobster permit is only required to fill out a VTR if he or she has another federal permit. Approximately 63% of the lobster fleet fishing in statistical area 537, which encompasses most of the RI-MA WEA, reports through VTRs (Atlantic States Marine Fisheries Commission [ASMFC] 2018).

A second source of data was the website at NMFS (2021c), which summarizes commercial fisheries data for each proposed WEA along the U.S. Atlantic coast. These data were downloaded and used to summarize revenue at risk across all proposed offshore wind projects under the No Action alternative.

In addition, polar histograms (EIS Figure 3.5.1-1 through Figure 3.5.1-4) developed by BOEM based on NMFS Vessel Monitoring System (VMS) data provided by NMFS (2019) are included in Section 3.5.1.[3] From 2014–2019, VMS coverage levels ranged between 90% and 100% for the following FMP fisheries: Atlantic Herring; Bluefish; Mackerel, Squid, and Butterfish; Monkfish; Northeast Multispecies (large-mesh); Northeast Multispecies (small-mesh); Sea Scallop; Spiny Dogfish; Summer Flounder, Scup, Black Sea Bass; and Surfclam/Ocean Quahog. Average VMS coverage levels were lower for the following FMP fisheries: Skate (75%); Highly Migratory Species (48%); Jonah Crab (14%); and American Lobster (11%) (NMFS 2021a).

A final source of commercial fisheries revenue data was the website at BOEM (2020) under the section Socio-Economic Impact of Outer Continental Shelf Wind Energy Development on Fishing in the U.S. Atlantic. GIS data provided by the website were used to develop the revenue intensity figures provided in Appendix C. These data were also used for comparisons of alternative SFEC landfall sites, and for the assessment of impacts of the Vessel Transit Lane alternative (Transit alternative). The data provided revenue for each of the FMP fisheries in the form of raster files[4] for 2007–2018, with a separate file for each year.

The remainder of this section describes in more detail the data provided by NMFS (2021a). As indicated above, annual data were provided for seven specific geographic areas relevant to the Project, as shown in Table F-1. Tables F-2, F-3, and F-4 show the FMP fisheries, gears, and ports for which NMFS GARFO provided annual data subject to data confidentiality restrictions.[5]

Table F-1. Specific Geographic Areas for Which NMFS GARFO Provided VTR Data

Areas Directly Related to the Proposed Action	Areas Directly Related to the Transit Alternative	Other Relevant Areas
Lease Area (OCS-A 0517)	Reduced Lease Area (OCS-A 0517)	RI-MA WEA
Maximum work area (MWA)	Reduced MWA	Areas specifically excluded by BOEM from the RI-MA WEA
Offshore Export Cable to Beach Lane	Adjusted Offshore Export Cable to Beach Lane	All areas in the mid-Atlantic and New England region managed by NMFS
Offshore Export Cable to Hither Hills	Adjusted Offshore Export Cable to Hither Hills	

[3] VMS data are generated from automated transmissions from transponders that are required to be on board and operating whenever permitted vessels are fishing or transiting with the intent to harvest fish or shellfish. Data are transmitted once every 60 minutes for all FMPs except for the Sea Scallop FMP, which are transmitted once every 30 minutes. Each transmission includes the current directional bearing and vessel speed as well as the average bearing and vessel speed since the last transmission. Using the average vessel speed, NMFS uses an algorithm to assign an assumed activity (either fishing or transiting) to each transmission.

[4] A raster file is a matrix of cells organized into rows and column where each cell contains a value representing information about the cell. The raster files in the BOEM GIS data sets are 500 meters on each side and show the revenue that was estimated to have been generated from that cell. A raster file for a widely utilized FMP on the U.S. East Coast could contain 4 million or more cells, each representing the revenue generated in a 500 × 500–meter cell.

[5] In general, NMFS GARFO requires that a no less than three vessels and three dealers be included in any data point released to the public. FMP fishery, gear, or port data that did not meet these data confidentiality requirements were combined into a "Non-Disclosed" bin.

Table F-2. FMP Fisheries for Which NMFS GARFO Provided VTR Data

American Lobster	Atlantic Herring	Bluefish	Golden and Blueline Tilefish
Highly Migratory Species	Jonah Crab	Mackerel, Squid, and Butterfish	Northeast Multispecies (large-mesh)
Monkfish	Sea Scallop	Skate	Northeast Multispecies (small-mesh)
Spiny Dogfish	No federal FMP	Surfclam, Ocean Quahog	Summer Flounder, Scup, Black Sea Bass
Non-Disclosed FMPs			

Table F-3. Gears for Which NMFS GARFO Provided VTR Data

Dredge-clam	Dredge-scallop	Gillnet-other	Gillnet-sink
Handline	Longline-bottom	Other gears	Pot-other
Trawl-bottom	Trawl-midwater	Non-disclosed gears

Average Annual Revenues and Non-Disclosure Issues

In general, Section 3.5.1 provides information on the average annual revenue over the 2008–2018 period. However annual data were provided only for the years for which data could be disclosed. If an annual data-point for a given FMP, gear, or port within a given geographic area could not be disclosed because there were insufficient number of vessels or dealers, then NMFS-GARFO added the data-point to a "non-disclosed" category. By combining all the data-points that could not disclosed, NMFS-GARFO was able to report to the annual total revenue for every year. However, this methodology for reporting non-disclosed data points hampers accurate estimation of average annual revenue because there were often non-disclosed data for 1 or more years, particularly if the geographic area is small, or if there were relatively low levels of participation. Table F-5 is provided to demonstrate these issues.

Table F-5 shows the annual data for gears as provided by NMFS-GARFO for the SFWF Lease Area. Note that for nine of the gear types for which data were provided, there were no revenues reported for the SFWF Lease Area. For two gear types, fewer than 12 years of data were reported—there were 5 years of data reported for dredge-clam gear and 11 years reported for trawl-midwater gear. It is not possible to determine whether a gear that was not reported for a year had zero landings and revenue and thus were not provided, or whether there were landings and revenues, but they could not be disclosed because of data confidentiality restrictions. Due to these restrictions, the analytical team determined that unless six or more data points of the 12-year period from 2008 to 2019 were available, the data for that row could not be reported. Further, the analytical team determined that the average for rows that had 6 or more years of data that the "annual average" revenue would be calculated as the total reported revenue for the period divided by the number of reported years. Thus, in Table 3.5.1-11, the annual average revenue for dredge-clam gear is shown as NA (not available) and the revenues—estimated to be $64,100 in revenue from the 5 reported years—are assigned to the “All other gear” category.

Table F-5. National Marine Fisheries Service-Greater Atlantic Regional Fisheries Office Commercial Fishing Annual Revenue Data for the SFWF Lease Area

Gear	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	Reported Years

Notes: Revenue is adjusted for inflation to thousands of 2019 dollars. ND = not disclosed.

Caveats on the Use and Applicability of Commercial Fisheries Revenue Intensity Figures in EIS Appendix C

As indicated above, the revenue intensity figures for commercial fisheries shown in EIS Appendix C have been developed to provide a visual representation of harvesting locations across FMP fisheries, gears, and ports. These figures rely on raster files that were originally developed by NMFS specifically for the purpose of assessing the impacts of proposed wind energy projects. These raster files are available to the public at BOEM’s Renewable Energy GIS data website (BOEM 2020). The BOEM GIS raster files provide information specific to FMP fisheries as well as information for gears, ports, states, and specific species many of which are not included in FMP fisheries (e.g., American Lobster and Jonah Crab). Raster files for FMP fisheries are available for 2007–2018; however, raster files for gears, ports, states, and specific species are only available for 2007–2012.

Although the NMFS-GARFO data are deemed the best available data for numerical assessment of the existing conditions in commercial fisheries and for assessing impacts of the alternatives, NMFS has not yet released the corresponding GIS data raster files that enable the visualization of fishing activity associated with particular locations such as the SFWF. NMFS-GARFO indicates that GIS raster files summarizing these data will be available in early 2021. They also indicate that because NMFS-GARFO data (and eventually the raster files) use improved algorithms for estimation of revenues and improved algorithms for the assignment of harvests to specific geographic locations, they are superior to previously developed raster files available from BOEM (2020).

The average annual inflation-adjusted revenues for these two data sets were compared across all proposed wind energy projects included in the No Action alternative (summarized in EIS Table 3.5.1-16). Estimated average annual revenues using NMFS-GARFO data were 1.3% higher that estimated average annual revenue revenues using the BOEM GIS raster files. Thus, although the BOEM GIS data may slightly understate revenues within the proposed future wind energy project sites, they are clearly comparable and representative. In the absence of other GIS-based data, the revenue intensity figures provide insights into the fish harvesting locations.

The revenue intensity figures provided in Appendix C for gears and ports, and for American Lobster and Jonah Crab, summarize harvest locations for the years 2007–2012 rather than for 2007–2018. Although the overall inflation-adjusted average annual revenue for the 2007–2012 period is only 0.1% less than inflation-adjusted average annual revenue for the 2008–2018 period, it is possible that harvesting locations may have shifted in later years. Also please note that revenue intensity figures for gear have been aggregated into two broad gear types—mobile gear and fixed gear.

Analysis of the Economic Dependency on Fishing Grounds in the Lease Area among Commercial Fishing Vessels

To analyze differences in the economic importance of fishing grounds in the Lease Area across the commercial fishing fleet, information was obtained from NMFS (2021a) on the number of federally permitted commercial fishing vessel that fished annually in the Lease Area during the 2008–2019 period, together with the percentage of each vessel's total fishing revenue that came from within the area.

The vessel-level annual revenue percentages were divided into quartiles, which were created by ordering the data from lowest to highest percentage value and then dividing the data into four groups of equal size. The 1st quartile represents the lowest 25% of ranked percentages, while the 4th quartile represents the highest 25%. In addition, NMFS (2021a) reported the number of "outlier" vessels in the distribution of percent revenue. In addition, NMFS (2021a) reported the number of outlier vessels in the revenue distribution of the percentage of revenue. In the context of this analysis, an outlier is a vessel that derived an exceptionally high proportion of its annual revenue from the Lease Area in comparison to other vessels that fished in the area.[6]

[6] Technically, an outlier in a boxplot distribution is an observation that is more than 1.5 times the length of the box away from either the 1st quartile (Q1) or 3rd quartile (Q3). Specifically, if an observation is less than Q1 – (1.5 × IQR) or greater than Q3 + (1.5 × IQR), it is an outlier; where IQR = interquartile range = Q3 – Q1.

As shown in Table F-6, from 2008 through 2019, an average of 249 vessels per year fished in the Lease Area, with a high of 284 vessels in 2008 and a low of 213 vessels in 2019. The average annual number of outliers was 37 (15% of all vessels), with a high of 49 outliers in 2014 (18% of all vessels) and a low of 21 outliers in 2019 (9% of all vessels).

Table F-6. Number of Federally Permitted Vessels in the SFWF Lease Area (2008–2019)

	Number of Vessels	Number of Outliers	Number of Outliers as a Percentage of Total Vessels
2019	213	35	16%
2018	219	30	14%
2017	241	40	17%
2016	274	44	16%
2015	252	44	17%
2014	270	49	18%
2013	268	45	17%
2012	241	38	16%
2011	228	31	14%
2010	223	21	9%
2009	269	34	13%
2008	284	32	11%
Average	249	37	15%

Source: NMFS (2021a).

More detailed information about the distribution of the vessel-level annual revenue percentages is provided in the boxplot below (see Figure F-1). The boxplot begins at the 1st quartile, or the value beneath which 25% of all vessel-level revenue percentages fall. A thick line within the box identifies the median, the observation at which 50% of vessel-level revenue percentages are above or beneath. The box ends at the 3rd quartile, or the vessel-level revenue percentage beneath which 75% of observations fall. Nonparametric estimates of the minimum and maximum values are also indicated by the "whiskers" (dashed line terminating in a vertical line) that jut out from each side of the box. Any points outside of these whiskers are vessel-level revenue percentages that are considered outliers.

A total of three-quarters of the vessels that fished in the Lease Area derived less than 0.2% of their total annual revenue from the area (NMFS 2021b). The highest percentage of total annual revenue coming from within the Lease Area by an outlier varied from year to year, ranging from 39% in 2016 to 5% in 2012. Over the 2008–2019 period as a whole, the average maximum revenue percentage among outliers was 24% (NMFS 2021b). Although outliers derived a high proportion of their annual revenue from the Lease Area in comparison to other vessels that fished in the area, Figure F-1 shows that in any given year, the revenue percentage for the majority of outliers was below 5%. From 2008 through 2019, the average percentage of all vessels fishing in the Lease Area that derived 5% or more of their total fishing income from the Lease Area was around 2%. During any given year, the highest percentage, which occurred in 2008, was 5%, while the lowest was less than 1%. In short, some vessels depended heavily on the Lease Area, but most vessels derived a small percentage of their total annual revenue from the area.

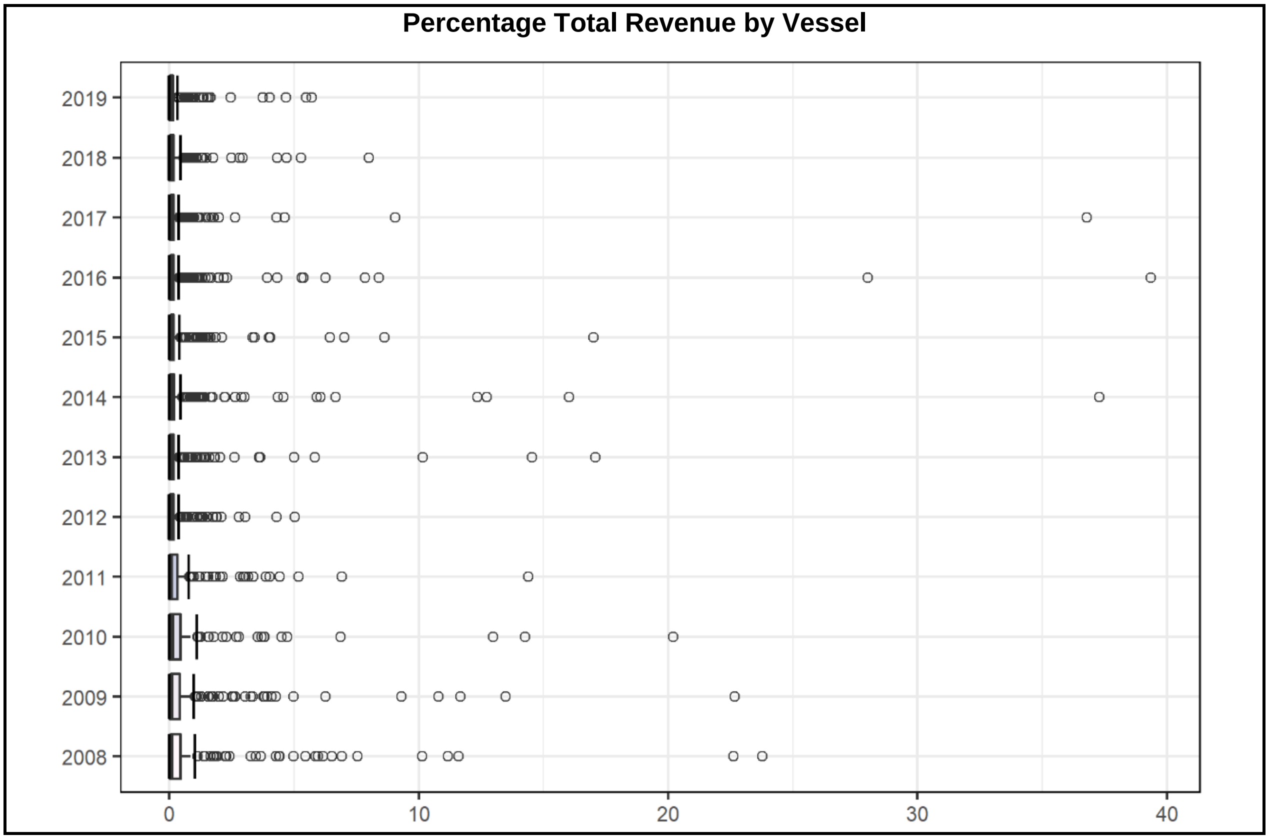

Figure F-1. Percentage of Total Commercial Fishing Revenue of Federally Permitted Vessels Derived from the SFWF Lease Area by Vessel (2008–2019).

Source: NMFS (2021a).

In addition to examining differences in the level of economic dependency on fishing grounds in the Lease Area across vessels, the analysis examined the relationship between vessels' average annual percent of total revenue inside the area and their average annual total revenue during the 2008–2019 period. As shown in Table F-7, average annual total revenue per vessel was negatively correlated with average annual revenue percentage. Vessels in the 4th quartile (i.e., vessels with a higher level of economic dependence on fishing grounds in the Lease Area), tended to have lower total commercial fishing incomes. In short, the Lease Area generally accounted for a higher proportion of the revenue of vessels that had lower total commercial fishing revenue.

Table F-7. Commercial Fishing Revenue of Federally Permitted Vessels in the SFWF Lease Area by Quartile (2008–2019)

	1st Quartile	2nd Quartile	3rd Quartile	4th Quartile	Outliers (included in 4th quartile)
Average annual number of vessels	63	63	63	64	37
Average annual revenue in the SFWF Lease Area as a percentage of total revenue	0.003%	0.020%	0.089%	0.989%	NA
Average annual total revenue in the mid-Atlantic and New England regions per vessel	$1,009,953	$810,655	$551,006	$219,899	NA
Average annual revenue in the SFWF Lease Area per vessel	$29	$164	$488	$2,175	$3,208

NA indicates that the number cannot be calculated with the available data. Average annual revenue per vessel or in total was not available for outliers alone.
Source: NMFS (2021a).

Table F-7 also shows the average annual revenue per vessel in the Lease Area and the mid-Atlantic and New England regions as a whole. The highest average annual revenue per vessel in the Mid-Atlantic and New England regions are from vessels in the first quartile—annual average revenue per vessel declines with each successive quartile. Average annual revenue per vessel in the mid-Atlantic and New England regions in the 4th quartile ($219,899) was 22% of the annual average revenue per vessel in the 1st quartile ($1,009,953). Average annual revenue per vessel within the Lease Area shows an opposite trend across quartiles. The highest average annual revenue per vessel from the Lease Area was among outliers. The average vessel in the 4th quartile Lease Area had an average annual revenue of around $2,175. This was 1% of the 4th quartile annual average revenue per vessel in the Mid-Atlantic and New England region as a whole. In other words, if the average vessel in the 4th quartile was displaced from the Lease Area, on average, it would likely need to increase its revenue in other fishing areas by 1% to maintain its level of annual fishing income. Vessels that were outliers on average earned $3,208 per year from the Lease Area. Sufficient information was not available for this analysis to calculate the percentage of revenue needed to maintain current levels of fishing revenue if outlier vessels are displaced from the Lease Area.

DEMOGRAPHICS, EMPLOYMENT, AND ECONOMICS

Project capital expenditures (CapEx) during development and construction of the Project coupled with annual operating expenditures once the Project is up and running would be the key drivers of economic activity in the analysis area. This appendix section summarizes the development of estimates of CapEx and operational expenditures (OpEx) for the SFWF. The intent of this section is to provide a basis for quantitative estimates of economic impacts of the SFWF in terms of local spending for materials, supplies, and services, and for estimates of direct, indirect, and induced employment and earnings generated in each phase of the Project: 1) the development and construction phase, 2) the operation and maintenance phase, and 3) the conceptual decommissioning phase.

Also included in this section are details of estimates of local employment from future wind farm projects.

Estimates of South Fork Wind Farm Capital and Operating Expenditures

Estimates of CapEx and OpEx for the Project were developed using the 2017 version of the *Jobs and Economic Development Impacts Offshore Wind Model* (JEDI-OWM)—an interactive spreadsheet model developed and maintained by the National Renewable Energy Laboratory (NREL). JEDI-OWM is available to the public (NREL 2017).

JEDI-OWM generates estimates of CapEx and OpEx for user-specified wind farms. Key user inputs to the JEDI-OWM include 1) the project state, 2) total farm capacity, 3) wind turbine generator (WTG) capacity, 4) water depth, 5) distance to primary port, 6) length of the export cable, and 7) length of the onshore interconnection cable(s).

A critical set of inputs into the JEDI-OWM are the assumptions with respect to the wind turbine itself. Table 3.1-3 of the construction and operations plan (COP) (Jacobs Engineering Group Inc. [Jacobs] 2021)[7] was used for these key inputs, including parameters for turbine blade lengths and the height of the hub. Estimates of the total cost of each 6-megawatt (MW) turbine assembly were based on information documented in the *2017 Cost of Wind Energy Review* (Stehly et al. 2018). Stehly et al. (2018) report that a

[7] The most recent COP—*South Fork Wind Farm and South Fork Export Cable Construction and Operations Plan*— is referred to frequently throughout the EIS, and therefore the author-date citation is provided here at first mention only.

5.64-MW turbine is expected to cost $1,557 per kilowatt (kW). This cost per kW was assumed for the Project's 6-MW turbines resulting in a total of $9.34 million per 6-kW turbine. Beiter et al. (2018), in the 2017 *Offshore Wind Technologies Market Update,* reports that in the future, CapEx savings are likely to be significant if using a 12-MW turbine rather than a 6-MW turbine because fewer turbines, towers, and interconnections would need to be purchased and installed. Although the cost per turbine for a 12-MW turbine would exceed the cost of a 6-MW turbine, the total Project CapEx would be much lower. Based on information in these reports, it is assumed that the cost per kW of a 12-MW turbine would be almost equal to $1,092 per kW or 13.1 million per 12-MW turbine.

JEDI-OWM was used to generate estimates of CapEx and OpEx for a range of assumptions including six of the potential primary ports (New Bedford, Massachusetts; Providence, Rhode Island; New London, Connecticut; Norfolk, Virginia; Sparrows Point, Maryland; and Paulsboro, New Jersey), two landing sites (Beach Lane and Hither Hills, Long Island, New York), and two levels of overall capacity each using 15 WTGs (90 MW total with 6 MW per WTG or 180 MW total with 12 MW per WTG). Water depth—the other key input for JEDI-OWM calculations—was set at 35.1 meters for all options. As reported in the COP, the onshore cable from the Hither Hills landing site to the new interconnection facility adjacent to the existing East Hampton substation would be 11.9 miles, whereas the length of the cable from the Beach Lane landing site to the interconnection facility would be 4.1 miles (Jacobs 2021). Table F-8 shows assumed distances from the WTG work area (WTG-WA) to each landing site and primary port.

Table F-8. Distances from the Wind Turbine Generator Work Area to Landing Sites and Selected Primary Ports

Port/ Landing Site	Beach Lane, NY	Hither Hills, NY	New Bedford, MA	Providence, RI	New London, CT	Norfolk, VA	Paulsboro, NJ	Sparrows Point, MD
Distance from WTG-WA (kilometers)	98.80	79.80	60.51	65.24	93.73	660.80	878.6	879.2

Notes: CT = Connecticut, MA = Massachusetts, MD = Maryland, NJ = New Jersey, NY = New York, RI = Rhode Island, VA = Virginia.

JEDI-OWM results for total CapEx without taxes or financing charges and interest for the options are shown in Table F-9. It is important to note that there is very little variation in these CapEx estimates across the different ports and states, even though there is considerable variation in the distance from the WTG-WA and the primary ports.[8, 9] There are much more noticeable differences when looking at CapEx across landing sites and capacity options. On average, the CapEx difference between using the Beach Lane landing site or the Hither Hills landing site is estimated by JEDI-OWM to range from $44.4 million to $49.0 million depending on SFWF capacity. The average CapEx of building a 180-MW wind farm is approximately $178 million greater than the CapEx of a 90-MW wind farm. The range of average cost is $4,133 to $4,533 per kW if total capacity is 180 MW, and $6,380 to $6,970 per kW if total capacity is 90 MW.

[8] Estimates of CapEx do not include costs of any port upgrades or expansions that may be needed.

[9] Estimates of CapEx using Quonset Point are not meaningfully different than CapEx estimates for Providence and are therefore not reported in Table F-9.

Table F-9. Estimated Total Capital Expenditures before Taxes and Financing Charges for the South Fork Wind Farm, Assuming a Range of Primary Ports, Landing Sites, and Capacity

Primary Port and State	Beach Lane @ 90 MW	Hither Hills @ 90 MW	Beach Lane @ 180 MW	Hither Hills @ 180 MW
New Bedford, MA	$618.39	$574.19	$792.63	$743.89
Providence, RI	$619.40	$575.00	$794.00	$745.07
New London, CT	$619.48	$575.08	$794.29	$745.36
Norfolk, VA	$624.65	$580.25	$809.49	$760.56
Paulsboro, NJ	$627.25	$582.66	$815.89	$766.76
Sparrows Point, MD	$627.26	$582.66	$815.91	$766.78
Average: All ports	$622.74	$578.31	$803.70	$754.74

Notes: CapEx is shown in millions of 2019 dollars. CT = Connecticut, MA = Massachusetts, MD = Maryland, NJ = New Jersey, RI = Rhode Island, VA = Virginia.

Estimates of annual OpEx (excluding taxes and finance charges) were set equal to $144,000 per installed MW of capacity based on OpEx estimates for the reference project in the *2017 Cost of Wind Energy Review* (Stehly et al. 2018). Total annual OpEx without taxes and finance charges for the SFWF are estimated by JEDI-OWM to be $25.9 million with 180 MW of installed capacity and $13.0 million with 90 MW of installed capacity.

Estimates of Total Conceptual Decommissioning Expenditures

Expenditures and employment for conceptual decommissioning of the offshore infrastructure are estimated to occur 25 years after Project startup. Bureau of Ocean Energy Management (BOEM) guidance indicates that estimates of conceptual decommissioning costs should be approximately 50% of the original installation and construction costs (AECOM 2017). As documented above, the JEDI-OWM model generates estimates of total CapEx. JEDI-OWM provides additional elements for CapEx including 1) materials and other equipment, 2) installation labor, 3) insurance during construction, 4) development costs and third-party contactors, and 5) other miscellaneous costs. It is assumed that conceptual decommissioning costs can therefore be approximated as 50% of the sum of elements 2 through 5. For the SFWF, the sum of these four CapEx elements ranges from $221.6 million to $272.5 million, and therefore conceptual decommissioning costs are expected to range from $110.8 million to $136.3 million. Because these costs are primarily labor and contracting costs, a relatively high percentage of these expenditures would accrue to local economies.

JOBS AND ECONOMIC DEVELOPMENT IMPACTS OFFSHORE WIND MODEL ESTIMATES OF LOCAL EXPENDITURES AND JOBS FOR THE SOUTH FORK WIND FARM

In addition to total CapEx and OpEx, JEDI-OWM also estimates local expenditures and local jobs. It should be noted that JEDI-OWM defines local expenditures as “in-state” or “in the region”—JEDI-OWM does not provide results indicating total United States spending or total spending outside of the United States. South Fork Wind, LLC (SFW) has indicated that during development and construction, it expects hiring and expenditures to occur throughout the four-state region of New York, Connecticut, Rhode Island, and Massachusetts. It is also important to note that SFW expects that development and construction of the SFWF and SFEC could take up to 48 months (as shown in Table 1.5-1 of the COP). For purposes of the EIS, is assumed that local expenditures and employment during development and construction would occur over a 3-year period from 2021 to 2023. SFW has also indicated (Table 3.0-1 of the COP) that operations and maintenance (O&M) facilities would be based in either Montauk, New York, or Quonset Point, Rhode Island.

Table F-10 summarizes JEDI-OWM estimates of the local share of CapEx with percentages of total pre-tax CapEx depending primarily on capacity of the WTGs and the landing site. Estimates of local CapEx shares are presented before and after estimated sales taxes. JEDI-OWM estimates of local shares of CapEx for the SFWF over the potential set of configurations range from 26.0% to 28.34% of pre-tax CapEx.[10] If sales taxes are added for each of the four states, the range of local shares increases to 29.6% to 32.34%.

Table F-10. Estimated Average Local Spending for Capital Expenditures for the South Fork Wind Farm by Landing Sites and Capacity

Estimate	Beach Lane @ 90 MW	Hither Hills @ 90 MW	Beach Lane @ 180 MW	Hither Hills @ 180 MW
Local CapEx before taxes	$161.85 (26.0%)	$160.80 (27.8%)	$214.56 (26.7%)	$213.36 (28.4%)
Local estimated sales tax	$22.48 (3.6%)	$21.64 (3.7%)	$32.35 (4.0%)	$30.70 (4.1%)
Local CapEx with taxes	$184.24 (29.6%)	$182.41 (31.6%)	$246.81 (30.7%)	$244.01 (32.4%)

Note: Each cell shows estimated local (i.e., in state) CapEx in millions of 2019 dollars with the percentage of average total CapEx, as shown in Table F-7.

Table F-11 summarizes estimates from JEDI-OWM of local shares for OpEx to be 48% of total OpEx, or $6.16 million annually for a 90-MW wind farm, and $12.32 million annually if a 180-MW wind farm is built. These estimates do not include local taxes.

Table F-11. Estimated Average Local Spending for Operational Expenditures for the South Fork Wind Farm by Landing Sites and Capacity

Estimate	Beach Lane @ 90 MW	Hither Hills @ 90 MW	Beach Lane @ 180 MW	Hither Hills @ 180 MW
Total OpEx (millions of 2019 dollars)	$12.96	$12.96	$25.92	$25.92
Local OpEx (millions of 2019 dollars)	$6.16	$6.16	$12.32	$12.32
Local OpEx as a percentage of total OpEx	48%	48%	48%	48%

Note: Each cell shows estimated local (i.e., in state) OpEx in millions of 2019 dollars.

Table F-12 summarizes JEDI-OWM estimates of local CapEx and OpEx spending in terms of full-time equivalent (FTE) jobs with the low- and high-generation capacity for the Project assuming the Beach Lane landing site. It must be noted that JEDI-OWM defines “local” as being within the state from which construction operations are based. There are two sections to the table: the upper section shows total local FTE jobs and income during the 3-year development and construction period. The lower section shows annual jobs and income during O&M. Both sections show direct, indirect, and induced jobs and income. Total jobs from CapEx in are expected to range from 1,226 to 1,611 FTE jobs over the assumed 3-year development period. It is important to note that the total number of jobs are presented in job-years, which does not account for the timing of the work or the duration of the work. In other words, if development and construction occur over a 3-year period (as assumed), then the number of FTE jobs per year would be

[10] Given the uncertainty with respect to hiring locations, primary port bases, and the location of suppliers likely to provide goods and services to SFW as it develops and builds the SFWF, it is not possible with the information currently available to make a reliable estimate regarding the distribution of local CapEx within the economic region of impact in the states of Virginia, Maryland, New Jersey, Connecticut, Rhode Island, and Massachusetts.

one-third the number shown in the table. Total direct, indirect, and induced local income for the entire 3-year development and construction period is estimated to range from $87.75 million to $115.82 million, depending on the final capacity of the SFWF. The table also indicates that annual FTE jobs related to Project OpEx are expected to range from 47 to 96 and are likely to be concentrated in Montauk, New York, and/or Quonset Point, Rhode Island. Local annual income for OpEx-related jobs are expected to range from $3.95 to $8.04 million.

In February 2019, Orsted North America provided an assessment of economic development of jobs that can be expected from the SFWF and SFEC (Navigant Consulting, Inc. 2019). The reported estimated levels of local jobs and income are similar to those reported in Table F-12. For example, the report estimates that 413 direct, indirect, and induced jobs would be generated in New York as a result of the Project.[11]

Table F-12. Estimated Local Jobs and Income from Capital Expenditures and Operational Expenditures for the South Fork Wind Farm, Average over All Ports and States

Source of Jobs and Income	Local FTE Jobs with SFWF/ Beach Lane @ 90 MW	Local FTE Jobs with SFWF/Beach Lane @ 180 MW	Local Income with SFWF/Beach Lane @ 90 MW*	Local Income with SFWF/Beach Lane @ 180 MW*
Jobs and income during the 3-year development and construction period				
Direct expenditures by SFW during 3-year development and construction period	331	432	$27.91	$31.96
Expenditures within the supply chain during 3-year development and construction period	538	704	$36.94	$52.55
Induced spending from direct and indirect income during 3-year development and construction period	357	475	$22.90	$31.31
Total jobs and income during 3-year development and construction period	**1,226**	**1,611**	**$87.75**	**$115.82**
Annual jobs and income during the operational period				
Annual direct expenditures by SFW during O&M	5	11	$0.55	$1.09
Annual expenditures within the supply chain during O&M	30	61	$2.61	$5.31
Annual induced spending from direct and indirect income during O&M	12	24	$0.79	$1.64
Total annual jobs and income during O&M	**47**	**96**	**$3.95**	**$8.04**

* Shown in millions of 2019 dollars.

[11] The Navigant Consulting, Inc. (2019) report does not directly specify the size of the individual turbines that were modelled—thus, it is unclear whether the total size of the modelled windfarm is 90 MW or 180 MW or some variant between the two extremes. Because of this uncertainty, the Navigant Consulting, Inc. (2019) report is used as a secondary resource.

ASSUMPTIONS REGARDING LOCAL HIRING PRACTICES

Section 4.6.1.2 of the COP provides indicative descriptions of SFW's expected hiring practices during construction of the SFWF (Jacobs 2021). These are summarized in the bulleted list below:

- The SFWF would be constructed using multiple ports and access locations in different states throughout the analysis area.
- Workers involved in the construction of the offshore portions of the Project would be housed on board vessels at the offshore work sites.
- Non-local construction personnel would typically include mariners, export cable manufacturing personnel, and other specialists.
- The size of the non-local construction workforce could be large relative to the construction workforce hired locally.
- Local workers would be hired to the extent practical for SFWF and SFEC management, fabrication, and construction.
- Because of the short duration of construction activities, it is unlikely that non-local workers would relocate families to the area.

ASSUMPTIONS REGARDING THE ABILITY OF "LOCAL SUPPLIERS" TO MEET PROJECT DEMANDS FOR SPECIALIZED PROJECT COMPONENTS

Several recent studies describe the offshore wind industry in the United States as being in its early developmental stages, and that as it currently exists, a relatively large share of the CapEx and the resulting jobs and income for offshore wind projects are likely to leak out to economies outside both the analysis area and the United States as a whole. In its study for the U.S. Department of Energy, Navigant Consulting, Inc. (2013) states that because of the lack of United States demand for offshore components, "no domestic manufacturing facilities are currently serving the offshore wind market." More recently, AECOM (2017) in its white paper, *Potential Economic Benefits of Offshore Wind*, developed for BOEM, states the following:

> At each phase of offshore wind energy development, there is the potential to generate economic benefits locally, regionally, nationally, and/or internationally, depending on the extent to which these geographic areas can deliver the materials and skills necessary to develop offshore wind energy. Imported materials and services into the particular region being assessed represent lost opportunities for local production and employment. As the offshore wind energy industry advances in the U.S., more opportunities for domestic value can be created along the value chain and for supporting services. Supporting services could include consulting services, financial services, education and training, and research and development. (AECOM 2017)

From a more quantitative perspective, BVG Associates Limited (BVG) (2017) concludes that for offshore projects constructed before 2022, the United States as a whole can expect to realize a minimum of 35% of the total expected jobs needed to meet United States demand—including jobs in the supply chain, development, and construction. In addition, BVG concludes that there is high probability that United States–based jobs could be between 50% and 63% offshore wind-related jobs by 2022.

For the SFWF, estimates of the local share of CapEx and OpEx and the jobs and income that result from those expenditures, were taken from the JEDI-OWM. The estimates of local shares within JEDI-OWM are limited to expenditures within the state with which the Project would be associated. As documented in this appendix, estimates of the local share of CapEx range from 26% to 28% of pre-tax CapEx. If sales taxes are added for each of the four states, the range of local shares increases to 30% to 32%. JEDI-OWM also estimates local shares for OpEx (excluding local taxes) would range from 48% of total OpEx (excluding taxes and finance charges), or $6.16 million annually for a 90-MW wind farm, and $12.32 million annually if a 180-MW wind farm is built.

ENVIRONMENTAL JUSTICE

This appendix section provides additional details on the methodology used to determine whether the minority or low-income percentages in an individual census block group in the analysis area (see EIS Section 3.5.4 for description) are meaningfully greater than the percentages in the reference populations of the county or state.

The section is organized into three parts:

1. Maps indicating the percentage of minority and low-income populations in each census block group in the analysis area
2. A discussion of the methodology used to determine whether a census block group has a meaningfully greater percentage of minority or low-income populations compared to the county or state in which it is located
3. Maps showing census block groups that are areas of potential environmental justice concern

Minority and Low-Income Populations in Census Block Groups

Figure F-2 shows low-income populations by census block groups for ports and landing sites from Eastern Long Island in the lower left to Providence and New Bedford with insets for wind farm ports in New Jersey, Maryland, and Virginia. Figure F-3 shows minority populations for the same areas.

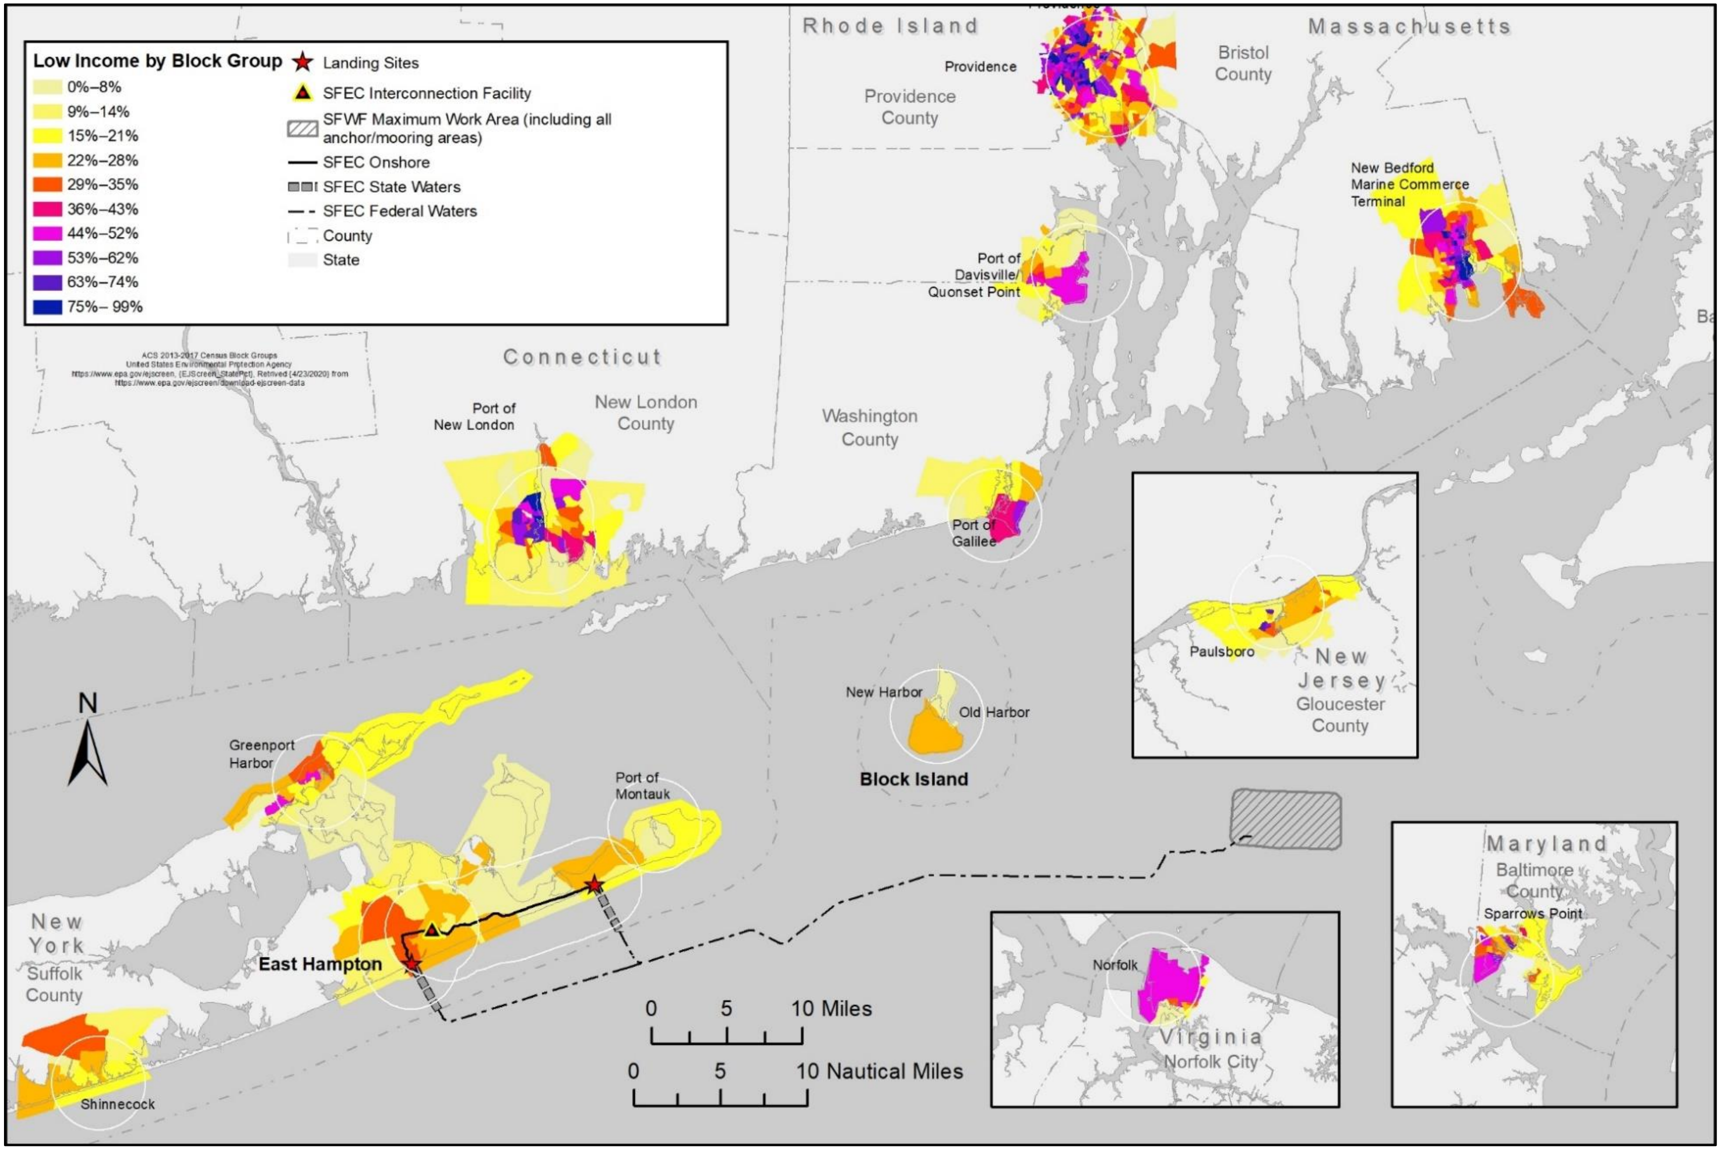

Figure F-2. Low-income populations: Eastern Long Island, Connecticut, Rhode Island, Massachusetts, New Jersey, Maryland, and Virginia.

Source: Developed by Northern Economics based on information from U.S. Environmental Protection Agency (EPA) (2020).

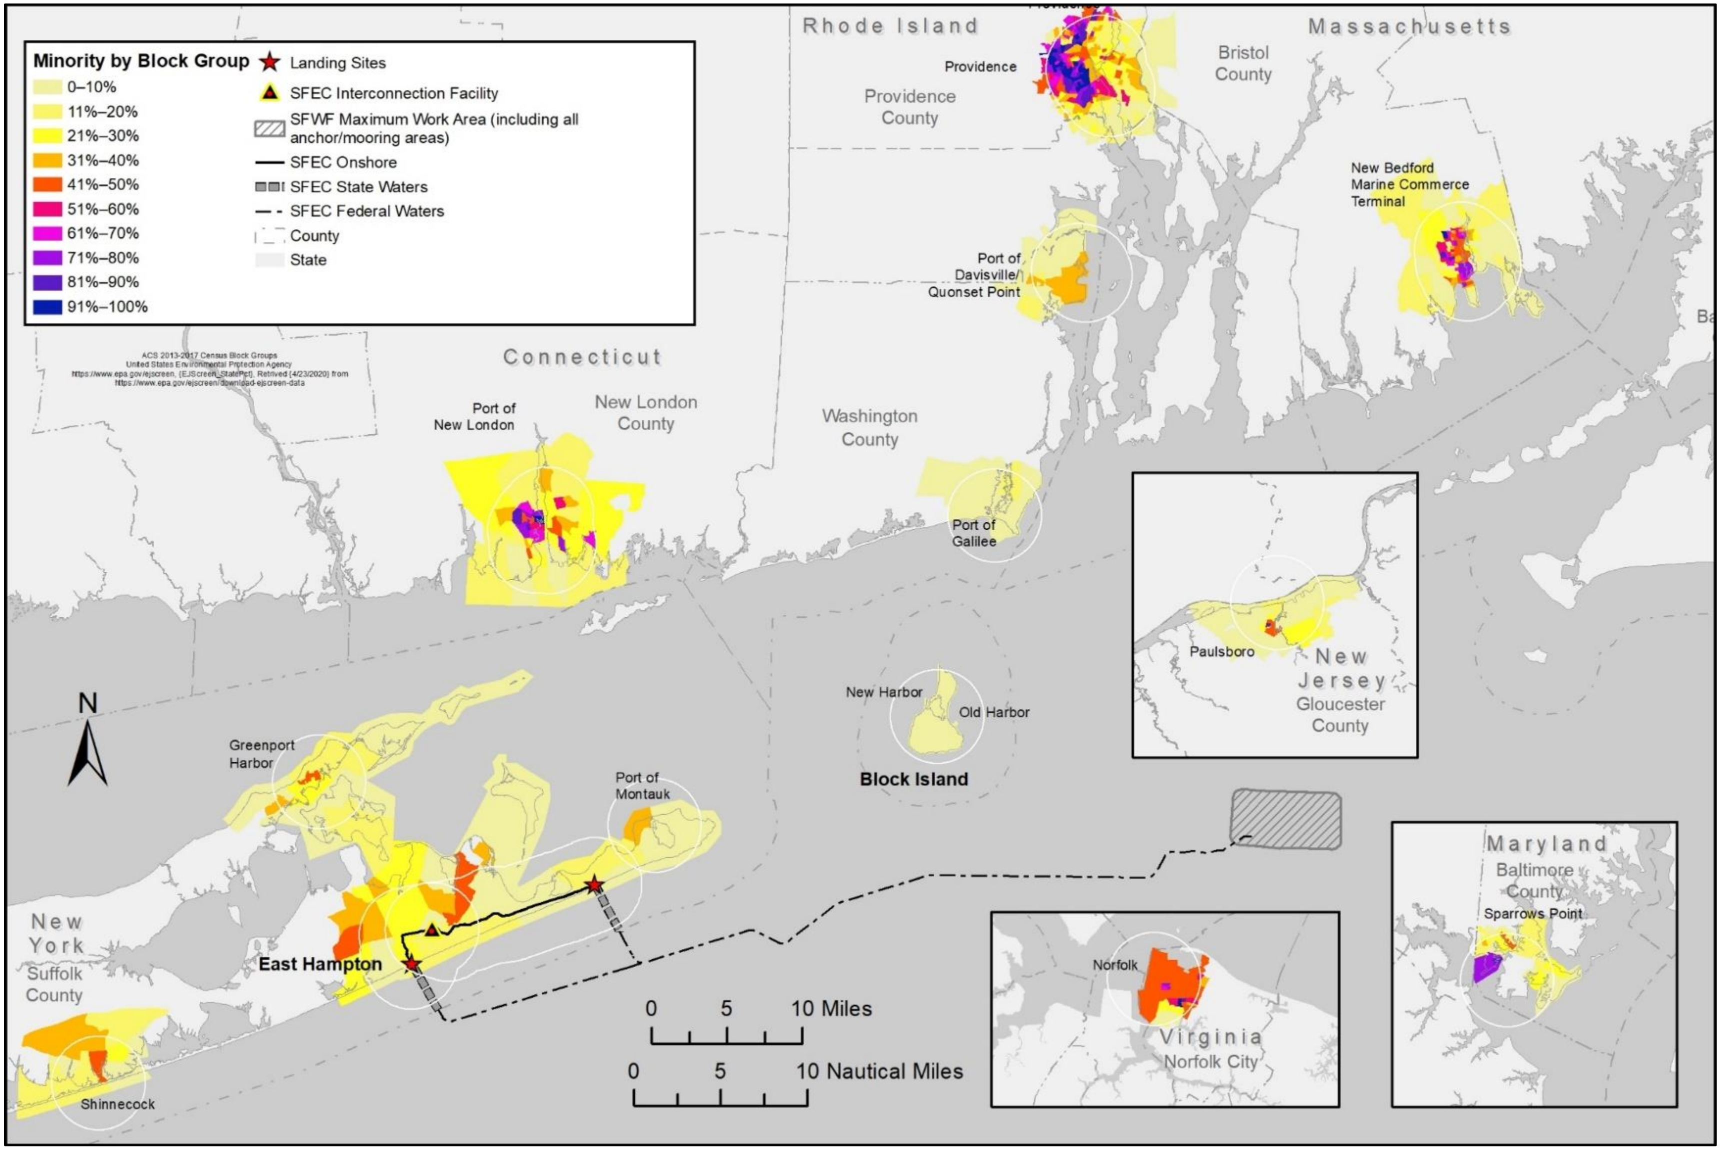

Figure F-3. Minority populations: Eastern Long Island, Connecticut, Rhode Island, Massachusetts, New Jersey, Maryland, and Virginia.

Source: Developed by Northern Economics based on information from EPA (2020).

Methodology

Factors used to estimate criteria for meaningfully greater percentages of minority or low-income populations in each census block group were scaled according to percentage sizes. As shown in Table F-13, for reference populations containing smaller percentages of minorities or low-income individuals, the factors in the middle column are larger. The factors decrease as the percentages within a reference population increase. The minority or low-income percentage of the population of a county or state (whichever is lowest) is multiplied by the factor in Table F-13. If the percent minority or low-income in a given census block population meets or exceed the resulting criterion, that population is considered to have a meaningfully greater percentage than the reference population.

Table F-13. Factors Used to Determine If Census Block Groups in 5-Kilometer Zones Have Meaningfully Greater Percentages of Minority or Low-Income Populations

Range of Percentages for Minority and Low-Income Populations for the County or State	Factor Used to Estimate Criteria for Meaningfully Greater Minority and Low-Income Populations for the Census Block Group	Range of Meaningfully Greater Minority and Low-Income Populations for the Census Block Group to Meet the Criteria
0%–5%	200%	0%–10%
5%–10%	189%	9%–19%
10%–15%	179%	18%–27%
15%–20%	169%	25%–34%
20%–25%	159%	32%–40%
25%–30%	151%	38%–45%
30%–35%	142%	43%–50%
35%–40%	135%	47%–54%
40%–45%	127%	51%–57%
45%–50%	120%	54%–60%
50%–55%	113%	57%–62%

Census Block Groups That Are Areas of Potential Environmental Justice Concern

This section provides maps showing the locations of census block groups that have been determined to have meaningfully greater percentages of low-income or minority populations relative to the county or state in which they are located. In all, 563 census block groups were compared to county or state populations, 227 block groups were determined to have meaningfully greater minority populations, and 213 were determined to have meaningfully greater low-income populations. In Figures F-4 though F-7, census block groups shaded yellow have meaningfully greater percentages of low-income populations; census block groups shaded blue have meaningfully greater percentages of minority populations; and census block groups shaded red have meaningfully greater percentages of both minority and low-income populations. Maps are provided for the following groups of communities:

- Eastern Long Island including Montauk, East Hampton, Greenport Harbor, and Shinnecock.
- New London, Old Harbor/New Harbor (Block Island), and the Port of Galilee (Narragansett/Point Judith)
- Providence, Davisville/Quonset Point and New Bedford
- Norfolk, Sparrows Point, and Paulsboro

CONTENTS

Tables

This page intentionally left blank.

INTRODUCTION

The South Fork Wind Farm (SFWF) and the South Fork Export Cable (SFEC) Project final environmental impact statement (final EIS) assesses the potential biological, socioeconomic, physical, and cultural impacts that could result from the construction and installation, operations and maintenance (O&M), and conceptual decommissioning of a wind energy project (Project) located in Bureau of Ocean Energy Management's (BOEM's) Renewable Energy Lease Area OCS-A 0517, approximately 18 miles southeast of Block Island, Rhode Island, and 34 miles east of Montauk Point, New York in the Atlantic Ocean. The Project comprises the siting and development of the SFWF and the SFEC. South Fork Wind, LLC (SFW) is proposing the Project, which is designed to contribute to New York's renewable energy requirements, particularly, the state's goal of 2,400 megawatts of offshore wind energy generation by 2030.

As part of the Project, SFW has committed to self-implement measures to avoid, reduce, mitigate, and/or monitor impacts on the resources discussed in Chapter 3 of the final EIS. Said environmental protection measures (EPMs) are summarized in Table G-1 of this appendix. BOEM considers as part of the Proposed Action only those measures that SFW has committed to in the construction and operations plan (COP) (Jacobs Engineering Group Inc. [Jacobs] 2021). BOEM may select alternatives and/or require additional mitigation or monitoring measures to further protect and monitor these resources. Additional mitigation and monitoring measures may result from reviews under several environmental statutes (Clean Air Act, Endangered Species Act [ESA], Magnuson-Stevens Fisheries Conservation and Management Act, Marine Mammal Protection Act, and National Historic Preservation Act) as discussed in Appendix A of the final EIS. Additional mitigation measures identified by BOEM, as well as those that may result from reviews under these statutes, are shown in Table G-2. Please note that not all of these mitigation measures are within BOEM's statutory and regulatory authority but could be adopted and imposed by other governmental entities. Table G-2 provides descriptions of these mitigation or monitoring measures, as well as those that BOEM has identified for analysis in the final EIS.

BOEM is still undergoing consultation with NMFS under the ESA related to the full suite of proposed actions; once that consultation is concluded, which will occur before the issuance of the record of decision (ROD), additional mitigation measures may be required and added to the final mitigation table in the ROD. These measures will not alter the analyses contained within the final EIS because 1) any such additional measures will benefit listed species by minimizing, monitoring, and/or reporting incidental take; 2) the benefit of such measures may range from low to high benefit to listed species depending on the measure, and such measures may also result in incidental benefits to other non-listed marine wildlife; and 3) these measures, however, should not result in material changes to the proposed action described in the final EIS because such measures "may not alter the basic design, location, scope, duration, or timing of the action," and may "involve only minor changes" (50 Code of Federal Regulations [CFR] 402.14(i))(2)).

If BOEM decides to approve the COP, its record of decision (ROD) would state which of the mitigation and monitoring measures identified by BOEM in Table G-2 have been adopted, and if not, why they were not. Thus, the ROD would inform terms and conditions of COP approval and would compel compliance with or execution of identified mitigation and monitoring measures (40 CFR 1505.3). SFW would be required to certify compliance with certain terms and conditions, as required under 30 CFR 585.633(b). Furthermore, BOEM would periodically review the activities conducted under the approved COP. The frequency and extent of the review would be based on the significance of any changes in available information and on onshore or offshore conditions affecting, or affected by, the activities conducted under the COP. If the review indicated that the COP should be revised to meet the requirement of BOEM's renewable energy regulations, SFW would be required to submit the needed revisions (30 CFR 585.634(b)).

Monitoring measures may be required to evaluate the effectiveness of a mitigation measure or to identify if resources are responding as predicted to impacts from the Proposed Action. Monitoring programs would be developed in coordination between BOEM and agencies with jurisdiction over the resource to be monitored. The information generated by monitoring may be used to 1) adapt how a mitigation measure identified in the COP or ROD is being implemented, 2) revise or develop new mitigation or monitoring measures required under the SFW COP in accordance with 30 CFR 585.634(b) or develop measures for future projects, and/or 3) contribute to regional efforts for better understanding of the impacts and benefits resulting from offshore wind energy projects in the Atlantic (e.g., potential cumulative impact assessment tool). Unless specified, the proposed mitigation and monitoring measures described below would not change the impact ratings on the affected resource, as described in Chapter 3 of the final EIS, but would further reduce expected impacts or inform the development of addition mitigation measures if required.

In this appendix, distances in miles are in statute miles (miles used in the traditional sense) or nautical miles (miles used specifically for marine navigation). Statute miles are more commonly used and are referred to simply as *miles*, whereas nautical miles are referred to by name or by their abbreviation *nm*.

Table G-1. Environmental Protection Measures Committed to by South Fork Wind, LLC

Description	Resource Area Mitigated
Provided in COP Table ES-1	
Vessels providing construction or maintenance services for the SFWF will use low-sulfur fuel where possible.	Air quality
Vessel engines will meet the appropriate U.S. Environmental Protection Agency (EPA) air emission standards for nitrogen oxide emissions when operating within Emission Controls Areas.	Air quality
Equipment and fuel suppliers will provide equipment and fuels that comply with the applicable EPA or equivalent emission standards.	Air quality
Marine engines with a model year of 2007 or later and non-road engines complying with the Tier 3 standards (in 40 Code of Federal Regulations [CFR] 89 or 1039) will be used to satisfy best available control technology.	Air quality
The use of wind to generate electricity reduces the need for electricity generation from new traditional fossil fuel powered plants on the South Fork of Long Island that produce greenhouse gas emissions.	Air quality
Installation of the SFWF Inter-array Cable and SFEC - Offshore will occur using equipment such as a mechanical cutter, mechanical plow, and/or jet plow. Compared to open cut dredging, this method would minimize turbidity and total suspended solids.	Water quality
Vessels will comply with regulatory requirements related to the prevention and control of discharges and accidental spills.	Water quality
Accidental spill or release of oils or other hazardous materials will be managed through the Oil Spill Response Plan (OSRP) (COP Appendix D).	Water quality
At the onshore horizontal directional drilling (HDD) work area for the SFEC, drilling fluids will be managed within a contained system to be collected for reuse as necessary	Water quality
An HDD Inadvertent Release Plan will minimize the potential risks associated with release of drilling fluids or a frac-out.	Water quality
A Stormwater Pollution Prevention Plan, including erosion and sedimentation control measures, and a Spill Prevention, Control, and Countermeasures Pan, will minimize potential impacts to water quality during construction of the SFEC - Onshore.	Water quality
SFW has designed the Project to account for site-specific oceanographic and meteorological conditions within the Lease Area; therefore, no additional measures are necessary.	Water quality
Lighting during operations will be limited to the minimum required by regulation and for safety, therefore minimizing the potential for attraction (or attraction of insect prey) and possibly collision of bats at night.	Bats
SFEC - Onshore will be located underground in previously disturbed areas, such as roadways and railroad ROW, therefore minimizing potential impacts from clearing.	Bats
The SFWF and SFEC offshore will minimize impacts to complex bottom habitats and to important habitats for finfish species to the extent practicable.	Benthic habitat, EFH, invertebrates, and finfish
Installation of the SFWF Inter-array Cable and SFEC - Offshore will occur using equipment such as a mechanical cutter, mechanical plow, and/or jet plow. Compared to open cut dredging, this method will minimize sediment disturbance and alteration of demersal finfish habitat and minimize long-term impacts to the benthic habitat.	Benthic habitat, EFH, invertebrates, and finfish
Use of monopiles with associated scour protection will minimize impacts to benthic habitat compared to other foundation types.	Benthic habitat, EFH, invertebrates, and finfish
The SFWF Inter-array Cable and SFEC - Offshore will be buried to a target depth of 4 to 6 feet (1.2 to 1.8 m)	Benthic habitat, EFH, invertebrates, and finfish
Installation of the offshore sections of the SFEC will use equipment such as a mechanical cutter, mechanical plow, and/or jet plow. Compared to open cut dredging, this method will minimize turbidity and total suspended solids.	Benthic habitat, EFH, invertebrates, and finfish
Use of dynamic positioning vessel for cable installation for the SFWF Inter-array Cable and SFEC – Offshore will minimize impacts to benthic and shellfish resources, finfish and essential fish habitat (EFH) resources as compared to use of a vessel relying on multiple anchors.	Benthic habitat, EFH, invertebrates, and finfish
The SFEC sea-to-shore transition will be installed via HDD to avoid impacts to the dunes, beach, and nearshore zone, including benthic and shellfish, finish and EFH resources.	Benthic habitat, EFH, invertebrates, and finfish
A plan for vessels will be developed prior to construction to identify no-anchor areas inside the maximum work area (MWA) to protect sensitive areas or other areas to be avoided.	Benthic habitat, EFH, invertebrates, and finfish
The SFWF and SFEC - Offshore will minimize impacts to important habitats for finfish species.	Benthic habitat, EFH, invertebrates, and finfish
Siting of the SFWF and SFEC – Offshore were informed by site-specific benthic habitat assessments and Atlantic cod spawning surveys.	Benthic habitat, EFH, invertebrates, and finfish
SFW is committed to collaborative science with commercial and recreational fishing industries pre-, during, and post-construction.	Benthic habitat, EFH, invertebrates, and finfish
SFW will require all construction and operations vessels to comply with regulatory requirements related to the prevention and control of spills and discharges.	Benthic habitat, EFH, invertebrates, and finfish
Accidental spill or release of oils or other hazardous materials will be managed through the OSRP (COP Appendix D).	Benthic habitat, EFH, invertebrates, and finfish
The SFWF WTGs will be widely spaced apart allowing avian species to avoid individual WTGs and minimize risk of potential collision.	Birds
The location of the SFWF, more than 18 miles (30 kilometers [km], 16 nm) offshore, will avoid the coastal areas, which are known to attract birds, particularly shorebirds and seaducks.	Birds
Lighting during operations will be limited to the minimum required by regulation and for safety, therefore minimizing the potential for attraction or disorientation.	Birds
SFW will require all construction and operations vessels to comply with regulatory requirements related to the prevention and control of spills and discharges.	Birds
Accidental spill or release of oils or other hazardous materials will be managed through the OSRP (COP Appendix D).	Birds
The SFEC sea-to-shore transition will be installed via HDD to avoid impacts to the dunes, beach, and nearshore zone.	Birds
An avian management plan for listed species will be prepared for the SFEC - Onshore.	Birds
The SFEC - Onshore cable will be buried; therefore avoiding the risk to birds associated with overhead lines.	Birds
Exclusion and monitoring zones for marine mammals will be established for pile driving and high resolution geophysical (HRG) survey activities.	Marine mammals

Description	Resource Area Mitigated
Mitigation measures will be implemented for pile-driving and HRG survey activities. These measures will include soft-start measures, shut-down procedures, protected species monitoring protocols, use of qualified and National Oceanic and Atmospheric Administration (NOAA)–approved protected species observers (PSOs), and noise attenuation systems such as bubble curtains, as appropriate.	Marine mammals
Impact pile-driving activities will not occur at the SFWF from January 1 to April 30 to minimize potential impacts to the North Atlantic right whale (NARW), which will also have a protective effect for other marine mammal species.	Marine mammals
Vessels will follow NOAA guidelines for marine mammal strike avoidance measures, including vessel speed restrictions.	Marine mammals
All personnel working offshore will receive training on marine mammal awareness and marine debris awareness.	Marine mammals
SFW will require all construction and operations vessels to comply with regulatory requirements related to the prevention and control of spills and discharges.	Marine mammals
Accidental spill or release of oils or other hazardous materials will be managed through the OSRP (COP Appendix D).	Marine mammals
The SFWF inter-array cable and SFEC Offshore will be buried to a target depth of 4 to 6 feet (1.2 to 1.8 m).	Marine mammals
SFEC - Onshore will be sited within previously disturbed existing ROWs.	Terrestrial coastal habitats and fauna
The SFEC sea-to-shore transition will be installed via HDD to avoid impacts to the dunes, beach, and nearshore zone. Accidental spill or release of oils or other hazardous materials will be managed through the OSRP (COP Appendix D).	Terrestrial coastal habitats and fauna
A Stormwater Pollution Prevention Plan, including erosion and sedimentation control measures, and a Spill Prevention, Control, and Countermeasures Plan, will minimize potential impacts to water quality during construction of the SFEC - Onshore.	Terrestrial coastal habitats and fauna
Exclusion and monitoring zones will be established for sea turtles during pile-driving activities and HRG survey activities.	Sea turtles
Mitigation measures will be implemented for impact pile-driving and HRG survey activities. These measures would include soft-start measures, shut-down procedures, protected species monitoring protocols, use of qualified and NOAA-approved protected species observers, and noise attenuation systems such as bubble curtains, as appropriate. Impact pile driving activities will not occur at the SFWF from January 1 to April 30 to minimize potential impacts to the North Atlantic right whale, which would also have a protective effect for sea turtles.	Sea turtles
Vessels will follow NOAA guidelines for sea turtle strike avoidance measures, including vessel speed restrictions.	Sea turtles
All personnel working offshore will receive training on sea turtle awareness and marine debris awareness.	Sea turtles
SFW will require all construction and operations vessels to comply with regulatory requirements related to the prevention and control of spills and discharges.	Sea turtles
Accidental spill or release of oils or other hazardous materials will be managed through the OSRP (COP Appendix D).	Sea turtles
The SFWF inter-array Cable and SFEC Offshore would be buried to a target depth of 4 to 6 feet (1.2 to 1.8 m).	Sea turtles
SFW is committed to a spacing of approximately 1.15 mile (1.8 km), or one nautical mile (nm), between turbines.	Commercial fisheries and for-hire recreational fishing, navigation and vessel traffic
The inter-array cable and SFEC - Offshore will be buried to a target depth of 4 to 6 feet (1.2 to 1.8 m).	Commercial fisheries and for-hire recreational fishing
The SFEC sea-to-shore transition will be installed via HDD to avoid impacts to the dunes, beach, and nearshore zone, including sensitive shoreline habitats and shoreline fishing areas.	Commercial fisheries and for-hire recreational fishing
As appropriate and feasible, Best Management Practices would be implemented to minimize impacts on fisheries, as described in the *Guidelines for Providing Information on Fisheries Social and Economic Conditions for Renewable Energy Development* (BOEM 2015).	Commercial fisheries and for-hire recreational fishing
Siting of the SFWF and SFEC - Offshore were informed by site-specific benthic habitat assessments and Atlantic cod spawning surveys.	Commercial fisheries and for-hire recreational fishing
SFW is committed to collaborative science with the commercial and recreational fishing industries pre-, during, and post-construction.	Commercial fisheries and for-hire recreational fishing
Each WTG will be marked and lit with both USCG and approved aviation lighting.	Commercial fisheries and for-hire recreational fishing
SFW will require all construction and operations vessels to comply with regulatory requirements related to the prevention and control of spills and discharges.	Commercial fisheries and for-hire recreational fishing
Accidental spill or release of oils or other hazardous materials will be managed through the OSRP (COP Appendix D).	Commercial fisheries and for-hire recreational fishing
Communications and outreach with the commercial and recreational fishing industries will be guided by the Project-specific Fisheries Communications Plan (COP Appendix B). This outreach will be led by the SFW Fisheries Liaisons. Fisheries Representatives from the ports of Montauk, Point Judith, and New Bedford represent the fishing community.	Commercial fisheries and for-hire recreational fishing
SFW is committed to a gear loss SFW is committed to a Gear Loss Prevention and Claim Procedure for the commercial fishing industry	Commercial fisheries and for-hire recreational fishing
A comprehensive communication plan will be implemented during offshore construction to inform all mariners, including commercial and recreational fishermen, and recreational boaters of construction activities and vessel movements. Communication will be facilitated through a Fisheries Liaison, a Project website, and public notices to mariners and vessel float plans (in coordination with USCG).	Commercial fisheries and for-hire recreational fishing
The location of SFWF WTGs, approximately 19 miles (30.6 km, 16.6 nm) from Block Island, 21 miles (33.7 km, 18.2 nm) from Martha's Vineyard, and 35 miles (56.3 km, 30.4 nm) from Montauk, restricts available views from visually sensitive above-ground historic properties.	Cultural resources
SFWF WTGs will have uniform design, speed, height, and rotor diameter.	Cultural resources
The color of the SFWF WTGs (less than 5% grey tone) generally blends well with the sky at the horizon and eliminates the need for daytime lights or red paint marking of the blade tips.	Cultural resources
The SFEC - Onshore cable will be buried, therefore minimizing potential visual impacts to aboveground historic properties.	Cultural resources
The SFEC - Interconnection Facility will be located adjacent to an existing substation on parcel zoned for commercial and industrial/utility use.	Cultural resources
The SFEC interconnection facility land parcel is currently screened by mature trees. After construction, additional screening will be considered to further reduce potential visibility and visual impact.	Cultural resources

Description	Resource Area Mitigated
The SFWF and SFEC - Offshore will avoid or minimize impacts to potential submerged cultural sites, to the extent practicable.	Cultural resources
Native American tribes were involved, and will continue to be involved, in marine survey protocol design, execution of the surveys, and interpretation of the results.	Cultural resources
A plan for vessels will be developed prior to construction to identify no-anchor areas inside the MWA to protect sensitive areas or other areas to be avoided. An Unanticipated Discovery Plan will be implemented that will include stop-work and notification procedures to be followed if a cultural resource is encountered during installation.	Cultural resources
As appropriate, SFW will conduct additional archaeological analysis and/or investigation to further assess potential sensitive areas.	Cultural resources
Geophysical and geotechnical (G&G) survey coverage is sufficient to support design changes, if minor refinement of SFWF facility locations is necessary to avoid paleolandforms.	Cultural resources
The route for the SFEC - Onshore will minimize impacts to, or avoid, potential terrestrial archeological resources, to the extent practicable.	Cultural resources
Native American tribes were involved, and will continue to be involved, in terrestrial survey protocol design, execution of the surveys, and interpretation of the results.	Cultural resources
Analysis shows that most of the SFEC - Onshore route has been previously disturbed; therefore, the risk of potentially encountering undisturbed archaeological deposits is minimized.	Cultural resources
An Unanticipated Discovery Plan will be implemented that will include stop-work and notification procedures to be followed if a cultural resource is encountered during installation.	Cultural resources
SFW will conduct additional archaeological investigation to further assess potential sensitive areas.	Cultural resources
Where possible, local workers will be hired to meet labor needs for Project construction, O&M, and conceptual decommissioning.	Demographics, employment, and economics
The location of SFWF WTGs restricts available views from visually sensitive public resources and population centers.	Demographics, employment, and economics
The SFEC - Onshore construction schedule has been designed to minimize impacts to the local community during the summer tourist season.	Demographics, employment, and economics
At the SFEC Interconnection Facility, additional screening will be considered to further reduce potential visibility and noise.	Demographics, employment, and economics
New York State Law requires that the SFEC - Onshore be constructed in compliance with a detailed plan that includes traffic and other control measures.	Demographics, employment, and economics
The use of wind to generate electricity will have a beneficial impact on air emissions in East Hampton, as it reduces the need for electricity generation from traditional fossil fuel powered plants on the South Fork of Long Island that produce greenhouse gas emissions.	Environmental Justice
Where possible, local workers will be hired to meet labor needs for Project construction, O&M, and decommissioning.	Environmental Justice
New York State Law requires that the SFEC - Onshore be constructed in compliance with a detailed plan that includes traffic and other control measures.	Environmental Justice
SFW will also coordinate with local authorities during SFEC - Onshore construction to minimize local traffic and noise impacts	Environmental Justice
SFEC - Onshore will be located underground in previously disturbed areas, such as roadways and railroad ROW	Land use and coastal infrastructure
The SFEC sea-to-shore transition will be installed via HDD to avoid impacts to the dunes, beach, and near-shore zone. New York State Law requires that the SFEC - Onshore be constructed in compliance with a detailed plan that includes traffic and other control measures.	Land use and coastal infrastructure
SFW will also coordinate with local authorities during SFEC – Onshore construction to minimize local traffic and noise impacts.	Land use and coastal infrastructure
A Stormwater Pollution Prevention Plan, including erosion and sedimentation control measures, and a Spill Prevention, Control, and Countermeasures Plan, will minimize potential impacts to adjacent lands uses during construction of the SFEC - Onshore.	Land use and coastal infrastructure
The SFEC - Onshore cable will be buried; therefore, minimizing potential impacts to adjacent properties.	Land use and coastal infrastructure
SFW is committed to a spacing of approximately 1.15 mile (1.8 km), or one nautical mile, between turbines.	Navigation and vessel traffic
Each WTG will be marked and lit with both USCG and approved aviation lighting. An Automatic Identification System will be installed at the SFWF marking the corners of the wind farm to assist in safe navigation.	Navigation and vessel traffic
All appropriate lighting and marking schemes, based on current regulations, will be implemented.	Navigation and vessel traffic
SFW will require all construction and operations vessels to comply with regulatory requirements related to the prevention and control of spills and discharges.	Navigation and vessel traffic
Accidental spill or release of oils or other hazardous materials will be managed through the OSRP (COP Appendix D).	Navigation and vessel traffic
Project construction, O&M, and decommissioning activities will be coordinated with appropriate contacts at USCG and U.S. Department of Defense command headquarters.	Navigation and vessel traffic; Other Marine Uses
A comprehensive communication plan will be implemented during offshore construction to inform all mariners, including commercial and recreational fishermen, and recreational boaters of construction activities and vessel movements. Communication will be facilitated through a Fisheries Liaison, Project website, and public notices to mariners and vessel float plans (in coordination with USCG)	Navigation and vessel traffic
The location of SFWF WTGs restricts available views from visually sensitive public resources and population centers.	Recreation and tourism
A comprehensive communication plan will be implemented during offshore construction to inform all mariners, including commercial and recreational fishermen, and recreational boaters of construction activities and vessel movements. Communication will be facilitated through a Project website, public notices to mariners and vessel float plans, and a fisheries liaison. SFW will submit information to the USCG to issue Local Notice to Mariners during offshore installation activities.	Recreation and tourism
The communication plan will also include outreach to stakeholders in the offshore recreational and tourism industry to minimize impacts to recreational events (e.g., sailboat races).	Recreation and tourism
The SFEC - Onshore construction schedule has been designed to minimize impacts to the local community during the summer tourist season.	Recreation and tourism
New York State Law requires that the SFEC - Onshore be constructed in compliance with a detailed plan that includes traffic and other control measures.	Recreation and tourism
SFW will also coordinate with local authorities during SFEC onshore construction to minimize local traffic and noise impacts.	Recreation and tourism

Description	Resource Area Mitigated
The location of SFWF, approximately 19 miles (30.6 km, 16.6 nm) from Block Island, 21 miles (33.7 km, 18.2 nm) from Martha's Vineyard, and 35 miles (56.3 km, 30.4 nm) from Montauk, restricts available views from visually sensitive public resources and population centers	Visual resources
SFWF WTGs will have uniform design, speed, height, and rotor diameter.	Visual resources
The color of the SFWF WTGs (less than 5% grey tone) generally blends well with the sky at the horizon and eliminates the need for daytime lights or red paint marking of the blade tips.	Visual resources
Use of an Aircraft Detection Lighting System will mitigate nighttime visual impacts.	Visual resources
The SFEC - Interconnection Facility will be located adjacent to an existing substation on a parcel zoned for commercial and industrial use.	Visual resources
At the SFEC - Interconnection Facility, additional screening will be considered to further reduce potential visibility and noise	Visual resources

Table G-2. Potential Additional Mitigation and Monitoring Measures

Mitigation Number	Proposed Project Phase	Mitigation or Monitoring Measure	Description	Resource Area Mitigated
Potential Additional Mitigation and Monitoring Measures				
1	Construction and installation	Tree clearing time-of-year restriction	SFW agreed to a NYSDEC requirement that tree clearing activities occur between December 1 and February 28 to avoid potential impacts to northern long-eared bat. If any proposed clearing activities are performed outside of the December 1 through February 28 window, roosting tree surveys shall be conducted in accordance with a northern long-eared bat monitoring and impact minimization plan, in coordination with NYSDEC. A roosting tree survey plan will be developed for the SFEC-Interconnection Facility and SFEC-Onshore in the Project Area, in consultation with NYSDEC, and will be included as part of the EM&CP. As part of the survey, biological monitors shall identify and evaluate any potential roosting trees for the northern long-eared bat. Emergence counts will be taken no more than 24 hours before tree removal to confirm that there are no northern long-eared bats roosting. This would occur through a combination of acoustic and visual surveys. If the certificate holder or NYSDEC identify roosting trees within 150 feet of the Project Area, the certificate holder will coordinate with NYSDEC regarding any potential minimization and mitigation measures required to comply with 6 NYCRR § 182 and applicable federal laws and regulations promulgated by the U.S. Fish and Wildlife Service (USFWS). If presence/probable absence surveys are conducted pursuant to current U.S. Fish and Wildlife Service (USFWS) protocols and no northern long-eared bats are documented, this measure may not be necessary for ESA compliance relative to this species.	Bats
2	Construction and installation	Onshore time-of-year restrictions	In accordance with the conditions of the New York Article VII certification, SFW must eliminate onshore construction activities from Memorial Day through Labor Day that would impede traffic or access to recreational areas.	Recreation and tourism
3	Construction and installation	Vegetation Disturbance	Scenic easements near the interconnection facility will be staked or clearly identified to avoid vegetation disturbance.	Visual
4	Construction and installation	Vegetation Screening	SFW will work with local officials to identify appropriate vegetation screening options during governmental permitting processes.	Visual
5	Construction and installation	Nearshore time-of-year restrictions	To minimize impacts to threatened and endangered shorebirds, no construction or maintenance activities shall occur within 1,000 meters of the southern edge of the beach/pavement boundary between April 1 and September 1 and within 152 meters (500 feet) from September 2 to November 1. (USFWS ESA Consultation comment 3/4/21 & Ørsted permit with NY)	Birds
6	Construction and installation	Nearshore time-of-year restrictions	To protect nesting shorebirds on the beach front in the East Hampton locations, Red knot surveys should be conducted from April 1 to November 30. If red knots are detected a 300m buffer between project activities and red knots. (USFWS comment on DEIS 4/22/21)	Birds
7	Construction and installation	Nearshore time-of-year restrictions	Seabeach amaranth surveys and avoidance measures should also be applied from May 1 to November 1 for work on East Hampton beaches. (USFWS comment on DEIS 4/22/21)	Plant
8	Construction, O&M, and conceptual decommissioning	Annual bird mortality reporting	By January 31 of each year, the lessee must submit an annual report to DOI (renewable_reporting@boem.gov and protectedspecies@bsee.gov) and USFWS documenting any dead (or injured) birds or bats found on vessels and structures during construction, operations, and decommissioning. The report must contain the following information: the name of species, date found, location, a picture to confirm species identity (if possible), and any other relevant information. Carcasses with Federal or research bands must be reported to the United States Geological Survey Bird Band Laboratory, available at https://www.pwrc.usgs.gov/bbl/.Require an annual report of any dead or injured birds discovered on Project vessels or structures. The report would contain the following information: species, photographs to confirm species, location, date, and other relevant information. Carcasses with federal or research bands must be reported to the U.S. Geological Survey Bird Band Laboratory, BOEM, and USFWS.	Birds
9	O&M	Aircraft Detection Lighting System (ADLS)	Lessee must use FAA-approved ADLS, which will only activate the FAA hazard lighting when an aircraft is in the vicinity of the wind facility to reduce the visibility of nighttime lighting and nighttime visual impacts. The Lessee must confirm use of FAA-approved ADLS in the FIR. require use of Federal Aviation Administration (FAA)–approved ADLS, which would only activate the FAA hazard lighting when an aircraft is in the vicinity of the wind facility, to reduce the visibility of nighttime lighting and thus reduce nighttime visual impacts.	Birds, cultural resources, recreation and tourism
10	O&M	Post-installation cable monitoring	SFW must provide BOEM with a cable monitoring report within 45 calendar days following each inter-array and export cable inspection to determine cable location, burial depths, state of the cable, and site conditions. An inspection of the inter-array cable and export cable is expected to include HRG methods, such as a multi-beam bathymetric survey equipment, and identify seabed features, natural and man-made hazards, and site conditions along federal sections of the cable routing. In federal waters, the initial inter-array and export cable inspection would be carried out within 6 months of commissioning and subsequent inspections would be carried out at years 1, 2, and every 3 thereafter and after a major storm event. Major storm events are defined as when metocean conditions at the facility meet or exceed the 1 in 50-year return period calculated in the metocean design basis, to be submitted to BOEM with the Facility Design Report (FDR). If conditions warrant adjustment to the frequency of inspections following the Year 2 survey, a revised monitoring plan may be provided to BOEM for review. In addition to inspection, the export cable would be monitored continuously with the as-built Distributed Temperature Sensing System. If Distributed Temperature Sensing data indicate that burial conditions have deteriorated or changed significantly and remedial actions are warranted, the Distributed Temperature Sensing data, a seabed stability analysis, and report of remedial actions taken or scheduled must be provided to BOEM within 45 calendar days of the observations. The Distributed Temperature Sensing data, cable monitoring survey data, and cable conditions analysis for each year must be provided to BOEM as part of the Annual Compliance Reports, required by 30 CFR § 585.633(b).	Benthic habitat, EFH, invertebrates, and finfish; commercial fisheries and for-hire recreational fishing

Mitigation Number	Proposed Project Phase	Mitigation or Monitoring Measure	Description	Resource Area Mitigated
11	Construction, O&M	Dredging	Avoid dredging and placement between April 15 to July 15 minimizes potential impacts to horseshoe crab spawning. Dredge disposal/placement may result in the loss of horseshoe crabs and their eggs and larvae, and their habitat, resulting in a reduction in prey species for several federally managed species and adverse effects to their EFH. As noted in the EFH assessment, horseshoe crabs are known to occur within Lake Montauk.	Benthic habitat, EFH, invertebrates, and finfish
12	Construction, O&M	Gillnet surveys	Conduct surveys according to the Fisheries Research Monitoring Plan.	Benthic habitat, EFH, invertebrates, and finfish
13	Construction, O&M	Beam Trawl surveys	Conduct surveys according to the Fisheries Research Monitoring Plan.	Benthic habitat, EFH, invertebrates, and finfish
14	Construction, O&M	Ventless Trap, Lobster surveys	Conduct surveys according to the Fisheries Research Monitoring Plan.	Benthic habitat, EFH, invertebrates, and finfish
15	Construction, O&M	Ventless Fish Pot surveys	Conduct surveys according to the Fisheries Research Monitoring Plan.	Benthic habitat, EFH, invertebrates, and finfish
16	Construction, O&M	Acoustic Telemetry	Conduct surveys according to the Fisheries Research Monitoring Plan.	Benthic habitat, EFH, invertebrates, and finfish
17	Construction, O&M	Benthic surveys – sediment profile imaging	Conduct surveys according to the Fisheries Research Monitoring Plan.	Benthic habitat, EFH, invertebrates, and finfish
18	Construction	Removal of Turbines and inter-array cable	Remove turbine locations and associated cable from development to reduce adverse impacts to complex habitats. The proposed turbine locations WTG 5, WTG 6, WTG 9, WTG 16A, and WTG 17A would result in substantial adverse impacts to complex habitats. These locations were identified by SFW in a June 14, 2021, communication. The specific locations were selected taking into consideration the reduction of impacts to complex habitats from the WTGs and cabling along with other technical considerations such as minimizing boulder removal as well as transmission considerations.	Benthic habitat, EFH, invertebrates, and finfish
19	Construction	Avoid identified shipwrecks, debris fields, and submerged landform features that can be avoided	Require SFW to avoid the shipwrecks, potentially significant debris fields, and as many as possible of the submerged, landform features identified during marine archaeological surveys of the WDA and OECC. While avoidance of shipwrecks and debris fields is typically simple, avoidance of all submerged landform features is typically not possible due to their size and orientation.	Cultural resources
20	Construction, O&M, decommissioning	Submarine cable system burial plan	A copy of the submarine cable system burial plan shall be submitted by SFW as part of their FDR and Fabrication and Installation Report that depict precise planned locations and burial depths of the entire cable system. This plan shall be reviewed by the USCG and BOEM.	Navigation and vessel traffic
21	Construction	Boulder relocation reporting	The locations of any boulder (which would protrude >2 m or more on the sea floor) relocated during cable installation activities must be reported to BOEM, USCG, NOAA, and the local harbormaster within 30 days of relocation. These locations must be reported in latitude and longitude degrees to the nearest 10 thousandth of a decimal degree (roughly the nearest meter), or as precise as practicable.	Navigation and vessel traffic
22	Construction, O&M, decommissioning	Vessel safety practices	All Project vessels involved in construction, operations, maintenance, and decommissioning activities would comply with U.S. or SOLAS standards, as applicable, with regards to vessel construction, vessel safety equipment, and crewing practices.	Navigation and vessel traffic
23	Construction, O&M, decommissioning	WTG and OSS marking	Each WTG and OSS would be marked with PATONs, subject to the approval of the Commander (dpw-1), First Coast Guard District. SFW would do the following: Provide BOEM and USCG with a proposed lighting, marking, and signaling plan, which must be approved by BOEM after consultation with the USCG. The plan should conform to the International Association of Marine Aids to Navigation and Lighthouse Authorities Recommendation O-139, The Marking of Man-Made Offshore Structures. Should any part of the recommendation conflict with federal law or regulation, or if SFW seeks an alternative to the recommendation, SFW must consult with the USCG. Mark each individual WTG and OSS with clearly visible, unique, alphanumeric identification characters. Light each WTG and OSS in a manner that is visible by mariners in a 360-degree arc around the WTG and OSS. Apply to the First Coast Guard District to establish PATONs for the facility. Approval for all PATONs must be obtained before installation of the SFW structures begins. Ensure each WTG is lighted with red obstruction lighting consistent with the FAA Advisory Circular 70/7460-1L Change 2 (FAA 2018), so long as this requirement does not preclude the use of an ADLS. Provide signage that covers 360-degrees of the wind turbine structures warning vessels of the air draft of the turbine blades as determined at highest astronomical tide. Cooperate with USCG and NOAA to ensure that cable routes and wind turbines are depicted on appropriate government produced and commercially available nautical charts. Provide mariner information sheets on SFW's website with details on the location of the turbines and specifics such as blade clearance above sea level.	Navigation and vessel traffic
24	Construction, O&M, decommissioning	WTG shut-down mechanism	Equip all WTG rotors (blade assemblies) with control mechanisms operable from the SFW control centers available 24 hours a day, 7 days a week. The control mechanisms shall enable control room operators to shut down the requested WTGs within an agreed upon time of notification between the USCG and SFW. A formal shut-down procedure would be part of the standard operating procedures and periodically tested. Normally, USCG-ordered shut downs would be limited to those WTGs in the immediate vicinity of an emergency and for as short a period as is safely practicable under the circumstances, as determined by the USCG.	Navigation and vessel traffic: Other marine uses
25	Construction, O&M, decommissioning	USCG Training and Exercises	SFW would participate in periodic USCG-coordinated training and exercises to test and refine notification and shut-down procedures and to provide SAR training opportunities for USCG vessels and aircraft.	Navigation and vessel traffic; Other marine uses

Mitigation Number	Proposed Project Phase	Mitigation or Monitoring Measure	Description	Resource Area Mitigated
26	Construction, O&M, decommissioning	Operations and maintenance plan	Prior to operation of the Project, SFW shall submit a written plan for operations and maintenance, which includes control center(s), for review by BOEM and the USCG. The plan must demonstrate that the control center(s) would be adequately staffed to perform standard operating procedures, communications capabilities, and monitoring capabilities. The plan shall include, but not be limited to, the following topics, which may be modified through ongoing discussions with the USCG: Standard Operating Procedures: Methods for establishing and testing WTG rotor shut-down; methods of lighting control; method(s) for notifying the USCG of mariners in distress or potential/actual SAR incidents; method(s) for notifying the USCG of any events or incidents that may impact maritime safety or security; and methods for providing the USCG with environmental data, imagery, communications and other information pertinent to SAR or marine pollution response. Staffing: Number of personnel intended to staff the control center(s) to ensure continuous monitoring of WTG operations, communications, and surveillance systems. Communications: Capabilities to be maintained by the control center(s) to communicate with the USCG and mariners within and in the vicinity of the Project area. Communications capability shall at a minimum include VHF marine radio and landline and wireless for voice and data. Monitoring: The control center(s) should maintain the capability to monitor the SFW installation and operations in real time (including night and periods of poor visibility) for determining the status of all PATONs; and detection of a survivor who has climbed to the survivor's platform, if installed, on any WTG or OSS.	Navigation and vessel traffic; Other marine uses
27	Construction, O&M, decommissioning	WTG/OSS installation	No WTG/OSS installation work shall commence at the Project site (i.e., on or under the water) without prior review by BOEM and USCG of a plan to be submitted by SFW that describes the schedule and process for erecting each WTG, including all planned mitigations to be implemented to minimize any adverse impacts on navigation while installation is ongoing. Appropriate Notice to Mariners submissions would accompany the plan.	Navigation and vessel traffic
28	Construction, O&M, decommissioning	USCG reporting	**Complaints**: On a monthly basis during installation, SFW shall provide USCG with a description of any complaints received (either written or oral) by boaters, fishermen, commercial vessel operators, or other mariners regarding impacts on navigation safety allegedly caused by construction vessels, crew transfer vessels, barges, or other equipment. Describe any remedial action taken in response to complaints received. **Correspondence**: SFW shall provide to USCG copies of any correspondence received by SFW from other federal, state, or local agencies that mention or address navigation safety issues. **Maintenance Schedule**: SFW would provide the USCG with its planned WTG maintenance schedule, forecasted out to at least one quarter. Appropriate Notice to Mariners submissions would accompany each maintenance schedule.	Navigation and vessel traffic
29	Construction, O&M, decommissioning	Public participation	To ensure sufficient opportunity for the public to receive information directly from the owners/operators of the wind energy facility, SFW would attend periodic meetings of the Southeastern Massachusetts and Rhode Island Port Safety and Security Forums to provide briefs on the status of construction and operations and on any problems or issues encountered with respect to navigation safety.	Navigation and vessel traffic
30	Construction, O&M, decommissioning	Helicopter landing platforms	If SFW's OSSs include helicopter-landing platforms, those platforms would be designed and built to accommodate up to and including USCG H60 sized rescue helicopters.	Navigation and vessel traffic; Other marine uses
31	Construction, O&M, decommissioning	Scientific survey mitigation	South Fork Wind must participate in good faith with the establishment of the Federal Survey Mitigation Program. Participation could include information sharing and engagement in scientific studies needed to understand the impact of wind energy development on: (I) marine ecosystems and the human communities that use these marine ecosystems; and (II) the following surveys: (a) NOAA Spring and Autumn Bottom trawl surveys; (b) NOAA Ecosystem Monitoring surveys; (c) NOAA North Atlantic right whale aerial surveys; (d) NOAA Aerial and shipboard marine mammal and sea turtle surveys; (e) NOAA Atlantic surfclam and ocean quahog surveys; (f) NOAA and industry-based Atlantic sea scallop surveys; and (g) Any other surveys in the region impacted by wind energy development. Specific roles, responsibilities, resources and timeframes related to these efforts will be developed through the collaborative effort between NOAA and BOEM described above.	Other marine uses
32	Construction, O&M	Environmental data sharing with federally recognized tribes	No later than ninety (90) days after COP approval, South Fork Wind must, at a minimum, contact the federally recognized tribes currently participating in government-to-government consultations with BOEM for the Project in order to solicit their interest in receiving access to the results of reports generated as a result of the Fisheries Research Monitoring Plan; reporting of all NARW sightings; injured or dead protected species reporting (turtles and NARW); NARW PAM monitoring; PSO reports (e.g., weekly pile driving reports); pile-driving schedule and changes thereto. At a minimum, South Fork Wind should offer access to the following federally recognized tribes: the Mashpee Wampanoag Tribe, the Wampanoag of Gay Head (Aquinnah); the Mashantucket Pequot Indian Tribe; the Mohegan Tribe of Indians of Connecticut; the Shinnecock Indian Nation; the Narraganset Indian Tribe; and the Delaware Tribe of Indians. South Fork Wind must provide access to non-proprietary/non-confidential business information to the federally recognized tribe no later than 30 days after the information becomes available.	Environmental Justice
33	Construction, O&M	Coordination with federally recognized tribes in local hiring	No later than six (6) months after COP approval, SFW must prepare and implement a local hiring plan to maximize South Fork Wind's direct hiring of New York residents. Components of the plan shall include coordination with unions, training facilities, schools, the Mashpee Wampanoag Tribe, and the Wampanoag Tribe of Gay Head (Aquinnah).	Environmental Justice, New York Article VII
34	Construction, Operations and Maintenance, and Decommissioning	Rhode Island Fisheries Direct Compensation Program and Coastal Community Fund	A $4.25 million direct compensation fund to be held in escrow to compensate for any claims of direct losses or impacts on Rhode Island commercial and for-hire charter fishing operations caused by the construction, operation and decommissioning of the Project. A $950,000 Coastal Community Fund to be held in escrow for support of Rhode Island companies that support Rhode Island fishing interests. Implementation agreement executed between CRMC and South Fork Wind, LLC on June 30, 2021.	Voluntary by South Fork Wind Rhode Island CZM
35	Construction, Operations and Maintenance, and Decommissioning	Massachusetts Fisheries Innovation Fund	SFW has committed to provide $2.6 million in compensatory mitigation as part of its overall Project modifications and mitigations to achieve consistency with the enforceable policies of the Massachusetts Coastal Program. This total will be comprised of an upfront payment of $2.1 million for direct compensation for potential economic loss to Massachusetts commercial and for-hire (charter) fishermen through a claims process; an upfront payment of $200,000 to establish a Coastal Community Fund to support the coexistence of the fishing and offshore wind sectors through a grant program; and up to $300,000 (the "Navigational Enhancement and Training Funding") to fund claims when made through the Navigational Enhancement and Training Program.	Voluntary by South Fork Wind Massachusetts CZM
36	Construction, O&M, decommissioning	Add conditions of COP approval	Require the following conditions of COP approval mitigate potential impacts on Falmouth, MA, Air Surveillance Radar (ASR-8) : • Notify NORAD 30 to 60 days ahead of Project completion and when the Project is complete and operational for RAM scheduling • Contribute funds ($80,000) toward execution of the RAM • Curtailment of operations for national security or defense purposes as described in the leasing agreement•	Department of Defense

Mitigation Number	Proposed Project Phase	Mitigation or Monitoring Measure	Description	Resource Area Mitigated
	Mitigation measures from ESA consultation with USFWS			
37	Construction and installation, O&M, and conceptual decommissioning	Bird deterrent devices	The Lessee must install bird deterrent devices to minimize bird attraction to operating turbines and on the ESP(s) in locations where the Lessee determines are appropriate and that they can be installed safely. The Lessor must concur with the Lessee's proposed locations. The Lessee must confirm location(s) of bird deterrent devices as part of the as-built documentation submitted with the FIR.	Birds
38	O&M	Avian and bat post-construction monitoring program	• At least thirty (30) calendar days prior to the commencement of preconstruction surveys, the Lessee must finalize, obtain concurrence from DOI, and implement the Monitoring Plan described in Appendix F of the Final Environmental Impact Statement for this project ("South Fork Wind Farm Avian and Bat Post-Construction Monitoring Framework") in coordination with interested stakeholders. The Monitoring Plan must include, at a minimum: Installation of acoustic monitoring devices to monitor nocturnal birds and bats; installation of Motus receivers at up to four locations within the wind farm; refurbish up to two onshore Motus receiver stations near the SFWF (e.g., Block Island, Buzzards Bay); provide funding for up to 50 Motus tags per year will be provided to researchers working with Roseate Terns for up to three consecutive years; avian behavior point count surveys at individual WTGs. • The Lessee must submit to BOEM (renewable_reporting@boem.gov) a comprehensive report after each full year of monitoring (pre- and post-construction) within six (6) months of completion of the last survey. The report must include all data, analyses, and summaries regarding Endangered Species Act (ESA)-listed and non-ESA-listed birds and bats. DOI will use the annual monitoring reports to assess the need for, and reserves the right to require, revisions (based on subject matter expert analysis) to the Monitoring Plan and may include new technologies as they become available for use in offshore environments. Annual monitoring reports that would be used to assess the need for reasonable revisions to the monitoring plan • Post-Construction Quarterly Progress Reports: The Lessee must submit quarterly progress reports during the implementation of the Monitoring Plan to BOEM and USFWS by the 15th day of the month following the end of each quarter during the first full year that the project is operational. The progress reports must include a summary of all work performed, an explanation of overall progress, and any technical problems encountered. • Monitoring Plan Revisions: Within fifteen (15) calendar days of submitting the annual monitoring report, the Lessee must meet with BOEM and USFWS to discuss: the monitoring results; the potential need for revisions to the Monitoring Plan, including technical refinements and/or additional monitoring; and the potential need for any additional efforts to reduce impacts. If the Lessor determines after this discussion that revisions to the Monitoring Plan are necessary, the Lessor may require the Lessee to modify the Monitoring Plan. If the reported monitoring results deviate substantially from the impact analysis included in the FEIS, the Lessor may impose additional requirements on the Lessee to address these impacts. • The Lessee must store the raw data from all avian and bat surveys and monitoring activities according to accepted archiving practices. Such data must remain accessible to the Lessor and USFWS, upon request, for the duration of the lease. The Lessee must work with BOEM to ensure the data is publicly available.	Birds, bats
	Conservation Recommendations from the EFH Consultation[1]			
39	Construction and installation, O&M, conceptual decommissioning	Anchoring plan	Given the extent of complex habitats in the project areas, BOEM should require the applicant to develop an anchoring plan to ensure anchoring is avoided and minimized in complex habitats during construction and maintenance of the project. This plan should specifically delineate areas of complex habitat around each turbine and cable locations, and identify areas restricted from anchoring. Anchor chains should include mid-line buoys to minimize impacts to benthic habitats from anchor sweep where feasible. The habitat maps and inshore maps delineating eelgrass habitat adjacent to the O&M facility should be provided to all cable construction and support vessels to ensure no anchoring of vessels be done within or immediately adjacent to these complex habitats. The anchoring plan should be provided for our review and comment prior to BOEM approval.	Benthic habitat, EFH, invertebrates, and finfish
40	Construction	Turbine removal	Based on the available habitat delineations and data, we have determined that the proposed turbine locations WTG 1, WTG 5, WTG 15, WTG 16A, and WTG 17A would result in substantial adverse impacts to complex habitats. BOEM should remove these turbine locations from the proposed project and prohibit development at these locations.	Benthic habitat, EFH, invertebrates, and finfish
41	Construction	Micrositing Plan	Based on the available habitat delineations and data, we have also determined that micrositing turbine locations will be necessary to avoid and minimize substantial adverse impacts to complex habitats. We recommend that turbine locations WTG 2, WTG 4, WTG 6, WTG 8, WTG 9, WTG 10, WTG 12, WTG 13, TG 14, OSS, and the associated inter-array cables be microsited into low multibeam backscatter return areas and that restrictions on seafloor disturbance (e.g. anchoring) during construction be required to avoid impacts to higher multibeam backscatter return areas. BOEM should require a micrositing plan be developed for each of the identified turbine locations and associated cable routes. The micrositing plan should be submitted for our review and comment prior to BOEM approval.	Benthic habitat, EFH, invertebrates, and finfish
42	Construction	Scour and cable protection	BOEM should require scour and cable protection within complex habitats of the lease area use natural, rounded stone of consistent grain size to match existing conditions. Scour and cable protection placed within soft-sediment habitats should incorporate natural, rounded cobble and boulders (2.5-10 inches in diameter for cobble or >10-inch diameter for boulder). Concrete mattresses should not be permitted to be used as scour protection within hard bottom and structurally complex habitats, and any required use of concrete mattresses for cable protection should be mitigated through the addition of natural, rounded stone. Should the use of any engineered stone be necessary, it should be designed and selected to provide three-dimensional structural complexity that creates a diversity of crevice sizes. BOEM should require that the applicant provide descriptions and specifications for any proposed engineered stone for agency comment and review prior to final design selection.	Benthic habitat, EFH, invertebrates, and finfish
43	Construction	Pile-driving	BOEM should restrict pile driving and all bottom-disturbing activities within the lease area during periods of Atlantic cod spawning. Pile driving activity and bottom-tending disturbances should be prohibited during peak spawning, from November through March to avoid and minimize substantial adverse impacts to Atlantic cod EFH.	Benthic habitat, EFH, invertebrates, and finfish
44	Construction	Pile-driving	BOEM should require the applicant to use noise mitigating measures during construction, such as soft start procedures, to ensure fish have the opportunity to evacuate the area prior to pile driving activity, and the deployment of noise dampening equipment such as bubble curtains. BOEM should require the development of a plan outlining noise mitigation procedures in consultation with the resource agencies prior to any construction activities. This should include a minimum of 30 days for the resource agencies to review and provide comments. The noise mitigation plan should be filed with BOEM for approval before construction commences. The noise mitigation plan should include a process for notifying resource agencies within 24 hours if any evidence of a fish kill during construction activity is observed, and contingency plans to resolve issues.	Benthic habitat, EFH, invertebrates, and finfish

[1] The language in the Mitigation or Monitoring Measure column under this heading is taken verbatim from the National Marine Fisheries Service letter (June 7, 2021) transmitting its conservation recommendations, concluding the essential fish habitat consultation under the Magnuson-Stevens Fisheries Conservation and Management Act and the Fish and Wildlife Coordination Act.

Mitigation Number	Proposed Project Phase	Mitigation or Monitoring Measure	Description	Resource Area Mitigated
45	Construction, O&M	Benthic Habitat Monitoring Plan	BOEM should require the applicant to revise the proposed Benthic Habitat Monitoring Plan to address agency concerns related to the adequacy of the proposed methods to detect changes, and to require that the plan address potential changes to macrobenthic communities across and within each habitat type in the project area, including the artificial substrates to be constructed. The plan should include monitoring of invasive species growth on constructed habitats, habitats impacted by project construction as well as expansion to the adjacent habitats. The monitoring plan should also include measures to evaluate demersal juvenile fish species response to habitat impacts as a result of the project. The applicant should consult with the resource agencies in the revision and refinement of this plan and give the resource agencies a minimum of 30 days to review and comment on the plan. The applicant should ultimately file the plan with BOEM for approval. BOEM should ensure that the applicant's filing addresses, and includes, all resource agency comments, as well as the applicant's response to those comments.	Benthic habitat, EFH, invertebrates, and finfish
46	Construction	Dredging, Nearshore time-of-year restrictions	BOEM should restrict nearshore dredging and silt-producing activities associated with the sea-to-shore cable installation and proposed O&M facility improvements that occur at or adjacent to water depths of 5 meters or less, from January 1 through May 31, of any calendar year, to protect sensitive life history stage winter flounder EFH.	Benthic habitat, EFH, invertebrates, and finfish
47	Construction	Passive Acoustic Monitoring Plan	BOEM should require passive acoustic monitoring to be conducted along a range of gradients from the proposed turbine locations before, during, and after pile driving activities. Resource agencies should be provided a draft of the acoustic monitoring plan for review and comment. The plan should also include sound verification monitoring during pile driving activities. Additional noise dampening technology should be applied should real-time monitoring indicate noise levels are not attenuated to the minimum required 10 decibels. Acoustic monitoring reports should be provided to the resource agencies.	Benthic habitat, EFH, invertebrates, and finfish
	Proposed by BOEM in the NOAA Biological Assessment as amended			
48	Construction and installation	Impact Pile-driving seasonal restriction for NARWs	No impact pile-driving activities will occur from January 1 to April 30 as described in measure 4(a) of the Proposed IHA.	Marine mammals and Sea Turtles
49	Construction and installation	Impact pile driving time restrictions	Sunrise and sunset conditions as described in measure 4(b) of the Proposed IHA.	Marine Mammals and Sea Turtles
50	Construction and installation	Pile driving visibility requirements	PSOs must have effective visual monitoring in all directions and must not commence pile-driving until all clearance zones are fully visible (i.e., are not obscured by darkness, rain, fog, etc.) for at least 30 minutes. If conditions (e.g., darkness, rain, fog, etc.) prevent the visual detection of marine mammals in the clearance zones, construction activities must not be initiated until the full extent of all clearance zones are fully visible. The lead PSO will make a determination as to when there is sufficient light to ensure effective visual monitoring can be accomplished in all directions. South Fork Wind must develop and implement measures for alternative monitoring in the event that poor visibility conditions unexpectedly arise and pile-driving cannot be stopped due to safety or operational feasibility. South Fork Wind must prepare and submit an Alternative Monitoring Plan to NMFS and BOEM for NMFS' review and approval at least 90 days prior to the planned start of pile-driving. This plan may include deploying additional observers, alternative monitoring technologies such as night vision, thermal, and infrared technologies, or use of PAM with the goal of ensuring the ability to maintain all clearance and shutdown zones for all ESA-listed species in the event of unexpected poor visibility conditions.	Marine Mammals and Sea Turtles
51	Construction and installation	Establishment of Clearance Zones and Clearance Measures for Impact Pile Driving	For ESA listed whales: as described in measure 4(c) and (d) of the Proposed IHA. For sea turtles: To ensure that impact pile-driving operations are carried out in a way that minimizes the exposure of listed sea turtles to noise that may result in injury or behavioral disturbance, PSOs will establish a 1,640-foot (500-meter) clearance zone for all pile-driving activities. Adherence to the 1,640-foot (500-meter) clearance zones must be reflected in the PSO reports. Any visual detection of sea turtles the 500-m clearance zones must trigger the required delay in pile installation. Upon a visual detection of a sea turtles entering or within the relevant clearance zone during pile-driving, South Fork Wind must not determine the area is clear to start pile driving until: 1) The lead PSO verifies that the animal(s) voluntarily left and headed away from the clearance area; or 2) 30 minutes have elapsed without re-detection of the sea turtle(s) by the lead PSO	Marine Mammals and Sea Turtles
52	Construction and installation	Establishment of Shutdown Zones for Impact Pile Driving	For ESA listed whales: as described in measure 4(e) of the Proposed IHA. For sea turtles: To ensure that impact pile-driving operations are carried out in a way that minimizes the exposure of listed sea turtles to noise that may result in injury or behavioral disturbance, PSOs will establish a 1,640-foot (500-meter) shutdown zone for all pile-driving activities. Adherence to the 1,640-foot (500-meter) shutdown zones must be reflected in the PSO reports. Any visual detection of sea turtles the 500-m shutdown zones must trigger the required shutdown in pile installation. Upon a visual detection of a sea turtles entering or within the shutdown zone during pile-driving, South Fork Wind must shut down the pile-driving hammer (unless activities must proceed for human safety or for concerns of structural failure) from when the PSO observes, until: 1) The lead PSO verifies that the animal(s) voluntarily left and headed away from the clearance area; or 2) 30 minutes have elapsed without re-detection of the sea turtle(s) by the lead PSO Additionally, if shutdown is called for but SFWF determines shutdown is not technically feasible due to human safety concerns or to maintain installation feasibility, reduced hammer energy must be implemented, when the lead engineer determines it is technically feasible to do so.	Marine Mammals and Sea Turtles
53	Construction and installation	Soft Start for impact pile driving	As described in measure 4(f) of the Proposed IHA. Also proposed to provide minimization of potential impacts to listed sea turtles and finfish.	Marine Mammals, Sea Turtles, Finfish
54	Construction and installation	Noise mitigation for impact pile driving	As described in measure 4(h) of the Proposed IHA. Also proposed to provide minimization of potential impacts to listed sea turtles and finfish.	Marine Mammals, Sea Turtles, Finfish
55	Construction and installation	Pile-driving sound source verification plan	Field verification during pile-driving to be conducted as described in measures 5(d) and (e) of the Proposed IHA. Additionally, a Sound Source Verification Plan will be submitted to the USACE, BOEM at *renewable_reporting@boem.gov*, and NMFS at *incidental.take@noaa.gov* for review and written approval by the agencies 90 days prior to the commencement of field activities for pile-driving. Sound source verification must be carried out for the first monopile to be installed. Should larger diameter piles be installed, or greater hammer size or energy used, additional field measurements must be conducted. The plan must describe how South Fork Wind will ensure that the location selected is representative of the rest of the piles of that type to be installed and, in the case that it is not, how additional sites will be selected for sound source verification or how the results from the first pile can be used to predict actual installation noise propagation for subsequent piles. The plan must describe how the effectiveness of the sound attenuation methodology will be evaluated based on the results. The plan must be sufficient to document sound propagation from the pile and distances to isopleths for potential injury and harassment. The measurements must be compared to the Level A and Level B harassment zones for marine mammals (and the injury and behavioral disturbance zones for sea turtles and Atlantic sturgeon).	Marine Mammals, Sea Turtles, Finfish Benthic habitat, EFH, invertebrates,

Mitigation Number	Proposed Project Phase	Mitigation or Monitoring Measure	Description	Resource Area Mitigated
56	Construction and installation	Pile driving noise reporting and clearance zone adjustment	Before driving any additional piles following underwater noise measurements, South Fork Wind must review the initial field measurement results of at least one (1) WTG foundation of each type. The Lessee may request modification of the clearance and shutdown zones based on the field measurements of three (3) foundations but must meet or exceed minimum seasonal distances for threatened and endangered species that may be specified in the Biological Opinion. If the initial field measurements indicate that the isopleths of concern are larger than those considered in the Proposed Action, in coordination with BOEM, NMFS, and USACE, South Fork Wind must implement additional sound attenuation measures and/or enhanced clearance and/or shutdown zones before driving any additional piles. South Fork Wind must submit the initial results of the field measurements to NMFS, USACE, and BOEM (renewable_reporting@boem.gov) as soon as they are available; NMFS, USACE, and BOEM will discuss these as soon as feasible with a target for that discussion within two business days of receiving the results. BOEM and NMFS will provide direction to South Fork Wind on whether any additional modifications to the sound attenuation system or changes to the clearance and shutdown zones are required.	Marine Mammals and Sea Turtles
57	Construction and installation	Establishment of Clearance Zones and Clearance Measures for Vibratory Pile Driving	For ESA listed whales: as described in measure 4(c) and (d) of the Proposed IHA. For sea turtles: To ensure that impact pile-driving operations are carried out in a way that minimizes the exposure of listed sea turtles to noise that may result in injury or behavioral disturbance, PSOs will establish a 1,640-foot (500-meter) clearance zone for all pile-driving activities. Adherence to the 1,640-foot (500-meter) clearance zones must be reflected in the PSO reports. Any visual detection of sea turtles the 500-m clearance zones must trigger the required delay in pile installation. Upon a visual detection of a sea turtles entering or within the relevant clearance zone during pile-driving, South Fork Wind must not determine the area is clear to start pile driving until: 1) The lead PSO verifies that the animal(s) voluntarily left and headed away from the clearance area; or 2) 30 minutes have elapsed without re-detection of the sea turtle(s) by the lead PSO	Marine Mammals and Sea Turtles
58	Construction and installation	Establishment of Shutdown Zones for Vibratory Pile Driving	For ESA listed whales: as described in measure 4(e) of the Proposed IHA. For sea turtles: To ensure that impact pile-driving operations are carried out in a way that minimizes the exposure of listed sea turtles to noise that may result in injury or behavioral disturbance, PSOs will establish a 1,640-foot (500-meter) shutdown zone for all pile-driving activities. Adherence to the 1,640-foot (500-meter) shutdown zones must be reflected in the PSO reports. Any visual detection of sea turtles the 500-m shutdown zones must trigger the required shutdown in pile installation. Upon a visual detection of a sea turtles entering or within the shutdown zone during pile-driving, South Fork Wind must shut down the pile-driving hammer (unless activities must proceed for human safety or for concerns of structural failure) from when the PSO observes, until: 1) The lead PSO verifies that the animal(s) voluntarily left and headed away from the clearance area; or 2) 30 minutes have elapsed without re-detection of the sea turtle(s) by the lead PSO Additionally, if shutdown is called for but SFWF determines shutdown is not technically feasible due to human safety concerns or to maintain installation feasibility, reduced hammer energy must be implemented, when the lead engineer determines it is technically feasible to do so.	Marine Mammals and Sea Turtles
59	Construction and installation, O&M, and conceptual decommissioning	Establishment of Clearance Zones and Clearance Measures for HRG Surveys	For ESA listed whales: as described in measure 4(e) of the Proposed IHA. For sea turtles: 100 m clearance zone must be maintained for at least 30 minutes as described in the June 29, 2021 Data Collection Programmatic Consultation.	Marine Mammals and Sea Turtles
60	Construction and installation, O&M, and conceptual decommissioning	Ramp-up for HRG acoustic sources	As described in 4(g) of the Proposed IHA.	Marine Mammals
61	Construction and installation, O&M, and conceptual decommissioning	Establishment of Shutdown Zones for HRG Surveys	For ESA listed whales: as described in measure 4(e) of the Proposed IHA or the conditions specified in the Data Collection Programmatic Consultation, whichever is greater.	Marine Mammals
62	Construction and installation, O&M, and conceptual decommissioning	Vessel Strike Avoidance Measures for Marine Mammals during the term of the IHA	As described in 4(i) of the Proposed IHA.	Marine mammals

Mitigation Number	Proposed Project Phase	Mitigation or Monitoring Measure	Description	Resource Area Mitigated
63	O&M, and conceptual decommissioning	Vessel Strike Avoidance Measures for Marine Mammals following the term of the IHA	• Vessel captain and crew must maintain a vigilant watch for all ESA-listed species and slow down, stop their vessel, or alter course, as appropriate and regardless of vessel size, to avoid striking any listed species. The presence of a single individual at the surface may indicate the presence of submerged animals in the vicinity; therefore, precautionary measures should always be exercised. • A PSO (or crew lookout if PSOs are not required) must be posted during all times a vessel is underway (transiting or surveying) to monitor for listed species within a 180-degree direction of the forward path of the vessel (90 degrees port to 90 degrees starboard). • Visual observers monitoring the vessel strike avoidance zone can be either PSOs or crew members (if PSOs are not required). If the trained lookout is a vessel crew member, this must be their designated role and primary responsibility while the vessel is transiting. Any designated crew lookouts must receive training on protected species identification, vessel strike minimization procedures, how and when to communicate with the vessel captain, and reporting requirements. All observations must be recorded per reporting requirements. • Regardless of monitoring duties, all crew members responsible for navigation duties must receive site-specific training on ESA-listed species sighting/reporting and vessel strike avoidance measures. • All vessel crew members must be briefed in the identification of ESA-listed species and marine mammals that may occur in the survey area and in regulations and best practices for avoiding vessel collisions. Reference materials must be available aboard all project vessels for identification of listed species. The expectation and process for reporting of protected species sighted during surveys must be clearly communicated and posted in highly visible locations aboard all project vessels, so that there is an expectation for reporting to the designated vessel contact (such as the lookout or the vessel captain), as well as a communication channel and process for crew members to do so. • Vessels underway must not divert their course to approach any listed species. • If an ESA-listed whale or large unidentified whale is identified within 500 m of the forward path of any vessel, the vessel operator must steer a course away from the whale at 10 knots (18.5 km/hr.) or less until the 500 m minimum separation distance has been established. Vessels may also shift to idle if feasible. • If an ESA-listed large whale is sighted within 200 m of the forward path of a vessel, the vessel operator must reduce speed and shift the engine to neutral. Engines must not be engaged until the whale has moved outside of the vessel's path and beyond 500 m. If stationary, the vessel must not engage engines until the ESA-listed large whale has moved beyond 500 m. • Regardless of vessel size, vessel operators must reduce vessel speed to 10 knots (18.5 mph) or less while operating in any Seasonal Management Area (SMA) and Dynamic Management Area (DMA) (or Slow Zone otherwise designated as a DMA). • All vessel operators must check for information regarding mandatory or voluntary ship strike avoidance (DMAs and SMAs) and daily information regarding North Atlantic right whale sighting locations. These media may include, but are not limited to: NOAA weather radio, U.S. Coast Guard NAVTEX and channel 16 broadcasts, Notices to Mariners, the Whale Alert app, or WhaleMap website. North Atlantic right whale Sighting Advisory System info can be accessed at https://whalemap.org/WhaleMap/. • The only exception to these requirements is when the safety of the vessel or crew necessitates deviation from these requirements. If any such incidents occur, they must be reported (see reporting requirements). • South Fork may file for consideration by NMFS and BOEM a request for a waiver of any of these restrictions by submitting a vessel strike risk reduction plan that details revised measures along with an analysis to demonstrate that the measure(s) will provide a level of risk reduction at least equivalent to the measure(s) being proposed for replacement. The plan must be provided to NMFS and BOEM at least 60 days prior to a request for approval and will not be implemented unless NMFS and BOEM reach consensus on approval.	Marine mammals
64	Construction and installation, O&M, and conceptual decommissioning	Vessel Strike Avoidance Measures for Sea Turtles (non HRG survey vessels)	• Training and Observers • Regardless of monitoring duties, all crew members responsible for navigation duties must receive site-specific training on ESA-listed species sighting/reporting and vessel strike avoidance measures. • All vessel crew members must be briefed in the identification of ESA-listed species of sea turtles that may occur in the survey area and in regulations and best practices for avoiding vessel collisions. Reference materials must be available aboard all project vessels for identification of listed species. The expectation and process for reporting of protected species sighted during surveys must be clearly communicated and posted in highly visible locations aboard all project vessels, so that there is an expectation for reporting to the designated vessel contact (such as the lookout or the vessel captain), as well as a communication channel and process for crew members to do so. • Visual observers monitoring the vessel strike avoidance zone can be either PSOs or crew members (if PSOs are not required). If the trained lookout is a vessel crew member, this must be their designated role and primary responsibility while the vessel is transiting. Any designated crew lookouts must receive training on protected species identification, vessel strike minimization procedures, how and when to communicate with the vessel captain, and reporting requirements. Vessel personnel must be provided an Atlantic reference guide that includes and helps identify sea turtles that may be encountered in the Project area. All observations must be recorded per reporting requirements. • Vessel captain and crew must maintain a vigilant watch for all ESA-listed species and slow down, stop their vessel, or alter course, as appropriate and regardless of vessel size, to avoid striking any listed species. • To monitor the Vessel Strike Avoidance Zone, a PSO (or crew lookout if PSOs are not required) must be posted during all times a vessel is underway (transiting or surveying) to monitor for listed species within a 180-degree direction of the forward path of the vessel (90 degrees port to 90 degrees starboard). • If a vessel is carrying a visual observer for the purposes of maintaining watch for NARWs, an additional lookout is not required and this visual observer must maintain watch for whales, giant manta rays, and sea turtles. If the trained lookout is a vessel crewmember, this must be their designated role and primary responsibility while the vessel is transiting. Any designated crew observers should be trained in the identification of sea turtles and in regulations and best practices for avoiding vessel strikes. • Vessels underway must not divert their course to approach any listed species. • If a sea turtle is sighted within 100 m of the operating vessel's forward path, the vessel operator must slow down to 4 knots (unless unsafe to do so) and may resume normal vessel operations once the vessel has passed the individual. If a sea turtle is sighted within 50 m of the forward path of the operating vessel, the vessel operator must shift to neutral when safe to do so and then proceed away from the individual at a speed of 4 knots or less until there is a separation distance of at least 100 m at which time normal vessel operations may be resumed. • Between June 1 and October 30, vessels must avoid transiting through areas of visible jellyfish aggregations or floating vegetation (e.g., sargassum lines or mats). In the event that operational safety prevents avoidance of such areas, vessels must slow to 4 knots while transiting through such areas. • The only exception to these requirements is when the safety of the vessel or crew necessitates deviation from these requirements. If any such incidents occur, they must be reported (see reporting requirements).	Sea turtles

Mitigation Number	Proposed Project Phase	Mitigation or Monitoring Measure	Description	Resource Area Mitigated
65	Construction and installation	Pile driving monitoring plan and PSO requirements	A final pile-driving monitoring plan (PDM Plan) must be submitted to BOEM (at renewable_reporting@boem.gov), BSEE (at protectedspecies@bsee.gov), and NMFS for review and approval by lead agency in writing a minimum of 90 days prior to the commencement of pile-driving activities. The PDM Plan must: • Contain information on the visual and PAM components of the monitoring describing all equipment, procedures, and protocols; • The PAM system must demonstrate a near-real-time capability of detection to the full extent of the 160 dB distance from the pile-driving location; • The PAM plan must include a detection confidence that a vocalization originated from within the clearance and shutdown zones to determine that a possible NARW has been detected. Any PAM detection of a NARW within the clearance/shutdown zone surrounding a pile must be treated the same as a visual observation and trigger any required delays in pile installation. • Ensure that the full extent of the harassment distances from piles are monitored for marine mammals and sea turtles to document all potential take; • Include number of PSOs or Native American monitors, or both, that will be used, the platforms or vessels upon which they will be deployed, and contact information for the PSO providers; • Include measures for enhanced monitoring capabilities in the event that poor visibility conditions unexpectedly arise, and pile driving cannot be stopped. • Include an Alternative Monitoring Plan that provides for enhanced monitoring capabilities in the event that poor visibility conditions unexpectedly arise, and pile driving cannot be stopped. The Alternative Monitoring Plan must also include measures for deploying additional observers, using night vision goggles, or using PAM with the goal of ensuring the ability to maintain all clearance and shutdown zones in the event of unexpected poor visibility conditions. Describe a communication plan detailing the chain of command, mode of communication, and decision authority must be described. PSOs as determined by NMFS and BOEM must be used to monitor the area of the clearance and shutdown zones. Seasonal and species-specific clearance and shutdown zones must also be described in the PDM Plan including time-of-year requirements for NARWs. A copy of the approved PDM Plan must be in the possession of the lessee representative, the PSOs, impact-hammer operators, and any other relevant designees operating under the authority of the approved COP and carrying out the requirements on site.	Marine mammals, sea turtles, finfish, birds
66	Construction and installation	PSO and reporting requirements for pile driving shutdown events	Within 24 hours, SFW must report to BOEM at renewable_reporting@boem.gov all marine mammals and/or sea turtles in the exclusion zone that result in a shutdown or a power-down. In addition, the PSO provider must submit the data report (raw data collected in the field) and must include the daily form with the date, time, species, pile identification number, GPS coordinates, time and distance of the animal when sighted, time the shutdown or power-down occurred, behavior of the animal, direction of travel, time the animal left the exclusion zone, time the pile driver was restarted or powered back up, and any photographs that may have been taken.	Marine mammals and sea turtles
67	Construction and installation	Weekly and final Pile Driving Reporting Requirements	Weekly Pile-Driving Reports (Construction). Weekly PSO and PAM monitoring reports must be submitted to NMFS and DOI during the pile-driving and construction period of the wind farm installation. Weekly reports must document daily start and stop times of all pile-driving activities, daily start and stop times of associated observation periods by the PSOs, details on the deployment of PSOs, and a record of all observations of marine mammals and sea turtles. The third party PSO providers must submit the weekly monitoring reports to BOEM at renewable_reporting@boem.gov and NMFS at incidental.take@noaa.gov every Wednesday during construction for the previous week (Sunday through Saturday) of monitoring of pile-driving activity. Weekly reports can consist of raw data. Required data and reports provided to DOI may be archived, analyzed, published, and disseminated by BOEM. PSO data must be reported weekly (Sunday through Saturday) from the start of visual and/or PAM efforts during pile-driving activities, and every week thereafter until the final reporting period upon conclusion of pile-driving activity. Any editing, review, and quality assurance checks must be completed only by the PSO provider prior to submission to NMFS and DOI. The Lessee must submit to DOI at renewable_reporting@boem.gov and protectedspecies@bsee.gov a final summary report of PSO monitoring 90 days following the completion of pile driving.	Marine mammals and sea turtles

68	Construction and installation	Weekly and final Requirements Data Fields	Data fields must be reported in Excel format as weekly reports during construction. Data categories must include Project, Operations, Monitoring Effort, and Detection. Data must be generated through software applications or otherwise recorded electronically by PSOs. Applications developed to record PSO data are encouraged as long as the data fields listed below can be recorded and exported to Excel. Alternatively, BOEM has developed an Excel spreadsheet with all the necessary data fields that is available upon request. Required data fields include: <u>Project Information:</u> • Project Name • Lease Number • State Coastal Zones • PSO Contractor(s) • Vessel Name(s) • Reporting Date(s) • Visual monitoring equipment used (e.g., bionics, magnification, IR cameras, etc.) • Distance finding method used • PSO names (last, first) and training • Observation height above sea surface <u>Operations Information:</u> • Date (YYYY-MM-DD) • Hammer type used (make and model) • Greatest hammer power used for each pile • Pile identifier and pile number for the day (e.g., pile 2 of 3 for the day) • Pile diameters • Pile length • Pile locations (latitude and longitude) <u>Monitoring Effort Information</u>: • Date (YYYY-MM-DD) • Noise Source (ON=Hammer On; OFF=Hammer Off) • PSO name(s) (Last, First) • If visual, how many PSOs on watch at one time? • Time pre-exclusion visual monitoring began in UTC (HH:MM) • Time pre-exclusion monitoring ended in UTC (HH:MM) • Time pre-exclusion PAM monitoring began in UTC (HH:MM) • Time PAM monitoring ended in UTC (HH:MM) • Duration of pre-exclusion and PAM visual monitoring • Time power up/ramp up began • Time equipment full power was reached • Duration of power up/ramp up • Time pile driving began (hammer on) • Time pile-driving activity ended (hammer off) • Duration of activity • Duration of visual observation • Wind speed (knots), from direction • Swell height (meters) • Water depth (meters) • Visibility (km) • Glare severity • Latitude (decimal degrees), longitude (decimal degrees) • Compass heading of vessel (degrees) • Beaufort scale • Precipitation • Cloud coverage (%) • Did a shutdown/power-down occur? • Time shutdown was called for (UTC) • Time equipment was shutdown (UTC) • Record any habitat or prey observations • Record any marine debris sighted <u>Detection Information</u>: • Date (YYYY-MM-DD) • Sighting ID (V01, V02, or sequential sighting number for that day) (multiple sightings of same animal or group uses the same ID) • Date and time at first detection in UTC (YY-MM-DDT HH:MM) • Time at last detection in UTC (YY-MM-DDT HH:MM)	Marine mammals and sea turtles

Mitigation Number	Proposed Project Phase	Mitigation or Monitoring Measure	Description	Resource Area Mitigated

			• PSO name(s) (Last, First)
			• Effort (ON=Hammer On; OFF=Hammer Off)
			• If visual, how many PSOs on watch at one time?
			• Start time of observations
			• End time of observations
			• Duration of visual observation
			• Wind speed (knots), from direction
			• Swell height (meters)
			• Water depth (meters)
			• Visibility (km)
			• Glare severity
			• Latitude (decimal degrees), longitude (decimal degrees)
			• Compass heading of vessel (degrees)
			• Beaufort scale
			• Precipitation
			• Cloud coverage (%)
			• Sightings including common name, scientific name, or family
			• Certainty of identification
			• Number of adults
			• Number of juveniles
			• Total number of animals
			• Bearing to animal(s) when first detected (ship heading + clock face)
			• Range from vessel (reticle distance in meters)
			• Description (include features such as overall size; shape of head; color and pattern; size, shape, and position of dorsal fin; height, direction, and shape of blow, etc.)
			• Detection narrative (note behavior, especially changes in relation to survey activity and distance from source vessel)
			• Direction of travel/first approach (relative to vessel)
			• Behaviors observed: indicate behaviors and behavioral changes observed in sequential order (use behavioral codes)
			• If any bow-riding behavior observed, record total duration during detection (HH:MM)
			• Initial heading of animal(s) (degrees) Final heading of animal(s) (degrees)
			• Exclusion zone size during detection (meters)
			• Was the animal inside the exclusion zone?
			• Closest distance to vessel (reticle distance in meters)
			• Time at closest approach (UTC HH:MM)
			• Time animal entered exclusion zone (UTC HH:MM)
			• Time animal left exclusion zone (UTC HH:MM)
			• If observed/detected during ramp up/power up: first distance (reticle distance in meters), closest distance (reticle distance in meters), last distance (reticle distance in meters), behavior at final detection
			• Did a shutdown/power-down occur?
			    ○ Time shutdown was called for (UTC)
			    ○ Time equipment was shutdown (UTC)
			• Detections with PAM	

Mitigation Number	Proposed Project Phase	Mitigation or Monitoring Measure	Description	Resource Area Mitigated
69	Construction and installation, O&M, and conceptual decommissioning	Injured/protected species reporting	SFW must report any potential takes, strikes, or dead/injured protected species caused by project vessels to NMFS Protected Resources Division, incidental.take@noaa.gov; to NOAA Fisheries 24-hour Stranding Hotline number (866-755-6622); to BOEM at renewable_reporting@boem.gov, and to BSEE at protectedspecies@bsee.gov as soon as practicable. In the event that an injured or dead marine mammal or sea turtle is sighted, regardless of the cause, the Lessee must report the incident to NMFS Protected Resources Division, ; to NOAA Fisheries 24-hour Stranding Hotline number (866-755-6622); to BOEM at renewable_reporting@boem.gov; and to BSEE at protectedspecies.gov as soon as practicable (for crew and vessel safety), but no later than 24 hours from the sighting. incidental.take@noaa.gov; to NOAA Fisheries 24-hour Stranding Hotline number (866-755-6622); to BOEM at renewable_reporting@boem.gov; and to BSEE at protectedspecies.gov as soon as practicable (for crew and vessel safety), but no later than 24 hours from the sighting. • A Detected Protected Species Report must include the following information: ○ Time, date, and location (latitude/longitude) of the first discovery (and updated location information if known and applicable); ○ Species identification (if known) or description of the animal(s) involved; ○ Condition of the animal(s) (including carcass condition if the animal is dead); ○ Observed behaviors of the animal(s), if alive; ○ If available, photographs or video footage of the animal(s); and ○ General circumstances under which the animal was discovered. Staff responding to the hotline call will provide any instructions for handling or disposing of any injured or dead animals by individuals authorized to collect, possess, and transport sea turtles. • An Impacted Protected Species Report (e.g., a vessel injury or dead animal detected during a pile driving event) must include the following information: ○ Time, date, and location (latitude/longitude) of the incident; ○ Species identification (if known) or description of the animal(s) involved; ○ Lessee and vessel(s) information; ○ Vessel's speed during and leading up to the incident; ○ Vessel's course/heading and what operations were being conducted (if applicable); ○ Status of all sound sources in use (if applicable); ○ Description of avoidance measures/ requirements that were in place at the time of the strike and what additional measures were taken, if any, to avoid strike; ○ Environmental conditions (e.g., wind speed and direction, Beaufort scale, cloud cover, visibility) immediately preceding the strike; ○ Estimated size and length of animal that was struck; ○ Description of the behavior of the animal immediately preceding and following the strike; ○ Estimated fate of the animal (e.g., dead, injured but alive, injured and moving, blood or tissue observed in the water, status unknown, disappeared); and ○ To the extent practicable, photographs or video footage of the animal(s).	Benthic habitat, EFH, invertebrates, and finfish; marine mammals; sea turtles
70	Construction and installation, O&M,	Passive Acoustic Monitoring	Use PAM devices to record ambient noise and marine mammal species vocalizations in the Lease Area before, during, and immediately after construction (at least 3 years of operation) to monitor impacts. The archival recorders must have a minimum capability of detecting and storing acoustic data on vessel noise, pile-driving, WTG operation, and marine mammal vocalizations in the lease area. No later than 30 days prior to buoy deployment, the Lessee must submit to BOEM and BSEE (renewable_reporting@boem.gov and protectedspecies@bsee.gov) the PAM plan and receive written concurrence from BOEM and BSEE. Results must be provided within 90 days of buoy collection and again within 90 days of the 1-year and 2-year anniversary of collection. The underwater acoustic monitoring must follow standardized measurement and processing methods and visualization metrics developed by the Atlantic Deepwater Ecosystem Observatory Network (ADEON) for the U.S. Mid- and South Atlantic Outer Continental Shelf (see https://adeon.unh.edu/) and NMFS requirements for marine mammal detections. At least two devices must be independently deployed within the lease area or one or more buoys must be deployed in coordination with other acoustic monitoring efforts in the RI and MA Lease Areas.	Marine mammals
71	Construction and installation, O&M, and conceptual decommissioning	Periodic underwater surveys, reporting, and monofilament and other fishing gear cleanup around WTG foundations	Monitor impacts associated with charter and recreational gear lost from expected increases in fishing around WTG foundations by surveying at least 5 of the WTG foundations in the lease area annually. Surveys by remotely operated vehicles, divers, or other means will inform frequency and locations of marine debris. The results of the surveys will be reported to BOEM and BSEE (renewable_reporting@boem.gov and marinedebris@bsee.gov) in an annual report submitted by April 30 for the preceding calendar year in which the survey is performed. Reports must be submitted in Word format. Photographic and videographic materials will be provided on a drive in a lossless format such as TIFF or Motion JPEG 2000. Reports must include daily survey reports that include the survey date, contact information of the operator, location, and pile identification number, photographic and/or video documentation of the survey and debris encountered, any animals sighted, and the disposition of any located debris (i.e., removed or left in place). Required data and reports may be archived, analyzed, published, and disseminated by BOEM.	Marine mammals, sea turtles, finfish, birds

Mitigation Number	Proposed Project Phase	Mitigation or Monitoring Measure	Description	Resource Area Mitigated
72	Construction and installation, O&M, and conceptual decommissioning	Marine debris awareness and elimination	"Marine trash and debris" is defined as any object or fragment of wood, metal, glass, rubber, plastic, cloth, paper or any other solid, man-made item or material that is lost or discarded in the marine environment by the Lessee or an authorized representative of the Lessee (collectively, the "Lessee") while conducting activities on the Outer Continental Shelf (OCS) in connection with a lease, grant, or approval issued by the Department of the Interior (DOI). To understand the type and amount of marine debris generated, and to minimize the risk of entanglement in and/or ingestion of marine debris by protected species, lessees must implement the following Best Management Practices ("BMPs"). 1. Training: All vessel operators, employees, and contractors performing OCS survey activities on behalf of the Lessee (collectively, "Lessee Representatives") must complete marine trash and debris awareness training annually. The training consists of two parts: (1) viewing a marine trash and debris training video or slide show (described below); and (2) receiving an explanation from management personnel that emphasizes their commitment to the requirements. The marine trash and debris training videos, training slide packs, and other marine debris related educational material may be obtained at https://www.bsee.gov/debris. The training videos, slides, and related material may be downloaded directly from the website. Lessee Representatives engaged in OCS survey activities must continue to develop and use a marine trash and debris awareness training and certification process that reasonably assures that they, as well as their respective employees, contractors, and subcontractors, are in fact trained. The training process must include the following elements: a. viewing of either a video or slide show by the personnel specified above; b. an explanation from management personnel that emphasizes their commitment to the requirements; c. attendance measures (initial and annual); and d. recordkeeping and availability of records for inspection by DOI. By January 31 of each year, the Lessee must submit to DOI an annual report signed by the Lessee that describes its marine trash and debris awareness training process and certifies that the training process has been followed for the previous calendar year. You must send the reports via email to renewable_reporting@boem.gov and to marinedebris@bsee.gov. 2. Marking: Materials, equipment, tools, containers, and other items used in OCS activities which are of such shape or properly secured to prevent loss overboard. All markings must clearly identify the owner and must be durable enough to resist the effects of the environmental conditions to which they may be exposed. 3. Recovery: Lessees must recover marine trash and debris that is lost or discarded in the marine environment while performing OCS activities when such incident is likely to: (a) cause undue harm or damage to natural resources, including their physical, atmospheric, and biological components, with particular attention to those that could result in the entanglement of or ingestion by marine protected species; or (b) significantly interfere with OCS uses (e.g., are likely to snag or damage fishing equipment, or present a hazard to navigation). Lessees must notify DOI when recovery activities are (i) not possible because conditions are unsafe; or (ii) not practicable because the marine trash and debris released is not likely to result in any of the conditions listed in (a) or (b) above. The lessee must recover the marine trash and debris lost or discarded if DOI does not agree with the reasons provided by the Lessee to be relieved from the obligation to recover the marine trash and debris. If the marine trash and debris is located within the boundaries of a potential archaeological resource/avoidance area, or a sensitive ecological/benthic resource area, the Lessee must contact DOI for approval prior to conducting any recovery efforts. Recovery of the marine trash and debris should be completed immediately, but no later than 30 days from the date in which the incident occurred. If the Lessee is not able to recover the marine trash or debris within 48 hours (See BMP (4)), the Lessee must submit a recovery plan to DOI explaining the recovery activities to recover the marine trash or debris ("Recovery Plan"). The Recovery Plan must be submitted no later than 10 calendar days from the date in which the incident occurred. Unless otherwise objected by DOI within 48 hours of the filing of the Recovery Plan, the Lessee can proceed with the activities described in the Recovery Plan. The Lessee must request and obtain approval of a time extension if recovery activities cannot be completed within 30 days from the date in which the incident occurred. The Lessee must enact steps to prevent similar incidents and must submit a description of these actions to BOEM and BSEE within 30 days from the date in which the incident occurred. 4. Reporting: The Lessee must report all marine trash and debris lost or discarded to DOI (using the email address listed on DOI's most recent incident reporting guidance). This report applies to all marine trash and debris lost or discarded, and must be made monthly, no later than the fifth day of the following month. The report must include the following: a. project identification and contact information for the lessee, operator, and/or contractor; b. the date and time of the incident; c. the lease number, OCS area and block, and coordinates of the object's location (latitude and longitude in decimal degrees); d. a detailed description of the dropped object to include dimensions (approximate length, width, height, and weight) and composition (e.g., plastic, aluminum, steel, wood, paper, hazardous substances, or defined pollutants); e. pictures, data imagery, data streams, and/or a schematic/illustration of the object, if available; f. Indication of whether the lost or discarded item could be a magnetic anomaly of greater than 50 nanotesla (nT), a seafloor target of greater than 0.5 meters (m), or a sub-bottom anomaly of greater than 0.5m when operating a magnetometer or gradiometer, side scan sonar, or sub-bottom profile in accordance with DOI's applicable guidance; g. an explanation of how the object was lost; and h. a description of immediate recovery efforts and results, including photos. In addition to the foregoing, the Lessee must submit a report within 48 hours of the incident ("48-hour Report") if the marine trash or debris could (a) cause undue harm or damage to natural resources, including their physical, atmospheric, and biological components, with particular attention to those that could result in the ingestion by or entanglement of marine protected species; or (b) significantly interfere with OCS uses (e.g., are likely to snag or damage fishing equipment, or present a hazard to navigation). The information in the 48-hour Report would be the same as that listed above, but just for the incident that triggered the 48-hour Report. The Lessee must report to DOI if the object is recovered and, as applicable, any substantial variation in the activities described in the Recovery Plan that were required during the recovery efforts. Information on unrecovered marine trash and debris must be included and addressed in the description of the site clearance activities provided in the decommissioning application required under 30 C.F.R. § 585.906. The Lessee is not required to submit a report for those months in which no marine trash and debris was lost or discarded.	Marine mammals, sea turtles, finfish, birds
73	Construction and installation, O&M, and conceptual decommissioning	Reporting of all NARW sightings	If a NARW is observed at any time by PSOs or personnel on any Project vessels, during any Project-related activity or during vessel transit, SFWF must report the sighting information to NMFS and BOEM immediately after conclusion of the detection event (the time, location, and number of animals) to BOEM at renewable_reporting@boem.gov and the NOAA Fisheries 24-hour Stranding Hotline number (866-755-6622), the USCG via channel 16, and through the WhaleAlert app (http://www.whalealert.org/).	Marine mammals
74	Construction and installation, O&M, and conceptual decommissioning	Vessel communication of threatened and endangered species sightings	Whenever multiple Project vessels are operating, any visual observations of listed species (marine mammals and sea turtles) must be communicated to a PSO and/or vessel captains associated with other Project vessels.	Marine mammals and sea turtles
75	Construction and installation, O&M, and conceptual decommissioning	Geophysical survey off-effort PSO monitoring	Measures will be required in accordance with project design criteria and associated best management practices in the June 29, 2021 Data Collection Programmatic ESA Consultation with NMFS.	Marine mammals and sea turtles
76	Construction and installation, O&M, and conceptual decommissioning	Geophysical survey vessel whale strike-avoidance and equipment shutdown protocols	Measures will be required in accordance with project design criteria and associated best management practices in the June 29, 2021Data Collection Programmatic ESA Consultation with NMFS.	Marine mammals and sea turtles

Mitigation Number	Proposed Project Phase	Mitigation or Monitoring Measure	Description	Resource Area Mitigated
77	Construction and installation, O&M, and conceptual decommissioning	Geophysical survey clearance of exclusion zone and restart protocols following shutdowns	Measures will be required in accordance with project design criteria and associated best management practices in the June 29, 2021Data Collection Programmatic ESA Consultation with NMFS.	Marine mammals and sea turtles
78	Construction and installation, O&M, and conceptual decommissioning	Sea turtle avoidance and exclusion zones during geophysical surveys	Measures will be required in accordance with project design criteria and associated best management practices in the June 29, 2021 Data Collection Programmatic ESA Consultation with NMFS.	Marine mammals and sea turtles
79	Construction and installation, O&M, and conceptual decommissioning	Geophysical survey exclusion zone, power-up, and re-start procedures	Measures will be required in accordance with project design criteria and associated best management practices in the June 29, 2021 Data Collection Programmatic ESA Consultation with NMFS.	Marine mammals and sea turtles
Conditions Proposed by NMFS in the February 2021 Incidental Harassment Authorization				
80	Construction	Seasonal Restriction (Section 4(a) of the Proposed IHA)	Seasonal Restriction: Impact pile driving must not occur from January 1 through April 30	Marine Mammals
81	Construction	Impact Pile Driving Time Restrictions (Section 4(b) of the Proposed IHA)	Impact pile driving may commence only during daylight hours no earlier than one hour after (civil) sunrise. Impact pile driving may not be initiated any later than 1.5 hours before (civil) sunset. Pile driving may continue after dark only when the installation of the same pile began during daylight (1.5 hours before (civil) sunset), when clearance zones were fully visible for at least 30 minutes (as described under condition 4(c)(ix)), and must proceed for human safety or installation feasibility reasons.	Marine Mammals
82	Construction	Establishment of clearance zones for all activities (Section 4(c) of the Proposed IHA)	(i) South Fork Wind must deploy at least two PSOs on duty on the impact pile driving platform and at least two PSOs on duty on a dedicated PSO vessel at all times during impact pile driving to monitor for marine mammals. PSO requirements are described under condition 5(a). (ii) Monitoring must take place from 60 minutes prior to initiation of impact pile driving through 30 minutes post-completion of impact pile driving activity. (iii) South Fork Wind must deploy at least two PSOs on duty on the vibratory pile driving platform, or nearby construction vessel, at all times during vibratory pile driving to monitor for marine mammals. PSO requirements are described under condition 5(a). (iv) Monitoring must take place from 30 minutes prior to initiation of vibratory pile driving through 30 minutes post-completion of vibratory pile driving. (v) South Fork Wind must deploy a minimum of one PSO on duty during daytime high resolution geophysical (HRG) survey activities and two PSOs during nighttime HRG survey activities to monitor for marine mammals. PSO requirements are described under condition 5(a). (vi) Monitoring must take place 30 minutes prior to initiation of HRG acoustic sources through 30 minutes post-termination of HRG acoustic sources. (vii) For all impact pile driving, vibratory pile driving, and HRG survey activity, South Fork Wind must designate clearance and monitoring zones with radial distances as identified in Table 2. (viii) Impact pile driving, vibratory pile driving, and HRG survey activity must only commence when all clearance zones are fully visible (i.e., are not obscured by darkness, rain, fog, etc.) for at least 30 minutes as determined by the lead PSO. If conditions (e.g., darkness, rain, fog, etc.) prevent the visual detection of marine mammals in the clearance zones, construction activities must not be initiated until the full extent of all clearance zones are fully visible as determined by the lead PSO.	Marine Mammals

Mitigation Number	Proposed Project Phase	Mitigation or Monitoring Measure	Description	Resource Area Mitigated
83	Construction	Clearance Measures for all pile driving and HRG surveys (Section 4(d) of the Proposed IHA)	South Fork Wind must use PSOs to establish clearance zones around the impact pile driving, vibratory pile driving, and HRG equipment (Table 2) to ensure these zones are clear of marine mammals prior to the initiation of activities. Clearance requirements are as follows: (i) If a marine mammal is observed entering or within the relevant clearance zones (Table 2) prior to the initiation of impact pile driving, vibratory pile driving, or HRG survey equipment, all activity must be delayed. (ii) Impact pile driving, vibratory pile driving, and HRG survey activity must be delayed upon observation of a North Atlantic right whale that is visually observed by PSOs at any distance from the pile or acoustic source. (iii) Impact pile driving must be delayed upon a confirmed passive acoustic monitoring (PAM) detection of a North Atlantic right whale, if the detection is confirmed to have been located within the clearance zone (Table 2). (iv) Impact pile driving, vibratory pile driving, and HRG survey activity must only commence after PSOs have confirmed all clearance zones (Table 2) are clear of marine mammals, as described in conditions 4(c)(ii)(iv)(vi). (v) Any large whale sighted by a PSO within 1,000 m of the pile or HRG acoustic source that cannot be identified to species must be treated as if it were a North Atlantic right whale. (vi) Pile driving and may commence and HRG acoustic sources may be activated when either the marine mammal(s) has voluntarily left the respective clearance zone and been visually confirmed beyond that clearance zone, or, when 30 minutes have elapsed without re-detection (for mysticetes, sperm whales, Risso's dolphins and pilot whales) or 15 minutes have elapsed without re-detection (in the case of all other marine mammals). (viii) Requirements for real-time PAM during impact pile driving are as follows: 1. Real-time PAM must begin at least 60 minutes prior to pile driving. 2. The real-time PAM system must be designed and established such that detection capability extends to 5 km from the pile driving location, for all monopile installations. 3. The real-time PAM system must be configured to ensure that the PAM operator is able to review acoustic detections within approximately 15 minutes of the original detection in order to verify whether a right whale has been detected. 4. The PAM operator responsible for determining if the acoustic detection originated from a North Atlantic right whale must be trained in identification of mysticete vocalizations. 5. If the PAM operator has at least 75 percent confidence that a vocalization originated from a right whale located within 5 km of the pile driving location, the PAM operator must determine that a right whale has been detected and appropriate associated mitigation and monitoring measures must be implemented. 6. A record of the PAM operator's review of any acoustic detections must be reported to NMFS.	Marine Mammals

Mitigation Number	Proposed Project Phase	Mitigation or Monitoring Measure	Description	Resource Area Mitigated
84	Construction	Shutdown Measures for all pile driving and HRG surveys (Section 4(e) of the Proposed IHA)	(i) If a marine mammal is observed entering or within the respective clearance zones (Table 2) after pile driving has commenced or HRG acoustic sources are activated, a shutdown of impact pile driving (when practicable as described under 4(e)(v)), vibratory pile driving, and HRG acoustic sources must be implemented. (ii) Pile driving must be halted (when practicable as described under 4(e)(v)) upon visual observation of a North Atlantic right whale observed by PSOs at any distance from the pile. (iii) Pile driving must be halted (when practicable as described under 4(e)(v)) upon a confirmed PAM detection of a North Atlantic right whale within the Level A harassment exclusion zone of the pile being driven. (iv) Following shutdown, pile driving may not commence and HRG acoustic sources may not be reactivated until either the animal has voluntarily left and been visually confirmed beyond the respective clearance zone or 15 minutes have elapsed without subsequent detection for delphinids and pinnipeds, or 30 minutes have elapsed without subsequent detection for all other marine mammals. (v) In cases where impact pile driving has commenced and a shutdown is called for due to a marine mammal entering or within an exclusion zone, the lead engineer on duty must evaluate the following to determine whether shutdown is practicable: (1) Use site-specific soil data and real-time hammer log information to judge whether a stoppage would risk causing piling refusal at re- start of piling; and (2) Check that the pile penetration is deep enough to secure pile stability in the interim situation, taking into account weather statistics for the relevant season and the current weather forecast. (3) Determinations by the lead engineer on duty will be made for each pile as the installation progresses and not for the site as a whole. vi) For impact pile driving, if shutdown is called for but South Fork Wind determines shutdown is not practicable due to an imminent risk of injury or loss of life to an individual, or risk of damage to a vessel that creates risk of injury or loss of life for individuals, reduced hammer energy must be implemented, when the lead engineer determines it is practicable. (vii) After a shutdown, impact pile driving must only be initiated once all clearance zones are confirmed by PSOs to be clear of marine mammals for the minimum species-specific and activity-specific time periods 4(c)(ii)(iv)(vi) or, if required to maintain installation practicability. (viii) If a delphinid(s) from the genera *Delphinus*, *Lagenorhynchus*, *Stenella*, or *Tursiops* is visually detected approaching the HRG vessel (e.g., to bow ride) or towed HRG survey equipment, shutdown is not required. If there is uncertainty regarding identification of a marine mammal species (i.e., whether the observed marine mammal(s) belongs to one of the delphinid genera for which shutdown is waived), PSOs must use best professional judgment in making the decision to call for a shutdown. (ix) If an individual from a species for which authorization has not been granted, or a species for which authorization has been granted but the authorized take number has been met, is observed entering or within the clearance zone, impact pile driving (when practicable as described under 4(e)(v)), vibratory pile driving, and HRG survey activities must shut down immediately. Activities must not resume until the animal has been confirmed to have left the clearance zone or the observation time period, as indicated in conditions 4(ii)(iv)(vi), has elapsed with no further sightings. For in-water construction, heavy machinery activities other than pile driving, if a marine mammal comes within 10 meters of equipment, South Fork Wind must cease operations (when practicable as described under 4(e)(v)).	Marine Mammals
85	Construction	Soft Start for impact pile driving (Section 4(f) of the Proposed IHA)	(ix) South Fork Wind must implement soft start techniques for all impact pile driving, both at the beginning of a monopile installation and at any time following the cessation of impact pile driving of 30 minutes or longer. The soft start procedure must include a minimum of 20 minutes of 4-6 strikes/minute at 10-20 percent of the maximum hammer energy.	Marine Mammals
86	Construction	Ramp-up for HRG acoustic sources (Section 4(g) of the Proposed IHA)	(x) When practicable, acoustic sources must be ramped up at the start or restart of survey activities. Ramp-up must begin with the power of the smallest acoustic source at its lowest practical power output. The power must then be increased and other acoustic sources added in a way such that the source level would increase gradually.	Marine Mammals
87	Construction	Noise Mitigation for impact pile driving (Section 4(h) of the Proposed IHA)	(i) South Fork Wind must employ a noise mitigation device(s) during all impact pile driving. (ii) The noise mitigation device(s) must perform such that measured ranges to the Level B harassment threshold is consistent with those modeled assuming 10 dB attenuation, determined via sound source verification (described under condition 5(e)). (iii) If a bubble curtain is used, the following requirements apply: (1) The bubble curtain(s) must distribute air bubbles around 100 percent of the piling perimeter for the full depth of the water column. (2) The lowest bubble ring must be in contact with the seafloor for the full circumference of the ring, and the weights attached to the bottom ring must ensure 100 percent seafloor contact. (3) No parts of the ring or other objects may prevent full seafloor contact. (iv) Construction contractors must train personnel in the proper balancing of air flow to the bubblers. Construction contractors must submit an inspection/performance report for approval by South Fork Wind within 72 hours following the performance test. Corrections to the attenuation device to meet the performance standards must occur prior to impact driving.	Marine Mammals

Mitigation Number	Proposed Project Phase	Mitigation or Monitoring Measure	Description	Resource Area Mitigated
88	Construction	Vessel Strike Avoidance Measures (Section 4(i) of the Proposed IHA)	Vessel operators and crews must maintain a vigilant watch for all marine mammals and slow down, stop their vessel, or alter course, as appropriate and regardless of vessel size, to avoid striking any marine mammal. A visual observer aboard the vessel must monitor a vessel strike avoidance zone around the vessel (distances stated below). Visual observers monitoring the vessel strike avoidance zone may be third-party observers (i.e., PSOs) or crew members, but crew members responsible for these duties must be provided sufficient training to distinguish marine mammals from other phenomena and broadly to identify a marine mammal as a right whale, other whale (defined in this context as sperm whales or baleen whales other than right whales), or other marine mammal. South Fork Wind must adhere to the following measures: (i) All vessels greater than or equal to 65 ft. (19.8 m) in overall length must comply with the 10-knot speed restriction in any Seasonal Management Area (SMA) per the NOAA ship strike reduction rule (73 FR 60173; October 10, 2008). (ii) Vessels of all sizes will operate port to port at 10 knots or less between November 1 and April 30, except for vessels transiting inside Narragansett Bay or Long Island Sound. (iii) A trained, dedicated visual observer and alternative visual detection system (e.g., thermal cameras) will be stationed on all transiting vessels that intend to operate at greater than 10 knots from November 1 through April 30. The primary role of the visual observer is to alert the vessel navigation crew to the presence of marine mammals and to report transit activities and marine mammal sightings to the designated South Fork Wind information system. (iv) Vessels of all sizes will operate at 10 knots or less in any North Atlantic right whale Dynamic Management Area (DMA) (v) Outside of DMAs, SMAs, and the November 1 through April 30 time period, localized detections of North Atlantic right whales, using passive acoustics, would trigger a slow-down to 10 knots or less in the area of detection (zone) for the following 12 hours (hrs.). Each subsequent detection would trigger a 12-hr reset. A slow-down in that zone expires when there has been no further visual or acoustic detection in the past 12- hr. within the triggered zone (vi) For all vessels greater than or equal to 65 ft. (19.8 m) in overall length, vessel speeds must be reduced to 10 knots or less when mother/calf pairs, pods, or large assemblages of cetaceans are observed near a vessel (vii) All vessels must maintain a minimum separation distance of 500 m from North Atlantic right whales. If a whale is observed but cannot be confirmed as a species other than a right whale, the vessel operator must assume that it is a right whale and take appropriate action (viii) All vessels must maintain a minimum separation distance of 100 m from sperm whales and all other baleen whales (ix) All vessels must, to the maximum extent practicable, attempt to maintain a minimum separation distance of 50 m from all other marine mammals, with an exception made for those that approach the vessel (x) When marine mammals are sighted while a vessel is underway, the vessel must take action as necessary to avoid violating the relevant separation distance, e.g., attempt to remain parallel to the animal's course, avoid excessive speed or abrupt changes in direction until the animal has left the area. If marine mammals are sighted within the relevant separation distance, the vessel must reduce speed and shift the engine to neutral, not engaging the engines until animals are clear of the area. This does not apply to any vessel towing gear or any vessel that is navigationally constrained (xi) These requirements do not apply in any case where compliance would create an imminent and serious threat to a person or vessel or to the extent that a vessel is restricted in its ability to maneuver and, because of the restriction, cannot comply (xii) When not on active watch duty, members of the monitoring team must consult NMFS' North Atlantic right whale reporting systems for the presence of North Atlantic right whales in the project area (v) Project-specific training must be conducted for all vessel crew prior to the start of in-water construction activities. Confirmation of the training and understanding of the requirements must be documented on a training course log sheet.	Marine Mammals

APPENDIX H

Assessment of Other Resources

This page intentionally left blank.

CONTENTS

Tables

ASSESSMENT OF OTHER RESOURCES

This appendix provides an assessment of resources with negligible to minor impacts from implementation of the Proposed Action and other considered alternatives. Because these sections were originally part of Chapter 3 of the South Fork Wind Farm (SFWF) and South Fork Export Cable (SFEC) Project environment impact statement (EIS), chapter and section naming and numbering were maintained for simplicity. All abbreviations and references for these sections are provided in the main EIS and Appendix B, respectively.

3.1 ANALYSIS APPROACH (SEE SECTION IN MAIN EIS)

3.2 MITIGATION IDENTIFIED FOR ANALYSIS IN THE ENVIRONMENTAL IMPACT STATEMENT (*SEE SECTION IN MAIN EIS*)

3.3 PHYSICAL RESOURCES

3.3.1 Air Quality

3.3.1.1 Affected Environment

Air quality within a region is measured in comparison to the National Ambient Air Quality Standards (NAAQS), which are standards established by the U.S. Environmental Protection Agency (EPA) under the Clean Air Act (CAA) (42 USC 7409) for criteria pollutants. The EPA has developed these standards to protect human health and welfare (primary standards) and provide public welfare protection, including protection against decreased visibility and damage to animals, crops, vegetation, and buildings (secondary standards). The criteria pollutants for which NAAQS have been established are carbon monoxide (CO), sulfur dioxide (SO_2), particulate matter 10 microns or less (PM_{10}), particulate matter 2.5 microns or less ($PM_{2.5}$), nitrogen dioxide (NO_2), ozone (O_3), and lead. The EPA uses design values to designate and classify non-attainment areas. A design value is a statistic that describes pollutant levels at a given location so they can be compared to the NAAQS. Non-attainment occurs if any criteria air pollutant concentration design value exceeds its NAAQS. If a region is designated as non-attainment for a NAAQS, the CAA requires the state to develop a state implementation plan (SIP). A SIP provides for the implementation, maintenance, and enforcement of the NAAQS, and includes emission limitation and control measures to attain and maintain the NAAQS. The CAA also prohibits federal agencies from approving any activity that does not conform to a SIP, and this prohibition applies only with respect to nonattainment or maintenance areas (i.e., areas that were previously nonattainment and for which a maintenance plan is required). Conformity to a SIP means conformity to a SIP's purpose of reducing the severity and number of violations of the NAAQS to achieve attainment of such standards. The activities for which the Bureau of Ocean Energy Management (BOEM) has authority are outside of any non-attainment or maintenance area and therefore not subject to the requirement to show conformity.

The EPA (2018a) reports the following:

- Rhode Island is currently in attainment for all criteria pollutants.
- The greater Connecticut area, encompassing Hartford, New London, Tolland, and Windham Counties, Connecticut, is currently in marginal non-attainment with the 2015 8-hour O_3 standard.

- The New York-Northern New Jersey-Long Island area, also known as the New York Metro Area, which encompasses Middlesex County, Connecticut, and Suffolk County, New York, is currently in serious non-attainment with the 2008 8-hour O_3 standard and moderate non-attainment with the 2015 8-hour O_3 standard. Suffolk County is also maintenance for the 2006 24-hour NAAQS for fine particulates ($PM_{2.5}$).
- Massachusetts is currently in attainment for all criteria pollutants with the exception of Dukes County, which is currently in marginal non-attainment for the 2008 8-hour O_3 standard.

Connecticut, New York, and Massachusetts have all adopted, and will continue to adopt, SIPs to mitigate the impact that regulated air pollutant emissions have on air quality.

Depending on the final Project design, Project air emissions could affect seven non-attainment areas in the analysis area: Hartford, Middlesex, New London, Tolland, and Windham Counties, Connecticut; Dukes County, Massachusetts; and Suffolk County, New York. The EPA classifies these seven counties as being in non-attainment for 2008 and/or 2015 8-hour O_3. In addition, Suffolk County is also maintenance for the 2006 24-hour NAAQS for $PM_{2.5}$. The EPA reports no other pollutants in non-attainment status in these counties (EPA 2018a).

Sheet Harbor in Novia Scotia, Canada, may be used as a backup port if needed for the marshalling of wind turbine generators (WTGs) and possibly foundation components. The use of this port would result in a minimal number of trips directly between the port of Sheet Harbor and the SFWF. The use of Sheet Harbor would be minimal as it relates to the overall Project construction, and, if used, could marginally reduce the level of U.S. port use.

A photochemical reaction between volatile organic compounds (VOCs), NO_2 or other nitrogen oxides (generically termed NO_x), and sunlight forms O_3. VOCs and NO_x are known as O_3 precursor pollutants. O_3 is considered a regional pollutant because both local and regional sources of VOCs and NO_x can contribute to its formation since they accumulate in the atmosphere until the next sunny day, when they then combine with the sunshine, creating O_3. In the northeastern United States, NO_x emissions are primarily from on-road vehicles while off-road engines, such as those on construction equipment, are the second-largest source. VOC emissions in that region are primarily from vegetation sources, and solvent use in industry is the second-largest source (EPA 2017).

Hartford County, Connecticut, includes urban areas, such as Hartford, with a high population density and a sizable industrial base. Emission sources within the boundaries of Hartford County, as well as regional sources and sources in neighboring metro areas outside of the county, affect the county's air quality. In Hartford County, NO_x emissions are primarily from on-road vehicles, with fuel combustion being the second-largest source. VOC emissions are primarily from vegetation sources, solvent use in industry, and highway vehicles. Although the EPA currently classifies Hartford County as being in moderate non-attainment for the 2008 8-hour O_3 standard and marginal non-attainment for the 2015 8-hour O_3 standard, ambient air quality monitors located in Hartford County reported a steady decrease in O_3 concentration levels from 2014 to 2019 (EPA 2020a). The design value for O_3 is the annual fourth-highest daily maximum 8-hour ozone concentration averaged over 3 years. Hartford County reported an O_3 design value of 72.0 parts per billion (ppb) on average for the 2015 to 2017 period and 69.0 ppb on average for both the 2016 to 2018 period and the 2017 to 2019 period (EPA 2020a).

Middlesex, New London, Tolland, and Windham Counties are rural counties in Connecticut with a low population density and small industrial bases. Neighboring metro areas outside of their respective boundaries heavily affect the air quality of these counties in addition to regional sources. For this reason, changes to pollutant emissions by sources within their boundaries have little impact on the overall air quality trends. NO_x emissions in these counties are primarily from on-road vehicles, with fuel combustion for industrial purposes, electric generation, and other needs being the second-largest source. Vegetation sources and solvent use are the primary VOC emissions in these counties. Although the EPA currently classifies these counties as being in moderate non-attainment for the 2008 8-hour O_3 standard and marginal non-attainment for the 2015 8-hour O_3 standard, ambient air quality monitors in these counties reported a small decrease in O_3 levels from 2017 to 2019 (EPA 2020a). Middlesex County reported an O_3 design value of 79.0 ppb for the 2015 to 2017 time period, 78.0 ppb for the time period from 2016 to 2018, and 77.0 ppb for the 2017 to 2019 time period (EPA 2020a). New London County reported an O_3 design value of 76.0 ppb over the 2015 to 2017 time period and 75.0 ppb for both the 2016 to 2018 time period and the 2017 to 2019 time period (EPA 2020a). Tolland County reported an O_3 design value of 71.0 ppb during the 2015 to 2017, 2016 to 2018, and 2017 to 2019 time periods (EPA 2020a). Windham County reported an O_3 design value of 70.0 ppb over the 2015 to 2017 time period and 71.0 ppb for both the 2016 to 2018 and the 2017 to 2019 time periods (EPA 2020a).

Dukes County is an island community with a relatively low population density and little heavy industry. As is common in the northeastern region, non-road engines used for construction activities and on-road vehicle traffic are the main sources of NO_x in Dukes County (EPA 2017). Vegetation sources and non-road engines are the primary VOC emission sources in Dukes County. Although the EPA currently classifies Dukes County as being in marginal non-attainment for the 2008 8-hour O_3 standard, ambient air quality monitors in Dukes County reported a steady decrease in O_3 levels from 2012 to 2015 (EPA 2020a). The EPA also recently (August 2018) designated Dukes County in attainment for the more stringent 2015 8-hour O_3 standard of 70.0 ppb based on the 2014 to 2016 O_3 design value of 64.3 ppb (EPA 2018b). Recently, Dukes County reported an O_3 design value of 70.0 ppb for the 2016 to 2018 time period and 71.0 ppb for the 2017 to 2019 time period (EPA 2020a).

Suffolk County is an area with a high population density and a large industrial base. Emissions from the New York Metro Area, outside of Suffolk County, heavily affect the county's air quality. For this reason, changes to pollutant emissions by sources within Suffolk County have little impact on overall air quality trends. Suffolk County reported a decrease in O_3 concentration levels from 2017 to 2019 (EPA 2020a). The O_3 design value based on observations at the Riverhead air monitor in Suffolk County was 76.7 ppb during the 2015 to 2017 time period, 75.3 ppb for the 2016 to 2018 time period, and 72.0 ppb for the 2017 to 2019 time period (EPA 2020a). Thus, the EPA currently classifies Suffolk County as being in serious non-attainment for 8-hour O_3 according to the 2008 8-hour standard and in moderate non-attainment for the 8-hour O_3 2015 8-hour standard. Suffolk County is also maintenance for the 2006 24-hour NAAQS for $PM_{2.5}$. The EPA reports that on-road vehicles are the primary source of NO_x emissions in Suffolk County; non-road engines are the second-largest source. Vegetation sources, solvent use in industry, off-highway engines, and on-road vehicles provide the most VOC emissions in Suffolk County (EPA 2017).

Because of Project developments, the Project may affect an additional 14 non-attainment counties, depending on whether SFW uses the ports considered for temporary use to support construction and installation, O&M, and conceptual decommission. These counties are New Castle County, Delaware; Anne Arundel, Baltimore City, Baltimore, and Harford Counties, Maryland; Atlantic, Burlington, Camden, Cumberland, Gloucester, and Salem Counties, New Jersey; and Bucks, Delaware, and Philadelphia Counties, Pennsylvania. The EPA classifies these 14 counties as being in marginal non-attainment for 2015 8-hour O_3.

Table 3.3.1-1. presents the total emission inventory in tons per year (tpy) for select regulated pollutants in non-attainment counties in 2017.

Table 3.3.1-1. Non-Attainment Counties, 2017 Emission Inventory

County, State	Regulated Pollutant (tpy)					
	CO	NO_X	PM_{10}	$PM_{2.5}$	SO_2	VOC
Hartford County, CT	76,982.45	11,271.45	5,052.28	2,377.24	572.78	22,725.16

Designation as a Class I area allows only very small increments of new pollution above already existing air pollution levels. Class I areas include national parks larger than 6,000 acres and wilderness areas larger than 5,000 acres that were in existence before August 1977. No federal Class I areas are located within 100 km of the Lease Area; therefore, no visibility or deposition modeling was conducted as part of this final EIS. Visibility and deposition modeling was conducted in support of the air quality permit application, however. A Q/D screening assessment[1] was provided to the both the U.S. Forest Service and the U.S. Fish and Wildlife Service (USFWS) for the nearest Class I area, the Lye Brook Wilderness Area, 167 miles away, as well as for the Brigantine Class I area, the second-closest Class I area, 196 miles away. The screening analysis confirmed that the Project is not likely to impact visibility or other air quality related values at either Class I area. The U.S. Forest Service did not request further air quality related values analyses. A screening visibility analysis was conducted for Class II vistas at Block Island and Martha’s Vineyard using the EPA VISCREEN model for operations and maintenance emissions. The results demonstrated that the Project does not exceed the operations and maintenance significance criteria at the Class II vistas; thus, further visibility analysis was not required (Jacobs 2020).

[1] Estimate of emissions in tons/year divided by distance to an affected Class I area in miles or kilometers, also known as Q/D.

Climate change is a global issue that results from the increase in greenhouse gases (GHGs) in the atmosphere. An analysis of regional climate impacts prepared by the Fourth National Climate Assessment (U.S. Global Change Research Program 2018) concludes that the rate of warming in the Northeast has markedly accelerated over the past few decades with seasonal differences in temperature decreasing in recent years as winters have warmed three times faster than summers. Higher temperatures from the increase of GHGs in the atmosphere increase the number of heat events and extreme rain events that cause coastal flooding. The higher temperatures also extend the duration of the pollen season. Analysis of past records and future projections indicates an overall increase in regional temperatures, including near the Lease Area. The most recently available data on GHG emissions in the United States indicate that annual GHG emissions in 2019 were an estimated 6,558 million metric tons of carbon dioxide equivalents (CO_2e) (EPA 2021).

Few hurricanes pass through New England, but the area is subjected to frequent nor'easters that form offshore between Georgia and New Jersey, and typically reach maximum intensity in New England. These storms are usually characterized by winds from the northeast, and can bring heavy precipitation, wind, storm surges, and rough seas. They primarily occur between September and April but can form any time of the year. Although hurricanes are relatively infrequent in New England, wave heights up to 30 feet (9 meters [m]) were recorded south of Block Island (Scripps Buoy 44097) during Hurricane Sandy in 2012 (NOAA 2012). Section 4.2.4 of the COP provides additional weather information, including wind and extreme weather events (cyclones, hurricanes).

3.3.1.2 Environmental Consequences

3.3.1.2.1 ISSUES, INDICATORS, AND SIGNIFICANCE CRITERIA

Table 3.3.1-2 lists the issues identified for this resource and the indicators and significance criteria used to assess impacts for this final EIS. Jacobs (2021) provides detailed methodology for emission calculations presented in this final EIS.

Table 3.3.1-2. Issues, Indicators, and Significance Criteria Used to Assess Impacts to Air Quality

Issue	Impact Indicator	Significance Criteria
Compliance with NAAQS	Emissions (tpy) from construction marine vessels, vehicles, and equipment activity within 25 nm of the center of the Lease Area	Negligible: Project emissions would not be detectable. Minor to moderate: Project emissions would be detectable but would not exceed NAAQs or de minimis thresholds. Major: Project emissions would exceed NAAQS.
GHG emissions	GHG emissions (tpy) during construction; operational GHG and O_3 precursors emissions (tpy) reductions	There are currently no significance thresholds for GHG emissions.

3.3.1.2.2 NO ACTION ALTERNATIVE

The Affected Environment section provides information on existing air quality trends from past and present activities. Attachment 2 in Appendix E provides additional information regarding past and present activities and associated air quality impacts. Future non-Project sources of air pollution include future energy development (onshore and offshore wind, tidal, liquefied natural gas, and other fossil fuels), marine mineral use, and other construction activities. Attachment 2 in Appendix E also discloses future non-offshore wind activities and associated air quality impacts. Impacts associated with future offshore wind activities are described below.

Future Activities (without the Proposed Action)

Air emissions and climate change: Under the No Action alternative, assuming no other future offshore wind projects are developed, electric generation needs would continue to be met by fossil fuel–generating technologies, resulting in air emissions. Specific impacts would depend on the type of fossil fuel used (natural gas, oil, coal), the technology and pollution control systems chosen, and site-specific issues associated with individual electric generation facilities. However, the continued use of existing fossil fuel–generation sources would result in annual emissions that could have been avoided by using non–fossil fuel energy sources. These emissions, presented in Table 3.3.1-3, were estimated using the EPA's AVoided Emissions and geneRation Tool (AVERT) for the New York region based on the design capacity of the offshore wind projects that would not be developed.

Table 3.3.1-3. Estimated Annual Avoided Emissions (tpy) for the Operation of Future Offshore Wind Projects within the Air Quality Geographic Analysis Area

Pollutant	CO_2	NO_X	SO_X	$PM_{2.5}$
Lower limit	16,506,291.00	4,845.64	2,526.22	731.97
Upper limit	21,272,422.61	6,236.17	3,244.05	942.84

Notes: Emissions are presented in tons and were obtained using the EPA's AVERT (EPA 2020b). AVERT limits the maximum input generation capacity for the New York region to 1,300 megawatts (MW), which, according to AVERT, is to limit any project from displacing more than approximately 30% of regional fossil generation in any hour. For each of the offshore wind projects within the geographic analysis area with a generation capacity greater than 1,300 MW, the avoided emissions were calculated via AVERT based on a 1,300-MW energy generation capacity. The AVERT avoided emission values were then scaled up to represent the full energy generation capacity for offshore wind projects with a generation capacity greater than 1,300 MW. For example, an offshore wind project generating 2,600 MW would have twice the avoided emissions values calculated by AVERT for a 1,300-MW offshore wind project.

The lower limit represents the sum of the avoided emissions, as calculated by AVERT, for all of the various offshore wind projects within the geographic analysis area limited to a maximum energy generation capacity of 1,300 MW per project. The upper limit represents the sum of the avoided emissions for the same offshore wind projects based on their actual energy generation capacity, scaling up the avoided emission values for the projects with an energy generation capacity greater than 1,300 MW.

Assuming the development of other future wind development and other renewable energy sources[2], these sources would decrease emissions over the long term, likely reduce the need for more traditional fossil fuel power generation in the region, and could result in improved air quality by increasing the proportion of energy generated from renewables contributing to the grid. Adjacent states have also proposed emission-reduction targets and renewable goals that overlap the operations of the Project and that are aimed at reducing air emissions and shifting energy sources from traditional fossil fuel generation to cleaner sources of energy. These plans could further reduce, but would not eliminate, air emissions.

During construction, adverse impacts from future wind development activities on air quality under the No Action alternative would be temporary and minor to moderate, depending on the extent and duration of emissions. Primary emission sources would include increased vessel and air traffic, combustion emissions from construction equipment, and fugitive emissions. Based on assumed construction schedules, offshore wind development would occur with overlapping construction schedules between 2022 to 2030. As shown in Table 3.3.1-4, construction of these projects in the geographic analysis area with sufficient details to estimate emissions would generate an estimated 42,929 tons of NO_x, 244 tons of SO_2, 1,425 tons of PM_{10}, and 2,964,561 tons of CO_2. For comparison purposes, according to the EPA's 2017 National Emissions Inventory, Suffolk County reported 8,122 tons of NO_X, 124 tons of SO_2, and 872 tons of PM_{10} from highway vehicles; 6,566 tons of NO_X, 34 tons of SO_2, and 537 tons of PM_{10} from off-highway vehicles; and 860 tons of NO_X, 421 tons of SO_2, and 146 tons of PM_{10} from electrical utilities' combustion of fuel (EPA 2017).

[2] Consisting of other offshore and onshore solar, wind, geothermal, or other types of renewable sources.

As shown in Table 3.3.1-5, the operations phase of future offshore wind projects in the geographic analysis area would have a proportionally small contribution of long-term and intermittent emissions, including 2,246 tons of NO_x, 4 tons of SO_2, 565 tons of PM_{10}, and 160,858 tons of CO_2. Similarly, future offshore wind project GHG emissions during construction would be negligible (160,858 tons of CO_2) as compared to aggregate global emissions, and these projects may beneficially contribute to a broader combination of actions to reduce future impacts from climate change over the long term.

Table 3.3.1-4. Projected Construction Emissions for Projects in the Air Quality Geographic Analysis Area from 2022 to 2030

Project	CO_2	Regulated Pollutant (tons)					
		NO_X	SO_2	CO	PM_{10}	$PM_{2.5}$	VOC
Vineyard Wind 1, part of OCS-A 0501	318,660	4,961	38	1,116	172	166	122
Sunrise, parts of OCS-A 0500 and OCS-A 0487	637,986	5,876	6	2,441	108	108	138
Revolution, OCS-A 0486	449,456	6,691	21	1,617	220	216	130
Vineyard Wind South OCS-A 0501 remainder (Park City Wind)	505,810	9,014	53	2,110	355	344	190
Remaining Massachusetts/Rhode Island Lease Area	1,052,650	16,388	127	3,686	569	547	401
Total	2,964,561	42,929	244	10,969	1,425	1,381	981

See EIS Appendix E Attachment 4 for calculation details.

Table 3.3.1-5. Projected Operations and Maintenance Emissions for Projects in the Air Quality Geographic Analysis Area from 2022 to 2030

Project	CO_2	Regulated Pollutant (tons)					
		NO_X	SO_2	CO	PM_{10}	$PM_{2.5}$	VOC
Vineyard Wind 1, part of OCS-A 0501	5,487	71	0.3	18	2	2	2
Sunrise, parts of OCS-A 0500 and OCS-A 0487	64,145	590	1	246	11	11	14
Revolution, OCS-A 0486	64,391	953	1	234	31	30	14
Vineyard Wind South OCS-A 0501 remainder (Park City Wind)	8,710	398	1	98	13	13	7
Remaining Massachusetts/ Rhode Island Lease Area	18,126	234	1	60	8	8	7
Total	160,858	2,246	4	655	65	64	43

Notes: See EIS Appendix E, Attachment 4 for calculation details.

Additional projects are planned in this area, but do not yet have emission estimates available. These include the Bay State Wind Project and the OCS-A 0500 and OCS-A 0487 remainder.

Accidental releases: Air quality impacts associated with accidental spills from other reasonably foreseeable projects could also occur; however; releases would be short term, localized, generally small volume, and would not contribute to air quality in measurable amounts (see Section 3.3.2.2.2).

Conclusions

Under the No Action alternative, BOEM would not approve the COP; Project construction and installation, O&M, and conceptual decommissioning would not occur; and potential impacts on air quality associated with the Project would not occur. However, ongoing and future activities would have continuing temporary to long-term impacts on air quality, primarily through construction-related air emissions.

BOEM anticipates that the impacts of ongoing activities, such as air emissions and GHGs, would be **moderate**. In addition to ongoing activities, reasonably foreseeable activities other than offshore wind may also contribute to impacts on air quality. Reasonably foreseeable activities other than offshore wind include increasing air emissions and GHGs through construction and operation of new energy generation facilities to meet future power demands. These facilities may consist of new natural-gas-fired power plants or coal-fired, oil-fired, or clean-coal-fired plants. BOEM anticipates that the impacts of reasonably foreseeable activities other than offshore wind would be **moderate**. BOEM expects the combination of ongoing activities and reasonably foreseeable activities other than offshore wind to result in **moderate** impacts on air quality, primarily driven by recent market and permitting trends indicating future electric generating units would most likely include natural-gas-fired and oil-fired dual fuel facilities, a mix of natural gas and dual fuel natural gas/oil.

Considering all the IPFs together, BOEM anticipates that the impacts associated with future offshore wind activities in the geographic analysis area combined with ongoing activities, reasonably foreseeable environmental trends, and reasonably foreseeable activities other than offshore wind would result in **minor** adverse impacts due to air quality emissions released primarily during construction and decommissioning. Other future offshore wind projects could also lead to reduced emissions from fossil-fuel power generating facilities, resulting in **minor to moderate** beneficial impacts on air quality.

3.3.1.2.3 PROPOSED ACTION ALTERNATIVE

Construction and Installation

Table 3.3.1-6 presents a summary of the Project's estimated construction emissions. Estimated emissions would represent a small (< 0.10% to 10.0%), temporary increase in air pollutants for most counties within the geographic analysis area over 1 to 2 years. These emission totals presented in the analysis represent a worst-case construction scenario in which all construction activities would occur in a single year. Though NO_x emissions resulting from the construction of the SFWF (521.5 tons) appear to be a large portion of Dukes County's total emission inventory (989.64 tpy), Dukes County is an island with a low population density and low overall NO_x emissions. Non-attainment for this county has been attributed to drifting pollutants from other counties and not from the emissions occurring within the county. Therefore, Project construction activities would only have a minor to moderate, temporary adverse impact on Dukes County's air quality. Similarly, the NO_x emissions from Project construction (521.5 tons) appear to be a large portion of Newport County, Rhode Island's annual emission inventory (1,842.5 tpy). However, adverse impacts to Newport County's air quality would also be minor to moderate because Newport County is in attainment with the NAAQS, and construction emissions would be temporary and localized. The development of the Project could result in improved air quality conditions in the geographic analysis area once operational by reducing levels of pollutants over the No Action alternative.

Table 3.3.1-7 presents a summary of Project emissions. Estimates for the amount of selected pollutants emitted during a worst-case scenario in which all construction activities would occur in a single year are also compared to the emission inventories of the impacted counties. Offshore emissions at any port considered would exceed the de minimis threshold for NO_x in the non-attainment counties evaluated, except in Hartford, Middlesex, New London, Tolland, and Windham Counties, Connecticut, under the scenario that considers the Port of New London, Connecticut, as the base of operations for shipping activities. However, these emissions would be temporary and could be reduced by staggering construction time frames and implementation of SFW-proposed environmental protection measures (EPMs) (see Table G-1 in Appendix G). Total Project emissions would account for less than 20.0% of each affected county's total emission inventory and would be temporary in nature. The maximum impact relative to the counties' emission inventories is predicted to occur in Salem County, New Jersey, with Project NO_x emissions (428.8 tons) being equal to 18.0% of the county's total NO_x emissions (2,385.5 tpy).

Onshore emissions at any considered port would not exceed the de minimis threshold, except in Suffolk County, New York. Estimated onshore emissions that would occur in this county are calculated to be 101.3 tpy of NO_x because of the proposed interconnection facility, which is planned to be constructed in Long Island, New York. However, these estimates would be temporary and could be reduced by staggering construction time frames and implementation of SFW-proposed EPMs (Table G-1 in Appendix G). Therefore, minor to moderate, temporary adverse impacts to air quality are anticipated.

Operations and Maintenance and Conceptual Decommissioning

Table 3.3.1-8 and Table 3.3.1-9 present a summary of Project O&M emissions. Emissions from the Project O&M would be much lower than those produced during construction because there would be no direct emissions associated with wind turbine operation. There could, however, be some tailpipe emissions from onshore vehicles and minor VOC emission during routine changes of lubricating and cooling fluids and greases. The primary source of offshore emissions during operation would be vessel travel (three crew transport vessels, one floating/jack-up crane barge, and two feeder barges) to and from the Lease Area. Planned maintenance and unplanned maintenance activities are each expected to require only 1 week of work each year and should have minor, temporary adverse air quality impacts. Emissions that would impact non-attainment counties during the Project O&M would fall well below the de minimis thresholds.

Project O&M would also generate long-term, minor beneficial impacts by providing energy to the region from a renewable resource. Currently, the region in which this wind farm would serve obtains between 40% and 70% of its power through the combustion of natural gas (U.S. Energy Information Administration 2019). By replacing a portion of the air pollutant emissions generated by fossil fuel–fired power plants, significant reductions in air pollutants emissions can be achieved. A recent study of current wind turbines found that there is a net reduction in emissions within 6 months of the commencement of operations, meaning that there is a very short period of time before benefits from the Project begin to be realized (Inderscience Publishers 2014).

BOEM obtained avoided emissions from EPA's AVERT for the New York region. The EPA's AVERT is not a long-term projection tool. It is not intended to analyze avoided emissions more than 5 years from baseline. The estimated annual and lifetime (25 years, plus up to an additional 2 years for conceptual decommissioning) emissions are based on design capacity of the Project (180 MW). In order to provide a rough estimate of the lifetime avoided emissions of the Project, the annual avoided emissions estimated by AVERT were multiplied by the life of the turbine. As presented in Table 3.3.1-10, the Project would annually displace CO_2, NO_X, and SO_2 produced by the New York electric grid and decrease the creation of air pollutant emissions in the atmosphere from traditional fossil fuel–fired power plants. It must be recognized that this is just a general upper-boundary estimate of the potential lifetime avoided emissions, and the AVERT model is unable to provide any type of certainty for the long-term avoided emissions associated with the Project.

Table 3.3.1-10. Estimated Annual and Lifetime Avoided Emissions (tons) for the Operation of the South Fork Wind Farm over a 25-year Period

Pollutant	CO_2	NO_X	SO_X	$PM_{2.5}$
Annual avoided emissions	319,080	97.39	53.20	14.28
Lifetime avoided emissions	7,977,000	2,434.75	1,329.88	356.88

Notes: Emissions are presented in tons and were obtained from AVERT (EPA 2020b).

The EPA's CO-Benefits Risk Assessment (COBRA) screening model web edition was used to estimate the health impacts of avoided emissions in the United States, and the area of Connecticut, Massachusetts, New York, and Rhode Island, combined. The model used the following inputs: New York was selected as the state where the emission changes would occur; Fuel Combustion: Electric Utility was the sector where the emission changes would occur; and the change of emissions used the annual avoided emissions for NO_X, SO_X, and $PM_{2.5}$, as noted in Table 3.3.1-10 (97.39 tons of NO_X, 53.20 tons of SO_X, and 14.28 tons of $PM_{2.5}$). The model provides estimated ranges of reduced occurrences of health events due to air pollution, such as mortality, nonfatal heart attacks, and hospitalizations. It also estimates the total health benefit, which encompasses all saved costs of the avoided health events. COBRA includes a discount rate of either 3%, to account for the interest that may be earned from government backed securities, or 7%, to account for private capital opportunity costs. The EPA recommends using both for a bounding approach. For the entire United States, COBRA estimates the total health benefit ranges to be $6,126,919 to $13,808,379 at a 3% discount rate and $5,468,112 to $12,313,726 at a 7% discount rate. COBRA estimates statistical lives saved within the entire United States to range from 0.55 to 1.25 (EPA 2020c). For Connecticut, Massachusetts, New York, and Rhode Island, combined, COBRA estimates the total health benefit ranges to be $4,228,540 to $9,525,791 at a 3% discount rate and $3,774,085 to $8,494,914 at a 7% discount rate. COBRA estimates statistical lives saved within Connecticut, Massachusetts, New York, and Rhode Island, combined, to range from 0.38 to 0.86 (EPA 2020c). This would represent a long-term, minor beneficial impact due to avoided health events.

Conceptual decommissioning activities would take approximately 1 year and would include the removal of the piles, the scour protection, and underwater cable as well as the decommissioning of the turbines. Table 3.3.1-11 presents a summary of emissions resulting from the decommissioning of the Project in the Outer Continental Shelf (OCS) Air Permit Area. Table 3.3.1-12 presents a summary of emissions resulting from the conceptual decommissioning of the Project. Decommissioning-related emissions would be temporary, would fall below the de minimis thresholds, and would therefore have a minor, temporary adverse impact on both the overall air quality of the region and non-attainment counties.

Cumulative Impacts

Air emissions and climate change: The Proposed Action would result in temporary minor and long-term minor beneficial incremental impacts to air quality through the generation of construction and installation, O&M, and conceptual decommissioning emissions. The Proposed Action's construction emissions (see Table 3.3.1-6 and Table 3.3.1-7) would increase construction emissions of regulated pollutants (NO_x, SO_2, PM_{10}, and CO_2) over the construction emissions generated by other offshore wind projects associated with the No Action alternative (see Table 3.3.1-4). Therefore, total cumulative construction-related air emissions from all of the planned wind projects, including the Proposed Action, in the OCS Air Permit Area would consist of an estimated 43,471 tons of NO_x, 248 tons of SO_2, 1,443 tons of PM_{10}, and 2,998,333 tons of CO_2. These effects would be localized and would cease when Project construction is complete. For context, the incremental construction emissions contributed by the Proposed Action within the OCS Air Permit Area would result in a 1.0% to 4.0% increase in regulated pollutants that are currently emitted due to highway vehicle emissions in Suffolk County.

Air quality impacts from O&M of the Proposed Action, provided in Table 3.3.1-8 and Table 3.3.1-9, would be combined with the air quality impacts from all other O&M activities that may occur under the No Action alternative (see Table 3.3.1-5), albeit at lower emission quantities as compared to the construction and installation period. Total cumulative operation-related air emissions from all of the planned wind projects, including the Proposed Action, in the OCS Air Permit Area would consist of an estimated 2,339 tons of NO_x, 5 tons of SO_2, 568 tons of PM_{10}, and 166,574 tons of CO_2. Compared to electrical utilities' fuel combustion emissions in Suffolk County, however, the incremental O&M emissions contributed by the Proposed Action within the OCS Air Permit Area would only result in a 1.0% to 5.0% increase in regulated pollutants. O&M emissions would incrementally add emissions in localized areas, several times per year, for the lifetime of the Project.

Air quality in the region could be improved in the long term because an additional operating wind farm would offset emissions from fossil fuel–generated energy sources. As presented in Table 3.3.1-10, the Proposed Action would avoid an estimated 234 tons of NO_x, 164 tons of SO_2, and 217,653 tons of CO_2 every year by providing energy generation that existing fossil fuel–generated energy sources would have otherwise provided (EPA 2020b). This represents up to an estimated 1.6% to 2.4% increase in avoided emissions over the No Action alternative on an annual basis.

The Proposed Action would also have an incremental contribution on existing GHG emissions. The construction and installation, O&M, and the eventual conceptual decommissioning of the Proposed Action would cause a 1% to 4% increase in CO_2 emissions over the No Action alternative within the OCS Air Permit Area. However, these contributions would be negligible compared to aggregate global emissions. In 2019, U.S. GHG emissions totaled 6,558 million metric tons of CO_2e (EPA 2021). The Proposed Action could also contribute to a long-term net decrease in GHG emissions because fossil fuel–generated energy facilities reduce operations from the increased energy generation from offshore wind projects.

Based on above findings, the Proposed Action when combined with past, present, and reasonably foreseeable projects would result in minor to moderate cumulative impacts to air quality due to air emissions, as well as a long-term minor beneficial impact to climate change due to reduced reliance on fossil fuel-generated energy sources.

Accidental releases: Accidental releases of air emissions could also occur from potential Project chemical spills. Surface evaporation of these potential chemical spills could lead to short-term, localized periods of toxic pollutant emissions. However, the potential volumes of oils, lubricants, and diesel spilled would result in very small emissions of pollutants into the atmosphere relative to construction and installation, O&M and conceptual decommissioning activities (see Section 3.3.2.2.3). BOEM estimates that the

Project would result in a negligible 2% incremental increase in total chemical usage over the No Action alternative. For this reason, the incremental additional of accidental releases from the Proposed Action would not contribute appreciably to overall impacts on air quality. Therefore, the Proposed Action when combined with past, present, and reasonably foreseeable projects would result in negligible cumulative impacts to air quality due to accidental releases.

Conclusions

Project construction and installation and conceptual decommissioning would temporarily increase air emissions. Emissions from Project O&M would be much lower than those produced during construction and installation and conceptual decommissioning but could also result in limited emissions, primarily from vehicle and vessel traffic. BOEM anticipates the impacts resulting from the Proposed Action alone would range from **minor** to **moderate**. Project O&M would also generate long-term, **minor** beneficial impacts by providing energy to the region from a renewable resource and reducing health events due to air pollution. Therefore, BOEM expects the overall impact on air quality from the Proposed Action alone to be **minor** because the overall effect would be small and would recover completely without remedial or mitigating action.

In the context of other reasonably foreseeable environmental trends and planned actions, the incremental impacts under the Proposed Action resulting from individual IPFs would range from **negligible** to **moderate** adverse and **minor beneficial**. Considering all the IPFs together, BOEM anticipates that the overall impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would result in **minor** adverse impacts and **minor beneficial** impacts to air quality. BOEM made this call because the overall effect would be small and the resource would recover completely from adverse impacts.

3.3.1.2.4 VESSEL TRANSIT LANE ALTERNATIVE

The Transit alternative would result in impacts on air quality from air emission and inadvertent spills due to construction and installation, O&M, and conceptual decommissioning. However, construction under this alternative could result in a decrease in Project-related emissions if SFW requires less trenching and/or vessel traffic to install the reduced number of WTGs and their associated inter-array cables. Therefore, emissions from construction and installation would be minor to moderate, temporary, and reduced through implementation of EPMs (see Table G-1 in Appendix G). Additionally, although SFW would construct fewer WTGs under this alternative, SFW could use 12-MW WTGs to meet their 130-MW power purchase agreement. Therefore, during O&M, this alternative would also result in long-term beneficial impact on air quality by providing energy to the region from a renewable resource and reducing the region’s reliance on fossil fuels and reducing health events.

Cumulative Impacts

As noted above, the Transit alternative would result in incremental impacts to air quality at quantities and durations similar to, or slightly reduced from, the Proposed Action. Therefore, the overall cumulative impacts of this alternative to air quality when combined with past, present, and reasonably foreseeable activities would be temporary, negligible to minor, and adverse during construction and installation, and long-term, minor, and beneficial during operations.

If the Transit alternative is implemented, the WTGs for other reasonably foreseeable offshore wind projects may need to be relocated or eliminated within lease areas to avoid the transit lanes. These shifts could shorten or increase vessel trips, transmission cable lengths, and installation times for other future projects, depending on what WTG changes occur. If WTG shifts require additional fossil fuel consumption for vessel and equipment activity, these effects could increase cumulative, construction-related air emissions relative to the Proposed Action. Conversely, if these shifts result in WTG reductions that reduce fuel-consuming activities, these effects could decrease cumulative, construction-related air quality impacts relative to the Proposed Action.

Conclusions

Although the Transit alternative would reduce the number of WTGs and their associated inter-array cables, which would have an associated reduction in associated vessel and equipment use and air emissions, BOEM expects that the impacts resulting from the alternative alone would be similar to the Proposed Action and range from **minor** to **moderate** due to air emissions related to construction activities. Project O&M would also generate long-term, **minor beneficial** impacts by providing energy to the region from a renewable resource and reducing health events due to air pollution.

In the context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that the Transit alternative's incremental impacts would be similar to the Proposed Action (with individual IPFs leading to impacts ranging from **negligible** to **moderate** and **minor beneficial**). The overall impacts of the Transit alternative when combined with past, present, and reasonably foreseeable activities would therefore be the same level as under the Proposed Action: **minor** adverse impacts and **minor beneficial** impacts to air quality. BOEM made this call because the overall effect would be small, and the resource would recover completely from adverse impacts.

3.3.1.2.5 FISHERIES HABITAT IMPACT MINIMIZATION ALTERNATIVE

The Habitat alternative under either layout option would result in impacts on air quality from air emission and inadvertent spills due to construction and installation, O&M, and conceptual decommissioning. However, construction under this alternative could result in a decrease in Project-related emissions due to less trenching and/or vessel traffic to install the reduced number of WTGs and their associated inter-array cables. Therefore, emissions from construction and installation would be minor to moderate, temporary, and reduced through implementation of EPMs (see Table G-1 in Appendix G). Additionally, SFW could use 12-MW WTGs to meet their 130-MW power purchase agreement. Therefore, during O&M, this alternative would also result in long-term beneficial impact on air quality by providing energy to the region from a renewable resource and reducing the region's reliance on fossil fuels and reducing health events.

Cumulative Impacts

As noted above, the Habitat alternative under either layout option would result in incremental impacts to air quality at quantities and durations similar to, or slightly reduced from, the Proposed Action. Therefore, the overall cumulative impacts of this alternative to air quality when combined with past, present, and reasonably foreseeable activities would be temporary, negligible to minor, and adverse during construction and installation, and long term and beneficial during operations.

Conclusions

Although the Habitat alternative under either layout option would reduce the number of WTGs and their associated inter-array cables, which would have an associated reduction in associated vessel and equipment use and air emissions, BOEM expects that the impacts resulting from the alternative alone would be similar to the Proposed Action and range from **minor** to **moderate** due to air emissions related to construction activities. Project O&M would also generate long-term, **minor beneficial** impacts by providing energy to the region from a renewable resource and reducing health events due to air pollution.

In context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that the Habitat alternative's incremental impacts would be similar to the Proposed Action (with individual IPFs leading to impacts ranging from **negligible** to **moderate** and **minor beneficial**). The overall impacts of the Habitat alternative under either layout option when combined with past, present, and reasonably foreseeable activities would therefore be the same level as under the Proposed Action: **minor** adverse impacts and **minor beneficial** impacts to air quality. BOEM made this call because the overall effect would be small, and the resource would recover completely from adverse impacts.

3.3.1.3 Action Alternative Comparison

As discussed above, the impacts associated with Proposed Action alone do not change substantially under other evaluated action alternatives. Although the number of WTGs and their associated inter-array cables vary slightly, BOEM expects that air quality impacts would range from **minor** to **moderate** and **minor beneficial** for all action alternatives. The main driver for the adverse impact rating is air emissions related to construction activities. However, all action alternatives would result in a net decrease in overall emissions over the region compared to the installation of a traditional fossil fuel power generating station.

In context of reasonably foreseeable environmental trends and planned actions, all action alternatives would occur within the same overall environment (e.g., ongoing and future activities). Therefore, impacts would only vary if the alternatives' incremental contributions differ. However, as noted above, BOEM expects that the incremental impact from any action alternative would be similar, with the level of individual impacts ranging from **negligible** to **moderate** and **minor beneficial**. Therefore, the overall impact of any action alternative when combined with past, present, and reasonably foreseeable activities would be **minor** and **minor beneficial**. BOEM made this call because the overall effect would be small, and the resource would recover completely from adverse impacts.

3.3.1.4 Mitigation

No potential additional mitigation measures for air quality are identified in Appendix G.

3.3.2 Water Quality

3.3.2.1 Affected Environment

3.3.2.1.1 ONSHORE SURFACE WATER

The onshore analysis area is located within the Georgica Pond-Frontal Atlantic Ocean subwatershed (Hydrologic Unit Code [HUC] 020302020606) and Moriches Bay-Atlantic Ocean subwatershed (HUC-020302020902). The Georgica Pond-Frontal Atlantic Ocean subwatershed falls within the western portion of the analysis area, which includes five named and 13 unnamed surface waterbodies or segments (Figure C-2 in Appendix C). The Moriches Bay-Atlantic Ocean subwatershed encompasses the entire eastern portion of the analysis area, which includes one named and seven unnamed surface waterbodies. Within these two subwatersheds, two waterbodies that fall within the analysis area are currently listed as impaired. Fairfield Pond (Class C [supports fisheries and suitable for non-contact activities]) and Georgica Pond (Class SA [saline waters; shellfishing for market purposes; primary and secondary contact recreation and fishing]) were listed as impaired in 2016 because of low dissolved oxygen (DO) from undetermined causes and pathogens from agricultural sources, respectively (New York State Department of Environmental Conservation [NYSDEC] 2016a, 2016b).

3.3.2.1.2 ONSHORE GROUNDWATER

The Long Island aquifer supplies groundwater to the onshore analysis area and is designated by the EPA as a sole source aquifer, meaning it serves as a primary drinking water resource. Special Groundwater Preserve Areas, which are critical areas identified by NYSDEC (2019a) for protection because of their roles in providing drinking water resources, recharging groundwater, or protecting groundwater, are also located in the analysis area. Groundwater is measured at approximately 40 feet below grade at the proposed interconnection facility and is relatively shallower along the two onshore South Fork Export Cable (SFEC) routes, with the depth to groundwater being approximately 4 to 5 feet around the landing sites (Beach Lane and Hither Hills).

Overall, existing groundwater quality in the analysis area appears to be good and meets NYSDEC (2018) groundwater quality standards. However, as indicated by NYSDEC (2021a), four NYSDEC Environmental Remediation Sites are mapped near the interconnection facility (NYSDEC 2021b). Sampling and analysis at the following three sites have not confirmed or revealed elevated or significant remaining contamination: NYSDEC #152156, which served as an airport hangar for the East Hampton Airport before it was abandoned in 1991; NYSDEC #152213 (the Hortonsphere site), a gas storage facility east of the proposed interconnection facility and upgradient of the onshore SFEC route from the Hither Hills landing site; and NYSDEC #152219, a former gasoline refinery facility that predates the 1930s. These sites are therefore not a concern for the onshore SFEC route. Sampling at the fourth site, NYSDEC #152250, has indicated the presence of perfluorinated compounds. Site-related compounds have been identified in soil and groundwater within and around the site.

3.3.2.1.3 OFFSHORE WATERS

Offshore waters comprise coastal waters (e.g., ports/harbors, rivers, bays, and estuaries; marine waters) located within the state territory (within 3 nm of shore) and within the federal waters. The coastal waters, including the Long Island Sound and Atlantic Ocean, are located offshore and include existing port facilities in New York, Rhode Island, Massachusetts, Connecticut, New Jersey, Maryland, and/or Virginia that could be used for the Project. Marine waters are considered temperate because of their highly seasonal variations in temperature, stratification, and productivity. Water currents in the analysis area generally flow southwest, although bottom water currents may flow northward. Currents near the shoreline flow east. Average year-round surface currents were measured at approximately 8 inches per second, with the strongest currents measured at 20 inches per second (Fugro 2021).

NOAA (2021a, 2021b, 2021c) reported increases in relative sea level trends at three tide stations along the Long Island coast, with increases over the 1947 to 2020 period ranging from approximately 2.3 millimeter (mm)/year at Kings Point, NY to 3.41 mm/year at Montauk, NY. This information was collected using NOAA Tides and Currents data (https://tidesandcurrents.noaa.gov/). Higher sea levels in addition to storm surges, which are increasing in both frequency and magnitude, have contributed to coastal erosion on Long Island that in turn have eroded Long Island’s shorelines and increased susceptibility to flooding (New York Sea Grant 2018).

Offshore water quality is characterized by temperature, salinity, DO, nutrients, chlorophyll *a*, and turbidity. These parameters, which are described in detail in COP Section 4.2.2, influence coastal and marine environments and are indicators of ecosystem health.

Water quality in the Long Island Sound has improved over the last decade and is rated as “very good” with the exception of the western-most portion, which has been experiencing water quality degradation from nutrient (nitrogen) pollution (University of Maryland 2018). Coastal waters off Rhode Island, including Narragansett Bay and nearby coastal ponds, have also experienced degraded water quality from nutrients and storm water runoff carrying contaminants (Rhode Island Division of Planning 2016). Water quality in the area generally improves north to south with distance from pollutant sources in urbanized areas. The water quality of the coastal waters ranging from Maine to North Carolina, which include the SFWF and offshore SFEC, was rated as “good” to “fair” (EPA 2012). EPA surveyed four sites within the Block Island Sound and near the Lease Area. These surveys revealed surface and bottom water DO concentrations above established levels for the “highest quality marine waters.” Chlorophyll *a* was found at slightly elevated levels, resulting in “fair” water quality conditions. Currents and storms contribute to turbidity throughout the water column from the resuspension of clay, silt, and fine-grained sand making up the sediment. Federal marine waters typically have very low concentrations of total suspended solids (TSS). Little information exists on algal and bacteria dynamics within the analysis area. However, there have been no documented reports of harmful algal blooms or waterborne pathogen outbreaks (EPA 2012). Temperature of offshore waters fluctuates seasonally. Water temperatures are highest in July and August, with surface waters at approximately 68 degrees Fahrenheit (°F) and bottom waters at 50°F, and lowest in the winter, with surface waters at approximately 39°F to 41°F. Salinity also fluctuates throughout the year with lower concentrations in the spring because of water inflows from ice melt and precipitation and higher concentrations in the fall and winter. See Section 4.2.4 of the COP for additional information regarding physical oceanographic and meteorological conditions within the Lease Area.

Contaminants could also reside within the sediment column and contribute to water quality conditions. However, 12 cores obtained within the state marine waters for the offshore SFEC and analyzed for an array of anthropogenic contaminants did not reveal contamination, and the sediment met the Class A (No Appreciable Contamination) as defined in the Sediment Quality Thresholds described in the *Technical Guidance for Screening Contaminated Sediments* (NYSDEC 1999).

3.3.2.2 Environmental Consequences

3.3.2.2.1 ISSUES, INDICATORS, AND SIGNIFICANCE CRITERIA

Table 3.3.2-1 lists the issues identified for this resource and the indicators and significance criteria used to assess impacts for this final EIS.

Table 3.3.2-1. Issues, Indicators, and Significance Criteria Used to Assess Impacts to Water Quality

Issue	Impact Indicator	Significance Criteria
Runoff, sedimentation, sediment movement, suspension or resuspension, changes to stratification or mixing patterns of sediments, or spills of hazardous materials	Changes to turbidity, nutrients, DO, temperature, salinity, and/or Chlorophyll *a* Introduction of new contaminants/oil or changes to sediments, or changes in flows	Negligible: Changes would be undetectable. Minor: Changes would be detectable but would not result in degradation of water quality in exceedance of water quality standards. Moderate: Changes would be detectable and would result in localized, short-term degradation of water quality in exceedance of water quality standards. Major: Changes would be detectable and would result in extensive, long-term degradation of water quality in exceedance of water quality standards.
Disturbance or seepage to groundwater resources		

3.3.2.2.2 NO ACTION ALTERNATIVE

The Affected Environment section provides information on existing water quality trends from past and present activities. Attachment 2 in Appendix E provides additional information regarding past and present activities and associated water quality impacts. Future non-Project onshore sources of water pollution include electrical transmission lines, port development and expansion, and U.S. Army Corps of Engineers

(USACE) shore development and cleanup projects. Future non-Project offshore sources of water pollution include an undersea transmission line, a gas pipeline, submarine cable projects, one tidal energy project (the Roosevelt Island Tidal Energy Project), vessel traffic, and offshore wind projects. Attachment 2 in Appendix E also discloses future non–offshore wind activities and associated water quality impacts. Impacts associated with future onshore activities and future offshore wind activities are described below.

Onshore Future Activities (without the Proposed Action)

Reasonably foreseeable onshore activities could contribute to changes in water quality from erosion and sedimentation, discharges, and dispersal of contaminants during routine spills (i.e., spills less than 10 barrels, or 420 gallons) or accidental release of contaminated or hazardous materials or debris. These activities would be expected to comply with any applicable permit requirements to implement erosion, storm water, and spill controls to minimize, reduce, or avoid impacts on water quality. Degradations to onshore water quality from future onshore activities are expected to be localized and temporary to long term, depending on the nature of the activities, although overall water quality is expected to continue to meet NYSDEC (2018) water quality standards. Onshore water quality of impaired waterbodies, including Fairfield and Georgica Ponds, would also be maintained or improved through established total maximum daily loads (NYSDEC 2016a, 2016b). Other surface and ground waterbodies would be monitored and managed to meet water quality standards and drinking water resource protections. Ongoing onshore water quality impacts from these activities are anticipated to continue regardless of the offshore wind industry. As a result, adverse impacts from future activities on onshore water quality under the No Action alternative would be temporary to long term and minor to moderate.

Some onshore future projects, such as flood risk management, storm preparedness, climate adaptation planning, and sediment management projects identified in Appendix E could result in beneficial impacts to onshore water quality through reductions in erosion, sedimentation, storm water runoff, and flooding. Improvements to onshore water quality from these future projects could be localized or widespread, depending on the nature of the activities, and long term. Ongoing benefits to onshore water quality from these activities would continue regardless of the offshore wind industry. As a result, impacts from these future activities on onshore water quality under the No Action alternative would be long term, minor, and beneficial.

Offshore Future Activities (without the Proposed Action)

<u>Accidental releases and discharges</u>: Future offshore wind activities could contribute to changes in offshore water quality from a spill or release during routine vessel or equipment use, spill at an offshore wind facility, spill during construction due to a vessel allision or collision, or the accidental discharge of trash and debris.

Based on assumed construction schedules (see Appendix E), numerous offshore wind projects could occur with overlapping construction schedules between 2022 and 2030. This final EIS estimates that up to approximately 760,000 gallons of coolants and 1.9 million gallons of oils and lubricants could be stored within WTG foundations and the offshore substation (OSS) within the water quality geographic analysis area. A total of approximately 2.3 million gallons of coolants and 10.5 million gallons of oils and lubricants could be stored within WTG foundations and the OSS across all projected offshore wind projects along the Atlantic coast. Other chemicals, including grease, paints, and sulfur hexafluoride, would also be used at the offshore wind projects. BOEM anticipates that the likelihood of a major spill of these chemicals during construction is very low (once per 1,000 years) due to vessel allisions, collisions, O&M activities, or weather events (Bejarano et al. 2013). All future offshore wind projects would be required to comply with regulatory requirements related to the prevention and control of accidental spills administered by the USCG and the Bureau of Safety and Environmental Enforcement. Oil Spill Response

Plans are required for each project and would provide for rapid spill response, clean-up, and other measures that would help to minimize potential impact on affected resources from spills. WTGs and the OSS are generally self-contained and would not generate discharge. Vessels would also have their own onboard containment measures that would further reduce the impact of an allision. A release during construction or operation would generally be localized, short term, and result in little change to water quality. In the unlikely event an allision or collision involving project vessels or components resulted in a large spill, impacts on water quality would be minorly to moderately adverse, and short term to long term, depending on the type and volume of material released and the specific conditions (e.g., depth, currents, weather conditions) at the location of the spill.

Accidental releases of trash and debris would be infrequent and negligible because operators would comply with federal and international requirements for management of shipboard trash. All vessels would also need to comply with the USCG ballast water management requirements outlined in 33 CFR 151 and 46 CFR 162; allowed vessel discharges such as bilge and ballast water would be restricted to uncontaminated or properly treated liquids.

<u>Anchoring</u>: Offshore wind activities would contribute to changes in offshore water quality from resuspension and deposition of sediments during anchoring. BOEM estimates that approximately 41 acres of seabed could be impacted by anchoring under the No Action alternative within the water quality geographic analysis area. Disturbances to the seabed during anchoring would temporarily increase suspended sediment and turbidity levels in and immediately adjacent to the anchorage area. As described in Section 3.3.2.1.3, currents and storms currently contribute to turbidity throughout the water column from the resuspension of clay, silt, and fine-grained sand making up the sediment. As a result, adverse impacts on offshore water quality under the No Action alternative would be minor and temporary.

<u>New cable emplacement/maintenance</u>: BOEM estimates that approximately 1,291 acres of seabed could be impacted by cable placement under the No Action alternative within the water quality geographic analysis area due to reasonably foreseeable offshore wind development. As described under anchoring, these activities would contribute to changes in offshore water quality from the resuspension and deposition of sediment. Sediment modeling for the Proposed Action indicates that sediment suspension and deposition would occur within an approximate 1-acre area and would settle shortly (hours to days) after their release (Vinhateiro et al. 2018). BOEM anticipates that future offshore wind projects would use dredging only when necessary and rely on other cable laying methods for reduced impacts (such as jet plow or mechanical plow) where feasible. For these reasons, sediment suspension associated with other wind projects would be localized, minor, and temporary.

<u>Port utilization</u>: Offshore wind development would use nearby ports, and could also require port expansion or modification, resulting in increased vessel traffic or increased suspension and turbidity from any in-water work. These activities could also increase the risk of accidental spills or discharge. However, these actions would be localized and port improvements would comply with all applicable permit requirements to minimize, reduce, or avoid impacts on water quality. As a result, adverse impacts on offshore water quality under the No Action alternative would be short to long term but minor.

<u>Presence of structures</u>: Reasonably foreseeable offshore wind projects are estimated to result in no more than 412 structures by 2030 within the water quality geographic analysis area. These structures could disturb up to 360 acres of seabed within the water quality geographic analysis area from foundation and scour protection installation and disrupt bottom current patterns leading to increased movement, suspension, and deposition of sediments. Scouring, which could lead to impacts on water quality through the formation of sediment plumes (Harris et al. 2011), would generally occur in shallow areas with tidally dominated currents. Structures may reduce wind-forced mixing of surface waters, whereas water flowing around the foundations may increase vertical mixing (Carpenter et al. 2016; Cazenave et al. 2016).

Alterations in currents and mixing would affect water quality parameters such as temperature, DO, and salinity, but would vary seasonally and regionally. WTGs and the OSS associated with reasonably foreseeable offshore wind projects would be placed in average water depths of 100 to 200 feet where current speeds are relatively low, and offshore cables would be buried where possible. Cable armoring would be used where burial is not possible, such as in hard-bottomed areas. BOEM anticipates that developers would implement best management practices to minimize seabed disturbance from foundations, scour, and cable installation. As a result, adverse impacts on offshore water quality under the No Action alternative would be localized, short term, and minor.

Conclusions

Under the No Action alternative, BOEM would not approve the COP; Project construction and installation, O&M, and conceptual decommissioning would not occur; and potential impacts on water quality associated with the Project would not occur. However, ongoing and future activities would have continuing temporary to long-term impacts on water quality from onshore erosion and sedimentation, discharges, dispersal of contaminants during routine spills as well as offshore spills or discharge, resuspension and deposition of sediments, scouring, or changes to current patterns and mixing.

BOEM anticipates that the range of impacts for reasonably foreseeable offshore wind activities and onshore activities would be **minor to moderate**, due to short-term erosion and sedimentation, discharges, and dispersal of contaminants during routine spills, and **minor beneficial** from shoreline improvements. As described in Attachment 2 in Appendix E, BOEM anticipates that the range of impacts for ongoing activities and reasonably foreseeable offshore activities other than offshore wind would be **minor** to **moderate**, due to temporary or short-term disturbance to sediments during construction activities.

Considering all the IPFs together, BOEM anticipates that the impacts associated with future offshore wind activities in the geographic analysis area combined with ongoing activities, reasonably foreseeable environmental trends, and reasonably foreseeable activities other than offshore wind would result in **minor** adverse impacts because the effects would be small and the resource would recover completely.

3.3.2.2.3 PROPOSED ACTION ALTERNATIVE

Construction and Installation

Onshore

Construction of the onshore portion of the Project would require temporary (up to 12 months) ground-disturbing activities including surficial digging, land clearing, trenching, HDD, use of equipment and vehicles, and installation of permanent (over the life of the Project) onshore infrastructure (e.g., underground transmission/export cables, O&M facility, and interconnection facility). Fill materials would be used for installation of structures. Equipment and vehicles would require the use of fuels and oils during onshore construction. Dredging to a depth of 12.4 feet below mean lower low water would be required at the Montauk O&M facility to allow for suitable depths for navigation and berthing. Initial dredging would occur during construction, and intermittent dredging would occur throughout maintenance.

None of the onshore Project facilities or SFEC routes directly intersect any surface waterbodies. However, onshore construction activities upgradient of surface waterbodies would expose soils and sediments, resulting in potential erosion and sedimentation into onshore surface waters and changes to flows that could affect water quality. Onshore ground disturbance during construction would also require the disturbance of soils near existing remediation sites. In addition, infrastructure construction would result in the long-term increase in impervious surfaces in the onshore water quality analysis area. If disturbed or eroded soils or fill materials contain pollutants or contaminants, their direct release or indirect deposition in onshore surface waters could also lead to degradations to water quality, particularly for waterbodies with existing impairments, the causes of which could be exacerbated with additional pollutant loads. However, total maximum daily loads established for impaired waterbodies and continued water quality monitoring would help identify and manage water quality degradations, should they occur. Dredging may temporarily result in increased turbidity; however, in addition to navigation improvements, dredging material from the navigation channel would be placed in shoreline areas that have experienced erosional damages, thereby offering long-term coastal storm risk management benefits. Section 4.2.2.3 of the COP includes features that would avoid or minimize impacts on water quality, including encasement of the cable in areas where HDD is required. New impervious surfaces as a result of infrastructure would be minimal (up to 4 acres) compared to the extent of the entire analysis area. Onshore SFEC routes would also be located within public roadways and the Metropolitan Transportation Authority–owned LIRR ROW, or along roadway corridors that are characterized as impervious road surfaces or railroad beds, thereby minimizing impacts to undisturbed areas. Because overall construction activities and infrastructure would disturb more than 1 acre, discharges would be permitted through a general construction permit under the National Pollutant Discharge Elimination System program. SFW would also develop a storm water pollution prevention plan (SWPPP) as part of the permitting process that would result in implementation of erosion and sediment controls prior to and during construction. Placement of dredged material on shorelines could result in temporary turbidity but would also help with beach erosion and provide coastal storm risk protections. Therefore, any adverse impact on water quality would be temporary and minor.

Fuels and oils would be required for onshore construction equipment and vehicles and for infrastructure. Most inadvertent spills of fuels and oils used during construction would be classified as routine because of their size (i.e., spills less than 10 barrels, or 420 gallons) and rapid dispersion (BOEM 2015). Routine spills could lead to direct (spill directly into waterbody) or indirect (spill reaches waterbody through soil erosion or water runoff) degradations to water quality in surface waterbodies downgradient of the onshore route or infrastructure. As previously noted, Table G-1 in Appendix G includes EPMs to avoid or minimize potential spill impacts on water quality, comply with all general construction permit requirements, and implement runoff controls and buffers. In addition, SFW would develop and implement a spill prevention control and countermeasures (SPCC) plan and HDD inadvertent release plan to protect nearby surface waters. Although these procedures would reduce the likelihood and extent of routine spills, spills in or near surface waterbodies would contribute to detectable changes that could result in an exceedance of water quality standards. Therefore, the adverse impact on water quality would be short term and minor to moderate, depending on the severity of potential spills or releases.

There are no onshore construction activities under the Proposed Action that would require ground disturbance at depths at or near groundwater resources, and all activities would meet permit and regulatory requirements to continue protecting groundwater as drinking water resources. The use of HDD at the landing sites would negate the need for trenching in areas where shallow groundwater would intersect the trench excavation. Onshore subsurface ground-disturbing activities would not be placed at a depth that could encounter groundwater, and would therefore not result in impacts on water quality. As described for onshore surface water, potential spills would be avoided or managed through an SPCC plan and HDD inadvertent release plan and proper storage and handling procedures. Therefore, adverse impacts on groundwater quality would be short term and minor to moderate, depending on the severity of potential spills or releases.

Offshore

Construction of the offshore portion of the Project would require temporary (up to 12 months) seafloor-disturbing activities including trenching, boulder relocation, HDD, use of equipment and vessels, vessel mooring/anchoring, dredging (depending on the port selected), and installation of in-water infrastructure (turbine foundations, transmission/export cables, and electrical service platform). Equipment and vessels would require the use of fuels and oils during offshore construction. The total area of the foundation footprint and scour protection is provided in Appendix D under the maximum-case scenario.

Offshore construction activities would contribute to the movement and resuspension of sediments into the water column. This movement and resuspension would contribute to turbidity, and deposition of these sediments would directly affect water quality or indirectly affect water quality through changes in flows. If sediments contain pollutants or contaminants, their resuspension would lead to degradations of water quality. Installation activities for turbine foundations on the seafloor could disrupt bottom current patterns, resulting from or leading to increased movement, suspension, and deposition of sediments (see Section 3.4.2 Benthic Habitat, Essential Fish Habitat, Invertebrates, and Finfish).

EPMs in Table G-1 in Appendix G would avoid or minimize impacts on water quality, and SFW would comply with all permit and regulatory requirements related to water quality. Vessels that support Project activities would be large enough to be subject to USCG regulations regarding waste and discharge. Foreign-flagged vessels would also have a USCG-compliant and certified ballast water management system. Any disturbance to sediment from vessel mooring/anchoring would be negligible because of the limited duration (minutes to hours) and magnitude (a total of 821 acres, limited to the immediate area where vessel mooring/anchoring would contact the seafloor) of disturbance. Modeling of the extent and timing of other offshore sediment releases concluded that sediment suspension and deposition would occur within an approximate 1-acre area and would settle shortly (hours to days) after their release (Vinhateiro et al. 2018). For these reasons, sediment suspension would be localized and temporary. Changes to water quality would be detectable but would not result in degradation of water quality that would exceed water quality standards. SFW-modeled TSS levels expected to result from offshore Project construction (Fugro 2019, 2021). Model results indicated that elevated TSS plumes could extend 330 feet and last up to 1 hour before returning to background levels. Elliott et al. (2017) monitored TSS levels during construction of the Block Island Wind Farm (BIWF). The observed TSS levels were far lower than levels predicted using the same modeling methods, dissipating to baseline levels less than 50 feet from the disturbance. Both the modeled and the observed TSS effects were short term in duration. Construction dredging activities at the Montauk O&M facility would temporarily increase TSS levels up to 100 milligrams (mg)/L (Vinhateiro et al. 2018) over the duration of activity. Existing restoration and protection initiatives established for offshore areas, including those developed as part of the Long Island Sound Study initiative (Long Island Sound Study 2019), would help identify and manage water quality degradations, should they occur. Therefore, the adverse impact on water quality would be temporary and minor.

Offshore construction equipment, vessels, and infrastructure would require fuels and oils over the construction period. As described for onshore waters, most inadvertent spills in offshore waters during construction would be classified as routine and minor, such as the release of fuels and oils from vessels or turbines, which would disperse rapidly. In addition, secondary containment measures would be implemented for all diesel tanks at WTGs. Under the Project, the highest possible spill would be the inadvertent release of fuels and oils stored at WTGs and OSS, which would contain up to 2,582 gallons of fuels and oils. Project EPMs (see Table G-1 in Appendix G), permit requirements, controls, and procedures described above to reduce the potential or extent of onshore spills would also be applied in offshore waters, thereby avoiding or minimizing impacts on water quality. Should a spill occur, response and containment procedures would limit the reach of the spill to a localized area, where changes to water quality would be detectable and would exceed water quality standards. As a result, adverse impacts on water quality would be short term, with spills generally dispersing within days (BOEM 2013), and minor to moderate, depending on the severity of the spill. The Project could also result in accidental releases of trash and debris; however, these releases would be infrequent and negligible because operators would comply with federal and international requirements for management of shipboard trash, and the extent of an accidental release would be limited to the localized area.

Operations and Maintenance and Conceptual Decommissioning

Onshore

O&M and conceptual decommissioning of the onshore portion of the Project would include the same permit requirements and erosion, storm water, and spill controls as described for onshore construction activities and would lead to the same types of minor to moderate adverse impacts on surface water and groundwater quality from erosion, sedimentation, and inadvertent spills or releases. Impacts on water quality during O&M would be less in terms of frequency and intensity than impacts during construction and conceptual decommissioning.

Offshore

O&M and conceptual decommissioning of the offshore portion of the Project would include the same permit requirements and sediment controls as described for offshore construction activities and would lead to the same types of minor adverse impacts on water quality from sediment resuspension, deposition, and minor to moderate adverse impacts on water quality from inadvertent spills. Spills would be temporarily detectable and would disperse rapidly, thereby limiting the magnitude and extent of changes to water quality.

The presence of structures during O&M could disrupt bottom current patterns leading to scour from the increased movement, suspension, and deposition of sediments. Project EPMs (see Table G-1 in Appendix G), permit requirements, controls, and procedures described above for reducing or avoiding changes to sediment would also be applied during operation. Disturbed sediments would be limited to a localized area (within approximately 1 acre) and would settle shortly (hours to days) after their release. Alterations in currents and mixing would affect water quality parameters such as temperature, DO, and salinity, but would vary seasonally and regionally. Changes to water quality would be detectable but would not result in degradation of water quality that would exceed water quality standards. Therefore, the adverse impact on water quality would be temporary and minor.

Cumulative Impacts

Onshore

The Proposed Action would result in minor to moderate incremental impacts to onshore water quality impacts on surface water and groundwater due to erosion and sedimentation, discharges, and dispersal of contaminants during routine spills (i.e., spills less than 10 barrels, or 420 gallons) or inadvertent releases. The Proposed Action would also incrementally add to other onshore habitat disturbance actions through the development of 2.4 acres for the interconnection facility and redevelopment of a small area (0.1 acre) of land at the selected O&M facility. State and local agencies would be responsible for minimizing and avoiding water quality and other impacts during construction. The Project and other reasonably foreseeable projects would be expected to comply with any applicable permit requirements to implement erosion, storm water, and spill controls to minimize, reduce, or avoid impacts on water quality. As a result, the Proposed Action when combined with past, present, and other reasonably foreseeable projects would result in short-term, and minor to moderate cumulative impacts on onshore water quality.

Offshore

Accidental releases and discharge: The Proposed Action could incrementally add accidental releases of fuel, fluids, or hazardous material; sediment; and/or trash and debris to conditions under the No Action alternative. BOEM estimates that the Project would result in up to 5% increase in total chemical usage over the No Action alternative within the water quality geographic analysis area. This risk would be increased primarily during construction but also during O&M and conceptual decommissioning. When the Project is combined with other offshore wind projects, up to approximately 770,000 gallons of coolants and 2.1 million gallons of oils and lubricants could cumulatively be stored within WTG foundations and the OSS within the water quality geographic analysis area. All vessels associated with the Proposed Action and other offshore wind projects would comply with the USCG requirements for the prevention and control of oil and fuel spills. Additionally, training and awareness of EPMs (see Table G-1 in Appendix G) proposed for waste management and mitigation of marine debris would be required of SFWF Project personnel. These releases, if any, would occur infrequently at discrete locations and vary widely in space and time. For this reason, the Proposed Action, when combined with other past, present, and reasonably foreseeable projects, would result in minor to moderate and short-term or long-term impacts.

Anchoring: The Proposed Action would result in localized, temporary, minor incremental impacts to water quality through an estimated 821 acres of anchoring and mooring-related disturbance, which would temporarily increase suspended sediment and turbidity levels in and immediately adjacent to anchorage areas. The Proposed Action would add to the estimated 41 acres of seabed that could be impacted by anchoring from other reasonably foreseeable offshore wind activities. This would result in a cumulative total of 862 acres of anchoring-related disturbance for the Proposed Action plus all other future offshore wind projects. Therefore, the Proposed Action when combined with past, present, and reasonably foreseeable projects would result in minor cumulative impacts to water quality.

New cable emplacement/maintenance: The Proposed Action would result in localized, short-term, minor incremental impacts to water quality through an estimated 913 acres of seafloor disturbance from SFEC and inter-array cable installation. This would result in additional turbidity effects, increasing seafloor disturbance due to cable installation over the No Action alternative. BOEM estimates a cumulative total of 2,204 acres of anchoring-related disturbance for the Proposed Action plus all other future offshore wind projects. Sediment modeling for the Proposed Action indicates that sediment suspension and deposition would occur within an approximate 1-acre area and would settle shortly (hours to days) after the release of sediment (Vinhateiro et al. 2018). Suspended sediment concentrations during activities other than dredging would be within the range of natural variability typical for the affected area. As a result, the Proposed Action when combined with past, present, and reasonably foreseeable projects would result in minor cumulative impacts to water quality.

Port utilization: Although dredging or in-water work for the Port of Montauk could be required for the Proposed Action, these actions would occur within heavily modified habitats. BOEM expect impacts to water quality due to the incremental increase in port expansion resulting from the Proposed Action to be negligible to minor. Other offshore wind development would use nearby ports, and could also require port expansion or modification. However, SFW and all other developers would comply with all permit requirements to avoid or minimize water quality impacts. Therefore, cumulative impacts associated with the Proposed Action and past, present, and reasonably foreseeable future activities would be negligible to minor.

Presence of structures: The Proposed Action would result in long-term, minor incremental impacts to water quality through the installation of 16 structures (15 WTGs and one OSS), as well as in-water dock structures. This represents a minor, 4% increase over total estimated WTG and OSS foundations under the No Action alternative within the geographic analysis area. BOEM estimates a cumulative total of 428 structures for the Proposed Action plus all other future offshore wind projects within the geographic analysis area. These additional structures could cumulatively add to other offshore impacts to water quality from turbidity due to scour and water current alteration. However, because of the limited extent of impacts and BOEM's expectation that SFW and other developers would comply with all applicable permit requirements to minimize, reduce, or avoid impacts on water quality, the Proposed Action when combined with past, present, and reasonably foreseeable projects would result in minor and long-term impacts to water quality.

Conclusions

Project construction and installation, O&M, and conceptual decommissioning would expose and disturb soils and sediments, resulting in potential erosion, sedimentation, or inadvertent release of contamination or hazardous materials or debris into onshore surface waters and changes to flows that could affect water quality. Offshore, Project construction and installation and conceptual decommissioning would contribute to increased movement, suspension, and deposition of sediments; changes to water column stratification; and mixing patterns that would affect water quality parameters. Impacts from Project O&M would be much lower than those produced during construction and installation and conceptual decommissioning but could also result in erosion, sediment resuspension, deposition, and inadvertent spills. BOEM anticipates the impacts resulting from the Proposed Action alone would range from **negligible** to **moderate**. Therefore, BOEM expects the overall impact on water quality from the Proposed Action alone to be **minor** because the effect would be small and the resource would be expected to recover completely without remedial or mitigating action.

In the context of other reasonably foreseeable environmental trends and planned actions, the incremental impacts under the Proposed Action resulting from individual IPFs would range from **negligible** to **moderate**. Considering all the IPFs together, BOEM anticipates that the overall impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would result in **minor** impacts to water quality. BOEM made this call as the effect would be small and the resource would be expected to recover completely.

3.3.2.2.4 VESSEL TRANSIT LANE ALTERNATIVE

The Transit alternative would not affect Project onshore activities; therefore, effects would be similar to the Proposed Action and would lead to the same types of minor to moderate adverse impacts on surface water and groundwater quality from erosion, sedimentation, and inadvertent spills.

Offshore, the Project under the Transit alternative would lead to the same types of impacts on water quality from construction and installation, O&M, and conceptual decommissioning activities as described for the Proposed Action. However, the reduced number of turbines under the Transit alternative would reduce the potential for vessel collisions or allisions with WTGs that could lead to accidental releases and result in degradations to water quality. This alternative could also result in decreased impacts to water quality during construction (due to decreased suspended sediment and turbidity) if less trenching and/or vessel traffic is needed to install a reduced number of WTGs and their associated inter-array cables. As a result, the Transit alternative would have negligible to moderate, short-term impacts on water quality related to spills, anchoring, cable emplacement and management, port expansion, structures, discharges, and sediment disturbance.

Cumulative Impacts

The Transit alternative would not affect Project onshore activities; therefore, cumulative effects would be the same as the Proposed Action and would lead to minor to moderate cumulative impacts on onshore water quality.

As noted above, the Transit alternative would result in incremental impacts to water quality at quantities and durations similar to, or slightly reduced from, the Proposed Action. Therefore, the overall cumulative impacts of this alternative to water quality when combined with past, present, and reasonably foreseeable activities would be negligible to moderate and short term, mostly as a result of construction activities. Impacts related to spills could also be long term, depending on the severity of the spill.

If the Transit alternative is implemented, the WTGs for other reasonably foreseeable offshore wind projects may need to be relocated or eliminated within lease areas to avoid the transit lanes. These shifts could shorten or increase vessel trips, transmission cable lengths, and installation times for other future projects, depending on what WTG changes occur. If WTG shifts result in changes that increase turbidity and sedimentation, alter water currents, or increase risks of inadvertent spills, these effects could increase cumulative water quality impacts relative to the Proposed Action.

Conclusions

Although the Transit alternative would reduce the number of WTGs and their associated inter-array cables, which would have an associated reduction in potential changes to movement, suspension, and deposition of sediments; water column stratification and mixing patterns, BOEM expects that the impacts resulting from the alternative alone would be similar to the Proposed Action and range from **negligible** to **moderate**.

In context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that the Transit alternative’s incremental impacts would be similar to the Proposed Action (with individual IPFs leading to impacts ranging from **negligible** to **moderate**). The overall impacts of the Transit alternative when combined with past, present, and reasonably foreseeable activities would therefore be the same level as under the Proposed Action: **minor**.

3.3.2.2.5 FISHERIES HABITAT IMPACT MINIMIZATION ALTERNATIVE

The Habitat alternative under either layout option would not affect Project onshore activities; therefore, all onshore effects would be the same as the Proposed Action and would lead to the same types of minor to moderate temporary adverse impacts on surface water and groundwater quality from erosion, sedimentation, and inadvertent spills.

Offshore, the Project under the Habitat alternative for either layout option would lead to the same types of impacts on water quality from construction and installation, O&M, and conceptual decommissioning as described for the Proposed Action. However, this alternative could result in decreased impacts to water quality during construction (due to decreased suspended sediment and turbidity) if less trenching and/or vessel traffic is needed to install a reduced number of WTGs and their associated inter-array cables. As a result, this alternative would have negligible to moderate, short-term impacts on water quality related to spills, anchoring, cable emplacement and management, port expansion, structures, discharges, and sediment disturbance.

Cumulative Impacts

The Habitat alternative under either layout option would not affect Project onshore activities; therefore, cumulative effects would be the same as the Proposed Action and would lead to minor to moderate cumulative impacts on onshore water quality.

As noted above, the Habitat alternative under either layout option would result in incremental impacts to water quality at quantities and durations similar to, or slightly reduced from, the Proposed Action. Therefore, the overall cumulative impacts of this alternative to water quality when combined with past, present, and reasonably foreseeable activities are anticipated to be negligible to moderate and short term, mostly as a result of construction activities. Impacts related to spills could also be long term, depending on the severity of the spill.

Conclusions

Although the Habitat alternative under either layout option would reduce the number of WTGs and their associated inter-array cables, which would have an associated reduction in potential changes to movement, suspension, and deposition of sediments; water column stratification and mixing patterns, BOEM expects that the impacts resulting from the alternative alone would be similar to the Proposed Action and range from **negligible** to **moderate**.

In context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that the Habitat alternative's incremental impacts would be similar to the Proposed Action (with individual IPFs leading to impacts ranging from **negligible** to **moderate**). The overall impacts of the Habitat alternative under either layout option when combined with past, present, and reasonably foreseeable activities would therefore be the same level as under the Proposed Action: **minor**.

3.3.2.3 Action Alternative Comparison

As discussed above, the impacts associated with Proposed Action alone do not change substantially under other evaluated action alternatives. Although the number of WTGs and their associated inter-array cables varies slightly, BOEM expects that water quality impacts would range from **negligible** to **moderate** for all action alternatives due to potential spills and increased movement, suspension, and deposition of sediments; changes to water column stratification; and mixing patterns that would affect water quality parameters.

In context of reasonably foreseeable environmental trends and planned actions, all action alternatives would occur within the same overall environment (e.g., ongoing and future activities). Therefore, impacts would only vary if the alternatives' incremental contributions differ. However, as noted above, BOEM expects that the incremental impact from any action alternative would be similar, with the level of individual impacts ranging from **negligible** to **moderate**. Therefore, the overall impact of any action alternative when combined with past, present, and reasonably foreseeable activities would be **minor**. BOEM made this call as the effect would be small, and the resource would be expected to recover completely.

3.3.2.4 Mitigation

If the USACE requires establishment of a no-work window for dredging at Montauk through their permitting process, some adverse impacts to water quality would be further reduced although still identified as negligible to moderate.

3.4 BIOLOGICAL RESOURCES

3.4.1 Bats

3.4.1.1 Affected Environment

Bat species consist of two distinct groups based on their overwintering strategy: cave-hibernating bats (cave bats) and migratory tree bats (tree bats). Bats are terrestrial species that spend almost their entire lives on or over land. On occasion, tree bats can occur offshore during spring and fall migration and under very specific conditions such as low wind and high temperatures. Recent studies, combined with historical anecdotal accounts, indicate that tree bats sporadically travel offshore during spring and fall migration, with 80% of acoustic detections occurring in August and September (Dowling et al. 2017; Hatch et al. 2013; Pelletier et al. 2013; Stantec 2016). However, unlike tree bats, the likelihood of detecting a *Myotis* species or other cave bat is substantially less in offshore areas (Pelletier et al. 2013). Regionally, both resident and migrant tree and cave bat species occur on islands within Nantucket Sound, indicating that overwater crossings do occur (MMS 2008).

Bat species that may occur in the offshore and onshore portions of the Lease Area include the long-distance migrants and the non-migrating cave-dwelling bats. Long-distance migrants include hoary bat (*Lasiurus cinereus*), eastern red bat (*Lasiurus borealis*), and silver-haired bat (*Lasionycteris noctivagans*).

Non-migratory cave-dwellers include northern long-eared bat (*Myotis septentrionalis*), little brown bat (*Myotis lucifugus*), eastern small-footed bat (*Myotis leibii*), big brown bat (*Eptesicus fuscus*), and tri-colored bat (*Perimyotis subflavus*) (Stantec 2018a). Species detected within the SFWF and offshore SFEC during surveys for the Project included silver-haired bat, hoary bat, eastern red bat, tri-colored bat, and little brown bat (Stantec 2018b). During these surveys, most bat calls were detected in August and September between 1 and 5 hours past sunset and primarily when wind speeds were < 5.0 meters per second and temperatures were ≥ 15.0 degrees Celsius, which is consistent with the migratory chronology of these species (Stantec 2018b).

Bats use a variety of terrestrial environments on Long Island for foraging and roosting during summer breeding and migration periods. The location of the interconnection facility would be in a wooded area, which would provide suitable habitat for bats. Although other onshore Project components occur in already developed areas, bats could use other types of nearby undeveloped habitats. For more information regarding onshore bat abundance, seasonal use, and behavior see Stantec 2018a.

3.4.1.1.1 SPECIAL-STATUS BAT SPECIES

The USFWS Information for Planning and Consultation (IPaC) official species list for the Project, dated September 17, 2020, includes the northern long-eared bat as one of the potentially present species in the analysis area listed under the Endangered Species Act of 1973 (ESA) (VHB Engineering, Surveying and Landscape Architecture, P.C [VHB] 2018). The northern long-eared bat is both federally and state-listed (6 NYCRR 182) as threatened (with 4(d) rule). The final (4(d) rule for the northern long-eared bat, 81 *Federal Register* 9 [January 14, 2016]), conditionally exempts from prohibition the incidental take of the northern long-eared bat within the white nose syndrome zone from energy development and operation (USFWS 2019). A detailed species account is included in the biological assessment (BA) for this Project (BOEM 2021a).

3.4.1.2 Environmental Consequences

3.4.1.2.1 ISSUES, INDICATORS, AND SIGNIFICANCE CRITERIA

Table 3.4.1-1 lists the issues identified for this resource and the indicators and significance criteria used to assess impacts for this final EIS.

Table 3.4.1-1. Issues, Indicators, and Significance Criteria Used to Assess Impacts to Bats

Issue	Impact Indicator	Significance Criteria
Collision/attraction	Qualitative estimate of collision	Negligible: There would be no measurable impacts.
Displacement/barrier effects/disturbance	Changes to noise levels Projected traffic patterns/volume changes	Minor: Most impacts could be avoided with EPMs; if impacts occur, the loss of one or a few individuals or temporary alteration of habitat could represent a minor impact, depending on the time of year and number of individuals involved.
Habitat loss and modification	Acres of suitable habitat removed or modified	Moderate: Impacts are unavoidable but would not result in population-level effects or threaten overall habitat function.
		Major: Impacts would result in severe, long-term habitat or population-level effects to species.

3.4.1.2.2 NO ACTION ALTERNATIVE

The Affected Environment section provides information on existing bat species and habitat trends from past and present activities. The Vineyard Wind final EIS provides a detailed discussion of existing bat resources and species and habitat trends along the east coast and is incorporated here by reference

(BOEM 2021b). Attachment 2 in Appendix E provides additional information regarding past and present activities and associated bat impacts. Future non-Project actions include onshore and offshore wind projects, municipal development projects, communications towers, port upgrades, tidal energy, and dredging/port improvement projects. Attachment 2 in Appendix E also discloses future non-offshore wind activities and associated bat impacts. Impacts associated with future onshore and future offshore wind activities are described below.

Future Activities (without the Proposed Action)

Onshore reasonably foreseeable activities could temporarily displace bats or could deter bats from using potentially suitable foraging habitat. These impacts would not be biologically significant because bats frequently switch roosts (Hann et al. 2017; Whitaker 1998). Onshore land development or port expansion activities could result in habitat loss for some bat species. However, such impacts would only represent a minor and temporary adverse impact because impacts would be limited in extent, as described further in Section 3.5.5.2.2 (No Action Alternative), and not expected to measurably impact bat population abundance or viability.

Impacts associated with future offshore wind activities are described below.

<u>Noise</u>: Construction of numerous offshore wind projects is projected between 2022 to 2030 (see Table E-3 in Appendix E). Construction noise from these projects, most notably from pile driving, would create noise and may temporarily impact some migrating bats if present during construction periods. However, these noise impacts are not expected because recent research indicates that bats may be less sensitive to temporary threshold shifts than other terrestrial mammals so no temporary or permanent hearing loss would be expected (Simmons et al. 2016). Other noise impacts (i.e., displacement from potentially suitable habitats or migration routes) could occur as a result of construction noise (Schaub et al. 2008), but the likelihood of impact is low because little use of the OCS is expected and the use would occur only during spring and fall migration. As a result, adverse impacts to bats would be short to long term and minor.

<u>Presence of structures</u>: The primary threat to bats would be from collisions with offshore WTGs. Up to 2,547 structures (WTGs and OSS) could be constructed in the geographic analysis area (see Table E-3 in Appendix E), which could impact migration patterns or pose a collision risk to individual bats. Although adverse impacts to bats resulting from fatal interactions with operating WTGs cannot be quantified, some level of mortality during operation of offshore wind facilities is assumed. Any new operating wind facility would require a thorough regulatory and environmental review to appropriately site the facility to avoid, minimize, and mitigate adverse impacts on bat species. In addition, the likelihood of an individual bat encountering the rotor swept zone (RSZ) of one or more operating WTG would be negligible. Outside of migration, bats are infrequently present offshore. Because of the proposed 1-nm (1.9-km) spacing between structures associated with future offshore wind development and the distribution of anticipated projects, individual bats migrating over the RSZ of project WTGs would also pass through projects with only slight course corrections, if any, to avoid operating WTGs. As a result, adverse impacts to bats would be short to long term and minor.

Conclusions

Under the No Action alternative, bats would continue to follow current regional trends and respond to current and future environmental and societal activities.

Although the Project would not be built as proposed under the No Action alternative, ongoing activities, future non-offshore wind development, and future offshore wind development would continue to have temporary to permanent impacts (disturbance, displacement, injury, mortality, and habitat conversion) on bats primarily through the onshore construction impacts, the presence of structures, and climate change.

BOEM anticipates that the potential impacts of ongoing activities would be **negligible**. In addition to ongoing activities, the impacts of planned actions other than offshore wind development may also contribute to impacts on bats, including increasing onshore construction (Appendix E Attachment 2), but that these impacts would be negligible. BOEM expects the combination of ongoing and planned actions other than offshore wind development to result in **negligible** impacts on bats.

Considering all the IPFs together, the overall impacts associated with future offshore wind activities in the geographic analysis area would result in **negligible** adverse impacts because of ongoing climate change, interactions with operating WTGs on the OCS, and onshore habitat loss. Future offshore wind activities are not expected to materially contribute to the IPFs discussed above. Given the infrequent and limited anticipated use of the OCS by migrating tree bats during spring and fall migration, and given that cave bats do not typically occur on the OCS, none of the IPFs associated with future offshore wind activities that occur offshore would be expected to appreciably contribute to overall impacts on bats. Some potential for temporary disturbance and permanent loss of onshore habitat may occur as a result of future offshore wind development. However, habitat removal would be minimal when compared with other past, present, and reasonably foreseeable activities, and any impacts resulting from habitat loss or disturbance would not result in individual fitness or population-level effects within the geographic analysis area.

3.4.1.2.3 PROPOSED ACTION ALTERNATIVE

Construction and Installation

Bats are expected to seasonally occur in the SFWF and offshore SFEC while migrating, commuting, or foraging. Although these structures or vessels might attract bats (Stantec 2016), these objects would not pose a collision risk because of a bat's ability to echolocate and detect stationary structures (Stantec 2018a). Therefore, adverse impacts to bats from offshore construction would be negligible. Bats would also not be impacted by seafloor disturbances during construction because they do not interact with the subsurface environment and their occurrence over open water is infrequent. Traffic and noise during construction could result in displacement or avoidance behavior; however, this adverse increase would be short term (see Section 3.5.5.2.3, Proposed Action Alternative). Additionally, bats are only anticipated to occur occasionally in the airspace of the SFWF during migration, so adverse impacts to bats would be negligible.

The onshore SFEC would be installed within existing ROWs (primarily existing roads and railroad ROWs), and negligible adverse impacts to bats are expected because this area has been previously developed and has limited habitat for bats. Installation of the interconnection facility would remove approximately 2.4 acres of deciduous forest. Although the facility would eliminate suitable foraging and roosting habitat, the affected area represents only 0.02% of available deciduous forest habitat within 3 miles of the facility. Removal of upland wildlife habitat and the in-water work at the Montauk O&M facility site would not result in impacts because the commercially zoned area has a mixture of structures, outbuildings, and paved surfaces with no suitable roosting habitat and limited foraging habitat. Although there would be noise and traffic associated with construction of the onshore SFEC and interconnection facility, these activities would predominately occur in already developed areas with existing sources of noise and human activity, however, only negligible, temporary adverse impacts to bats are expected.

Special-Status Species

As noted above, installation of the interconnection facility would convert approximately 2.4 acres of undeveloped deciduous forest to utility use. Although the facility would eliminate suitable foraging and roosting habitat, the affected area only represents 0.02% of available deciduous forest habitat within 3 miles of the facility, which is the typical home range of the northern long-eared bat (USFWS 2014). Per the Project BA prepared for the USFWS (BOEM 2021a), construction activities would comply with 4(d) rule requirements for avoiding adverse effects on northern long-eared bat, meaning that tree removal, vegetation clearing, and other major noise-producing activities near potential bat habitat would take place during winter months when northern long-eared bats are not present, which would effectively avoid impacts to bats because there are no hibernacula present. Because northern long-eared bat summer habitat is not limited and summer habitat loss is not a range-wide threat to the species (USFWS 2014), construction of the interconnection facility would result in negligible, temporary adverse impacts to northern long-eared bats. Northern long-eared bats would not be impacted by the in-water work or by the removal of upland wildlife habitat during construction of the Montauk O&M facility, as described above.

The USFWS's correspondence on the BA, dated March 4, 2021, provides concurrence on BOEM's determination that the Project may affect, but is not likely to adversely affect, the northern long-eared bat.

Operations and Maintenance and Conceptual Decommissioning

During Project O&M, individual bats could collide with WTGs, resulting in mortality or injury. It is difficult to estimate the actual number of bats that could collide with turbines, and currently there is no way to confirm bat fatalities at offshore WTGs; however, offshore bat occurrences are infrequent and primarily seasonal (during migration), and activity declines as the distance from shore increases. Specific weather conditions may contribute to bat mortality from turbines. Mortality data from onshore wind farms indicate that bat collision mortality is expected to occur mainly on nights with calm winds during migratory periods, when relatively more bats are migrating at greater altitudes in favorable conditions (Arnett et al. 2008). Likewise, coastal and offshore acoustic studies (Stantec 2016) found that greater wind speeds and cool temperatures have an adverse effect on bat activity. However, during fall migration, bats may take advantage of favorable wind directions and may be more likely to fly during colder weather (Stantec 2016). Most offshore bat activity took place at wind speeds less than 5 meters per second. Because average wind speeds in the SFWF are between 5 and 10 meters per second, with stronger wind in the winter, bat activity can be expected to be low during WTG operation and limited to warmer periods in the summer or during fall migration, and thus, the risk of injury and/or mortality to bats would also be minor.

The lack of bat carcasses reported during large-scale, bird-related fatality events at illuminated lighthouses, lightships, and oil or research platforms indicates that bats do not appear to be as susceptible to these collision risks as some birds (Stantec 2018a). Further, aviation lighting has not been found to influence bat collision risk at onshore facilities in North America (Arnett et al. 2008). However, the WTGs may provide roosting opportunities for bats. Overall, collision-related mortality or injury could result in negligible to minor adverse impacts to bats at the SFWF, with long-distance migratory bats most at risk because they are most likely to seasonally occur in the airspace of the SFWF.

Boat activity and noise already occur within and adjacent to the SFWF area based on existing levels of vessel traffic as described in Section 3.5.6 (Navigation and Vessel Traffic). Increases in activity and associated disturbances during SFWF maintenance activities would have a negligible impact on bats because of the limited additional vessel activity and low likelihood of bat occurrence near the SFWF. There would also be no impacts to bats during O&M of the offshore SFEC because these components are underwater, and there would be no routine maintenance at these components.

Insect prey could be drawn in by lighting at the onshore interconnection facility and thus attract foraging bats. However, the surrounding area is currently developed, and lighting-related effects would be abated using minimum intensity, motion-activation, and shielding and downward angling of light sources where practicable. Therefore, impacts would be long term but negligible.

Conceptual decommissioning of the Project would have similar impacts as construction.

Special-Status Species

Impacts from O&M of the SFWF to the listed northern long-eared bat are not expected because of their low collision risk and the rarity of their occurrence offshore (Stantec 2018b). Based on Project timing, the limited area of effect relative to available habitat, and proposed impact avoidance and minimization measures, adverse impacts of the Proposed Action on northern long-eared bat would be negligible. The USFWS's correspondence on the BA dated March 4, 2021, provides concurrence on BOEM's determination that the Project may affect, but is not likely to adversely affect, the northern long-eared bat.

Cumulative Impacts

Onshore construction and installation would incrementally add to other limited onshore bat habitat disturbance actions through the removal of 2.4 acres of deciduous forest for the interconnection facility and a small area (0.1 acre) of upland wildlife habitat at the selected O&M facility. This land disturbance could result in the loss of potentially suitable roosting and/or foraging habitat for bats. Additionally, SFW and other future land developers would adhere to USFWS northern long-eared bat conservation measures. As a result, cumulative impacts would not result in population-level effects given the limited amount of habitat removal and the presence of high-quality habitat in the vicinity. Therefore, the cumulative impact of the Proposed Action when combined with past, present, and reasonably foreseeable projects would result in short-term and negligible to minor adverse impacts to bats.

Offshore cumulative impacts would primarily consist of the following offshore wind IPFs.

<u>Noise</u>: Pile driving and other construction noise and activity associated with the Proposed Action would incrementally add to baseline noise and activity associated with other offshore wind projects with overlapping construction periods. However, the Proposed Action's incremental contribution would be limited in duration, would be negligible, and would cease when construction ends. Therefore, the cumulative impact of the Proposed Action when combined with other past, present, and reasonably foreseeable projects would result in short to long-term negligible to minor adverse impacts to bats.

<u>Presence of structures</u>: The Proposed Action would incrementally add up to 15 additional WTGs and one OSS to the No Action alternative. Therefore, the total cumulative structures would be 2,563. Impacts to migration patterns or collision risk from these additional turbines would persist until conceptual decommissioning is complete. However, the Project's incremental impacts on bats would be negligible because 1) the use of the OCS by migrating bats would be limited, and 2) the Project would account for less than 1% of the total future structures on the OCS. Therefore, the Proposed Action when combined with past, present, and reasonably foreseeable projects would result in long-term and negligible to minor cumulative adverse impacts to bats.

Conclusions

Project construction and installation and conceptual decommissioning would introduce noise, lighting, human activity, and new structures and vessels (increasing potential collision risk) to the geographic analysis area and would alter existing bat habitat. Noise, lighting, and human activity impacts from Project O&M would occur, although at lower levels than those produced during construction and installation and conceptual decommissioning. Offshore structures would also represent a long-term collision risk. BOEM anticipates the impacts resulting from the Proposed Action alone would range from temporary to long term and **negligible** to **minor**. Therefore, BOEM expects the overall impact on bats from the Proposed Action alone to be **minor** because the effect would be small and the resource would be expected to recover completely without remedial or mitigating action.

In the context of other reasonably foreseeable environmental trends and planned actions, the incremental impacts under the Proposed Action resulting from individual IPFs would range from **negligible** to **minor**. Considering all the IPFs together, BOEM anticipates that the overall impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would result in **minor** impacts to bats. BOEM made this call as the effect would be small and the resource would be expected to recover completely.

3.4.1.2.4 VESSEL TRANSIT LANE ALTERNATIVE

The Transit alternative would not affect Project onshore activities; therefore, effects to bats would be the same as the Proposed Action: negligible, temporary, and adverse.

Offshore, the Project under the Transit alternative would lead to the same types of impacts on bat from construction and installation, O&M, and conceptual decommissioning activities as described for the Proposed Action. However, this alternative could decrease the risk of migrating bats encountering an operating WTG because SFW would reduce the number of turbines (although the decrease in risk might not be measurable). Therefore, this alternative would result in negligible to minor, short- and long-term adverse impacts on bats from Project construction and installation, O&M, and conceptual decommissioning.

Cumulative Impacts

The Transit alternative would not affect Project onshore activities; therefore, cumulative effects to bats would be the same as those described under the Proposed Action: negligible to minor, temporary, and adverse.

Offshore, the Transit alternative would incrementally add sources of noise, human activity, and collision risk at quantities and durations similar to the Proposed Action. Therefore, the overall offshore cumulative impacts of the Transit alternative on bats when combined with past, present, and reasonably foreseeable activities would be negligible to minor.

If the Transit alternative is implemented, the WTGs for other reasonably foreseeable offshore wind projects may need to be relocated or eliminated within lease areas to avoid the transit lanes. If these shifts result in WTG reductions that further decrease risks of collision, these effects could decrease cumulative bat impacts relative to the Proposed Action. Conversely, if WTG shifts result in increased human activity, noise, and habitat disturbance or species displacement due to increased vessel trips, cable length, and installation times, these effects could increase cumulative bat impacts relative to the Proposed Action.

Conclusions

Although the Transit alternative would reduce the number of WTGs and their associated inter-array cables, which would have an associated reduction in potential collision risk, BOEM expects that the impacts resulting from the alternative alone would be similar to the Proposed Action and range from temporary to long term and **negligible** to **minor**.

In context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that the Transit alternative’s incremental impacts would be similar to the Proposed Action (with individual IPFs leading to impacts ranging from **negligible** to **minor**). The overall impacts of the Transit alternative when combined with past, present, and reasonably foreseeable activities would therefore be the same level as under the Proposed Action: **minor**.

3.4.1.2.5 FISHERIES HABITAT IMPACT MINIMIZATION ALTERNATIVE

The Habitat alternative under either layout option would not alter Project onshore activities; therefore, effects to bats would be the same as the Proposed Action: negligible, temporary, and adverse.

Offshore, the Project under the Habitat alternative for either layout option would lead to the same types of impacts on bats from construction and installation, O&M, and conceptual decommissioning as described for the Proposed Action. However, this alternative could decrease the risk of migrating bats encountering an operating WTG because SFW would reduce the number of turbines (although the decrease in risk might not be measurable). Therefore, this alternative would result in negligible to minor, short- and long-term adverse impacts on bats from Project construction and installation, O&M, and conceptual decommissioning.

Cumulative Impacts

The Habitat alternative under either layout option would not affect Project onshore activities; therefore, cumulative effects to bats would be the same as those described under the Proposed Action: negligible to minor.

Offshore, the Habitat alternative under either layout option would incrementally add sources of noise, human activity, and collision risk at quantities and durations similar to the Proposed Action. Therefore, the overall offshore cumulative impacts on bats when combined with past, present, and reasonably foreseeable activities would be negligible to minor.

Conclusions

Although the Habitat alternative under either layout option would reduce the number of WTGs and their associated inter-array cables, which would have an associated reduction in potential collision risk, BOEM expects that the impacts resulting from the alternative alone would be similar to the Proposed Action and range from temporary to long term and **negligible** to **minor**.

In context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that the Habitat alternative's incremental impacts would be similar to the Proposed Action (with individual IPFs leading to impacts ranging from **negligible** to **minor**). The overall impacts of the Habitat alternative under either layout option when combined with past, present, and reasonably foreseeable activities would therefore be the same level as under the Proposed Action: **minor**.

3.4.1.3 Action Alternative Comparison

As discussed above, the impacts associated with Proposed Action alone do not change substantially under other evaluated action alternatives. Although the number of WTGs and their associated inter-array cables varies slightly, BOEM expects that bat impacts would range from temporary to long term and **negligible** to **minor** for all action alternatives due to noise, lighting, human activity, and new structures and vessels (increasing potential collision risk) in the geographic analysis area, as well as altered existing bat habitat.

In context of reasonably foreseeable environmental trends and planned actions, all action alternatives would occur within the same overall environment (e.g., ongoing and future activities). Therefore, impacts would only vary if the alternatives' incremental contributions differ. However, as noted above, BOEM expects that the incremental impact from any action alternative would be similar, with the level of individual impacts ranging from **negligible** to **minor**. Therefore, the overall impact of any action alternative when combined with past, present, and reasonably foreseeable activities would be **minor**. BOEM made this call as the effect would be small and the resource would be expected to recover completely.

3.4.1.4 Mitigation

If implemented, tree-clearing time-of-year restrictions would minimize the expected negligible onshore impacts on bats, if present, by limiting impacts on the time of year when both adults and young of the year are able to leave the area when tree clearing occurs. Should presence/probable absence surveys be conducted pursuant to current USFWS protocols and no northern long-eared bats are documented, this measure may not be necessary for ESA compliance relative to the species. Establishment of a post-construction monitoring program for bats would not reduce impacts, but the data gathered would be used to evaluate impacts and potentially lead to additional mitigation measures, if required (30 CFR 585.633(b)).

3.4.2 Benthic Habitat, Essential Fish Habitat, Invertebrates, and Finfish (see section in main EIS)

3.4.3 Birds

3.4.3.1 Affected Environment

3.4.3.1.1 OFFSHORE

Despite the level of human development and activity present, the mid-Atlantic Coast plays an important role in the ecology of many bird species. The Atlantic Flyway is a major route for migratory birds, which are protected under the Migratory Bird Treaty Act of 1918 (MBTA). Chapter 4.2.9.3 of the Atlantic OCS EIS/EA (BOEM 2014) discusses the use of Atlantic Coast habitats by migratory birds. The official list of migratory birds protected under the MBTA, and the international treaties that the MBTA implements, is found at 50 CFR 10.13. The MBTA makes it illegal to “take” migratory birds, their eggs, feathers, or nests. Under Section 3 of Executive Order 13186, BOEM and USFWS established a memorandum of understanding (MOU) on June 4, 2009, which identifies specific areas in which cooperation between the agencies would substantially contribute to the conservation and management of migratory birds and their habitats (MMS and USFWS 2009). The purpose of the MOU is to strengthen migratory bird conservation through enhanced collaboration between the agencies. One of the underlying tenets identified in the MOU is to evaluate potential impacts to migratory birds and design or implement measures to avoid, minimize, and mitigate such impacts as appropriate (MMS and USFWS 2009:Sections C, D, E(1), F(1-3, 5), G(6)).

BOEM funds scientific studies and partners with USFWS to better understand how migratory birds use the OCS and to refine the understanding of the risks from development to migratory species (BOEM 2020). BOEM uses information from these studies, USFWS, and the scientific literature to avoid leasing areas with high concentrations of migratory birds that are most vulnerable to offshore wind development. In addition, BOEM’s stakeholder engagement during the delineation of the MA-WEA resulted in the exclusion of 14 OCS blocks that overlapped with high value sea duck habitat (BOEM 2013).

BOEM worked with USFWS to develop standard operating conditions for commercial leases and as terms and conditions of plan approval and are intended to ensure that the potential for adverse impacts on birds is minimized. The standard operating conditions have been analyzed in recent EAs and consultations for lease issuance and site assessment activities, and BOEM’s recent approval of the Virginia Offshore Wind Technology Advancement Project (BOEM 2016a). Some of the standard operating conditions originated from best management practices in the ROD for the 2007 *Programmatic Environmental Impact Statement for Alternative Energy Development and Production and Alternate Use of Facilities on the Outer Continental Shelf* (MMS 2007:Section 2.7). BOEM and USFWS work with the lessees to develop post-construction plans aimed at monitoring the effectiveness of measures considered necessary to minimize impacts to migratory birds with the flexibility to consider the need for modifications or additions to the measures.

The SFWF would be located in deep water (approximately 108 to 125 feet deep where fish, crustaceans, and other zooplankton are available at different depths). Bird groups expected to use deeper offshore waters within the geographic analysis area at least seasonally include loons (*Gavia* spp.), shearwaters and fulmars (Procellariidae spp.), storm-petrels (Hydrobatidae spp.), gannets (*Morus* spp.), sea ducks (Merginae spp.), jaegers (Stercorariidae spp.), gulls and terns (Laridae spp.), alcids (Alcidae spp.), and to a lesser extent, migrating shorebirds and land birds (see Table 4.3-35 in the COP). Shorebirds (except for phalaropes [*Phalaropus* spp.]) are not expected to occur offshore unless flying during migration (Stantec 2018). Many marked (e.g., tagged or banded) sea ducks have been observed up to 70 miles offshore with aggregations of birds up to 20 miles offshore. However, the SFWF would be located in areas with relatively few sea ducks that is between two Sea Duck Joint Venture key sites at Nantucket, Massachusetts, and the south shore of Long Island, New York (see Appendix A, Avian Distribution Maps, and Figures E–I in Stantec 2018). Regardless, almost 86,000 sea ducks such as the long-tailed duck (*Clangula hyemalis*) (27,000), common eider (*Somateria mollissima*) (12,500), black scoter (*Melanitta americana*) (19,400), white-winged scoter (*Melanitta deglandi*) (3,300), and surf scoter (*Melanitta perspicillata*) (23,500) are harvested each year on the Atlantic Flyaway (Roberts 2019). Sea duck mortality from hunting is expected to continue at the current rate commensurate with the current trend in hunting effort.

The offshore SFEC is primarily a pelagic environment, and bird species composition, distribution, seasonality, and resource base are expected to be similar to that described for the SFWF (see Table 4.3-35 in the COP). Species known to occur near state waters include terns, gulls, cormorants (Phalacrocoracidae spp.), and shorebirds during summer and sea ducks, bay ducks (Aythyinae spp.), fish ducks (Anatidae spp.), dabblers (*Anas* spp.), loons, grebes (Podicipedidae spp.), and alcids during migration and winter. Other more pelagic species that could occur include Cory's shearwater (*Calonectris borealis*), northern gannet (*Morus bassanus*), and black-legged kittiwake (*Rissa tridactyla*) (see Table 4.3-35 in the COP).

Within the Atlantic Flyway along the North American Atlantic Coast, much of the bird activity is concentrated along the coastline (Watts 2010). Waterbirds use a corridor between the coast and several kilometers out onto the OCS, whereas land birds tend to use a wider corridor extending from the coastline to tens of kilometers inland (Watts 2010). Although both groups may occur over land or water within the flyway and may extend considerable distances from shore, the highest diversity and density are centered on the shoreline. Robinson Wilmott and Forcey (2014) evaluated the sensitivity of bird populations to collision and/or displacement due to future wind development on the Atlantic OCS. In many cases, high collision sensitivity was driven by high occurrence on the OCS, low avoidance rates with high uncertainty, and time spent in the RSZ. Many of the bird populations addressed in Robinson Willmott and Forcey (2014) had low collision sensitivity and included passerines that spend very little time on the Atlantic OCS during migration and typically fly above the RSZ.

Bird populations in the analysis area that are more susceptible to collision with WTGs include gulls, terns, jaegers, phalaropes, cormorants, northern gannet, and scoters (*Melanitta* spp.). These populations are more susceptible because of their high occurrence in the OCS, their at-risk population status, and/or their relatively high proportion of flights in the RSZ (Stantec 2018). These species are most abundant within 1 to 2 miles of the shoreline (Northeast Regional Ocean Council 2019), as depicted in Figure C-4 in Appendix C. Populations with the lowest vulnerability to collision risk include passerines that would only cross the OCS during migration and would typically fly above the RSZ (i.e., approximately 840 feet). Many of the populations with low collision sensitivities also have large global populations, making them less sensitive to mortality impacts (Stantec 2018).

Bird populations considered most sensitive to displacement impacts include sea ducks, loons, and some alcids due to restrictions in their prey sources and high macro avoidance rates (Stantec 2018). However, these populations are most abundant within 2 miles of the shoreline (Northeast Regional Ocean Council 2019), as depicted in Figure C-5 in Appendix C, and are well outside of the Lease Area.

3.4.3.1.2 ONSHORE

The landcover types near the onshore SFEC routes and landing sites represent habitat for a variety of birds, including species commonly associated with marine shorelines, tidal and freshwater wetlands, surface waters, forests, successional habitats, agricultural fields, and developed areas. Breeding shorebirds on Long Island include American oystercatcher (*Haematopus palliatus*), piping plover (*Charadrius melodus*), and killdeer (*Charadrius vociferous*). Several species overwinter on Long Island (e.g., black-bellied plover [*Pluvialis squatarola*], sanderling [*Calidris alba*], dunlin [*C. alpina*], purple sandpiper [*C. maritima*], ruddy turnstone [*Arenaria interpres*]), and others migrate through. Species expected to occur on Long Island during migration include semipalmated plover (*Charadrius semipalmatus*), semipalmated sandpiper (*Calidris pusilla*), and short-billed dowitcher (*Limnodromus griseus*) (Stantec 2018).

Resident land bird species include corvids (Corvidae spp.), chickadees (Paridae spp.), and tufted titmouse (*Baeolophus bicolor*) (Stantec 2018). A variety of passerines and other birds migrate along the Atlantic Coast and could fly over the onshore SFEC routes and landing sites. Bird species that could breed in the area include marsh and wading birds using nearby coastal wetlands and common swallows (Hirundinidae spp.), thrushes (Turdidae spp.), warblers (Parulidae spp.), sparrows (Passerellidae spp.), and blackbirds (Icteridae spp.) using residential, backyard, and small field habitats proximal to the onshore SFEC cable routes. Winter-resident species are fewer and could include snow bunting (*Plectrophenax nivalis*) and snowy owl (*Bubo scandiacus*). Surveys for the Project detected 87 bird species (VHB 2018:Appendix D [Table A]). The Montauk O&M facility contains a small portion of upland habitat and a sandy shoal immediately northwest of the in-water work area. These areas could be opportunistically used by shorebirds, raptors, or wintering birds; however, birds would not persist here for nesting or foraging in any significant capacity because of the overall lack of habitat and a high level of human disturbance.

3.4.3.1.3 SPECIAL-STATUS SPECIES

The USFWS IPaC official species list for the Project, dated September 17, 2020, contains the following three bird species: piping plover (federally threatened and state endangered), rufa red knot (*Calidris canutus rufa*) (federally threatened), and roseate tern (*Sterna dougallii*) (federally and state endangered) (VHB 2018). BOEM has prepared a BA to address Project effects to federally listed species under the jurisdiction of the USFWS, pursuant to Section 7 of the ESA (BOEM 2021a). The BA also provides detailed accounts for each of these species.

New York Natural Heritage Program (NYNHP) records include 21 New York State–listed and protected species for the analysis area (VHB 2018:Appendix F). State-listed bird species documented or potentially present in the SFWF and portions of the offshore and onshore SFEC include the state-threated northern harrier (*Circus hudsonius*), bald eagle (*Haliaeetus leucocephalus*), least tern (*Sternula antillarum*), and common tern (*Sterna hirundo*) (Stantec 2018:Table 5). Bald eagles are federally protected by the Bald and Golden Eagle Protection Act, 16 USC 668 et seq. No bald eagle nests have been recorded near onshore Project components, and suitable bald eagle habitat on Long Island is limited (Stantec 2018).

3.4.3.2 Environmental Consequences

3.4.3.2.1 ISSUES, INDICATORS, AND SIGNIFICANCE CRITERIA

Table 3.4.3-1 lists the issues identified for this resource and the indicators and significance criteria used to assess impacts for this final EIS.

Table 3.4.3-1. Issues, Indicators, and Significance Criteria Used to Assess Impacts to Birds

Issue	Impact Indicator	Significance Criteria
Collision/injury/ electrocution	Qualitative estimate of species vulnerability to collision/electrocution	Negligible: There would be no measurable impacts Minor: Most impacts could be avoided with EPMs; if impacts occur, the loss of one or a few individuals or temporary alternation of habitat could represent a minor impact, depending on the time of year and number of individuals involved. Moderate: Impacts are unavoidable but would not result in population-level effects or threaten overall habitat function. Major: Impacts would result in severe, long-term habitat or population-level effects to species.
Displacement/ barrier effects	Changes to noise levels Projected traffic patterns/volume changes	
Habitat loss/ modification	Acres of habitat removal or modification	

3.4.3.2.2 NO ACTION ALTERNATIVE

The Affected Environment section provides information on existing bird species and habitat trends from past and present activities. The Vineyard Wind final EIS provides a detailed discussion of existing bird resources and species and habitat trends along the east coast and is incorporated here by reference (BOEM 2021b). Attachment 2 in Appendix E provides additional information regarding past and present activities and associated bird impacts. Future non-Project actions include offshore and onshore wind development activities, tidal energy projects, dredging and port improvement projects, onshore development projects, and communications tower replacement (see Appendix E) and future marine transportation and fisheries use and management. Attachment 2 in Appendix E discloses future non-offshore wind activities and associated bird impacts. Impacts associated with future onshore and future offshore wind activities are described below.

Future Activities (without the Proposed Action)

Onshore construction noise from other human activities could result in localized, minor, and temporary impacts to birds, including avoidance and displacement, though no population-level effects would occur. Onshore land development or port expansion activities could also result in limited loss of nesting and/or foraging habitat for some bird species. However, such minor impacts would be limited in extent, as described in Section 3.5.5.2 (Environmental Consequences), and would not measurably impact bird population abundance or viability.

Impacts associated with future offshore wind activities are described below.

Accidental releases and discharges: Offshore, future wind and non-wind activities could result in accidental releases of contaminants or trash into the water (see Section 3.3.2.2.2, No Action Alternative, for quantities and details). Blockages caused by both hard and soft plastic debris could result in mortality or adverse health effects such as decreased hematological function, dehydration, drowning, hypothermia, starvation, and weight loss (Briggs et al. 1997; Haney et al. 2017; Paruk et al. 2016).Vessel compliance with USCG regulations would minimize trash or other debris; therefore, BOEM expects accidental trash releases from offshore wind vessels to be rare. Small exposures that result in the oiling of feathers can lead to adverse effects that include changes in flight efficiencies and result in increased energy expenditure during daily and seasonal activities (Maggini et al. 2017). Based on estimated volumes of oils, lubricants, and diesel fuel needed for other offshore wind projects (see Section 3.3.2.2.2, No Action Alternative) and the low risk of spills due to implementation of safe handling, storage, and cleanup procedures, impacts from accidental spills and trash would represent a negligible impact to birds.

Noise: Table E-3 in Appendix E indicates that multiple offshore wind project construction periods are anticipated between 2022 to 2030. Construction noise from these projects—most notably pile driving, but also noise from geological and geophysical surveys, offshore construction, and vessel traffic—would create noise and may temporarily impact some bird species by displacing them and changing their behavior. Potential impacts could be greater if avoidance and displacement of birds occur during seasonal migration periods.

Aircraft flying at low altitudes may cause birds to flush, resulting in increased energy expenditure. Disturbance to birds, if any, would be temporary and localized, with impacts dissipating once the aircraft has left the area. No individual or population-level effects to birds would be expected.

Noise transmitted through water could temporarily displace diving birds in a limited space around each pile and could cause short-term stress and behavioral changes ranging from mild annoyance to escape behavior (BOEM 2014, 2016b). Vessel noise could also disturb some individual diving birds, but they would acclimate to the noise or move away, potentially resulting in temporary displacement. Collectively, these noise sources would be temporary and localized, resulting in a minor impact to these birds.

Light: Nighttime lighting associated with offshore structures and vessels could also represent a source of bird attraction. Under the No Action alternative, up to 2,547 WTGs and OSS would have hazard and aviation lighting that would be incrementally added beginning in 2021 and continuing through 2030. Construction vessels are also a source of artificial lighting. Vessel lighting would result in temporary and minor impacts to birds; structure lighting may pose an increased collision or predation risk (Hűppop et al. 2006), though this risk would be localized in extent and minimized through the use of BOEM lighting guidelines (BOEM 2019; Kerlinger et al. 2010).

New cable emplacement/maintenance: Up to 10,131 acres of localized, temporary seabed disturbance and associated increased suspended sedimentation could occur during construction of proposed wind farm cables (see Table E-4 in Appendix E). Disturbed seafloor from construction of future offshore wind projects may affect diving birds’ foraging success or may affect some prey species (e.g., benthic assemblages); however, impacts would be temporary and localized, birds would be able to successfully forage in adjacent areas and would not be affected by increased suspended sediments. Suspended sediment concentrations during activities other than dredging would be within the range of natural variability for this location. Therefore, impacts would be minor, and no population-level effects on birds would occur. See Section 3.4.2 (Benthic Habitat, Essential Fish Habitat, Invertebrates, and Finfish) for detailed information on potential effects to benthic habitat.

Presence of structures: The presence of structures can lead to impacts, both beneficial and adverse, on birds through fish aggregation and the associated increase in foraging opportunities as well as entanglement and gear loss/damage, migration disturbances, and WTG strikes and displacement. These impacts may arise from buoys, met towers, foundations, scour/cable protections, and transmission cable infrastructure.

The primary threat to birds from the presence of structures would be from collision with WTGs. As discussed above, the Atlantic Flyway is an important migratory pathway for up to 164 species of waterbirds, and a similar number of land birds, with the greatest volume of birds using the Atlantic Flyway during annual migrations between wintering and breeding grounds (Watts 2010). As discussed in BOEM (2012), 55 bird species could encounter operating WTGs on the Atlantic OCS. However, the abundance of bird species that overlap with the anticipated development of wind energy facilities on the Atlantic OCS is relatively small (see Figures C-4 and C-5 in Appendix C). Of these 55 bird species, a 47 have sufficient survey data to calculate the modeled percentage of a species population that would overlap with the anticipated offshore wind development on the OCS (Winship et al. 2018); the relative seasonal exposure is generally very low, ranging from 0.0% to 5.2% (Table 3.4.3-2). BOEM assumes that the 47 species (85%) with sufficient data to model the relative distribution and abundance are representative of the 55 species that may overlap offshore wind development on the Atlantic OCS.

Table 3.4.3-2. Percentage of Each Atlantic Seabird Population That Overlaps with Anticipated Offshore Wind Energy Development on the Outer Continental Shelf by Season

Species	Spring	Summer	Fall	Winter
Artic tern (*Sterna paradisaea*)	N/A	0.2%	N/A	N/A
Atlantic puffin (*Fratercula arctica*)	0.2%	0.1%	0.1%	0.2%
Audubon shearwater (*Puffinus lherminieri)*	0.0%	0.0%	0.0%	0.0%
Black-capped petrel (*Pterodroma hasitata)*	0.0%	0.0%	0.0%	0.0%
Black guillemot (*Cepphus grille)*	N/A	0.3%	N/A	N/A
Black-legged kittiwake (*Rissa tridactyla*)	0.7%	N/A	0.7%	0.5%
Black scoter (*Melanitta americana)*	0.2%	N/A	0.4%	0.5%
Bonaparte's gull (*Chroicocephalus philadelphia*)	0.5%	N/A	0.4%	0.3%
Brown pelican (*Pelecanus occidentalis*)	0.1%	0.0%	0.0%	0.0%
Band-rumped storm-petrel (*Oceanodroma castro*)	N/A	0.0%	N/A	N/A
Bridled tern (*Onychoprion anaethetus*)	N/A	0.1%	0.1%	N/A
Common eider (*Somateria mollissima*)	0.3%	0.1%	0.5%	0.6%
Common loon (*Gavia immer*)	3.9%	1.0%	1.3%	2.1%
Common murre (*Uria aalge*)	0.4%	N/A	N/A	1.9%
Common tern (*Sterna hirundo*)	2.1%	3.0%	0.5%	N/A
Cory's shearwater (*Calonectris borealis*)	0.1%	0.9%	0.3%	N/A
Double-crested cormorant (*Phalacrocorax auritus*)	0.7%	0.6%	0.5%	0.4%
Dovekie (*Alle alle*)	0.1%	0.1%	0.3%	0.2%
Great black-backed gull (*Larus marinus*)	1.3%	0.5%	0.7%	0.6%
Great shearwater (*Puffinus gravis*)	0.1%	0.3%	0.3%	0.1%
Great skua (*Stercorarius skua*)	N/A	N/A	0.1%	N/A
Herring gull (*Larus argentatus*)	1.0%	1.3%	0.9%	0.5%
Horned grebe (*Podiceps auritus*)	N/A	N/A	N/A	0.3%
Laughing gull (*Leucophaeus atricilla*)	1.0%	3.6%	0.9%	0.1%
Leach's storm-petrel (*Oceanodroma leucorhoa*)	0.1%	0.0%	0.0%	N/A
Least tern (*Sternula antillarum*)	N/A	0.3%	0.0%	N/A
Long-tailed duck (*Clangula hyemalis*)	0.6%	0.0%	0.4%	0.5%
Manx shearwater (*Puffinus puffinus*)	0.0%	0.5%	0.1%	N/A
Northern fulmar (*Fulmarus glacialis*)	0.1%	0.2%	0.1%	0.2%
Northern gannet (*Morus bassanus*)	1.5%	0.4%	1.4%	1.4%
Parasitic jaeger (*Stercorarius parasiticus*)	0.4%	0.5%	0.4%	N/A
Pomarine jaeger (*Stercorarius pomarinus*)	0.1%	0.3%	0.2%	N/A
Razorbill (*Alca torda*)	5.2%	0.2%	0.4%	2.1%
Ring-billed gull (*Larus delawarensis*)	0.5%	0.5%	0.9%	0.5%
Red-breasted merganser (*Mergus serrator*)	0.5%	N/A	N/A	0.7%
Red phalarope (*Phalaropus fulicarius*)	0.4%	0.4%	0.2%	N/A
Red-necked phalarope (*Phalaropus lobatus*)	0.3%	0.3%	0.2%	N/A

Species	Spring	Summer	Fall	Winter
Roseate tern (*Sterna dougallii*)	0.6%	0.0%	0.5%	N/A

Notes: N/A = not applicable.

The primary operational impact to bird resources would be collision with the rotating turbine blades. In the contiguous United States, bird collisions with operating WTGs are a relatively rare event, with an estimated 140,000 to 328,000 (mean = 234,000) birds killed annually by 44,577 onshore turbines (Loss et al. 2013). Estimating bird (or bat) mortality at a terrestrial wind facility is a relatively simple and straightforward process that involves conducting ground searches for bodies and statistically adjusting the counts upward to account for the probability of not seeing the body and for the probability that the body was devoured by scavengers. Based on a mortality rate of 6.9 birds per turbine in the eastern United States (Loss et al. 2013), an estimated 15,575 birds could be killed annually under the No Action alternative. This represents a worst-case scenario and does not consider mitigating factors such as landscape and weather patterns, or bird species that are expected to occur, and the actual mortality rate would be expected to be much lower. First, 75% of the documented onshore mortality is composed of bird groups (small passerines, diurnal raptors, doves, pigeons, and upland game birds) that would not frequently encounter offshore WTGs in large numbers. Second, factors such as landscape features and weather patterns that influence collision risk are different on the OCS compared to onshore wind facilities. Third, empirical studies suggest that bird fatalities due to collision with offshore turbines is low. For instance, unlike the planned development on the U.S. Atlantic OCS, most of the offshore wind development in Europe is relatively close to shore, where bird densities tend to be greater in part because they are closer to some nesting colonies. In addition, the European wind energy facilities that are farther out are usually between large land masses (e.g., the North Sea), thus creating more opportunities for birds to move from the shore of one land mass to another. Given that the relative density of birds in the OCS is low, relatively few birds are likely to encounter wind turbines (see Figures C-4 and C-5 in Appendix C).

Additionally, with the proposed 1-nm (1.9-km) spacing between structures associated with future offshore wind development and the distribution of anticipated projects, only a small percentage of bird species migrating over the OCS would encounter WTGs, with most flying above or below spinning turbines; plus the spacing between turbines would also permit birds to fly through individual lease areas without changing course or only making minor course corrections to avoid operating WTGs. Any additional flight distances would be miniscule when compared with the overall migratory distances traveled by migratory birds. Therefore, impacts would be minor, and no population-level effects would be expected.

The addition of WTGs to the offshore environment could result in increased functional loss of habitat for those bird species with higher displacement sensitivity. However, substantial foraging habitat for resident birds would remain available (Section 3.4.2.2.2, No Action Alternative, estimates that less than 1% of total benthic habitat would be affected by seabed-disturbing activities). Therefore, impacts would be minor, and no population-level impacts would occur.

In the Northeast and mid-Atlantic waters, there are 2,570 seabird fatalities through interaction with commercial fishing gear each year; of those, 84% are with gillnets involving shearwaters/fulmars and loons (Hatch 2017). The addition of new WTGs could also increase risk of entanglement with fishing gear, which could lead to bird injury or mortality. Impacts from fishing gear would be localized; however, the risk of occurrence would remain as long as structures remain. WTGs and foundations could also increase pelagic productivity in local areas (English et al. 2017), and new structures may also create habitat for structure-oriented and/or hard-bottom species. This reef effect has been observed around WTGs, leading to local increases in biomass and diversity within the first year or two after construction (English et al. 2017; Causon and Gill 2018), indicating that offshore wind farms can generate beneficial long-term impacts on local ecosystems, translating to increased foraging opportunities for individuals of some marine bird species. Therefore, the presence of structures may also result in minor beneficial impacts for the duration of the Project (Dierschke et al. 2016). For details on the effects of WTGs on benthic habitat and recreational fishing, see Section 3.4.2 (Benthic Habitat, Essential Fish Habitat, Invertebrates, and Finfish) and Section 3.5.1 (Commercial Fisheries and For-Hire Recreational Fishing).

Climate change: Impacts associated with climate change, including increased storm severity and frequency, ocean acidification, altered migration patterns, increased disease frequency, habitat conversion, and increased erosion and sediment deposition, could result in minor, long-term risks to birds and could lead to changes in prey abundance and distribution, changes in nesting and foraging habitat abundance and distribution, and changes to migration patterns and timing.

Conclusions

Under the No Action alternative, the resource would continue to follow the current general decreasing trends and respond to current and future environmental and societal activities.

Although the Project would not be built as proposed under the No Action alternative, ongoing activities and future offshore wind would continue to have temporary to permanent impacts (disturbance, displacement, injury, mortality, habitat degradation, habitat conversion) on birds primarily through accidental releases, anthropogenic noise, presence of structures, and climate change. Ongoing activities, especially interactions with commercial fisheries, anthropogenic light in the coastal environment, and climate change, would be minor. In addition to ongoing activities, the impacts of planned actions other than offshore wind development, including new submarine cables and pipelines, increasing onshore construction, marine minerals extraction, port expansions, and the installation of new structures on the OCS would be minor. The combination of ongoing activities and reasonably foreseeable activities other than offshore wind would result in **minor** impacts on birds in the geographic analysis area.

Considering all the IPFs together, the overall impacts associated with offshore wind activities in the geographic analysis area would result in **moderate** adverse impacts but could include **moderate beneficial** impacts because of presence of structures. Most of the offshore structures in the geographic analysis area would be attributable to the offshore wind development. Migratory birds that use the offshore wind development areas (WDAs) during all or parts of the year would either be exposed to new collision risk, or would have long-term functional habitat loss due to behavioral avoidance and displacement from WDAs on the OCS. The offshore wind development would also be responsible for most of the impacts related to new cable emplacement and pile-driving noise, but impacts on birds resulting from these IPFs would be localized and temporary and would not be biologically significant.

The No Action alternative would forgo post-construction avian monitoring for migratory birds and ESA-listed species and annual mortality reporting, the results of which could provide an understanding of the effects of offshore wind development, benefit the future management of these species, and inform planning of other offshore development; however, ongoing and future surveys and monitoring could still supply similar data.

3.4.3.2.3 PROPOSED ACTION ALTERNATIVE

Construction and Installation

Offshore

Negligible to minor, temporary adverse impacts from bird collisions with visible structures could occur during construction, depending on the species and number of individuals involved. Birds are susceptible to collision with structures, particularly at night and/or during other periods of low visibility (e.g., rain or fog) (Stantec 2018). Brightly illuminated offshore structures such as research platforms also pose a risk to birds migrating at night when birds can become disoriented by sources of artificial light. Lighting used during construction would be limited to the minimum required for safety during construction to minimize potential impacts. Therefore, adverse impacts to birds from lighting would be negligible to minor.

Construction of the WTG foundations and the installation of the subsea cables could result in short-term habitat disturbance for foraging birds. However, adverse impacts would be negligible to minor given the localized nature of these impacts and the abundance of surrounding foraging habitat. Negligible to minor adverse impacts to birds from associated noise and vessel traffic are also expected during construction. These activities could flush birds in the path of vessels, causing temporary displacement from the area; alternatively, these activities could attract certain groups of birds. However, impacts would be temporary and similar to baseline conditions because vessel traffic already occurs in the analysis area (Stantec 2018). These impacts could be greater if avoidance and displacement of birds occur during seasonal migration periods. Potential adverse impacts to birds from contaminant discharges or releases or from improper disposal of trash or debris during construction would be avoided or minimized with adherence to federal, state, and local regulations regarding disposal of solid and liquid wastes (see Section 4.1.6 in the COP), resulting in negligible to minor, short-term adverse impacts.

Onshore

At the sea-to-shore transition, the use of HDD for SFEC installation would minimize potential construction impacts on the inter-tidal community near the selected landing site; no long-term changes in inter-tidal habitat structure or prey availability are expected. Any increase in turbidity and sedimentation would be temporary, localized, and minor, resulting in no lasting physical changes to coastal areas or beaches; see Section 3.3.2 (Water Quality) for additional discussion. No physical impacts to beach nesting areas are expected because installation for the SFEC would occur under the beach. However, noise and human activity from installation of the cofferdam, from HDD in the sea-to-shore transition, and at beach work areas could result in temporary, localized disturbance or displacement. Therefore, only negligible to minor adverse impacts to shorebirds are expected from onshore construction.

The onshore SFEC routes would be constructed within existing ROWs comprising predominantly developed land cover type (Homer et al. 2015) with limited bird use, thus minimizing possible disturbances to land birds. Approximately 2.4 acres of disturbed woodland habitat would be cleared for construction of the new interconnection facility, and a small amount of additional clearing could occur along the LIRR, resulting in negligible adverse impacts to bird habitats. During the breeding season, clearing of trees or vegetation could result in destruction of nests, adversely impacting some individuals; however, lasting impacts to local breeding populations are not anticipated.

Noise and traffic associated with construction of the onshore SFEC and the interconnection facility could also affect shorebirds, some seabirds, and land birds that use the terrestrial habitats in the immediate vicinity of construction activities. Noise- and traffic-related impacts would have temporary, minor adverse impacts on these birds because construction would occur in already developed areas where birds are habituated to these types of activities, and impacts associated with construction would be similar to existing sources of noise and traffic in the local area. At the Montauk O&M facility site, no construction activities are proposed in the small sandy shoal area immediately northwest of the dredge area, which provides only limited stopover habitat for shorebirds, raptors, or wintering birds and limited nesting substrate for shorebirds. Dredged materials used for beach renourishment would be placed outside of the shorebird breeding season. Therefore, no impacts to birds are expected from construction of the Montauk O&M facility.

Special-Status Species

Federally and state-listed bird species may be at risk of collision during construction, although risk of collision is considered low because these species are expected to infrequently occur over the SFWF (Stantec 2018). Although the loss of one or a few individuals to at-risk bird populations would represent an adverse impact, conservation measures identified during the ongoing ESA Section 7 consultation with the USFWS would minimize adverse impacts to federally listed bird species. Therefore, adverse effects from the Project would be minor.

Noise from installation of the cofferdam and from HDD in the sea-to-shore transition and activities at beach work areas could also result in temporary, localized disturbance or displacement of listed shorebirds. The plover and tern could nest, and all three species could forage or rest near the sea-to-shore transition and onshore SFEC routes. The potential for impacts to these species was considered during the Project siting process. As a result, to avoid nesting habitat and to minimize the potential for impacts, the HDD work area was set back at least 650 feet from the MHWL so that the entrance point would be in interior land areas and the exit point would be offshore beyond the intertidal zone. Additionally, construction activities are scheduled to occur outside of the tern and plover breeding periods (i.e., April 1 through August 31); red knots do not nest in the United States. Because construction work at the selected landing site would occur largely outside of the breeding period of listed species that might nest in the area, and because use of the shoreline by shorebirds at the landing sites would be minimal (Stantec 2018), adverse onshore impacts for listed species from noise and human activity would be negligible to minor. A detailed impacts analysis to federally listed birds from construction activities is in the BA (BOEM 2021a).

No federally listed land bird species are expected to nest near the interconnection facility location. Northern harriers could occur in the analysis area (eBird 2019) but are not expected to nest within the construction footprint based on land cover type; therefore, no adverse impacts are expected. Impacts to other special-status birds from construction would be similar to those described above.

The USFWS’s correspondence on the BA, dated March 4, 2021, provides concurrence on BOEM’s determination that the Project may affect, but is not likely to adversely affect, the roseate tern, piping plover, and rufa red knot.

Operations and Maintenance and Conceptual Decommissioning

Offshore

The primary impact expected for birds during O&M is collision with WTGs at the SFWF. However, the abundance of bird species with high collision sensitivity is low within the offshore portion of the Project during all seasons (see Figure C-4 in Appendix C), and that risk of collision would be reduced with implementation of EPMs listed in Table G-1 in Appendix G.

The presence and operation of the SFWF may result in displacement of waterbirds, waterfowl, seabirds, and phalaropes that use the area for foraging, resting, or nighttime roosting. And some species can be displaced several kilometers outside the Lease Area (Welcker and Nehls 2016). These long-term adverse impacts would be negligible to minor, depending on whether birds are at high risk for displacement or are able to access preferred habitat, and these impacts may change over time if birds become habituated to the presence of the WTGs. Generally, the relative abundance of bird species that are most sensitive to displacement is low within the offshore portion of the Project, including several kilometers outside the Lease Area during all seasons (see Figure C-5 in Appendix C).

The presence of WTGs may be a barrier to some migrating or commuting birds. As a result, these birds may avoid entering the wind farm and/or fly around the farm, potentially resulting in a greater expenditure of energy (Stantec 2018). The level of associated impacts resulting from barrier effects varies by species. Most bird species are expected to make minor changes to their flight trajectories when approaching WTGs, representing negligible increases in energy expenditure. Therefore, long-term, negligible adverse impacts associated with barrier effects are expected for many bird groups.

All other potential SFWF impacts (i.e., contaminant discharges or releases, traffic and noise, and trash and debris) are expected to generally be similar to offshore construction and result in negligible to minor adverse impacts with implementation of EPMs listed in Table G-1 in Appendix G.

No impacts to bird species are anticipated during the O&M phase for the offshore SFEC. The OSS could attract perching and pose an electrocution risk, which if realized would result in minor adverse impacts to birds from individual mortality or injury. Impacts to birds from conceptual decommissioning of the SFWF and offshore SFEC would be similar to those described for the construction phase.

Onshore

There would be no risk to bird species from electrocution because the onshore SFEC routes would be buried; however, the interconnection facility could pose an electrocution risk that might result in minor, long-term adverse impacts to bird species. No other impacts to bird species are anticipated during routine onshore operations. Conceptual decommissioning would have similar impacts as construction.

Special-Status Species

Federally and state-listed species are terrestrial or nearshore species that face low risk of collision during O&M. Although these species are not expected to frequent the SFWF, certain species (e.g., roseate tern) could cross the area during migration. The loss of individuals over the life of the SFWF, for a population already at risk, would represent an adverse impact; however, conservation measures identified during the ongoing ESA Section 7 consultation with the USFWS would be implemented to minimize adverse impacts to federally listed bird species. Additionally, the probability of these species' occurrence coupled with Project design and EPMs (see Table G-1 in Appendix G) would render effects as minor over the long term (BOEM 2021a). Impacts to special-status birds from O&M and conceptual decommissioning activities would be similar to those described above for other bird species.

The USFWS's correspondence on the BA, dated March 4, 2021, provides concurrence on BOEM's determination that the Project may affect, but is not likely to adversely affect, the roseate tern, piping plover, and rufa red knot.

Cumulative Impacts

Onshore construction activities would incrementally add to noise and land disturbance through the removal of 2.4 acres of deciduous forest for the interconnection facility and a small area (0.1 acre) of upland wildlife habitat at the selected O&M facility. These actions could result in localized and temporary impacts to birds, including avoidance and displacement, although no individual fitness or population-level effects would be expected. For this reason, the incremental onshore impacts of the Proposed Action would range from negligible to minor because only a small amount of habitat loss, if any, would be expected. Therefore, the Proposed Action when combined with past, present, and reasonably foreseeable projects would result in short term and negligible adverse cumulative impacts to birds.

Offshore cumulative impacts would primarily consist of the following offshore wind IPFs.
